Description

`lassoknots` shows a table of knots after a lasso. Knots are the values of λ at which variables in the model change.

`lassoknots` displays the names of the variables added or removed as models are fit for successive λ 's. When using cross-validation (CV) to select λ^* , `lassoknots` will display values of the CV function.

`lassoknots` also displays measures of fit. After viewing measures of fit, you can select an alternative λ^* using `lassoselect`.

When `telasso`, `ds`, `po`, and `xpo` commands fit models using `selection(cv)`, `selection(adaptive)`, or `selection(bic)` (see [LASSO] [lasso options](#)), `lassoknots` can be used to show the CV function (for `cv` and `adaptive`) or the BIC function or other measures of fit for each of the lassos computed.

`lassoknots` does work after `selection(plugin)` but only shows measures for the single λ^* estimated by the plugin formula.

Quick start

Show knot table after `lasso`, `sqrtlasso`, and `elasticnet`

```
lassoknots
```

Same as above, but show number of nonzero coefficients, out-of-sample R^2 , and variables added or removed after a linear model

```
lassoknots, display(nonzero osr2 variables)
```

Same as above, but show in-sample R^2 and CV mean-prediction error in addition to out-of-sample R^2

```
lassoknots, display(osr2 r2 cvmpe)
```

After `lasso logit`, `lasso probit`, or `lasso poisson`, show out-of-sample mean-deviance ratio, in-sample deviance ratio, and Bayes information criterion (BIC)

```
lassoknots, display(cvdevratio devratio bic)
```

After a lasso fit with `selection(adaptive)`, show knot tables for all adaptive steps

```
lassoknots, steps
```

After a `ds` or `po` estimation with `selection(cv)` or `selection(adaptive)`, show the knot table for the lasso for the dependent variable `y`

```
lassoknots, for(y)
```

After `poivregress`, show the knot table for the lasso for the prediction of the endogenous variable `whatup`

```
lassoknots, for(pred(whatup))
```

After `xporegress` with option `resample`, show the knot table for the lasso for `x` for the 4th cross-fit fold of the 9th resample

```
lassoknots, for(x) xfold(4) resample(9)
```

After `telasso` estimation with `selection(cv)` or `selection(adaptive)`, show the knot table for the lasso for the outcome variable `y` at treatment level 1

```
lassoknots, for(y) tlevel(1)
```

Menu

Statistics > Postestimation

Syntax

After `lasso`, `sqrtlasso`, and `elasticnet`

```
lassoknots [ , options ]
```

After `ds` and `po`

```
lassoknots, for(varspec) [ options ]
```

After `xpo` without `resample`

```
lassoknots, for(varspec) xfold(#) [ options ]
```

After `xpo` with `resample`

```
lassoknots, for(varspec) xfold(#) resample(#) [ options ]
```

After `telasso` for the outcome variable

```
lassoknots, for(varspec) tlevel(#) [ options ]
```

After `telasso` for the treatment variable

```
lassoknots, for(varspec) [ options ]
```

After `telasso` for the outcome variable with cross-fitting but without `resample`

```
lassoknots, for(varspec) tlevel(#) xfold(#) [ options ]
```

After `telasso` for the treatment variable with cross-fitting but without `resample`

```
lassoknots, for(varspec) xfold(#) [ options ]
```

After `telasso` for the outcome variable with cross-fitting and resample

```
lassoknots, for(varspec) tlevel(#) xfold(#) resample(#) [options]
```

After `telasso` for the treatment variable with cross-fitting and resample

```
lassoknots, for(varspec) xfold(#) resample(#) [options]
```

varspec is *varname*, except after `poivregress` and `xpoivregress`, when it is either *varname* or `pred(varname)`.

<i>options</i>	Description
<code>display(<i>di_opts</i>)</code>	specify what to display; maximum of three <i>di_opts</i> options
<code>alllambdas</code>	show all λ 's
<code>steps</code>	show all adaptive steps; <code>selection(adaptive)</code> only
<code>no!stretch</code>	do not stretch the width of the table to accommodate long variable names
* <code>for(<i>varspec</i>)</code>	lasso for <i>varspec</i> ; <code>telasso</code> , <code>ds</code> , <code>po</code> , and <code>xpo</code> commands only
* <code>xfold(#)</code>	lasso for the #th cross-fit fold; <code>xpo</code> commands and <code>telasso</code> with <code>xfolds</code> only
* <code>resample(#)</code>	lasso for the #th resample; <code>xpo</code> commands and <code>telasso</code> with <code>resample</code> only
* <code>tlevel(#)</code>	lasso for the outcome model with the treatment level #; <code>telasso</code> only

*`for(varspec)` is required for all `ds`, `po`, and `xpo` commands and for `telasso`.

`xfold(#)` is required for all `xpo` commands and for `telasso` when the option `xfolds(#)` was specified.

`resample(#)` is required for `xpo` and for `telasso` when the option `resample(#)` was specified.

`tlevel(#)` is required for the outcome model in `telasso`.

`collect` is allowed; see [U] 11.1.10 Prefix commands.

<i>di_opts</i>	Description
<code>nonzero</code>	number of nonzero coefficients
<code>variables</code>	names of variables added or removed
<code>cvmd</code>	CV mean deviance (the CV function)
<code>cvdevratio</code>	CV mean-deviance ratio
<code>devratio</code>	in-sample deviance ratio
<code>bic</code>	BIC
<code>l1</code>	relative ℓ_1 -norm of coefficients
<code>l2</code>	relative ℓ_2 -norm squared of coefficients

Linear models only

<code>cvmpe</code>	CV mean-prediction error (the CV function)
<code>osr2</code>	out-of-sample R^2
<code>r2</code>	in-sample R^2

Options

`display(di_opts)` specifies what to display in the knot table. A maximum of three `di_opts` options can be specified. For lassos fit using `selection(cv)` or `selection(adaptive)`, the default is `display(nonzero cvmpe variables)` for linear models and `display(nonzero cvmd variables)` for logit, probit, Poisson, and Cox models. For lassos fit using `selection(plugin)` or `selection(bic)`, the default is `display(nonzero r2 variables)` for linear models and `display(nonzero devratio variables)` for logit, probit, Poisson, and Cox models. The full set of `di_opts` is the following.

`nonzero` specifies that the number of nonzero coefficients be shown.

`variables` specifies that the names of variables added or removed at each knot be shown.

`cvmd` specifies that the CV mean deviance be shown. These are the values of the CV function that are searched for a minimum. For linear models, it is the same as the CV mean-prediction error given by `cvmpe`. `cvmd` is available only for lassos fit using `selection(cv)` or `selection(adaptive)`.

`cvdevratio` specifies that the CV mean-deviance ratio be shown. The CV mean-deviance ratio is an estimate of out-of-sample goodness of fit. As a measure of prediction performance, it is superior to `devratio`, the in-sample deviance ratio. It is typically between 0 and 1, but in some cases, it may be outside this range. For linear models, it is the same as out-of-sample R^2 given by `osr2`. `cvdevratio` is available only for lassos fit using `selection(cv)` or `selection(adaptive)`.

`devratio` specifies that the in-sample deviance ratio be shown. The in-sample deviance ratio is an indicator of in-sample goodness of fit. The in-sample deviance generalizes the in-sample R^2 to nonlinear models. As a measure of prediction performance, it is inferior to `cvdevratio`, the CV mean-deviance ratio. The in-sample deviance ratio is a poor measure of prediction performance because it does not capture the cost of including additional covariates for prediction. It is always between 0 and 1. For linear models, it is the same as in-sample R^2 given by `r2`.

`bic` specifies that the BIC be shown. Note that the BIC can be displayed for lassos fit using `selection(cv)` and `selection(adaptive)`, but the CV measures—`cvmd`, `cvdevratio`, and `cvmpe`—are not available for lassos fit using `selection(bic)`.

`l1` specifies that the relative ℓ_1 -norm of coefficients be shown.

`l2` specifies that relative ℓ_2 -norm squared of coefficients be shown.

Linear models only

`cvmpe` specifies that the CV mean-prediction error be shown. These are the values of the CV function that are searched for a minimum. `cvmpe` is available only for lassos fit using `selection(cv)` or `selection(adaptive)`.

`osr2` specifies that the out-of-sample R^2 be shown. The out-of-sample R^2 is an estimate of out-of-sample goodness of fit. As a measure of prediction performance, it is superior to `r2`, the in-sample R^2 . It is typically between 0 and 1, but in some cases, it may be outside this range.

`r2` specifies that the in-sample deviance ratio be shown. The in-sample deviance ratio is an indicator of in-sample goodness of fit. As a measure of prediction performance, it is inferior to `osr2`, the out-of-sample R^2 . The in-sample R^2 is a poor measure of prediction performance because it does not capture the cost of including additional covariates for prediction. It is always between 0 and 1.

`alllambdas` specifies that all λ 's are to be shown, not just the knots. Measures at λ 's that are not knots change slightly because the coefficient estimates change slightly. λ 's that are not knots can be selected as λ^* by `lassoselect`; however, this is typically not done.

`steps` applies to `selection(adaptive)` only. When specified, λ 's for all adaptive steps are shown. By default, λ 's for only the last adaptive step are shown.

`no!stretch` specifies that the width of the table not be automatically widened to accommodate long variable names. When `no!stretch` is specified, names are abbreviated to make the table width no more than 79 characters. The default, `!stretch`, is to automatically widen the table up to the width of the Results window. To change the default, use `set !stretch off`.

`for(varspec)` specifies a particular lasso after `telasso` or after a `ds`, `po`, or `xpo` estimation command fit using the option `selection(cv)`, `selection(adaptive)`, or `selection(bic)`. For all commands except `poivregress` and `xpoivregress`, `varspec` is always *varname*.

For the `ds`, `po`, and `xpo` commands except `poivregress` and `xpoivregress`, `varspec` is either *depvar*, the dependent variable, or one of *varsofinterest* for which inference is done.

For `poivregress` and `xpoivregress`, `varspec` is either *varname* or `pred(varname)`. The lasso for *depvar* is specified with its *varname*. Each of the endogenous variables have two lassos, specified by *varname* and `pred(varname)`. The exogenous variables of interest each have only one lasso, and it is specified by `pred(varname)`.

For `telasso`, `varspec` is either the outcome variable or the treatment variable.

This option is required after `telasso` and after the `ds`, `po`, and `xpo` commands.

`xfold(#)` specifies a particular lasso after an `xpo` estimation command or after `telasso` when the option `xfolds(#)` was specified. For each variable to be fit with a lasso, K lassos are done, one for each cross-fit fold, where K is the number of folds. This option specifies which fold, where $\# = 1, 2, \dots, K$. `xfold(#)` is required after an `xpo` command and after `telasso` when the option `xfolds(#)` was specified.

`resample(#)` specifies a particular lasso after an `xpo` estimation command or after `telasso` fit using the option `resample(#)`. For each variable to be fit with a lasso, $R \times K$ lassos are done, where R is the number of resamples and K is the number of cross-fitting folds. This option specifies which resample, where $\# = 1, 2, \dots, R$. `resample(#)`, along with `xfold(#)`, is required after an `xpo` command and after `telasso` with resampling.

`tlevel(#)` specifies the lasso for the outcome variable at the specified treatment level after `telasso`. This option is required to refer to the outcome model after `telasso`.

Remarks and examples

[stata.com](http://www.stata.com)

Remarks are presented under the following headings:

[Introduction](#)

[Measures of fit](#)

[In-sample measures versus estimates of out-of-sample measures](#)

[BIC](#)

[Examples](#)

Introduction

When a lasso is fit over a grid of λ 's, it starts with the smallest λ that produces a model with no selected variables. This initial λ is the largest λ in the grid. Lasso steps to the next λ and fits a model for it. One or more variables are selected for this second λ (if no variables were selected, it would be the starting λ). Lasso steps to the third λ , and more variables may be selected, or the model may have the same variables as the model for the second λ .

In this way, lasso iterates across the grid of λ values. λ 's at which the selected variables change are called “knots”. Variables are not only added at a knot but also sometimes removed. Typically, when a variable is removed, one or more variables are added in its place. Usually, the number of nonzero coefficients increases monotonically as λ gets smaller but not always. Occasionally, the net number of variables in the model goes down, rather than up, in an iteration to a smaller λ .

`lassoknots` displays a table of the knots, showing the names of variables that enter and leave the models. The option `alllambdas` can be specified to display all the λ 's in the grid. To view all variables selected at a particular λ , you can use `lassoselect` to select that λ and then `lassocoeff` to list the variables and, optionally, the coefficients.

Selection methods `selection(cv)`, `selection(adaptive)`, `selection(bic)`, and `selection(none)` fit models for each λ in the grid. The method `selection(plugin)` calculates λ^* using a formula so there is only one λ .

Measures of fit

`lassoknots` will also display other measures. The methods `selection(cv)` and `selection(adaptive)` use CV. When CV is performed, `lassoknots` by default displays the number of nonzero coefficients, the CV function, and the names of variables that enter or leave the model.

Optionally, there are five other measures that can be displayed. For linear models, they are in-sample R^2 (`r2`), estimates of out-of-sample R^2 (`osr2`), the BIC (`bic`), relative ℓ_1 -norm of coefficients (`l1`), and relative ℓ_2 -norm squared of coefficients (`l2`).

For nonlinear models, in place of the R^2 measures, there are the analogous measures, the in-sample deviance ratio (`devratio`) and estimates of out-of-sample deviance ratio (`cvdevratio`).

The in-sample measures, BIC, and relative norms are available regardless of whether CV was done.

The out-of-sample R^2 and out-of-sample deviance ratio are not computed on out-of-sample data, but rather they are estimates of what these measures would be on out-of-sample data. The CV procedure provides these estimates.

In-sample measures versus estimates of out-of-sample measures

Estimates of out-of-sample measures are superior to in-sample measures.

Consider a linear lasso. The set of covariates that produces the smallest out-of-sample MSE is the set that produces the best predictions. CV is used to estimate out-of-sample MSE and select the set that produces the smallest estimate.

In contrast, we should not use in-sample MSE to select the set of covariates. In-sample MSE systematically underestimates out-of-sample prediction error. In-sample MSE can be made smaller and smaller simply by including more covariates (as long as they are not collinear with covariates already in the model). In-sample MSE does not capture the cost of including more covariates.

For the same reason, estimates of out-of-sample R^2 are superior to in-sample R^2 for linear models. For logit, probit, and Poisson models, estimates of out-of-sample deviance ratios are superior to in-sample deviance ratios.

See [Hastie, Tibshirani, and Friedman \(2009, sec. 7.2\)](#) for an introduction to a comparison of in-sample and out-of-sample measures of the predictive ability of a model.

BIC

Information criteria, like the BIC, have a term that penalizes for each additional parameter. Selecting the set of covariates that minimizes the BIC is another way to select a set of covariates that will predict well out of sample. [Zhang, Li, and Tsai \(2010\)](#) show that the λ selected by minimizing the BIC will select a set of covariates close to the true set under the conditions described in their article.

In practice, the BIC is more informative than the in-sample measures reported by `lassoknots` for `selection(plugin)` and `selection(none)`.

Examples

► Example 1: lasso linear

Here is an example using lasso from [\[LASSO\] lasso examples](#). We load the data and make the `vl` variable lists active.

```
. use https://www.stata-press.com/data/r18/fakesurvey_vl
(Fictitious survey data with vl)
. vl rebuild
Rebuilding vl macros ...
(output omitted)
```

We fit a lasso linear model.

```
. lasso linear q104 $demographics $factors $v1continuous, rseed(1234)
10-fold cross-validation with 10 lambdas ...
Grid value 1:    lambda = .9090511    no. of nonzero coef. =    0
Folds: 1...5....10    CVF = 18.33331
(output omitted)
Grid value 28:    lambda = .0737359    no. of nonzero coef. =    80
Folds: 1...5....10    CVF = 11.92887
... cross-validation complete ... minimum found
Lasso linear model                No. of obs      =          914
                                No. of covariates =          277
Selection: Cross-validation        No. of CV folds =          10
```

* lambda selected by cross-validation.

The table ends at the 28th λ . The default grid had 100 λ 's. The iteration over the λ grid ended after a minimum of the CV function was found. There are other cases in which the iteration ends before the end of the grid is reached. See *The CV function* in [LASSO] [lasso](#) and [LASSO] [lasso fitting](#) for details.

The option `alllambdas` shows all the λ 's for which models were fit. In this case, the first 28 λ 's in the grid.

```
. lassoknots, alllambdas
```

28	.0737359	80	11.92887	A 0.q13 0.q30 0.q68 q52 q70 2.q110 0.q153 0.q159

* lambda selected by cross-validation.

The λ 's that are not knots have a U for unchanged in the variables column. At these λ 's, the variables in the model do not change, but their coefficient estimates do. In this example, the selected λ^* is a knot, but frequently the selected λ^* will not be a knot.

We display the number of nonzero coefficients again, but this time with estimates of out-of-sample R^2 and in-sample R^2 .

```

* lambda selected by cross-validation.

In-sample R^2 is significantly larger than the estimates of out-of-sample R^2 . As we discussed in *In-sample measures versus estimates of out-of-sample measures* above, in-sample R^2 should not be used for assessing fit. It is, however, occasionally useful for exposing problems with the specification of the set of potential covariates. For example, suppose our dependent variable is log-income and we accidentally include income as a potential covariate. It will no doubt be selected, and we will see an R^2 of 1 or close to it. Seeing that, we realize we made a mistake in the specification of potential variables.

We run `lassoknots` again to display BIC and the relative norms of the coefficient vectors.

```
. lassoknots, display(l1 l2 bic)
```

ID	lambda	BIC	Relative L1 length	Relative L2 length

28	.0737359	5232.569	1.0000	1.0000

* lambda selected by cross-validation.

The relative norms are relative to the coefficient vector for the last λ . If we were using BIC to select λ^* , we would have chosen λ at ID = 18.

◀

► Example 2: lasso logit

We fit a lasso logit model using the same data as in the [previous example](#).

```
. lasso logit q106 $idemographics $ifactors $v|continuous, rseed(1234)
10-fold cross-validation with 100 lambdas ...
Grid value 1: lambda = .0886291 no. of nonzero coef. = 0
Folds: 1...5....10 CVF = 1.386903
(output omitted)
Grid value 27: lambda = .0078899 no. of nonzero coef. = 87
Folds: 1...5....10 CVF = 1.103886
... cross-validation complete ... minimum found
Lasso logit model No. of obs = 914
No. of covariates = 277
Selection: Cross-validation No. of CV folds = 10
```

ID	Description	lambda	No. of nonzero coef.	Out-of-sample dev. ratio	CV mean deviance
1	first lambda	.0886291	0	-0.0004	1.386903
23	lambda before	.0114469	68	0.2102	1.094953
* 24	selected lambda	.01043	76	0.2103	1.09471
25	lambda after	.0095034	79	0.2091	1.096417
27	last lambda	.0078899	87	0.2037	1.103886

* lambda selected by cross-validation.

The default `lassoknots` gives a table that is the same as that for a linear model, except that instead of CV mean-prediction error, CV mean deviance is shown. The CV function for logit (and probit and Poisson) is the CV mean deviance.

```
. lassoknots
```

* lambda selected by cross-validation.

We can look at in-sample CV deviance ratio and estimates of out-of-sample CV deviance ratio. These are analogous to the linear in-sample R^2 and out-of-sample R^2 . The in-sample CV deviance

ratio is always between 0 and 1. The estimates of out-of-sample CV deviance ratio are usually, but not always, between 0 and 1.

```
. lassoknots, display(cvdevratio devratio bic)
```

27	.0078899	0.2037	0.3535	1419.149

* lambda selected by cross-validation.

◀

► Example 3: dsregress

We load the data used in [\[LASSO\] lasso examples](#). See that entry for details about the data.

```
. use https://www.stata-press.com/data/r18/fakesurvey_v1, clear
(Fictitious survey data with v1)
. v1 rebuild
Rebuilding v1 macros ...
(output omitted)
```

We are going to fit a `dsregress` model with `q104` as our dependent variable and variables of interest `q41` and `q22`. These variables of interest are currently in the variable lists `factors` and `vlcontinuous`, which we will use to specify the control variables. So we need to move them out of these variable lists.

```
. v1 modify factors = factors - (q41)
note: 1 variable removed from $factors.
. v1 move (q22) vlother
note: 1 variable specified and 1 variable moved.
(output omitted)
. v1 rebuild
Rebuilding v1 macros ...
(output omitted)
```

After we moved the variables out of the variable lists, we typed `v1 rebuild` to update the variable list `ifactors` created from `factors`. See [\[D\] v1](#) for details.

We fit our `dsregress` model using the default plugin selection method.

```
. dsregress q104 i.q41 q22, controls(($idemographics) $ifactors $v1continuous)
Estimating lasso for q104 using plugin
Estimating lasso for 1bn.q41 using plugin
Estimating lasso for q22 using plugin
Double-selection linear model      Number of obs      =      914
                                Number of controls =      274
                                Number of selected controls =      33
                                Wald chi2(2)           =      18.72
                                Prob > chi2           =      0.0001
```

q104	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
q41						
Yes	.8410538	.2691082	3.13	0.002	.3136114	1.368496
q22	-.0878443	.0310435	-2.83	0.005	-.1486884	-.0270001

Note: Chi-squared test is a Wald test of the coefficients of the variables of interest jointly equal to zero. Lassos select controls for model estimation. Type `lassoinfo` to see number of selected variables in each lasso.

`lassoinfo` shows the lassos that `dsregress` fit.

```
. lassoinfo
Estimate: active
Command: dsregress
```

Variable	Model	Selection method	lambda	No. of selected variables
q104	linear	plugin	.1467287	18
1bn.q41	linear	plugin	.1467287	16
q22	linear	plugin	.1467287	15

The knot table for the lasso for the dependent variable `q104` can be seen using the `for(q104)` option. We also show BIC and in-sample R^2 .

```
. lassoknots, display(nonzero r2 bic) for(q104)
```

ID	lambda	No. of nonzero coef.	In-sample R-squared	BIC
* 1	.1467287	14	0.1623	5191.862

* lambda selected by plugin assuming heteroskedastic errors.

A lasso fit with plugin fits only one model for one λ . So that is all we get from `lassoknots`.

If we wanted to see the same table for the variable of interest `i.q41`, we would type

```
. lassoknots, display(nonzero r2 bic) for(1bn.q41)
```

In the `for()` option, we specify the variable name for the lasso exactly as it is shown in `lassoinfo`.

We run `dsregress` again, this time specifying `selection(cv)`.

```
. dsregress q104 i.q41 q22,
> controls(($idemographics) $ifactors $vlncontinuous)
> selection(cv) rseed(1234)

Estimating lasso for q104 using cv
Estimating lasso for 1bn.q41 using cv
Estimating lasso for q22 using cv

Double-selection linear model      Number of obs      =      914
                                   Number of controls =      274
                                   Number of selected controls = 123
                                   Wald chi2(2)         =      10.96
                                   Prob > chi2          =      0.0042
```

q104	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
q41						
Yes	.6003918	.2848483	2.11	0.035	.0420994	1.158684
q22	-.0681067	.0306219	-2.22	0.026	-.1281246	-.0080888

Note: Chi-squared test is a Wald test of the coefficients of the variables of interest jointly equal to zero. Lassos select controls for model estimation. Type `lassoinfo` to see number of selected variables in each lasso.

`lassoknots` now shows knots up to the minimum and slightly passed it.

```
. lassoknots, display(nonzero cvmpe osr2) for(q104)
```

* lambda selected by cross-validation.

For a sensitivity analysis that uses `lassoselect` after `lassoknots`, see [\[LASSO\] lassoselect](#).

Stored results

`lassoknots` stores the following in `r()`:

Matrices

`r(table)` matrix containing the values displayed

Methods and formulas

Methods and formulas are presented under the following headings:

Overview

Statistics that measure the size of the coefficient vector

Statistics that measure fit

CV measures of fit

Single-sample measures of fit

Deviance formulas

Saturated log likelihood

Prediction error formulas

BIC formula

Overview

All the reported statistics depend on the p -dimensional coefficient vector $\widehat{\beta}_\lambda$, which is the penalized estimate of β for given penalty value λ .

We present the formulas in the context of `lasso`, but formulas for `elasticnet` and `sqrlasso` are the same, although the context would have some subtle differences that we can safely ignore.

Statistics that measure the size of the coefficient vector

Option `display(nonzero)` displays the number of nonzero coefficients, which is given by

$$\text{nonzero} = \sum_{j=1}^p d_j$$

$$d_j = \begin{cases} 1 & \text{if } \widehat{\beta}_{\lambda,j} \neq 0 \\ 0 & \text{otherwise} \end{cases}$$

Option `display(l1)` displays the sum of the absolute values of the coefficients, which is known as the ℓ_1 -norm:

$$l1 = \sum_{j=1}^p |\widehat{\beta}_{\lambda,j}|$$

Option `display(l2)` displays the sum of the squared values of the coefficients, which is the square of the ℓ_2 -norm:

$$l2 = \sum_{j=1}^p \widehat{\beta}_{\lambda,j}^2$$

Statistics that measure fit

All statistics that measure fit are functions of the observation-level contributions of either the squared prediction error, spe_i , or the log likelihood, ℓ_i .

The contribution of observation i to a statistic can be calculated using a single-sample calculation or using CV. The CV version estimates the out-of-sample equivalent. The single-sample versions are in-sample measures that do not reliably estimate their out-of-sample equivalents.

CV measures of fit

When CV is performed, CV versions of spe_i and ℓ_i are available. Here is how we compute these observation-level quantities.

1. The data are partitioned into K folds.
2. For each value of λ ,
 - a. the coefficients are estimated on the observations not in fold k using λ .
 - b. for each observation i in fold k , the fit measures spe_i and ℓ_i are computed using the penalized coefficient estimates.

Single-sample measures of fit

The single-sample measures of fit are computed as follows.

1. For each value of λ ,
 - a. the coefficients are estimated on all the observations using λ .
 - b. for each observation i the fit measures spe_i and ℓ_i are computed using the penalized coefficient estimates.

Deviance formulas

The CV version of ℓ_i is used in the formulas for `cvmd` and `cvdevratio`. The single-sample version of ℓ_i is used in the formula for `devratio`.

For all models, the deviance, D_i , for the i th observation is given by

$$D_i = -2(\ell_i - \ell_{\text{saturated}})$$

where ℓ_i is the value of the log-likelihood function at observation i , and $\ell_{\text{saturated}}$ is the value of the saturated log-likelihood function. Formulas for the ℓ_i and for the $\ell_{\text{saturated}}$ are given below. The penalized coefficient estimates are used in these computations.

The mean deviance \bar{D} is given by

$$\bar{D} = \frac{1}{N} \sum_{i=1}^N D_i$$

The formula for the deviance ratio D_2 is

$$D_2 = 1 - \frac{\bar{D}}{D_{\text{null}}}$$

where the D_{null} is the null deviance and is given by

$$D_{\text{null}} = \frac{1}{N} \sum_{i=1}^N -2(\ell_{0,i} - \ell_{\text{saturated}})$$

and $\ell_{0,i}$ is the i th observation of the log likelihood from the model that includes only a constant term.

Saturated log likelihood

For linear, logit, and probit models, the log-likelihood function of the saturated model is zero. For the Poisson model,

$$\ell_{\text{saturated}} = \frac{1}{N} \sum_{i=1}^N (-y_i + y_i \ln y_i)$$

For the Cox model,

$$\ell_{\text{saturated}} = -\frac{1}{N} \sum_{j=1}^{N_f} d_j \log(d_j)$$

where j indexes the ordered failure times $t_{(j)}$, $j = 1, \dots, N_f$; D_j is the set of observations that fail at $t_{(j)}$; and d_j is the number of observations in D_j .

Prediction error formulas

These formulas are used only for linear models. The squared prediction error for the i th observation is given by

$$\text{spe}_i = \left(y_i - \mathbf{x}_i \widehat{\beta}_\lambda \right)^2$$

where y_i is the i th observation of the dependent variable and $\mathbf{x}_i \widehat{\beta}_\lambda$ is the predicted mean of y_i conditional on \mathbf{x}_i .

For `cvmppe` and `osr2`, the CV version of spe_i is used. For `r2`, the single-sample version of spe_i is used.

R^2 is given by

$$R^2 = 1 - \frac{\text{MSE}}{\text{MSE}_{\text{null}}}$$

where the mean squared error (MSE) is given by

$$\text{MSE} = \frac{1}{N} \sum_{i=1}^N \text{spe}_i$$

and the MSE of the null model is given by

$$\text{MSE}_{\text{null}} = \frac{1}{N} \sum_{i=1}^N (y_i - \bar{y})^2$$

where \bar{y} is the sample average of y .

BIC formula

BIC is given by

$$\text{BIC} = -2\ell + k \ln N$$

where $\ell = \sum_{i=1}^N \ell_i$, $k = \text{nonzero} + 1$ is the number of coefficients in the model including the constant term, and each ℓ_i is always calculated using the single-sample methods.
