Instruments for equation eq1: 0.mbsmoke 1.mbsmoke 0.mbsmoke#c.mage
1.mbsmoke#c.mage 0o.mbsmoke#0b.prenatal1 0.mbsmoke#1.prenatal1
1o.mbsmoke#0b.prenatal1 1.mbsmoke#1.prenatal1
```

We specified the `coeflegend` option to learn the names of the coefficients on the factor variables in the linear combination. As expected, the point estimates are the same as those reported by `regress`.

Next, we illustrate the effect of the two-step estimation problem if we calculate the potential-outcome means by hand. We can calculate the mean when no mothers smoke by accessing these coefficients and then estimate the standard errors in the estimated means:

```
. generate mean0 = _b[xb:0.mbsmoke] + _b[xb:0.mbsmoke#c.mage]*mage
> + _b[xb:0.mbsmoke#1.prenatal1]*prenatal1
```

```
. mean mean0
```

```
Mean estimation                               Number of obs = 4,642
```

	Mean	Std. err.	[95% conf. interval]	
mean0	3407.506	1.085503	3405.378	3409.634

The estimated potential-outcome mean for no mothers smoking is the same as that reported by margins, but the standard error is much smaller because mean ignores the estimation error in the coefficients. This underscores the importance of accounting for the estimation error when estimating the standard errors.

Now, we use gmm to estimate the coefficients and the potential-outcome means simultaneously.

```
. gmm (eq1: bweight - {xb:ibn.mbsmoke ibn.mbsmoke#(c.mage i.prenatal1)})
> (eq2: {xb:0.mbsmoke} + {xb:0bn.mbsmoke#c.mage}*mage
> + {xb:0bn.mbsmoke#1.prenatal1}*1.prenatal1 - {m0})
> (eq3: {xb:1.mbsmoke} + {xb:1.mbsmoke#c.mage}*mage
> + {xb:1.mbsmoke#1.prenatal1}*1.prenatal1 - {m1}),
> instruments(eq1: ibn.mbsmoke ibn.mbsmoke#(c.mage i.prenatal1),
> noconstant)
> instruments(eq2 eq3:) winitial(identity) onestep
```

```
Step 1
```

```

This output has five noteworthy features.

1. We specify three different residual equations. The first, `eq1:`, defines the moment conditions for the regression using the covariates as instruments; `eq2:` is the moment condition for the potential outcome when no mothers smoke; and `eq3:` is the moment condition for the potential outcome when all mothers smoke.
2. In `eq2:` and `eq3:`, we refer to the individual coefficients on the factor variables in the linear combination `xb:` by enclosing their names in curly braces.
3. The option `instruments()` is repeatable. We first specify that the covariates in the regression are the instruments for the residual equation `eq1:` and then specify that only the unit variable, also known as the constant, is an instrument for each of `eq2:` and `eq3:`.
4. The point estimates and the standard errors match those reported by `regress` and `margins`, after accounting for the small-sample adjustment performed by `regress`.
5. Although the point estimates match, the standard errors reported by `gmm` are much larger than those reported by `mean` because `gmm` takes into account that the regression coefficients are estimated.

◀

## Parameter interpretation using margins

In the last section, we demonstrated how to use `gmm` to estimate potential-outcome means in a linear regression model jointly with the coefficients of the models. However, you can also estimate the potential-outcome mean, or any other predictive margins, by using the `margins` command after `gmm`. Using `margins` after `gmm` can allow more flexibility in the predictive margins that we estimate and is also more convenient. See *Obtaining margins of responses* in [R] [margins](#) for more information about predictive margins.

### ► Example 5: Predicting treatment effects after estimation

In [example 4](#), we used `gmm` to estimate potential-outcome means of a mother's smoking behavior on her baby's birthweight (in grams) after controlling for age and whether she had a prenatal visit in the first trimester. Here we demonstrate how to use `margins` after `gmm` to estimate the potential-outcome means.

First, we load the data and reestimate the regression coefficients.

```
. use https://www.stata-press.com/data/r18/cattaneo2
(Excerpt from Cattaneo (2010) Journal of Econometrics 155: 138-154)
. gmm (eq1: bweight - {xb:ibn.mbsmoke ibn.mbsmoke#(c.mage i.prenatal1)}),
> instruments(eq1: ibn.mbsmoke ibn.mbsmoke#(c.mage i.prenatal1), noconstant)
> onestep

Step 1
Iteration 0: GMM criterion Q(b) = 11316945
Iteration 1: GMM criterion Q(b) = 7.143e-19
Iteration 2: GMM criterion Q(b) = 2.051e-26
note: model is exactly identified.

GMM estimation
Number of parameters = 6
Number of moments = 6
Initial weight matrix: Unadjusted          Number of obs = 4,642
```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
mbsmoke						
Nonsmoker	3073.201	48.65752	63.16	0.000	2977.834	3168.568
Smoker	3217.973	93.57647	34.39	0.000	3034.566	3401.379

mbsmoke# prenatal1						
Nonsmoker # Yes	95.11727	26.80305	3.55	0.000	42.58425	147.6503
Smoker#Yes	64.61752	39.69749	1.63	0.104	-13.18813	142.4232

```
Instruments for equation eq1: 0.mbsmoke 1.mbsmoke 0.mbsmoke#c.mage
1.mbsmoke#c.mage 0o.mbsmoke#0b.prenatal1 0.mbsmoke#1.prenatal1
1o.mbsmoke#0b.prenatal1 1.mbsmoke#1.prenatal1
```

Now, we use `margins` to estimate the potential-outcome means. We specify `vce(unconditional)` to obtain standard errors for the potential-outcome means of the population rather than the sample. When we specify this option, the standard errors for the estimated means will account for the estimation error in the estimated coefficients from `gmm`.

```
. margins i.mbsmoke, vce(unconditional)
Predictive margins          Number of obs = 4,642
Expression: Linear prediction, predict()
```

	Margin	Unconditional std. err.	z	P> z	[95% conf. interval]	
mbsmoke						
Nonsmoker	3407.506	9.341858	364.76	0.000	3389.196	3425.815
Smoker	3138.23	21.19321	148.08	0.000	3096.692	3179.768

Our point estimates of the potential-outcome means exactly match those that appear as  $\mu_0$  and  $\mu_1$  in [example 4](#). However, the standard errors are slightly higher because `gmm` and `margins` use different values in the denominator for the formula for the robust covariance matrix. `gmm` uses  $N$  while `margins`

uses  $N - 1$ , so the standard errors differ by a factor of  $\sqrt{\{N/(N - 1)\}} = \sqrt{4,642/4,641} \approx 1.0002$ . More details about the calculation of the standard errors are provided in *Marginal predictions with unconditional standard errors* in the *Methods and formulas*.

In addition to potential-outcome means, we can use `margins` to estimate the average treatment effect (ATE) of the mother's smoking behavior on birthweight. We use the contrast operator `r.` to instruct `margins` to difference the potential-outcome means and estimate a treatment effect. We specify the `contrast(nowald)` option to suppress the Wald test that `margins` displays by default for contrasts.

```
. margins r.mbsmoke, vce(unconditional) contrast(nowald)
Contrasts of predictive margins                Number of obs = 4,642
Expression: Linear prediction, predict()
```

	Unconditional		
	Contrast	std. err.	[95% conf. interval]
mbsmoke (Smoker vs Nonsmoker)	-269.2759	23.16069	-314.67 -223.8818

The ATE of  $-269.28$  is interpreted as the difference between the average birthweight if all mothers in the population smoked and the average birthweight if all mothers in the population did not smoke. The average birthweight if all mothers were to smoke would be 269.28 grams less than if they did not smoke.

◀

## Exponential (Poisson) regression models

Exponential regression models are frequently encountered in applied work. For example, they can be used as alternatives to linear regression models on log-transformed dependent variables, obviating the need for post-hoc transformations to obtain predicted values in the original metric of the dependent variable. When the dependent variable represents a discrete count variable, exponential regression models are also known as Poisson regression models; see [Cameron and Trivedi \(2013\)](#).

For now, we consider models of the form

$$y = \exp(\mathbf{x}'\boldsymbol{\beta}) + u \quad (7)$$

where  $u$  is a zero-mean additive error term so that  $E(y) = \exp(\mathbf{x}'\boldsymbol{\beta})$ . Because the error term is additive, if  $\mathbf{x}$  represents strictly exogenous regressors, then we have the population moment condition

$$E[\mathbf{x}\{y - \exp(\mathbf{x}'\boldsymbol{\beta})\}] = \mathbf{0} \quad (8)$$

Moreover, because the number of parameters in the model is equal to the number of instruments, there is no point to using the two-step GMM estimator.

### ► Example 6: Exponential regression

[Cameron and Trivedi \(2022, 584\)](#) fit a model of the number of doctor visits based on whether the patient has private insurance, whether the patient has a chronic disease, gender, and income. Here we fit that model by using `gmm`. To allow for potential excess dispersion, we will obtain a robust VCE matrix, which is the default for `gmm` anyway. We type

```

. use https://www.stata-press.com/data/r18/docvisits
. gmm (docvis - exp({xb:private chronic female income _cons})),
> instruments(private chronic female income) onestep

Step 1
Iteration 0: GMM criterion Q(b) = 16.853973
Iteration 1: GMM criterion Q(b) = 2.2706472
Iteration 2: GMM criterion Q(b) = .19088097
Iteration 3: GMM criterion Q(b) = .00041101
Iteration 4: GMM criterion Q(b) = 3.939e-09
Iteration 5: GMM criterion Q(b) = 6.572e-19

note: model is exactly identified.

GMM estimation

Number of parameters = 5
Number of moments = 5
Initial weight matrix: Unadjusted          Number of obs = 4,412

```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
private	.7986654	.1089891	7.33	0.000	.5850507	1.01228
chronic	1.091865	.0559888	19.50	0.000	.9821291	1.201601

income	.003557	.0010824	3.29	0.001	.0014356	.0056784
_cons	-.2297263	.1108607	-2.07	0.038	-.4470093	-.0124434

Instruments for equation 1: private chronic female income \_cons

Our point estimates agree with those reported by [Cameron and Trivedi \(2022\)](#) to at least six significant digits; the small discrepancies are attributable to different optimization techniques and convergence criteria being used by `gmm` and `poisson`. The standard errors differ by a factor of  $\sqrt{4412/4411}$  because `gmm` uses  $N$  in the denominator of the formula for the robust covariance matrix, while the robust covariance matrix estimator used by `poisson` uses  $N - 1$ .

◀

## □ Technical note

That the GMM and maximum likelihood estimators of the exponential regression model coincide is not a general property of these two classes of estimators. The maximum likelihood estimator solves the score equations

$$\frac{1}{N} \sum_{i=1}^N \frac{\partial \ln \ell_i}{\partial \beta} = \mathbf{0}$$

where  $\ell_i$  is the likelihood for the  $i$ th observation. These score equations can be viewed as the sample analogues of the population moment conditions

$$E \left( \frac{\partial \ln \ell_i}{\partial \beta} \right) = \mathbf{0}$$

establishing that maximum likelihood estimators represent a subset of the class of GMM estimators.

For the Poisson model,

$$\ln \ell_i = -\exp(\mathbf{x}'_i \beta) + y_i \mathbf{x}'_i \beta - \ln y_i!$$

so the score equations are

$$\frac{1}{N} \sum_{i=1}^N \mathbf{x}_i \{y_i - \exp(\mathbf{x}'_i \boldsymbol{\beta})\} = \mathbf{0}$$

which are just the sample moment conditions implied by (8) that we used in the [previous example](#). That is why our results using `gmm` match Cameron and Trivedi's (2022) results using `poisson`.

On the other hand, an intuitive set of moment conditions to consider for GMM estimation of a probit model is

$$E[\mathbf{x}\{y - \Phi(\mathbf{x}'\boldsymbol{\beta})\}] = \mathbf{0}$$

where  $\Phi()$  is the standard normal cumulative distribution function. Differentiating the likelihood function for the maximum-likelihood probit estimator, we can show that the corresponding score equations are

$$\frac{1}{N} \sum_{i=1}^N \left[ \mathbf{x}_i \left\{ y_i \frac{\phi(\mathbf{x}'_i \boldsymbol{\beta})}{\Phi(\mathbf{x}'_i \boldsymbol{\beta})} - (1 - y_i) \frac{\phi(\mathbf{x}'_i \boldsymbol{\beta})}{1 - \Phi(\mathbf{x}'_i \boldsymbol{\beta})} \right\} \right] = \mathbf{0}$$

where  $\phi()$  is the standard normal density function. These two moment conditions are not equivalent, so the maximum likelihood and GMM probit estimators are distinct. □

## ► Example 7: Comparison of GMM and maximum likelihood

Using the automobile dataset, we fit a probit model of `foreign` on `gear_ratio`, `length`, and `headroom` using first the score equations and then the intuitive set of GMM equations. We type

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)

. gmm (foreign*normalden({xb:gear_ratio length headroom _cons})/
> normal({xb:}) - (1-foreign)*normalden({xb:})/(1-normal({xb:}))),
> instruments(gear_ratio length headroom) onestep
(output omitted)

. estimates store ml

. gmm (foreign - normal({xb:gear_ratio length headroom _cons})),
> instruments(gear_ratio length headroom) onestep
(output omitted)

. estimates store gmm

. estimates table ml gmm, b se
```

Variable	ml	gmm
gear_ratio	2.9586277 .64042341	2.8489213 .63570246
length	-.02148933 .01382043	-.02056033 .01396954
headroom	.01136927 .27278528	.02240761 .2849891
_cons	-6.0222289 3.5594588	-5.8595615 3.5188028

Legend: b/se

The coefficients on `gear_ratio` and `length` are close for the two estimators. The GMM estimate of the coefficient on `headroom` is twice that of the maximum likelihood estimate, though the relatively large standard errors imply that this difference is not significant. You can verify that the coefficients in the column marked “ml” match those you would obtain with `probit`. We have not discussed the differences among standard errors based on the various GMM and maximum-likelihood covariance matrix estimators to avoid tedious algebra. However, you can verify that the robust covariance matrix after one-step GMM estimation differs by only a finite-sample adjustment factor of  $(N/N - 1)$  from the robust covariance matrix reported by `probit`. Both the maximum likelihood and GMM `probit` estimators require the normality assumption, and the maximum likelihood estimator is efficient if that normality assumption is correct; therefore, in this example, there is no reason to prefer the GMM estimator.

◀

We can modify (8) easily to allow for endogenous regressors. Suppose that  $x_j$  is endogenous in the sense that  $E(u|x_j) \neq 0$ . Then, (8) is no longer a valid moment condition. However, suppose we have some variables other than  $\mathbf{x}$  such that  $E(u|\mathbf{z}) = \mathbf{0}$ . We can instead use the moment conditions

$$E(\mathbf{z}u) = E[\mathbf{z}\{y - \exp(\mathbf{x}'\boldsymbol{\beta})\}] = \mathbf{0}$$

As usual, if some elements of  $\mathbf{x}$  are exogenous, then they should appear in  $\mathbf{z}$  as well.

### ► Example 8: Exponential regression with endogenous regressors

Returning to the model discussed in [example 6](#), we treat `income` as endogenous; unobservable factors that determine a person’s income may also affect the number of times a person visits a doctor. We use a person’s age and race as instruments. These are valid instruments if we believe that age and race influence a person’s income but do not have a direct impact on the number of doctor visits. (Whether this belief is justified is another matter; we test that belief in [\[R\] gmm postestimation](#).) Because we have more instruments (seven) than parameters (five), we have an overidentified model. Therefore, the choice of weight matrix does matter. We will use the default two-step GMM estimator. In the first step, we will use a weight matrix that assumes the errors are i.i.d. In the second step, we will use a weight matrix that assumes heteroskedasticity. When you specify `twostep`, these are the defaults for the first- and second-step weight matrices, so we do not have to use the `winitial()` or `wmatrix()` options. We will again obtain a robust VCE, which is also the default. We type

```
. use https://www.stata-press.com/data/r18/docvisits
. gmm (docvis - exp({xb:private chronic female income_cons})),
> instruments(private chronic female age black hispanic) twostep

Step 1
Iteration 0: GMM criterion Q(b) = 16.910173
Iteration 1: GMM criterion Q(b) = .82276104
Iteration 2: GMM criterion Q(b) = .21832032
Iteration 3: GMM criterion Q(b) = .12685935
Iteration 4: GMM criterion Q(b) = .12672369
Iteration 5: GMM criterion Q(b) = .12672365

Step 2
Iteration 0: GMM criterion Q(b) = .00234641
Iteration 1: GMM criterion Q(b) = .00215957
Iteration 2: GMM criterion Q(b) = .00215911
Iteration 3: GMM criterion Q(b) = .00215911
```

GMM estimation

Number of parameters = 5

Number of moments = 7

Initial weight matrix: Unadjusted

Number of obs = 4,412

GMM weight matrix: Robust

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
private	.535335	.1599039	3.35	0.001	.2219291	.8487409
chronic	1.090126	.0617659	17.65	0.000	.9690668	1.211185
female	.6636579	.0959884	6.91	0.000	.4755241	.8517918
income	.0142855	.0027162	5.26	0.000	.0089618	.0196092
_cons	-.5983477	.138433	-4.32	0.000	-.8696713	-.327024

Instruments for equation 1: private chronic female age black hispanic \_cons

Once we control for the endogeneity of income, we find that its coefficient has quadrupled in size. Additionally, access to private insurance has less of an impact on the number of doctor visits and gender has more of an impact.

◀

## □ Technical note

Although you may be tempted to try, you cannot, as you can in a Poisson model, replace  $\mathbf{x}$  in the moment conditions for the probit (or logit) model with a vector of instruments,  $\mathbf{z}$ , if you have endogenous regressors. See [Wilde \(2008\)](#).

□

[Mullahy \(1997\)](#) considers a slightly more complicated version of the exponential regression model that incorporates nonadditive unobserved heterogeneity. His model can be written as

$$y_i = \exp(\mathbf{x}'_i \boldsymbol{\beta}) \eta_i + \epsilon_i$$

where  $\eta_i > 0$  is an unobserved heterogeneity term that may be correlated with  $\mathbf{x}_i$ . One result from his article is that instead of using the additive moment condition (8), we can use the multiplicative moment condition

$$E \left\{ \mathbf{z} \frac{y - \exp(\mathbf{x}'\boldsymbol{\beta})}{\exp(\mathbf{x}'\boldsymbol{\beta})} \right\} = E[\mathbf{z}\{y\exp(-\mathbf{x}'\boldsymbol{\beta}) - 1\}] = \mathbf{0}$$

[Windmeijer and Santos Silva \(1997\)](#) discuss the use of additive versus multiplicative moment conditions with endogenous regressors and note that a set of instruments that satisfies the additive moment conditions will not also satisfy the multiplicative moment conditions. They remark that the decision about which to use is an empirical issue that can at least partially be settled by using the test of overidentifying restrictions that is implemented by `estat overid` after `gmm` to see whether the instruments for a given model are valid. See [\[R\] gmm postestimation](#) for information on the test of overidentifying restrictions.

## Specifying derivatives

By default, `gmm` calculates derivatives numerically, and the method used produces accurate results for the vast majority of applications. However, if you refit the same model repeatedly or else have the derivatives available, then `gmm` will run more quickly if you supply it with analytic derivatives.

When you use the interactive version of `gmm`, you specify derivatives using substitutable expressions in much the same way you specify the residual equations. There are three rules you must follow:

1. As with the substitutable expressions that define residual equations, you bind parameters of the model in curly braces: `{b0}`, `{param}`, etc.
2. You must specify a derivative for each parameter that appears in each residual equation. If a parameter does not appear in a residual equation, then you do not specify a derivative for that parameter in that residual equation.
3. If you declare a linear combination in an equation, then you specify a derivative with respect to that linear combination. `gmm` applies the chain rule to obtain the derivatives with respect to the individual parameters encompassed by that linear combination.

We illustrate with several examples.

### ► Example 9: Derivatives for a single-equation model

Consider a simple exponential regression model with one exogenous regressor and a constant term. We have

$$u_i = y_i - \exp(\beta_0 + \beta_1 x_i)$$

Now,

$$\frac{\partial u_i}{\partial \beta_0} = -\exp(\beta_0 + \beta_1 x_i) \quad \text{and} \quad \frac{\partial u_i}{\partial \beta_1} = -x_i \exp(\beta_0 + \beta_1 x_i)$$

In Stata, we type

```
. gmm (docvis - exp({b0} + {b1}*income)), instruments(income)
> deriv(/b0 = -1*exp({b0} + {b1}*income))
> deriv(/b1 = -1*income*exp({b0}+{b1}*income)) onestep
```

Step 1

```
Iteration 0: GMM criterion Q(b) = 9.1548611
Iteration 1: GMM criterion Q(b) = 3.5146131
Iteration 2: GMM criterion Q(b) = .01344695
Iteration 3: GMM criterion Q(b) = 3.690e-06
Iteration 4: GMM criterion Q(b) = 4.606e-13
Iteration 5: GMM criterion Q(b) = 1.502e-26
```

note: model is exactly identified.

GMM estimation

```
Number of parameters = 2
Number of moments = 2
Initial weight matrix: Unadjusted          Number of obs = 4,412
```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
/b0	1.204888	.0462355	26.06	0.000	1.114268	1.295507
/b1	.0046702	.0009715	4.81	0.000	.0027662	.0065743

Instruments for equation 1: income\_cons

Notice how we specified the `derivative()` option for each parameter. We simply specified a slash, the name of the parameter, an equal sign, then a substitutable expression that represents the derivative. Because our model has only one residual equation, we do not need to specify equation numbers in the `derivative()` options.

◀

When you specify a linear combination of variables, your derivative should be with respect to the entire linear combination. For example, say we have the residual equation

$$u_i = y - \exp(\mathbf{x}'_i\boldsymbol{\beta} + \beta_0)$$

for which we would type

```
. gmm (y - exp({xb: x1 x2 x3} + {b0}) ...
```

Then, in addition to the derivative  $\partial u_i / \partial \beta_0$ , we are to compute and specify

$$\frac{\partial u_i}{\partial \mathbf{x}'_i\boldsymbol{\beta}} = -\exp(\mathbf{x}'_i\boldsymbol{\beta} + \beta_0)$$

Using the chain rule,  $\partial u_i / \partial \beta_j = \partial u_i / \partial (\mathbf{x}'_i\boldsymbol{\beta}) \times \partial (\mathbf{x}'_i\boldsymbol{\beta}) / \partial \beta_j = -x_{ij} \exp(\mathbf{x}'_i\boldsymbol{\beta} + \beta_0)$ . Stata does this last calculation automatically. It knows the variables in the linear combination, so all it needs is the derivative of the residual equation with respect to the linear combination. This allows you to change the variables in your linear combination without having to change the derivatives.

### ▶ Example 10: Derivatives with a linear combination

We refit the model described in the [example](#) illustrating exponential regression with endogenous regressors, now providing analytic derivatives. We type

```
. gmm (docvis - exp({xb:private chronic female income _cons})),
> instruments(private chronic female age black hispanic)
> derivative(/xb = -1*exp({xb:}))

Step 1
Iteration 0: GMM criterion Q(b) = 16.910173
Iteration 1: GMM criterion Q(b) = .82270871
Iteration 2: GMM criterion Q(b) = .21831995
Iteration 3: GMM criterion Q(b) = .12685934
Iteration 4: GMM criterion Q(b) = .12672369
Iteration 5: GMM criterion Q(b) = .12672365

Step 2
Iteration 0: GMM criterion Q(b) = .00234641
Iteration 1: GMM criterion Q(b) = .00215957
Iteration 2: GMM criterion Q(b) = .00215911
Iteration 3: GMM criterion Q(b) = .00215911

GMM estimation
Number of parameters = 5
Number of moments = 7
Initial weight matrix: Unadjusted          Number of obs = 4,412
GMM weight matrix: Robust
```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]

Instruments for equation 1: private chronic female age black hispanic \_cons

In the first `derivative()` option, we specified the name of the linear combination, `xb`, instead of an individual parameter's name. We already declared the variables of our linear combination in the substitutable expression for the residual equation, so in our substitutable expressions for the derivatives, we can use the shorthand notation `{xb:}` to refer to it.

Our point estimates are identical to those we obtained earlier. The standard errors and confidence intervals differ by only trivial amounts.

◀

## Exponential regression models with panel data

In addition to supporting cross-sectional and time-series data, `gmm` also works with panel-data models. Here we illustrate `gmm`'s panel-data capabilities by expanding our discussion of exponential regression models to allow for panel data. This also provides us the opportunity to demonstrate the moment-evaluator program version of `gmm`. Our discussion is based on [Blundell, Griffith, and Windmeijer \(2002\)](#). Also see [Wooldridge \(1999\)](#) for further discussion of nonlinear panel-data models.

First, we expand (7) for panel data. With individual heterogeneity term  $\eta_i$ , we have

$$E(y_{it} | \mathbf{x}_{it}, \eta_i) = \exp(\mathbf{x}'_{it} \boldsymbol{\beta} + \eta_i) = \mu_{it} \nu_i$$

where  $\mu_{it} = \exp(\mathbf{x}'_{it} \boldsymbol{\beta})$  and  $\nu_i = \exp(\eta_i)$ . Note that there is no constant term in this model, because its effect cannot be disentangled from  $\nu_i$ . With an additive idiosyncratic error term, we have the regression model

$$y_{it} = \mu_{it} \nu_i + \epsilon_{it}$$

We do not impose the assumption  $E(\mathbf{x}_{it}\eta_i) = \mathbf{0}$ , so  $\eta_i$  can be considered a fixed effect in the sense that it may be correlated with the regressors.

As discussed by [Blundell, Griffith, and Windmeijer \(2002\)](#), if  $\mathbf{x}_{it}$  is strictly exogenous, meaning  $E(\mathbf{x}_{it}\epsilon_{is}) = \mathbf{0}$  for all  $t$  and  $s$ , then we can estimate the parameters of the model by using the sample moment conditions

$$\sum_i \sum_t \mathbf{x}_{it} \left( y_{it} - \mu_{it} \frac{\bar{y}_i}{\bar{\mu}_i} \right) = \mathbf{0} \quad (9)$$

where  $\bar{y}_i$  and  $\bar{\mu}_i$  are the means of  $y_{it}$  and  $\mu_{it}$  for panel  $i$ , respectively. Because  $\bar{\mu}_i$  depends on the parameters of the model, it must be recomputed each time **gmm** needs to evaluate the residual equation. Therefore, we cannot use the substitutable expression version of **gmm**. Instead, we must use the moment-evaluator program version.

The moment-evaluator program version of **gmm** functions much like the function-evaluator program versions of **nl** and **nlsur**. The program you write is passed one or more variables to be filled in with the residuals evaluated at the parameter values specified in an option passed to your program. For the fixed-effects Poisson model with strictly exogenous regressors, our first crack at a function-evaluator program is

```

program gmm_poi
    version 18.0
    syntax varlist if, at(name)
    quietly {
        tempvar mu mubar ybar
        generate double 'mu' = exp(x1*'at'[1,1] + x2*'at'[1,2] //
                                + x3*'at'[1,3]) 'if'
        egen double 'mubar' = mean('mu') 'if', by(id)
        egen double 'ybar' = mean(y) 'if', by(id)
        replace 'varlist' = y - 'mu'*'ybar'/'mubar' 'if'
    }
end

```

You can save your program in an ado-file named *name.ado*, where *name* is the name you use for your program; here we would save the program in the ado-file **gmm\_poi.ado**. Alternatively, if you are working from within a do-file, you can simply define the program before calling **gmm**. The **syntax** statement declares we are expecting to receive a *varlist* that will contain the names of variables whose values we are to replace with the values of the residual equations and an *if* expression that will mark the estimation sample; because our model has one residual equation, *varlist* will consist of one variable. **at()** is a required option to our program, and it will contain the name of a matrix containing the parameter values at which we are to evaluate the residual equation. All moment-evaluator programs must accept the *varlist*, *if* condition, and **at()** option.

The first part of our program computes  $\mu_{it}$ . In the model we will fit shortly, we have three regressors, named **x1**, **x2**, and **x3**. The **'at'** vector will have three elements, one for each of those variables. Notice that we included **'if'** at the end of each statement that affects variables to restrict the computations to the relevant estimation sample. The two **egen** statements compute  $\bar{\mu}_i$  and  $\bar{y}_i$ ; in the example dataset we will use shortly, the panel variable is named **id**, and for simplicity, we hardcoded that variable into our program as well. Finally, we compute the residual equation, which is the portion of (9) bound in parentheses.

## ▶ Example 11: Panel Poisson with strictly exogenous regressors

To fit our model, we type

```
. use https://www.stata-press.com/data/r18/poisson1
. gmm gmm_poi, nequations(1) parameters(b1 b2 b3)
> instruments(x1 x2 x3, noconstant) vce(cluster id) onestep

Step 1
Iteration 0: GMM criterion Q(b) = 51.99142
Iteration 1: GMM criterion Q(b) = .04345191
Iteration 2: GMM criterion Q(b) = 8.720e-06
Iteration 3: GMM criterion Q(b) = 7.115e-13
Iteration 4: GMM criterion Q(b) = 5.130e-27

note: model is exactly identified.

GMM estimation
Number of parameters = 3
Number of moments = 3
Initial weight matrix: Unadjusted          Number of obs = 409
                                         (Std. err. adjusted for 45 clusters in id)
```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
/b1	1.94866	.1000265	19.48	0.000	1.752612	2.144709
/b2	-2.966119	.0923592	-32.12	0.000	-3.14714	-2.785099
/b3	1.008634	.1156561	8.72	0.000	.781952	1.235315

Instruments for equation 1: x1 x2 x3

All three of our regressors are strictly exogenous, so they can serve as their own regressors. There is no constant term in the model (it would be unidentified), so we exclude a constant term from our list of instruments. We have one residual equation as indicated by `nequations(1)`, and we have three parameters, named `b1`, `b2`, and `b3`. The order in which you declare parameters in the `parameters()` option determines the order in which they appear in the ‘at’ vector in the moment-evaluator program. We specified `vce(cluster id)` to obtain standard errors that allow for correlation among observations within each panel.

◀

The program we just wrote is sufficient to fit the model to the `poisson1` dataset, but if we want to fit that model to other datasets, we need to change the variable names and perhaps account for having a different number of parameters as well. Despite those limitations, if you just want to fit a single model, that program is adequate.

Next, we take advantage of the ability to specify full equation names in the `parameters()` option and rewrite our evaluator program so that we can more easily change the variables in our model. This approach is particularly useful if some of the residual equations are linear in the parameters because then we can use `matrix score` (see [P] [matrix score](#)) to evaluate those moments.

Our new evaluator program is

```

program gmm_poieq
    version 18.0
    syntax varlist if, at(name)
    quietly {
        tempvar mu mubar ybar
        matrix score double 'mu' = 'at' 'if', eq(#1)
        replace 'mu' = exp('mu')

        egen double 'mubar' = mean('mu') 'if', by(id)
        egen double 'ybar' = mean(y) 'if', by(id)
        replace 'varlist' = y - 'mu'*'ybar'/'mubar' 'if'
    }
end

```

Rather than using `generate` to compute the temporary variable `'mu'`, we used `matrix score` to obtain the linear combination  $\mathbf{x}'_{it}\beta$  and then called `replace` to compute  $\exp(\mathbf{x}'_{it}\beta)$ .

### ► Example 12: Panel Poisson using matrix score

To fit our model, we type

```

. use https://www.stata-press.com/data/r18/poisson1
. gmm gmm_poieq, nequations(1) parameters({y:x1 x2 x3})
> instruments(x1 x2 x3, noconstant) vce(cluster id) onestep

Step 1
Iteration 0:  GMM criterion Q(b) = 51.99142
Iteration 1:  GMM criterion Q(b) = .04345191
Iteration 2:  GMM criterion Q(b) = 8.720e-06
Iteration 3:  GMM criterion Q(b) = 7.115e-13
Iteration 4:  GMM criterion Q(b) = 5.130e-27

note: model is exactly identified.

GMM estimation
Number of parameters = 3
Number of moments = 3
Initial weight matrix: Unadjusted
                                Number of obs = 409
                                (Std. err. adjusted for 45 clusters in id)

```

	Robust				[95% conf. interval]	
	Coefficient	std. err.	z	P> z		
x1	1.94866	.1000265	19.48	0.000	1.752612	2.144709
x2	-2.966119	.0923592	-32.12	0.000	-3.14714	-2.785099
x3	1.008634	.1156561	8.72	0.000	.781952	1.235315

Instruments for equation 1: x1 x2 x3

Instead of specifying simple parameter names in the `parameters()` option, we specified a linear combination name and the variables associated with that combination. We named our linear combination `y`, but you could use any valid Stata name. When we use this syntax, the rows of the coefficient table are grouped by the equation names.

Say we wanted to refit our model using just `x1` and `x3` as regressors. We do not need to make any changes to `gmm_poieq`. We just change the specification of the `parameters()` option:

```

. gmm gmm_poieq, nequations(1) parameters(y:x1 y:x3)
> instruments(x1 x3, noconstant) vce(cluster id) onestep

```

In this evaluator program, we have still hardcoded the name of the dependent variable. The next two examples include methods to tackle that shortcoming.

◀

## □ Technical note

Say we specify the `parameters()` option like this:

```
. gmm ..., parameters({y1:x1 x2 _cons} {y2:_cons} {y3:x1 _cons})
```

Then, the ‘at’ vector passed to our program will have the following column names attached to it:

```
‘at’[1,6]
      y1:   y1:   y1:   y2:   y3:   y3:
      x1   x2  _cons  _cons  x1  _cons
```

Typing

```
. matrix score double eq1 = ‘at’, eq(#1)
```

is equivalent to typing

```
. generate double eq1 = x1*‘at’[1,1] + x2*‘at’[1,2] + ‘at’[1,3]
```

with one important difference. If we change some of the variables in the `parameters()` option when we call `gmm`, `matrix score` will compute the correct linear combination. If we were to use the `generate` statement instead, then every time we wanted to change the variables in our model, we would have to modify that statement as well.

The command

```
. matrix score double alpha = ‘at’, eq(#2)
```

is equivalent to

```
. scalar alpha = ‘at’[1,4]
```

Thus, even if you specify linear combination and variable names in the `parameters()` option, you can still have scalar parameters in your model.

□

When past values of the idiosyncratic error term affect the value of a regressor, we say that regressor is predetermined. When one or more regressors are predetermined, sample moment condition (8) is no longer valid. However, Chamberlain (1992) shows that a simple alternative is to consider moment conditions of the form

$$\sum_i \sum_{t=2}^T \mathbf{x}_{i,t-1} \left( y_{i,t-1} - \mu_{i,t-1} \frac{y_{it}}{\mu_{it}} \right) = \mathbf{0} \quad (10)$$

Also see Wooldridge (1997) and Windmeijer (2000) for other moment conditions that can be used with predetermined regressors.

## ▷ Example 13: Panel Poisson with predetermined regressors

Here we refit the previous model, treating all the regressors as predetermined and using the moment conditions in (10). Our moment-evaluator program is

```

program gmm_poipre
    version 18.0
    syntax varlist if, at(name) mylhs(varlist)
    quietly {
        tempvar mu
        matrix score double `mu' = `at' `if', eq(#1)
        replace `mu' = exp(`mu')
        replace `varlist' = L.`mylhs' - L.`mu'*`mylhs'/`mu' `if'
    }
end

```

To compute the residual equation, we used lag-operator notation so that Stata properly handles gaps in our panel dataset. We also made our program accept an additional option that we will use to pass in the dependent variable. When we specify this option in our `gmm` statement, it will get passed to our evaluator program because `gmm` will not recognize the option as one of its own. Equation (10) shows that we are to use the first lags of the regressors as instruments, so we type

```

. gmm gmm_poipre, mylhs(y) nequations(1) vce(cluster id) onestep
> parameters({y:x1 x2 x3}) instruments(L.(x1 x2 x3), noconstant)
note: 45 missing values returned for equation 1 at initial values.

Step 1
Iteration 0: GMM criterion Q(b) = 76.652367
Iteration 1: GMM criterion Q(b) = 1.9118192
Iteration 2: GMM criterion Q(b) = .06634724
Iteration 3: GMM criterion Q(b) = .0000233
Iteration 4: GMM criterion Q(b) = 2.998e-12
Iteration 5: GMM criterion Q(b) = 4.834e-26

note: model is exactly identified.

GMM estimation
Number of parameters = 3
Number of moments = 3
Initial weight matrix: Unadjusted
Number of obs = 364
(Std. err. adjusted for 45 clusters in id)

```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
x1	2.088246	.2513626	8.31	0.000	1.595584	2.580907
x2	-2.905504	.2133908	-13.62	0.000	-3.323742	-2.487266
x3	1.121081	.201654	5.56	0.000	.7258459	1.516315

```

Instruments for equation 1: L.x1 L.x2 L.x3

```

Here, like earlier with strictly exogenous regressors, the number of instruments equals the number of parameters, so there is no gain to using the two-step or iterated estimator. However, if you do have more instruments than parameters, you will most likely want to use one of those other estimators instead.

The note at the top of the output is given because we have 45 panels in our dataset. Our residual equation includes lagged terms and therefore cannot be evaluated for the first time period within each panel. Notes like this can be ignored once you know why they occurred. If you receive a note that you were not expecting, you should first investigate the cause of the note before trusting the results.

Instead of making our program accept the `mylhs()` option, we could have used Stata's `colc` macro function to determine the dependent variable based on the column names attached to the `'at'` vector; see [P] [macro](#). Then, we could refit our model with a different dependent variable by changing the `lname` used in the `parameters()` option. In the [next example](#), we take this approach.

In the [previous example](#), we used  $\mathbf{x}_{i,t-1}$  as instruments. A more efficient GMM estimator would also use  $\mathbf{x}_{i,t-2}, \mathbf{x}_{i,t-3}, \dots, \mathbf{x}_{i,1}$  as instruments in period  $t$  as well. `gmm`'s `xtinstruments()` option allows you to specify instrument lists that grow as  $t$  increases. Later, we discuss the `xtinstruments()` option in detail in the context of linear dynamic panel-data models.

When a regressor is contemporaneously correlated with the idiosyncratic error term, we say that regressor is endogenous. [Windmeijer \(2000\)](#) shows that we can use the moment condition

$$\sum_i \sum_{t=3}^T \mathbf{x}_{i,t-2} \left( \frac{y_{it}}{\mu_{it}} - \frac{y_{i,t-1}}{\mu_{i,t-1}} \right)$$

Here we use the second lag of the endogenous regressor as an instrument. If a variable is strictly exogenous, it can of course serve as its own instrument.

### ► Example 14: Panel Poisson with endogenous regressors

Here we refit the model, treating `x3` as endogenous and `x1` and `x2` as strictly exogenous. Our moment-evaluator program is

```

program gmm_poiend
    version 18.0
    syntax varlist if, at(name)
    quietly {
        tempvar mu
        matrix score double 'mu' = 'at' 'if', eq(#1)
        replace 'mu' = exp('mu')
        local mylhs : coleq 'at'
        local mylhs : word 1 of 'mylhs'
        replace 'varlist' = 'mylhs'/'mu' - L.'mylhs'/L.'mu' 'if'
    }
end

```

Now, we call `gmm` using `x1`, `x2`, and `L2.x3` as instruments:

```
. use https://www.stata-press.com/data/r18/poisson2
. gmm gmm_poiend, nequations(1) vce(cluster id) onestep
> parameters(y:x1 y:x2 y:x3) instruments(x1 x2 L2.x3, noconstant)
note: 500 missing values returned for equation 1 at initial values.

Step 1
Iteration 0:  GMM criterion Q(b) = 61.832288
Iteration 1:  GMM criterion Q(b) = .03402584
Iteration 2:  GMM criterion Q(b) = .01101288
Iteration 3:  GMM criterion Q(b) = 6.339e-06
Iteration 4:  GMM criterion Q(b) = 1.620e-12
Iteration 5:  GMM criterion Q(b) = 1.312e-25

note: model is exactly identified.

GMM estimation
Number of parameters = 3
Number of moments   = 3
Initial weight matrix: Unadjusted
                                Number of obs   = 3,766
                                (Std. err. adjusted for 500 clusters in id)
```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
x1	1.8141	.2688318	6.75	0.000	1.2872	2.341001
x2	-2.982671	.1086666	-27.45	0.000	-3.195653	-2.769688
x3	4.126518	6.369334	0.65	0.517	-8.357147	16.61018

Instruments for equation 1: x1 x2 L2.x3

The note at the top of the output is given because that we have 500 panels in our dataset. As in the [previous example](#), our residual equation includes lagged terms and therefore cannot be evaluated for the first time period within each panel. Instead of using just  $\mathbf{x}_{i,t-2}$  as an instrument, we could use all further lags of  $\mathbf{x}_{it}$  as instruments as well.

◀

## Rational-expectations models

Macroeconomic models typically assume that agents' expectations about the future are formed rationally. By rational expectations, we mean that agents use all information available when forming their forecasts, so the forecast error is uncorrelated with the information available when the forecast was made. Say that at time  $t$ , people make a forecast,  $\hat{y}_{t+1}$ , of variable  $y$  in the next period. If  $\Omega_t$  denotes all available information at time  $t$ , then rational expectations implies that  $E\{(\hat{y}_{t+1} - y_{t+1})|\Omega_t\} = 0$ . If  $\Omega_t$  denotes observable variables such as interest rates or prices, then this conditional expectation can serve as the basis of a moment condition for GMM estimation.

### ▶ Example 15: Fitting a Euler equation

In a well-known article, [Hansen and Singleton \(1982\)](#) consider a model of portfolio decision making and discuss parameter estimation using GMM. We will consider a simple example with one asset in which the agent can invest. A consumer wants to maximize the present value of his or her lifetime utility derived from buying a good. On the one hand, the consumer is impatient, so he or she would rather buy today than wait until tomorrow. On the other hand, by buying less today, the consumer can invest more money, earning more interest that can be used to buy more of the good tomorrow. Thus, there is a tradeoff between having cake today or sacrificing a bit today to have more cake tomorrow.

If we assume a specific form for the agent's utility function, known as the constant relative-risk aversion utility function, we can show that the Euler equation is

$$E \left[ \mathbf{z}_t \left\{ 1 - \beta(1 + r_{t+1})(c_{t+1}/c_t)^{-\gamma} \right\} \right] = \mathbf{0}$$

where  $\beta$  and  $\gamma$  are the parameters to estimate,  $r_t$  is the return to the financial asset, and  $c_t$  is consumption in period  $t$ .  $\beta$  measures the agent's discount factor. If  $\beta$  is near 1, the agent is patient and is more willing to forgo consumption this period. If  $\beta$  is close to 0, the agent is less patient and prefers to consume more now. The parameter  $\gamma$  characterizes the agent's utility function. If  $\gamma = 0$ , the utility function is linear. As  $\gamma$  tends toward 1, the utility function tends toward  $u = \log(c)$ .

We have data on three-month Treasury bills ( $r_t$ ) and consumption expenditures ( $c_t$ ). As instruments, we will use lagged rates of return and past growth rates of consumption. We will use the two-step estimator and a weight matrix that allows for heteroskedasticity and autocorrelation up to four lags with the Bartlett kernel. In Stata, we type

```
. use https://www.stata-press.com/data/r18/cr
. generate cgrowth = c / L.c
(1 missing value generated)
. gmm (1 - {b=1}*(1+F.r)*(F.c/c)^(-1*{gamma=1})),
> inst(L.r L2.r cgrowth L.cgrowth) wmat(hac nw 4) twostep
note: 1 missing value returned for equation 1 at initial values.

Step 1
Iteration 0: GMM criterion Q(b) = .00226482

HAC standard errors based on Bartlett kernel with 4 lags.  
 Instruments for equation 1: L.r L2.r cgrowth L.cgrowth\_cons

The note at the top of the output is given because the forward operator in our substitutable expression says that residuals cannot be computed for the last observation. In addition, two observations are omitted because the L2.r instrument has missing values in the first two time periods. Therefore, of the 242 observations in our dataset, 239 are used to fit the model. Our estimate of  $\beta$  is near 1, in line with expectations and published results. However, our estimate of  $\gamma$  implies risk-loving behavior and therefore a poorly specified model.

Also notice our use of the forward operator to refer to the values of  $r$  and  $c$  one period ahead; time-series operators are allowed in substitutable expressions as long as you have previously `tsset` (see [TS] `tsset`) your data. See [U] 13.10 Time-series operators for more information on time-series operators.

## System estimators

In many economic models, two or more variables are determined jointly through a system of simultaneous equations. Indeed, some of the earliest work in econometrics, including that of the Cowles Commission, was centered around estimation of the parameters of simultaneous equations. The 2SLS and IV estimators we have already discussed are used in some circumstances to estimate such parameters. Here we focus on the joint estimation of all the parameters of systems of equations, and we begin with the well-known three-stage least-squares (3SLS) estimator.

Recall that the 2SLS estimator is based on the moment conditions  $E(\mathbf{z}u) = \mathbf{0}$ . The 2SLS estimator can be used to estimate the parameters of one equation of a system of structural equations. Moreover, with the 2SLS estimator, we do not even need to specify the structural relationship among all the endogenous variables; we need to specify only the equation on which interest focuses and simply assume reduced-form relationships among the endogenous regressors of the equation of interest and the exogenous variables of the model. If we are willing to specify the complete system of structural equations, then assuming our model is correctly specified, by estimating all the equations jointly, we can obtain estimates that are more efficient than equation-by-equation 2SLS.

In [R] **reg3**, we fit a simple two-equation macroeconomic model,

$$\text{consump} = \beta_0 + \beta_1 \text{wagepriv} + \beta_2 \text{wagegovt} + \epsilon_1 \quad (11)$$

$$\text{wagepriv} = \beta_3 + \beta_4 \text{consump} + \beta_5 \text{govt} + \beta_6 \text{capital1} + \epsilon_2 \quad (12)$$

where `consump` represents aggregate consumption; `wagepriv` and `wagegovt` are total wages paid by the private and government sectors, respectively; `govt` is government spending; and `capital1` is the previous period's capital stock. We are not willing to assume that  $\epsilon_1$  and  $\epsilon_2$  are independent, so we must treat both `consump` and `wagepriv` as endogenous. Suppose that a random shock makes  $\epsilon_2$  positive. Then by (12), `wagepriv` will be higher than it otherwise would. Moreover,  $\epsilon_1$  will be either higher or lower, depending on the correlation between it and  $\epsilon_2$ . The shock to  $\epsilon_2$  has made both `wagepriv` and  $\epsilon_1$  move, which implies that in (11), `wagepriv` is an endogenous regressor. A similar argument shows that `consump` is an endogenous regressor in the second equation. In our model, `wagegovt`, `govt`, and `capital1` are all exogenous variables.

Let  $\mathbf{z}_1$  and  $\mathbf{z}_2$  denote the instruments for the first and second equations, respectively; we will discuss what comprises them shortly. We have two sets of moment conditions:

$$E \left\{ \begin{array}{l} \mathbf{z}_1(\text{consump} - \beta_0 - \beta_1 \text{wagepriv} - \beta_2 \text{wagegovt}) \\ \mathbf{z}_2(\text{wagepriv} - \beta_3 - \beta_4 \text{consump} - \beta_5 \text{govt} - \beta_6 \text{capital1}) \end{array} \right\} = \mathbf{0} \quad (13)$$

One of the defining characteristics of 3SLS is that the errors are homoskedastic conditional on the instrumental variables. Using this assumption, we have

$$E \left[ \left\{ \begin{array}{l} \mathbf{z}_1 \epsilon_1 \\ \mathbf{z}_2 \epsilon_2 \end{array} \right\} \left\{ \begin{array}{ll} \mathbf{z}'_1 \epsilon_1 & \mathbf{z}'_2 \epsilon_2 \end{array} \right\} \right] = \left\{ \begin{array}{ll} \sigma_{11} E(\mathbf{z}_1 \mathbf{z}'_1) & \sigma_{12} E(\mathbf{z}_1 \mathbf{z}'_2) \\ \sigma_{21} E(\mathbf{z}_2 \mathbf{z}'_1) & \sigma_{22} E(\mathbf{z}_2 \mathbf{z}'_2) \end{array} \right\} \quad (14)$$

where  $\sigma_{ij} = \text{cov}(\epsilon_i, \epsilon_j)$ . Let  $\Sigma$  denote the  $2 \times 2$  matrix with typical element  $\sigma_{ij}$ .

The second defining characteristic of the 3SLS estimator is that it uses all the exogenous variables as instruments for all equations; here  $\mathbf{z}_1 = \mathbf{z}_2 = (\text{wagegovt}, \text{govt}, \text{capital1}, 1)$ , where the 1 indicates a constant term. From our discussion on the weight matrix and two-step estimation, we want to use the sample analogue of the matrix inverse of the right-hand side of (14) as our weight matrix.

To implement the 3SLS estimator, we apparently need to know  $\Sigma$  or at least have a consistent estimator of it. The solution is to fit (11) and (12) by 2SLS, use the sample residuals  $\hat{\epsilon}_1$  and  $\hat{\epsilon}_2$  to estimate  $\Sigma$ , then estimate the parameters of (13) via GMM by using the weight matrix just discussed.

that the same instruments are being used for both equations; in a moment, we will discuss an estimator that does not use the same instruments in all equations. ◀

In the [previous example](#), if we omit the `twostep` option, the resulting coefficients will be equivalent to equation-by-equation 2SLS, which [Wooldridge \(2010, 216\)](#) calls the “system 2SLS estimator”. Eliminating the `twostep` option makes the `wmatrix()` option irrelevant, so that option can be eliminated as well.

So far, we have developed the traditional 3SLS estimator. [Wooldridge \(2010, chap. 8\)](#) discusses the “GMM 3SLS” estimator, which extends the traditional 3SLS estimator by allowing for heteroskedasticity and different instruments for different equations.

Generalizing (14) to an arbitrary number of equations, we have

$$E(\mathbf{Z}'\epsilon\epsilon'\mathbf{Z}) = E(\mathbf{Z}'\Sigma\mathbf{Z}) \quad (15)$$

where

$$\mathbf{Z} = \begin{bmatrix} \mathbf{z}_1 & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{z}_2 & \cdots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & \mathbf{z}_m \end{bmatrix}$$

and  $\Sigma$  is now  $m \times m$ . Equation (15) is the multivariate analogue of a homoskedasticity assumption; for each equation, the error variance is constant for all observations, as is the covariance between any two equations’ errors.

We can relax this homoskedasticity assumption by considering different weight matrices. For example, if we continue to assume that observations are independent but not necessarily identically distributed, then by specifying `wmatrix(robust)`, we would obtain a weight matrix that allows for heteroskedasticity:

$$\widehat{W} = \frac{1}{N} \sum_i \mathbf{z}'_i \widehat{\epsilon}_i \widehat{\epsilon}'_i \mathbf{z}_i$$

This is the weight matrix in [Wooldridge’s \(2010, 218\) Procedure 8.1](#), “GMM with Optimal Weighting Matrix”. By default, `gmm` would report standard errors based on his covariance matrix (8.27); specifying `vce(unadjusted)` would provide the optimal GMM standard errors. If you have multiple observations for each individual or firm in your dataset, you could specify `wmatrix(cluster id)`, where `id` identifies individuals or firms. This would allow arbitrary within-individual correlation, though it does not account for an individual-specific fixed or random effect. In both cases, we would continue to use `winitial(unadjusted, independent)` so that the first-step estimates are the system 2SLS estimates.

[Wooldridge \(2010, sec. 9.6\)](#) discusses instances where it is necessary to use different instruments in different equations. The GMM 3SLS estimator with different instruments in different equations but with conditional homoskedasticity is what [Hayashi \(2000, 275\)](#) calls the “full-information instrumental variables efficient” (FIVE) estimator. Implementing the FIVE estimator is easy with `gmm`. For example, say we have a two-equation system where `kids`, `age`, `income`, and `education` are all valid instruments for the first equation but where `education` is not a valid instrument for the second equation. Then, our syntax would take the form

```
gmm (rexp1) (rexp2), instruments(1:kids age income education)
    instruments(2:kids age income)
```

The following syntax is equivalent:

```
gmm (rexp1) (rexp2), instruments(kids age income)
    instruments(1:education)
```

Because we did not specify a list of equations in the second example's first `instruments()` option, those variables are used as instruments in both equations. You can use whichever syntax you prefer. The first requires a bit more typing but is arguably more transparent.

If all the regressors in the model are exogenous, then the traditional 3SLS estimator is the seemingly unrelated regression (SUR) estimator. Here you would specify all the regressors as instruments.

## Dynamic panel-data models

Commands in Stata that work with panel data expect the data to be in the “long” format, meaning that each row of the dataset consists of one subobservation that is a member of a logical observation (represented by the panel identifier variable). See [D] [reshape](#) for a discussion of the long versus “wide” data forms. `gmm` is no exception in this respect when used with panel data. From a theoretical perspective, however, it is sometimes easier to view GMM estimators for panel data as system estimators in which we have  $N$  observations on a system of  $T$  equations, where  $N$  and  $T$  are the number of observations and panels, respectively, rather than a single-equation estimator with  $NT$  observations. Usually, each of the  $T$  equations will in fact be the same, though we will want to specify different instruments for each of these equations.

In a dynamic panel-data model, lagged values of the dependent variable are included as regressors. Here we consider a simple model with one lag of the dependent variable  $y$  as a regressor and a vector of strictly exogenous regressors,  $\mathbf{x}_{it}$ :

$$y_{it} = \rho y_{i,t-1} + \mathbf{x}'_{it} \boldsymbol{\beta} + u_i + \epsilon_{it} \quad (16)$$

$u_i$  can be either a fixed- or a random-effect term in the sense that we do not require  $\mathbf{x}_{it}$  to be independent of it. Even with the assumption that  $\epsilon_{it}$  is i.i.d., the presence of both  $y_{i,t-1}$  and  $u_i$  in (16) renders both the standard fixed- and random-effects estimators to be inconsistent because of the well-known [Nickell \(1981\)](#) bias. OLS regression of  $y_{it}$  on  $y_{i,t-1}$  and  $\mathbf{x}_{it}$  also produces inconsistent estimates because  $y_{i,t-1}$  will be correlated with the error term.

### □ Technical note

Stata has the `xtabond`, `xtdpd`, and `xtdpdsys` commands (see [XT] [xtabond](#), [XT] [xtdpd](#), and [XT] [xtdpdsys](#)) to fit equations like (16); for everyday use, those commands are preferred because they offer features such as [Windmeijer \(2005\)](#) bias-corrected standard errors to account for the bias of traditional two-step GMM standard errors seen in dynamic panel-data models and, being linear estimators, only require you to specify variable names instead of complete equations. However, using `gmm` has several pedagogical advantages, including the ability to tie those model-specific commands into a more general framework, a clear illustration of how certain types of instrument matrices for panel-data models are formed, and demonstrations of several advanced features of `gmm`. □

First-differencing (16) removes the panel-specific  $u_i$  term:

$$y_{it} - y_{i,t-1} = \rho(y_{i,t-1} - y_{i,t-2}) + (\mathbf{x}_{it} - \mathbf{x}_{i,t-1})' \boldsymbol{\beta} + (\epsilon_{it} - \epsilon_{i,t-1}) \quad (17)$$

However, now  $(y_{i,t-1} - y_{i,t-2})$  is correlated with  $(\epsilon_{it} - \epsilon_{i,t-1})$ . Thus, we need an instrument that is correlated with the former but not the latter. The lagged variables in (17) mean that the equation is not estimable for  $t < 3$ , so consider when  $t = 3$ . We have

$$y_{i3} - y_{i2} = \rho(y_{i2} - y_{i1}) + (\mathbf{x}_{i3} - \mathbf{x}_{i2})'\boldsymbol{\beta} + (\epsilon_{i3} - \epsilon_{i2}) \quad (18)$$

In the Arellano–Bond (1991) estimator, lagged levels of the dependent variable are used as instruments. With our assumption that the  $\epsilon_{it}$  are i.i.d., (16) intimates that  $y_{i1}$  can serve as an instrumental variable when we fit (18).

Next, consider (17) when  $t = 4$ . We have

$$y_{i4} - y_{i3} = \rho(y_{i3} - y_{i2}) + (\mathbf{x}_{i4} - \mathbf{x}_{i3})'\boldsymbol{\beta} + (\epsilon_{i4} - \epsilon_{i3})$$

Now, (16) shows that both  $y_{i1}$  and  $y_{i2}$  are uncorrelated with the error term  $(\epsilon_{i4} - \epsilon_{i3})$ , so we have two instruments available. For  $t = 5$ , you can show that  $y_{i1}$ ,  $y_{i2}$ , and  $y_{i3}$  can serve as instruments. As may now be apparent, one of the key features of these dynamic panel-data models is that the available instruments depend on the time period,  $t$ , as was the case for some of the panel Poisson models we considered earlier. Because the  $\mathbf{x}_{it}$  are strictly exogenous by assumption, they can serve as their own instruments.

The initial weight matrix that is appropriate for the GMM dynamic panel-data estimator is slightly more involved than the unadjusted matrix that we have used in most of our previous examples and that assumes the errors are i.i.d. First, rewrite (17) for panel  $i$  as

$$\mathbf{y}_i - \mathbf{y}_i^L = \rho(\mathbf{y}_i^L - \mathbf{y}_i^{LL}) + (\mathbf{X}_i - \mathbf{X}_i^L)\boldsymbol{\beta} + (\boldsymbol{\epsilon}_i - \boldsymbol{\epsilon}_i^L)$$

where  $\mathbf{y}_i = (y_{i3}, \dots, y_{iT})$  and  $\mathbf{y}_i^L = (y_{i2}, \dots, y_{i,T-1})$ ,  $\mathbf{y}_i^{LL} = (y_{i1}, \dots, y_{i,T-2})$ , and  $\mathbf{X}_i$ ,  $\mathbf{X}_i^L$ ,  $\boldsymbol{\epsilon}_i$ , and  $\boldsymbol{\epsilon}_i^L$  are defined analogously. Let  $\mathbf{Z}$  denote the full matrix of instruments for panel  $i$ , including the variables specified in both the `instruments()` and `xtinstruments()` options; the exact structure is detailed in [Methods and formulas](#).

By assumption,  $\epsilon_{it}$  is i.i.d., so the first difference  $(\epsilon_{it} - \epsilon_{i,t-1})$  is necessarily autocorrelated with correlation  $-0.5$ . Therefore, we should not use a weight matrix that assumes the errors are independent. For dynamic panel-data models, we can show that the appropriate initial weight matrix is

$$\widehat{\mathbf{W}} = \left( \frac{1}{N} \sum_i \mathbf{Z}_i' \mathbf{H}_D \mathbf{Z}_i \right)^{-1}$$

where

$$\mathbf{H}_D = \begin{bmatrix} 1 & -0.5 & 0 & \dots & 0 & 0 \\ -0.5 & 1 & -0.5 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & -0.5 \\ 0 & 0 & 0 & \dots & -0.5 & 1 \end{bmatrix}$$

We can obtain this initial weight matrix by specifying `winitial(xt D)`. The letter D indicates that the equation we are estimating is specified in first differences.

### ► Example 17: Arellano–Bond estimator

Say we want to fit the model

$$n_{it} = \rho n_{i,t-1} + \beta_1 w_{it} + \beta_2 w_{i,t-1} + \beta_3 k_{it} + \beta_4 k_{i,t-1} + u_i + \epsilon_{it} \quad (19)$$

where we assume that  $w_{it}$  and  $k_{it}$  are strictly exogenous. First-differencing, our residual equation is

$$\begin{aligned} \epsilon_{it}^* = (\epsilon_{it} - \epsilon_{i,t-1}) = & n_{it} - n_{i,t-1} - \rho(n_{i,t-1} - n_{i,t-2}) - \beta_1(w_{it} - w_{i,t-1}) \\ & - \beta_2(w_{i,t-1} - w_{i,t-2}) - \beta_3(k_{it} - k_{i,t-1}) - \beta_4(k_{i,t-1} - k_{i,t-2}) \end{aligned} \quad (20)$$

In Stata, we type

```
. use https://www.stata-press.com/data/r18/abdata
. gmm (D.n - {rho}*LD.n - {xb:D.w LD.w D.k LD.k}),
> xtinstruments(n, lags(2/.)) instruments(D.w LD.w D.k LD.k, noconstant)
> deriv(rho = -1*LD.n) deriv(/xb = -1) winitial(xt D) onestep
```

Step 1

```
Iteration 0: GMM criterion Q(b) = .0011455
Iteration 1: GMM criterion Q(b) = .00009103
Iteration 2: GMM criterion Q(b) = .00009103
```

GMM estimation

Number of parameters = 5

Number of moments = 32

Initial weight matrix: XT D

Number of obs = 751

(Std. err. adjusted for 140 clusters in id)

		Robust		z	P> z	[95% conf. interval]

	k						
	D1.	.3520286	.0536546	6.56	0.000	.2468676	.4571897
	LD.	-.2160435	.0679689	-3.18	0.001	-.3492601	-.0828269

Instruments for equation 1:

XT-style: L(2/.)n

Standard: D.w LD.w D.k LD.k

Because  $w$  and  $k$  are strictly exogenous, we specified their variants that appear in (20) in the `instruments()` option; because there is no constant term in the model, we specified `noconstant` to omit the constant from the instrument list.

We specified `xtinstruments(n, lags(2/.))` to tell `gmm` what instruments to use for the lagged dependent variable included as a regressor in (19). On the basis of our previous discussion, lags two and higher of  $n_{it}$  can serve as instruments. The `lags(2/.)` suboption tells `gmm` that the first available instrument for  $n_{it}$  is the lag-two value  $n_{i,t-2}$ . The “.” tells `gmm` to use all further lags of  $n_{it}$  as instruments as well. The instrument matrices in dynamic panel-data models can become large if the dataset has many time periods per panel. In those cases, you could specify, for example, `lags(2/4)` to use just lags two through four instead of using all available lags.

Our results are identical to those we would obtain using `xtabond` with the syntax

```
xtabond n L(0/1).w L(0/1).k, lags(1) noconstant vce(robust)
```

If we had left off the `vce(robust)` option in our call to `xtabond`, we would have had to specify `vce(unadjusted)` in our call to `gmm` to obtain the same standard errors.

◀

## □ Technical note

`gmm` automatically excludes observations for which there are no valid observations for the panel-style instruments. However, it keeps in the estimation sample those observations for which fewer than the maximum number of instruments you requested are available. For example, if you specify the `lags(2/4)` suboption, you have requested three instruments, but `gmm` will keep observations even if only one or two instruments are available.

□

## ▷ Example 18: Two-step Arellano–Bond estimator

Here we refit the model from [example 17](#), using the two-step GMM estimator.

```
. gmm (D.n - {rho}*LD.n - {xb:D.w LD.w D.k LD.k}),
> xtinstruments(n, lags(2/.)) instruments(D.w LD.w D.k LD.k, noconstant)

```

◀

## □ Technical note

If we had specified `vce(robust)` in our call to `gmm`, we would have obtained the traditional sandwich-based robust covariance matrix, but our standard errors would not match those we would obtain by specifying `vce(robust)` with the `xtabond` command. The `xtabond`, `xtdpd`, and `xtdpdsys` commands implement a bias-corrected robust VCE for the two-step GMM dynamic panel-data estimator. Traditional VCEs computed after the two-step dynamic panel-data estimator have been shown to exhibit often-severe bias; see [Windmeijer \(2005\)](#). □

Neither of the two dynamic panel-data examples (17 and 18) we have fit so far include a constant term. When a constant term is included, the dynamic panel-data estimator is in fact a two-equation system estimator. For notational simplicity, consider a simple model containing just a constant term and one lag of the dependent variable:

$$y_{it} = \alpha + \rho y_{i,t-1} + u_i + \epsilon_{it}$$

First-differencing to remove the  $u_i$  term, we have

$$y_{it} - y_{i,t-1} = \rho(y_{i,t-1} - y_{i,t-2}) + (\epsilon_{it} - \epsilon_{i,t-1}) \quad (21)$$

This has also eliminated the constant term. If we assume  $E(u_i) = 0$ , which is reasonable if a constant term is included in the model, then we can recover  $\alpha$  by including the moment condition

$$y_{it} = \alpha + \rho y_{i,t-1} + \epsilon'_{it} \quad (22)$$

where  $\epsilon'_{it} = u_i + \epsilon_{it}$ . The parameter  $\rho$  continues to be identified by (21), so the only instrument we use with (22) is a constant term. As before, the error term  $(\epsilon_{i,t} - \epsilon_{i,t-1})$  is necessarily autocorrelated with correlation coefficient  $-0.5$ , though the error term  $\epsilon'_{it}$  is white noise. Therefore, our initial weight matrix should be

$$\widehat{\mathbf{W}} = \left( \frac{1}{N} \sum_i \mathbf{z}'_i \mathbf{H} \mathbf{z}_i \right)^{-1}$$

where

$$\mathbf{H} = \begin{bmatrix} \mathbf{H}_D & \mathbf{0} \\ \mathbf{0} & \mathbf{I} \end{bmatrix}$$

and  $\mathbf{I}$  is a conformable identity matrix.

One complication arises concerning the relevant estimation sample. Looking at (21), we apparently lose the first two observations from each panel because of the presence of  $y_{i,t-2}$ , but in (22), we need to sacrifice only one observation for  $y_{i,t-1}$ . For most multiple-equation models, we need to use the same estimation sample for all equations. However, in dynamic panel-data models, we can use more observations to fit the equation in level form [(22) here] than the equation in first differences [equation (21)]. To request this behavior, we specify the `nocommonesample` option to `gmm`. That option tells `gmm` to use as many observations as possible for each equation, ignoring the loss of observations due to lagging or differencing.

## ▷ Example 19: Arellano–Bond estimator with constant term

Here we fit the model

$$\mathbf{n}_{it} = \alpha + \rho \mathbf{n}_{i,t-1} + u_i + \epsilon_{it}$$

Without specifying derivatives, our command would be

```
. gmm (D.n - {rho}*LD.n) (n - {alpha} - {rho}*L.n),
> xtinstruments(1: n, lags(2/.)) instruments(1:, noconstant) onestep
> winitial(xt DL) vce(unadj) nocommonesample
```

We would specify `winitial(xt DL)` to obtain the required initial weight matrix. The notation DL indicates that our first residual equation is in first differences and that the second residual equation is in levels (not first-differenced). We exclude a constant in the instrument list for the first equation because first-differencing removed the constant term. Because we do not specify the `instruments()` option for the second residual equation, a constant is used by default.

This example also provides us the opportunity to illustrate how to specify derivatives for multiple-equation GMM models. Within the `derivative()` option, instead of specifying just the parameter name, now you must specify the equation name or number, a slash, and the parameter name to which the derivative applies. In Stata, we type

```
. gmm (D.n - {rho}*LD.n) (n - {alpha} - {rho}*L.n),
> xtinstruments(1: n, lags(2/.)) instruments(1:, noconstant)
> derivative(1/rho = -1*LD.n) derivative(2/alpha = -1)
> derivative(2/rho = -1*L.n) winitial(xt DL) vce(unadj) nocommonesample onestep
```

Step 1

Iteration 0: GMM criterion Q(b) = .09894466

Iteration 1: GMM criterion Q(b) = .00023508

Iteration 2: GMM criterion Q(b) = .00023508

GMM estimation

Number of parameters = 2

Number of moments = 29

Initial weight matrix: XT DL

Number of obs = \*

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
/rho	1.023349	.0608293	16.82	0.000	.9041259	1.142572
/alpha	-.0690864	.0660343	-1.05	0.295	-.1985112	.0603384

\* Number of observations for equation 1: 751

Number of observations for equation 2: 891

Instruments for equation 1:

XT-style: L(2/.).n

Instruments for equation 2:

Standard: \_cons

These results are identical to those we would obtain by typing

```
xtabond n, lags(1)
```

Because we specified `nocommonesample`, `gmm` did not report the number of observations used in the header of the output. In this dataset, there are in fact 1,031 observations on 140 panels. In the second equation, the presence of the lagged value of `n` reduces the sample size for that equation to  $1031 - 140 = 891$ . In the first equation, we lose the first two observations per panel because of lagging and differencing, which leads to 751 usable observations. These tallies are listed after the coefficient table in the output.

## □ Technical note

## Specifying

```
xtinstruments(x1 x2 x3, lags(1/3))
```

differs from

```
instruments(L(1/3).(x1 x2 x3))
```

in how observations are excluded from the estimation sample. When you use the latter syntax, `gmm` must exclude the first three observations from each panel when computing the residual equation: you requested that three lags of each regressor be used as instruments, so the first residual that could be interacted with those instruments is the one for  $t = 4$ . On the other hand, when you use `xtinstruments()`, you are telling `gmm` that you would like to use up to the first three lags of `x1`, `x2`, and `x3` as instruments but that using just one lag is acceptable. Because most panel datasets have a relatively modest number of observations per panel, dynamic instrument lists are typically used so that the number of usable observations is maximized. Dynamic instrument lists also accommodate the fact that there are more valid instruments for later time periods than earlier time periods.

Specifying panel-style instruments using the `xtinstruments()` option also affects how the standard instruments specified in the `instruments()` option are treated. To illustrate, we will suppose that we have a balanced panel dataset with  $T = 5$  observations per panel and that we specify

```
. gmm ..., xtinstruments(w, lags(1/2)) instruments(x)
```

We will lose the first observation because we need at least one lag of `w` to serve as an instrument. Our instrument matrix for panel  $i$  will therefore be

$$\mathbf{Z}_i = \begin{bmatrix} w_{i1} & 0 & 0 & 0 \\ 0 & w_{i1} & 0 & 0 \\ 0 & w_{i2} & 0 & 0 \\ 0 & 0 & w_{i2} & 0 \\ 0 & 0 & w_{i3} & 0 \\ 0 & 0 & 0 & w_{i3} \\ 0 & 0 & 0 & w_{i4} \\ x_{i2} & x_{i3} & x_{i4} & x_{i5} \\ 1 & 1 & 1 & 1 \end{bmatrix} \quad (23)$$

The vector of ones in the final row represents the constant term implied by the `instruments()` option. Because we lost the first observation, the residual vector  $\mathbf{u}_i$  will be  $4 \times 1$ . Thus, our moment conditions for the  $i$ th panel can be written in matrix notation as

$$E\{\mathbf{Z}_i \mathbf{u}_i(\boldsymbol{\beta})\} = E\left\{\mathbf{Z}_i \begin{bmatrix} u_{i2}(\boldsymbol{\beta}) \\ u_{i3}(\boldsymbol{\beta}) \\ u_{i4}(\boldsymbol{\beta}) \\ u_{i5}(\boldsymbol{\beta}) \end{bmatrix}\right\} = \mathbf{0}$$

The moment conditions corresponding to the final two rows of (23) say that

$$E\left\{\sum_{t=2}^{T=4} x_{it} u_{it}(\boldsymbol{\beta})\right\} = 0 \quad \text{and} \quad E\left\{\sum_{t=2}^{T=4} u_{it}(\boldsymbol{\beta})\right\} = 0$$

Because we specified panel-style instruments with the `xtinstruments()` option, `gmm` no longer uses moment conditions for strictly exogenous variables of the form  $E\{x_{it}u_{it}(\beta)\} = 0$  for each  $t$ . Instead, the moment conditions now stipulate that the average (over  $t$ ) of  $x_{it}u_{it}(\beta)$  has expectation zero. This corresponds to the approach proposed by [Arellano and Bond \(1991, 280\)](#) and others.

When you request panel-style instruments with the `xtinstruments()` option, the number of instruments in the  $\mathbf{Z}_i$  matrix increases quadratically in the number of periods. The dynamic panel-data estimators we have discussed in this section are designed for datasets that contain a large number of panels and a modest number of time periods. When the number of time periods is large, estimators that use standard (non-panel-style) instruments are more appropriate. □

We have focused on the Arellano–Bond dynamic panel-data estimator because of its relative simplicity. `gmm` can additionally fit any models that can be formulated using the `xtdpd` and `xtdpdsys` commands; see [\[XT\] xtdpd](#) and [\[XT\] xtdpdsys](#). The key is to determine the appropriate instruments to use for the level and difference equations. You may find it useful to fit a version of your model with those commands to determine what instruments and XT-style instruments to use. We conclude this section with an example using the Arellano–Bover/Blundell–Bond estimator.

### ▷ Example 20: Arellano–Bover/Blundell–Bond estimator

We fit a small model that includes one lag of the dependent variable `n` as a regressor as well as the contemporaneous and first lag of `w`, which we assume are strictly exogenous. We could fit our model with `xtdpdsys` by using the syntax

```
xtdpdsys n L(0/1).w, lags(1) twostep
```

When we apply virtually all the syntax issues we have discussed so far, the equivalent `gmm` command is

```
. gmm (n - {rho}*L.n - {w}*w - {lagw}*L.w - {c})
> (D.n - {rho}*LD.n - {w}*D.w - {lagw}*LD.w),
> xtinst(1: D.n, lags(1/1)) xtinst(2: n, lags(2/.))
> inst(2: D.w LD.w, noconstant)
> deriv(1/rho = -1*L.n) deriv(1/w = -1*w)
> deriv(1/lagw = -1*L.w) deriv(1/c = -1)
> deriv(2/rho = -1*LD.n) deriv(2/w = -1*D.w)
> deriv(2/lagw = -1*LD.w)
> winit(xt LD) wmatrix(robust) vce(unadjusted) nocommonesample
```

Step 1

```
Iteration 0: GMM criterion Q(b) = .10170339

## Details of moment-evaluator programs

In examples 11, 12, 13, and 14, we used moment-evaluator programs to evaluate moment conditions that could not be specified using the interactive version of `gmm`. In example 13, we also showed how to pass additional information to an evaluator program. Here we discuss how to make moment-evaluator programs provide derivatives and accept weights.

The complete specification for a moment-evaluator program's syntax statement is

```
syntax varlist if [weight], at(name) options [derivatives(varlist)]
```

The macro 'varlist' contains the list of variables that we are to fill in with the values of our residual equations. The macro 'if' represents an if condition that restricts the estimation sample. The macro 'at' represents a vector containing the parameter values at which we are to evaluate our

residual equations. `options` represent other options that you specify in your call to `gmm` and want to have passed to your moment-evaluator programs. In [example 13](#), we included the `mylhs()` option so that we could pass the name of the dependent variable to our evaluator program.

Two new elements of the `syntax` statement allow for weights and derivatives. `weight` specifies the types of weights your program allows. The interactive version of `gmm` allows for `fweights`, `aweight`s, and `pweight`s. However, unless you explicitly allow your moment evaluator program to accept weights, you cannot specify weights in your call to `gmm` with the moment-evaluator program version.

The `derivatives()` option is used to pass to your program a set of variables that you are to fill in with the derivatives of your residual equations with respect to the parameters.

To indicate that your program can calculate derivatives, you specify either the `hasderivatives` or the `haslfdderivatives` option to `gmm`. The `hasderivatives` option indicates that your program calculates parameter-level derivatives; that method requires more work but can be applied to any GMM problem. The `haslfdderivatives` option requires less work but can be used only when the model's residual equations satisfy certain restrictions and when you use the `{lname:varlist}` syntax with the `parameters()` option.

We first consider how to write the derivative computation logic to work with the `hasderivatives` option and provide an example; then, we do the same for the `haslfdderivatives` option.

Say that you specify  $k$  parameters in the `nparameters()` or `parameters()` option and  $q$  equations in the `nequations()` or `equations()` option and that you specify `hasderivatives`. Then, `'derivatives'` will contain  $k \times q$  variables. The first  $k$  variables are for the derivatives of the first residual equation with respect to the  $k$  parameters, the second  $k$  variables are for the derivatives of the second residual equation, and so on.

### ► Example 21: Specifying derivatives with simple parameter names

To focus on how to specify derivatives, we return to the simple moment-evaluator program we used in [example 11](#), in which we had three regressors, and extend it to supply derivatives. The residual equation corresponding to moment condition (9) is

$$u_{it}(\beta) = y_{it} - \mu_{it} \frac{\bar{y}_i}{\bar{\mu}_i}$$

where  $\mu_{it}$ ,  $\bar{\mu}_i$ , and  $\bar{y}_i$  were defined previously. Now,

$$\frac{\partial}{\partial \beta_j} u_{it}(\beta) = -\mu_{it} \frac{\bar{y}_i}{\bar{\mu}_i^2} \left( x_{it}^{(j)} \bar{\mu}_i - \frac{1}{T} \sum_{l=1}^{l=T} x_{il}^{(j)} \mu_{il} \right) \quad (24)$$

where  $x_{it}^{(j)}$  represents the  $j$ th element of  $\mathbf{x}_{it}$ .

Our moment-evaluator program is

```

program gmm_poideriv
  version 18.0
  syntax varlist if, at(name) [derivatives(varlist)]
  quietly {
    // Calculate residuals as before
    tempvar mu mubar ybar
    generate double 'mu' = exp(x1*'at'[1,1] + x2*'at'[1,2] //
                          + x3*'at'[1,3]) 'if'
    egen double 'mubar' = mean('mu') 'if', by(id)
    egen double 'ybar' = mean(y) 'if', by(id)
    replace 'varlist' = y - 'mu'*'ybar'/'mubar' 'if'
    // Did -gmm- request derivatives?
    if "'derivatives'" == "" {
      exit // no, so we are done
    }
    // Calculate derivatives
    // We need the panel means of x1*mu, x2*mu, and x3*mu
    tempvar work x1mubar x2mubar x3mubar
    generate double 'work' = x1*'mu' 'if'
    egen double 'x1mubar' = mean('work') 'if', by(id)
    replace 'work' = x2*'mu' 'if'
    egen double 'x2mubar' = mean('work') 'if', by(id)
    replace 'work' = x3*'mu' 'if'
    egen double 'x3mubar' = mean('work') 'if', by(id)
    local d1: word 1 of 'derivatives'
    local d2: word 2 of 'derivatives'
    local d3: word 3 of 'derivatives'
    replace 'd1' = -1*'mu'*'ybar'/'mubar'^2*(x1*'mubar' - 'x1mubar')
    replace 'd2' = -1*'mu'*'ybar'/'mubar'^2*(x2*'mubar' - 'x2mubar')
    replace 'd3' = -1*'mu'*'ybar'/'mubar'^2*(x3*'mubar' - 'x3mubar')
  }
end

```

The `derivatives()` option is made optional in the `syntax` statement by placing it in square brackets. If `gmm` needs to evaluate your residual equations but does not need derivatives at that time, then the `derivatives()` option will be empty. In our program, we check to see whether that is the case and, if so, `exit` without calculating derivatives. As is often the case with [\[R\] ml](#) as well, the portion of our program devoted to derivatives is longer than the code to compute the objective function.

The first part of our derivative code computes the term

$$\frac{1}{T} \sum_{l=1}^{l=T} x_{il}^{(j)} \mu_{il} \quad (25)$$

for  $x_{it}^{(j)} = x_1, x_2,$  and  $x_3$ . The `'derivatives'` macro contains three variable names corresponding to the three parameters of the `'at'` matrix. We extract those names into local macros `'d1'`, `'d2'`, and `'d3'` and then fill in the variables those macros represent with the derivatives shown in [\(24\)](#).

With our program written, we fit our model by typing

```
. use https://www.stata-press.com/data/r18/poisson1, clear
. gmm gmm_poideriv, nequations(1) parameters(b1 b2 b3)
> instruments(x1 x2 x3, noconstant) vce(cluster id) onestep hasderivatives

Step 1
Iteration 0: GMM criterion Q(b) = 51.99142
Iteration 1: GMM criterion Q(b) = .04345191
Iteration 2: GMM criterion Q(b) = 8.720e-06
Iteration 3: GMM criterion Q(b) = 7.115e-13
Iteration 4: GMM criterion Q(b) = 5.130e-27

note: model is exactly identified.

GMM estimation

Number of parameters = 3
Number of moments = 3
Initial weight matrix: Unadjusted                               Number of obs = 409
                                                                (Std. err. adjusted for 45 clusters in id)
```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]

Instruments for equation 1: x1 x2 x3

Our results are identical to those in [example 11](#). Another way to verify that our program calculates derivatives correctly would be to type

```
. gmm gmm_poideriv, nequations(1) parameters(b1 b2 b3)
> instruments(x1 x2 x3, noconstant) vce(cluster id) onestep
```

Without the `hasderivatives` or `haslfdderivatives` option, `gmm` will not request derivatives from your program, even if it contains code to compute them. If you have trouble obtaining convergence with the `hasderivatives` or `haslfdderivatives` option but do not have trouble without specifying one of them, then you need to recheck your derivatives.

◀

After [example 11](#), we remarked that the evaluator program would have to be changed to accommodate different regressors. We then showed how you can specify parameters using the syntax `{lname:varlist}` and then use `matrix score` to compute linear combinations of variables. To specify derivatives when you specify parameters using this notation, ensure that your residual equations satisfy the “linear-form restriction” analogous to the restrictions of linear-form evaluators used by `m1`. See [\[R\] ml](#) and [Pitblado, Poi, and Gould \(2024\)](#) for more information about linear-form evaluators.

A GMM residual equation satisfies the linear-form restriction if the equation can be written in terms of a single observation in the dataset and if the equation for observation  $i$  does not depend on any observations  $j \neq i$ . Cross-sectional models satisfy the linear-form restriction. Time-series models satisfy the linear-form restriction only when no lags or leads are used.

Panel-data models often do not satisfy the linear-form restriction. For example, recall moment condition (9) for a panel Poisson model. That residual equation included panel-level mean terms  $\bar{y}_i$  and  $\bar{\mu}_i$ , so the residual equation for an individual observation depends on all the observations in the same panel.

When a residual equation does not satisfy the linear-form restriction, neither will its derivatives. To apply the chain rule, we need a way to multiply the `lname`-level derivative by each of the variables

in the equation to obtain parameter-level derivatives. In (24), for example, there is no way to factor out each  $x_{it}^{(j)}$  variable and obtain an *lname*-level derivative that we then multiply by each of the  $x_{it}^{(j)}$  s.

Suppose we do have a model with  $q = 2$  moment conditions, both of which do satisfy the linear-form restriction, and we specify the `parameters()` option like this:

```
. gmm ..., parameters({eq1:x1 x2 _cons} {eq2:_cons} {eq3:x1 x2 _cons})
```

We have specified  $n = 3$  *lcnames* in the `parameters()` option: `eq1`, `eq2`, and `eq3`. When we specify the `haslfdderivatives` option, `gmm` will pass  $n \times q = 3 \times 2 = 6$  variables in the `derivatives()` option. The first three variables are to be filled with

$$\frac{\partial}{\partial \text{eq1}} u_{1i}(\beta) \quad \frac{\partial}{\partial \text{eq2}} u_{1i}(\beta) \quad \text{and} \quad \frac{\partial}{\partial \text{eq3}} u_{1i}(\beta)$$

where  $u_{1i}(\beta)$  is the  $i$ th observation for the first moment equation. Then, the second three variables are to be filled with

$$\frac{\partial}{\partial \text{eq1}} u_{2i}(\beta) \quad \frac{\partial}{\partial \text{eq2}} u_{2i}(\beta) \quad \text{and} \quad \frac{\partial}{\partial \text{eq3}} u_{2i}(\beta)$$

where  $u_{2i}(\beta)$  is the second moment equation. In this example, we filled in a total of six variables with derivatives. If we instead used the `hasderivatives` option, we would have filled  $k \times q = 7 \times 2 = 14$  variables; moreover, if we wanted to change the number of variables in our model, we would have modified our evaluator program.

## ► Example 22: Specifying derivatives with linear-form residual equations

In examples 9 and 10, we showed how to specify derivatives with an exponential regression model when using the interactive version of `gmm`. Here we show how to write a moment-evaluator program for the exponential regression model, including derivatives.

The residual equation for observation  $i$  is

$$u_i = y_i - \exp(\mathbf{x}'_i \beta)$$

where  $\mathbf{x}_i$  may include a constant term. The derivative with respect to the linear combination  $\mathbf{x}'_i \beta$  is

$$\frac{\partial u_i}{\partial \mathbf{x}'_i \beta} = -\exp(\mathbf{x}'_i \beta)$$

To verify that this residual equation satisfies the linear-form restriction, we see that for the  $j$ th element of  $\beta$ , we have

$$\frac{\partial u_i}{\partial \beta_j} = -x_{ij} \exp(\mathbf{x}'_i \beta) = \frac{\partial u_i}{\partial \mathbf{x}'_i \beta} \times x_{ij}$$

so that given  $\partial u_i / \partial \mathbf{x}'_i \beta$ , `gmm` can apply the chain rule to obtain the derivatives with respect to the individual parameters.

Our moment-evaluator program is

```

program gmm_poideriv2
    version 18.0
    syntax varlist if, at(name) [derivatives(varlist)]
    quietly {
        tempvar mu
        matrix score double 'mu' = 'at' 'if', eq(#1)
        replace 'mu' = exp('mu')
        local depvar : coleq 'at'
        local depvar : word 1 of 'depvar'
        replace 'varlist' = 'depvar' - 'mu' 'if'
        // Did -gmm- request derivatives?
        if "'derivatives'" == "" {
            exit // no, so we are done
        }
        // Calculate derivatives
        // The derivatives macro only has one variable
        // for this model.
        replace 'derivatives' = -1*'mu' 'if'
    }
end

```

To fit our model of doctor visits treating income as an endogenous regressor, we type

Our results match those shown in [example 10](#).

We can change the variables in our model just by changing the `parameters()` and `instruments()` options; we do not need to make any changes to the moment-evaluator program, because we used linear-form derivatives. ◀

Depending on your model, allowing your moment-evaluator program to accept weights may be as easy as modifying the `syntax` command to allow them, or it may require significantly more work. If your program uses only commands such as `generate` and `replace`, then just modifying the `syntax` command is all you need to do; `gmm` takes care of applying the weights to the observation-level residuals when computing the sample moments, derivatives, and weight matrices. On the other hand, if your moment-evaluator program computes residuals using statistics that depend on multiple observations, then you must apply the weights passed to your program when computing those statistics.

In our examples of panel Poisson with strictly exogenous regressors (11 and 21), we used the statistics  $\bar{\mu}_i$  and  $\bar{y}_i$  when computing the residuals. If we are to allow weights with our moment-evaluator program, then we must incorporate those weights when computing  $\bar{\mu}_i$  and  $\bar{y}_i$ . Moreover, looking at the derivative in (24), we see that the term highlighted in (25) is in fact a sample mean, so we must incorporate weights when computing it.

### ▶ Example 23: Panel Poisson with derivatives and weights

Here we modify the program in [example 21](#) to accept frequency weights. One complication arises: we had been using `egen` to compute  $\bar{\mu}_i$  and  $\bar{y}_i$ . `egen` does not accept weights, so we must compute  $\bar{\mu}_i$  and  $\bar{y}_i$  ourselves, incorporating any weights the user may specify. Our program is

```

program gmm_poiderivfw
    version 18.0
    syntax varlist if [fweight/], at(name) [derivatives(varlist)]
    quietly {
        if "'exp'" == "" {           // no weights
            local exp 1           // weight each observation equally
        }

        // Calculate residuals as before

```

Our syntax command now indicates that `fweights` are allowed. The first part of our code looks at the macro `'exp'`. If it is empty, then the user did not specify weights in their call to `gmm`; and we set the macro equal to 1 so that we weight each observation equally. After we compute  $\mu_{it}$ , we calculate  $\bar{\mu}_i$  and  $\bar{y}_i$ , accounting for weights. To compute frequency-weighted means for each panel, we just multiply each observation by its respective weight, sum over all observations in the panel, then divide by the sum of the weights for the panel. (See [U] 20.24 **Weighted estimation** for information on how to handle `aweight`s and `pweight`s.) We use the same procedure to compute the frequency-weighted variant of expression (25) in the derivative calculations. To use our program, we type

```

. use https://www.stata-press.com/data/r18/poissonwts
. gmm gmm_poiderivfw [fw=fwt], nequations(1) parameters(b1 b2 b3)
> instruments(x1 x2 x3, noconstant) vce(cluster id) onestep hasderivatives

Step 1
Iteration 0: GMM criterion Q(b) = 49.8292
Iteration 1: GMM criterion Q(b) = .11136736
Iteration 2: GMM criterion Q(b) = .00008519
Iteration 3: GMM criterion Q(b) = 7.110e-11
Iteration 4: GMM criterion Q(b) = 5.596e-23
note: model is exactly identified.

```

Testing whether our program works correctly with frequency weights is easy. A frequency-weighted dataset is just a compact form of a larger dataset in which identical observations are omitted and a frequency-weight variable is included to tell us how many times each observation in the smaller dataset appears in the larger dataset. Therefore, we can `expand` our smaller dataset by the frequency-weight variable and then refit our model without specifying frequency weights. If we obtain the same results, our program works correctly. When we type

```

. expand fw
. gmm gmm_poiderivfw, nequations(1) parameters(b1 b2 b3)
> instruments(x1 x2 x3, noconstant) vce(cluster id) onestep

```

we obtain the same results as before.

## Stored results

`gmm` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(n_moments)</code>	number of moments
<code>e(n_eq)</code>	number of equations in moment-evaluator program
<code>e(Q)</code>	criterion function
<code>e(J)</code>	Hansen $J$ $\chi^2$ statistic
<code>e(J_df)</code>	$J$ statistic degrees of freedom
<code>e(k_i)</code>	number of parameters in equation $i$
<code>e(has_xtinst)</code>	1 if panel-style instruments specified, 0 otherwise
<code>e(N_clust)</code>	number of clusters
<code>e(type)</code>	1 if interactive version, 2 if moment-evaluator program version
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations used by iterative GMM estimator
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>gmm</code>
<code>e(cmdline)</code>	command as typed
<code>e(title)</code>	title specified in <code>title()</code>
<code>e(title_2)</code>	title specified in <code>title2()</code>
<code>e(clustvar)</code>	name of cluster variable
<code>e(inst_i)</code>	equation $i$ instruments
<code>e(eqnames)</code>	equation names
<code>e(winit)</code>	initial weight matrix used
<code>e(winitname)</code>	name of user-supplied initial weight matrix
<code>e(estimator)</code>	<code>onestep</code> , <code>twostep</code> , or <code>igmm</code>
<code>e(rhs)</code>	variables specified in <code>variables()</code>
<code>e(params_i)</code>	equation $i$ parameters
<code>e(wmatrix)</code>	<code>wmtype</code> specified in <code>wmatrix()</code>
<code>e(vce)</code>	<code>vcetype</code> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(params)</code>	parameter names
<code>e(sexp_i)</code>	substitutable expression for equation $i$
<code>e(evalprog)</code>	moment-evaluator program
<code>e(evalopts)</code>	options passed to moment-evaluator program
<code>e(nocommonesample)</code>	<code>nocommonesample</code> , if specified
<code>e(technique)</code>	optimization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(marginsnotok)</code>	predictions disallowed by <code>margins</code>
<code>e(marginsprop)</code>	signals to the <code>margins</code> command
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(init)</code>	initial values of the estimators
<code>e(Wuser)</code>	user-supplied initial weight matrix
<code>e(W)</code>	weight matrix used for final round of estimation
<code>e(S)</code>	moment covariance matrix used in robust VCE computations
<code>e(G)</code>	averages of derivatives of moment conditions
<code>e(N_byequation)</code>	number of observations per equation, if <code>nocommonesample</code> specified
<code>e(V)</code>	variance–covariance matrix
<code>e(V_modelbased)</code>	model-based variance

Functions  
`e(sample)` marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices  
`r(table)` matrix containing the coefficients with their standard errors, test statistics,  $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Let  $q$  denote the number of moment conditions. For observation  $i$ ,  $i = 1, \dots, N$ , write the  $j$ th moment equation as  $\mathbf{z}_{ij}u_{ij}(\beta_j)$  for  $j = 1, \dots, q$ .  $\mathbf{z}_{ij}$  is a  $1 \times m_j$  vector, where  $m_j$  is the number of instruments specified for equation  $j$ . Let  $m = m_1 + \dots + m_q$ .

Our notation can incorporate moment conditions of the form  $h_{ij}(\mathbf{w}_{ij}; \beta_j)$  with instruments  $\mathbf{w}_{ij}$  by defining  $\mathbf{z}_{ij} = \mathbf{1}$  and  $u_{ij}(\beta_j) = h_{ij}(\mathbf{w}_{ij}; \beta_j)$ , so except when necessary, we do not distinguish between the two types of moment conditions. We could instead use notation so that all our moment conditions are of the form  $h_{ij}(\mathbf{w}_{ij}; \beta_j)$ , or we could adopt notation that explicitly combines both forms of moment equations. However, because moment conditions of the form  $\mathbf{z}'_{ij}u_{ij}(\beta_j)$  are arguably more common, we use that notation.

Let  $\beta$  denote a  $k \times 1$  vector of parameters, consisting of all the unique parameters of  $\beta_1, \dots, \beta_q$ . Then, we can stack the moment conditions and write them more compactly as  $\mathbf{Z}'_i \mathbf{u}_i(\beta)$ , where

$$\mathbf{Z}'_i = \begin{bmatrix} \mathbf{z}_{i1} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{z}_{i2} & \cdots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & \mathbf{z}_{iq} \end{bmatrix} \quad \text{and} \quad \mathbf{u}_i(\beta) = \begin{bmatrix} u_{i1}(\beta_1) \\ u_{i2}(\beta_2) \\ \vdots \\ u_{iq}(\beta_q) \end{bmatrix}$$

The GMM estimator  $\hat{\beta}$  is the value of  $\beta$  that minimizes

$$Q(\beta) = \left\{ N^{-1} \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\beta) \right\}' \mathbf{W} \left\{ N^{-1} \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\beta) \right\} \quad (\text{A1})$$

for  $q \times q$  weight matrix  $\mathbf{W}$ .

By default, `gmm` minimizes (A1) using the Gauss–Newton method. See Hayashi (2000, 498) for a derivation. This technique is typically faster than quasi-Newton methods and does not require second-order derivatives.

Methods and formulas are presented under the following headings:

*Initial weight matrix*  
*Weight matrix*  
*Variance–covariance matrix*  
*Hansen’s J statistic*  
*Panel-style instruments*  
*Marginal predictions with unconditional standard errors*

## Initial weight matrix

If you specify `winitial(unadjusted)`, then we create matrix  $\Lambda$  with typical submatrix

$$\Lambda_{rs} = N^{-1} \sum_{i=1}^N \mathbf{z}'_{ir} \mathbf{z}_{is}$$

for  $r = 1, \dots, q$  and  $s = 1, \dots, q$ . If you include the `independent` suboption, then we set  $\Lambda_{rs} = \mathbf{0}$  for  $r \neq s$ . The weight matrix  $\mathbf{W}$  equals  $\Lambda^{-1}$ .

If you specify `winitial(identity)`, then we set  $\mathbf{W} = \mathbf{I}_q$ .

If you specify `winitial(xt xtspec)`, then you must specify one or two items in `xtspec`, one for each equation. `gmm` allows you to specify at most two moment equations when you specify `winitial(xt xtspec)`, one in first-differences, and one in levels. We create the block-diagonal matrix  $\mathbf{H}$  with typical block  $\mathbf{H}_j$ . If the  $j$ th element of `xtspec` is “L”, then  $\mathbf{H}_j$  is the identity matrix of suitable dimension. If the  $j$ th element of `xtspec` is “D”, then

$$\mathbf{H}_j = \begin{bmatrix} 1 & -0.5 & 0 & \dots & 0 & 0 \\ -0.5 & 1 & -0.5 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & -0.5 \\ 0 & 0 & 0 & \dots & -0.5 & 1 \end{bmatrix}$$

Then,

$$\Lambda_H = N_G^{-1} \sum_{g=1}^{g=N_G} \mathbf{Z}'_g \mathbf{H} \mathbf{Z}_g$$

where  $g$  indexes panels in the dataset,  $N_G$  is the number of panels,  $\mathbf{Z}_g$  is the full instrument matrix for panel  $g$ , and  $\mathbf{W} = \Lambda_H^{-1}$ . See [Panel-style instruments](#) below for a discussion of how  $\mathbf{Z}_g$  is formed.

If you specify `winitial(matname)`, then we set  $\mathbf{W}$  equal to Stata matrix `matname`.

## Weight matrix

Specification of the weight matrix applies only to the two-step and iterative estimators. When you use the `onestep` option, the `wmatrix()` option is ignored.

We first evaluate (A1) using the initial weight matrix described above and then compute  $\mathbf{u}_i(\hat{\beta})$ . In all cases,  $\mathbf{W} = \Lambda^{-1}$ . If you specify `wmatrix(unadjusted)`, then we create  $\Lambda$  to have typical submatrix

$$\Lambda_{rs} = \sigma_{rs} N^{-1} \sum_{i=1}^N \mathbf{z}'_{ir} \mathbf{z}_{is}$$

where

$$\sigma_{rs} = N^{-1} \sum_{i=1}^N u_{ir}(\hat{\beta}) u_{is}(\hat{\beta})$$

and  $r$  and  $s$  index moment equations. For all types of weight matrices, if the `independent` suboption is specified, then  $\Lambda_{rs} = \mathbf{0}$  for  $r \neq s$ , where  $\Lambda_{rs}$  measures the covariance between moment conditions for equations  $r$  and  $s$ .

If you specify `wmatrix(robust)`, then

$$\mathbf{\Lambda} = N^{-1} \sum_{i=1}^N \mathbf{Z}_i \mathbf{u}_i(\hat{\boldsymbol{\beta}}) \mathbf{u}_i'(\hat{\boldsymbol{\beta}}) \mathbf{Z}_i'$$

If you specify `wmatrix(cluster clustvar)`, then

$$\mathbf{\Lambda} = N^{-1} \sum_{c=1}^{c=N_C} \mathbf{q}_c \mathbf{q}_c'$$

where  $c$  indexes clusters,  $N_C$  is the number of clusters, and

$$\mathbf{q}_c = \sum_{i \in c_j} \mathbf{Z}_i \mathbf{u}_i(\hat{\boldsymbol{\beta}})$$

If you specify `wmatrix(hac kernel [#])`, then

$$\begin{aligned} \mathbf{\Lambda} = & N^{-1} \sum_{i=1}^N \mathbf{Z}_i \mathbf{u}_i(\hat{\boldsymbol{\beta}}) \mathbf{u}_i'(\hat{\boldsymbol{\beta}}) \mathbf{Z}_i' + \\ & N^{-1} \sum_{l=1}^{l=N-1} \sum_{i=l+1}^N K(l, \lambda) \left\{ \mathbf{Z}_i \mathbf{u}_i(\hat{\boldsymbol{\beta}}) \mathbf{u}_{i-l}'(\hat{\boldsymbol{\beta}}) \mathbf{Z}_{i-l}' + \mathbf{Z}_{i-l} \mathbf{u}_{i-l}(\hat{\boldsymbol{\beta}}) \mathbf{u}_i'(\hat{\boldsymbol{\beta}}) \mathbf{Z}_i' \right\} \end{aligned}$$

where  $\lambda = \#$  if  $\#$  is specified and  $\lambda = N - 2$  otherwise. Define  $z = l/(\lambda + 1)$ . If *kernel* is `bartlett` or `nwest`, then

$$K(l, \lambda) = \begin{cases} 1 - z & 0 \leq z \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

If *kernel* is `parzen` or `gallant`, then

$$K(l, \lambda) = \begin{cases} 1 - 6z^2 + 6z^3 & 0 \leq z \leq 0.5 \\ 2(1 - z)^3 & 0.5 < z \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

If *kernel* is `quadraticspectral` or `andrews`, then

$$K(l, \lambda) = \begin{cases} 1 & z = 0 \\ 3\{\sin(\theta)/\theta - \cos(\theta)\}/\theta^2 & \text{otherwise} \end{cases}$$

where  $\theta = 6\pi z/5$ .

If `wmatrix(hac kernel opt)` is specified, then `gmm` uses Newey and West's (1994) automatic lag-selection algorithm, which proceeds as follows. Define  $\mathbf{h}$  to be an  $m \times 1$  vector of ones. Note that this definition of  $\mathbf{h}$  is slightly different from the one used by `ivregress`. There the element of  $\mathbf{h}$  corresponding to the constant term equals 0, effectively ignoring the effect of the constant in determining the optimal lag length. Here we include the effect of the constant term. Now, define

$$\begin{aligned}
 f_i &= \{\mathbf{Z}'_i \mathbf{u}_i(\boldsymbol{\beta})\}' \mathbf{h} \\
 \hat{\sigma}_j &= N^{-1} \sum_{i=j+1}^N f_i f_{i-j} \quad j = 0, \dots, \lambda^* \\
 \hat{s}^{(q)} &= 2 \sum_{j=1}^{j=\lambda^*} \hat{\sigma}_j j^q \\
 \hat{s}^{(0)} &= \hat{\sigma}_0 + 2 \sum_{j=1}^{j=\lambda^*} \hat{\sigma}_j \\
 \hat{\gamma} &= c_\gamma \left\{ \left( \frac{\hat{s}^{(q)}}{\hat{s}^{(0)}} \right)^2 \right\}^{1/(2q+1)} \\
 \lambda &= \hat{\gamma} N^{1/(2q+1)}
 \end{aligned}$$

where  $q$ ,  $\lambda^*$ , and  $c_\gamma$  depend on the kernel specified:

Kernel	$q$	$\lambda^*$	$c_\gamma$
Bartlett/Newey–West	1	$\text{int} \{20(T/100)^{2/9}\}$	1.1447
Parzen/Gallant	2	$\text{int} \{20(T/100)^{4/25}\}$	2.6614
Quadratic spectral/Andrews	2	$\text{int} \{20(T/100)^{2/25}\}$	1.3221

Here  $\text{int}(x)$  denotes the integer obtained by truncating  $x$  toward zero. For the Bartlett and Parzen kernels, the optimal lag is  $\min\{\text{int}(\lambda), \lambda^*\}$ . For the quadratic spectral kernel, the optimal lag is  $\min\{\lambda, \lambda^*\}$ .

If `wmatrix(hac kernel opt #)` is specified, then `gmm` uses `#` instead of 20 in the definition of  $\lambda^*$  above to select the optimal lag.

## Variance–covariance matrix

If you specify `vce(unadjusted)`, then the VCE matrix is computed as

$$\text{Var}(\hat{\boldsymbol{\beta}}) = N^{-1} \left\{ \overline{\mathbf{G}}(\hat{\boldsymbol{\beta}})' \mathbf{W} \overline{\mathbf{G}}(\hat{\boldsymbol{\beta}}) \right\}^{-1} \tag{A2}$$

where

$$\overline{\mathbf{G}}(\hat{\boldsymbol{\beta}}) = N^{-1} \sum_{i=1}^N \mathbf{z}'_i \left. \frac{\partial \mathbf{u}_i(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}'} \right|_{\boldsymbol{\beta}=\hat{\boldsymbol{\beta}}} \tag{A3}$$

For the two-step and iterated estimators, we use the weight matrix  $\mathbf{W}$  that was used to compute the final-round estimate  $\hat{\boldsymbol{\beta}}$ .

When you do not specify analytic derivatives, `gmm` must compute the Jacobian matrix (A3) numerically. By default, `gmm` computes each element of the matrix individually by using the Mata `deriv()` function; see [M-5] [deriv\(\)](#). This procedure results in accurate derivatives but can be slow if your model has many instruments or parameters.

When you specify the `quickderivatives` option, `gmm` computes all derivatives corresponding to parameter  $\beta_j$ ,  $j = 1, \dots, q$ , at once, using two-sided derivatives with a step size of  $|\beta_j| \epsilon^{1/3}$ , where  $\epsilon$  is the machine precision of a double precision number (approximately  $2.22045 \times 10^{-16}$ ). This method requires just two evaluations of the model's moments to compute an entire column of (A3) and therefore has the most impact when you specify many instruments or moment equations so that (A3) has many rows.

For the one-step estimator, how the unadjusted VCE is computed depends on the type of initial weight matrix requested and the form of the moment equations. If you specify two or more moment equations of the form  $h_{ij}(\mathbf{w}_{ij}; \beta_j)$ , then `gmm` issues a note and computes a heteroskedasticity-robust VCE because here the matrix  $\mathbf{Z}'\mathbf{Z}$  is necessarily singular; moreover, here you must use the identity matrix as the initial weight matrix. Otherwise, if you specify `winitial(unadjusted)` or `winitial(identity)`, then `gmm` first computes an unadjusted weight matrix based on  $\hat{\beta}$  before evaluating (A2). If you specify `winitial(matname)`, then (A2) is evaluated on the basis of *matname*; the user is responsible for verifying that the VCE and other statistics so produced are appropriate.

All types of robust VCEs computed by `gmm` take the form

$$\text{Var}(\hat{\beta}) = N^{-1} \left\{ \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \overline{\mathbf{G}}(\hat{\beta}) \right\}^{-1} \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \mathbf{S} \mathbf{W} \overline{\mathbf{G}}(\hat{\beta}) \left\{ \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \overline{\mathbf{G}}(\hat{\beta}) \right\}^{-1}$$

For the one-step estimator,  $\mathbf{W}$  represents the initial weight matrix requested using the `winitial()` option, and  $\mathbf{S}$  is computed on the basis of the specification of the `vce()` option. The formulas for the  $\mathbf{S}$  matrix are identical to the ones that define the  $\mathbf{\Lambda}$  matrix in [Weight matrix](#) above, except that  $\mathbf{S}$  is computed after the moment equations are reevaluated using the final estimate of  $\hat{\beta}$ . For the two-step and iterated GMM estimators, computation of  $\mathbf{W}$  is controlled by the `wmatrix()` option on the basis of the penultimate estimate of  $\hat{\beta}$ .

For details on computation of the VCE matrix with dynamic panel-data models, see [Panel-style instruments](#) below.

## Hansen's J statistic

Hansen's (1982)  $J$  test of overidentifying restrictions is  $J = N \times Q(\hat{\beta})$ .  $J \sim \chi^2(m - k)$ . If  $m < k$ , `gmm` issues an error message without estimating the parameters. If  $m = k$ , the model is just-identified and  $J$  is saved as missing (“.”). For the two-step and iterated GMM estimators, the  $J$  statistic is based on the last-computed weight matrix as determined by the `wmatrix()` option. For the one-step estimator, `gmm` recomputes a weight matrix as described in the second paragraph of [Variance-covariance matrix](#) above. To obtain Hansen's  $J$  statistic, you use `estat overid`; see [\[R\] gmm postestimation](#).

## Panel-style instruments

Here we discuss several issues that arise only when you specify panel-style instruments by using the `xtinstruments()` option. When you specify the `xtinstruments()` option, we can no longer consider the instruments for one observation in isolation; instead, we must consider the instrument matrix for an entire panel at once. In the following discussion, we let  $T$  denote the number of time periods in a panel. To accommodate unbalanced datasets, conceptually we simply use zeros as instruments and residuals for time periods that are missing in a panel.

We consider the case where you specify both an equation in levels and an equation in differences, yielding two residual equations. Let  $u_{pt}^L(\beta)$  denote the residual for the level equation for panel  $p$  in period  $t$ , and let  $u_{pt}^D(\beta)$  denote the residual for the corresponding difference equation. Now, define the  $(2T - 1) \times 1$  vector  $\mathbf{u}_p(\beta)$  as

$$\mathbf{u}_p(\beta) = [u_{p1}^L(\beta), u_{p2}^L(\beta), \dots, u_{pT}^L(\beta), u_{p2}^D(\beta), u_{p3}^D(\beta), \dots, u_{pT}^D(\beta)]$$

The  $T + 1$  element of  $\mathbf{u}_p$  is  $u_{p2}^D(\beta)$  because we lose the first observation of the difference equation because of differencing.

We write the moment conditions for the  $p$ th panel as  $\mathbf{Z}_p \mathbf{u}_p(\beta)$ . To see how  $\mathbf{Z}_p$  is defined, we will let  $\mathbf{w}_{pt}^L$  and  $\mathbf{w}_{pt}^D$  denote the vectors of panel-style instruments for the level and difference equations, respectively, and let time be denoted by  $t$ ; we discuss their dimensions momentarily. Also let  $\mathbf{x}_{pt}^L$  and  $\mathbf{x}_{pt}^D$  denote the vectors of instruments specified in `instruments()` for the level and difference equations at time  $t$ . Without loss of generality, for our discussion, we assume that you specify the level equation first. Then,  $\mathbf{Z}_p$  has the form

$$\mathbf{Z}_p = \begin{bmatrix} \mathbf{w}_1^L & \mathbf{0} & \dots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} \\ \mathbf{0} & \mathbf{w}_2^L & \dots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \dots & \mathbf{w}_T^L & \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} \\ \mathbf{x}_1^L & \mathbf{x}_2^L & \dots & \mathbf{x}_T^L & \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} & \mathbf{w}_1^D & \mathbf{0} & \dots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} & \mathbf{0} & \mathbf{w}_2^D & \dots & \mathbf{0} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \dots & \mathbf{w}_T^D \\ \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} & \mathbf{x}_1^D & \mathbf{x}_2^D & \dots & \mathbf{x}_T^D \end{bmatrix} \quad (\text{A4})$$

To see how the  $\mathbf{w}$  vectors are formed, we will suppose you specify

```
xtinstruments(1: d, lags(a/b))
```

Then,  $\mathbf{w}_t^L$  will be a  $(b - a + 1) \times 1$  vector consisting of  $d_{t-a}, \dots, d_{t-b}$ . If  $(t - a) \leq 0$ , then instead, we set  $\mathbf{w}_t^L = \mathbf{0}$ . If  $(t - a) > 0$  but  $(t - b) \leq 0$ , then we create  $\mathbf{w}_t^L$  to consist of  $d_{t-a}, \dots, d_1$ . With this definition,  $(b - a + 1)$  defines the maximum number of lags of  $d$  used, but `gmm` will proceed with fewer lags if all  $(b - a + 1)$  lags are not available. If you specify two panel-style instruments,  $\mathbf{d}$  and  $\mathbf{e}$ , say, then  $\mathbf{w}_t^L$  will consist of  $d_{t-a}, \dots, d_{t-b}, e_{t-a}, \dots, e_{t-b}$ .  $\mathbf{w}_t^D$  is handled analogously.

The  $\mathbf{x}_t^L$  vectors are simply  $j \times 1$  vectors, where  $j$  is the number of regular instruments specified with the `instruments()` option; these vectors include a “1” unless you specify the `noconstant` suboption.

Looking carefully at (A4), you will notice that for dynamic panel-data models, moment conditions corresponding to the instruments  $\mathbf{x}_{pt}^L$  take the form

$$E \left[ \sum_{t=1}^{t=T} \mathbf{x}_{pt}^L u_{pt}^L(\beta) \right] = \mathbf{0}$$

and likewise for  $\mathbf{x}_{pt}^D$ . Instead of having separate moment conditions for each time period, there is one moment condition equal to the average of individual periods’ moments. See [Arellano and Bond \(1991, 280\)](#). To include separate moment conditions for each time period, instead of specifying, say,

```
instruments(1: x)
```

you could instead first generate a variable called `one` equal to unity for all observations and specify

```
xtinstruments(1: x one)
```

(Creating the variable `one` is necessary because a constant is not automatically included in variable lists specified in `xtinstruments()`.)

Unbalanced panels are essentially handled by including zeros in rows and columns of  $\mathbf{Z}_p$  and  $\mathbf{u}_p(\hat{\beta})$  corresponding to missing time periods. However, the numbers of instruments and moment conditions reported by `gmm` do not reflect this trickery and instead reflect the numbers of instruments and moment conditions that are not manipulated in this way. Moreover, `gmm` includes code to work through these situations efficiently without actually having to fill in zeros.

When you specify `winitial(xt ...)`, the one-step unadjusted VCE is computed as

$$\text{Var}(\hat{\beta}) = \hat{\sigma}_1^2 \mathbf{\Lambda}_H$$

where  $\mathbf{\Lambda}_H$  is as defined previously,

$$\hat{\sigma}_1^2 = (N - k)^{-1} \sum_{p=1}^{p=P} \mathbf{u}_p^D(\hat{\beta})' \mathbf{u}_p^D(\hat{\beta})$$

and  $\mathbf{u}_p^D(\hat{\beta}) = [u_{p2}^D(\hat{\beta}), \dots, u_{pT}^D(\hat{\beta})]$ . Here we use  $(N - k)^{-1}$  instead of  $N^{-1}$  to match `xtdpd`.

## Marginal predictions with unconditional standard errors

Here we describe how `margins` computes unconditional standard errors when used with the `vce(unconditional)` option after `gmm`. These standard errors account for the estimation of parameters in `gmm` before `margins` is used to make marginal predictions. They also account for variation in the covariates over the population.

`margins` with the `vce(unconditional)` option uses linearization to estimate the unconditional variance of  $\hat{\beta}$ . Linearization uses the variance estimator for the total of a score variable for the marginal prediction  $p(\hat{\beta})$  as an approximate estimator for  $\text{Var}\{p(\hat{\beta})\}$ . See [SVY] [Variance estimation](#) for more details. Our derivation of the standard errors here is similar to the derivation of the standard errors for two-step  $M$  estimators. See [Wooldridge \(2010, sec. 12.4\)](#) for the latter.

Let  $\mathbf{x}_i$  be a vector of covariate values, which includes all variables used in calculating the moment conditions, and let  $f(\mathbf{x}_i, \beta)$  be a scalar-valued function returning the value of the predictions of interest.

Let  $\delta_i(S_p)$  indicate whether observation  $i$  is in the subpopulation of interest,  $S_p$ ,

$$\delta_i(S_p) = \begin{cases} 1, & i \in S_p \\ 0, & i \notin S_p \end{cases}$$

`margins` computes  $\hat{\theta} = p(\hat{\beta})$  via

$$\hat{\theta} = \frac{1}{w} \sum_{i=1}^N \delta_i(S_p) w_i f(\mathbf{x}_i, \hat{\beta})$$

where

$$w_i = \sum_{i=1}^N \delta_i(S_p) w_i$$

and  $w_i$  is the weight for the  $i$ th observation.

In minimizing (A1), we see that the GMM estimator  $\hat{\beta}$  is the value of  $\beta$  that solves the score equations

$$\mathbf{0} = \overline{\mathbf{G}}(\beta)' \mathbf{W} \left\{ N^{-1} \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\beta) \right\}$$

where  $\overline{\mathbf{G}}(\beta)$  was defined in (A3).

By the mean-value theorem, for some points  $\beta_1, \dots, \beta_q$  between  $\beta$  and  $\hat{\beta}$ , we have

$$\mathbf{0} = \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \left[ \left\{ N^{-1} \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\beta) \right\} + \overline{\mathbf{G}}_m(\hat{\beta} - \beta) \right]$$

where

$$\overline{\mathbf{G}}_{m(j,l)} = N^{-1} \sum_{i=1}^N \left[ \frac{\partial \{ \mathbf{Z}'_i \mathbf{u}_i(\beta_j) \}_l}{\partial \beta'_j} \right]_{j,l}$$

So we have

$$\sqrt{N}(\hat{\beta} - \beta) = - \left\{ \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \overline{\mathbf{G}}_m \right\}^{-1} \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \left\{ N^{-0.5} \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\beta) \right\} \quad (\text{A5})$$

The margin  $\hat{\theta}$  is the solution to the score equations

$$\frac{1}{N} \sum_{i=1}^N s_i(\theta, \hat{\beta}) = \mathbf{0}$$

where

$$s_i(\theta, \beta) = w_i \delta_i(S_p) \{ f(\mathbf{x}_i, \beta) - \theta \}$$

When we do a mean-value expansion about point  $\theta_1$  between  $\theta$  and  $\hat{\theta}$ , we get

$$\mathbf{0} = \frac{1}{N} \sum_{i=1}^N s_i(\theta, \hat{\beta}) - w_i(\hat{\theta} - \theta)$$

So we have

$$\sqrt{N}(\hat{\theta} - \theta) = w_i^{-1} N^{-0.5} \sum_{i=1}^N s_i(\theta, \hat{\beta})$$

Using the mean-value theorem again, for point  $\beta_m$  between  $\beta$  and  $\hat{\beta}$ , we have

$$w_i^{-1} N^{-0.5} \sum_{i=1}^N s_i(\theta, \hat{\beta}) = w_i^{-1} \left\{ N^{-0.5} \sum_{i=1}^N s_i(\theta, \beta) + \sqrt{N} \mathbf{J}(\beta_m) (\hat{\beta} - \beta) \right\}$$

where  $\bar{\mathbf{J}}(\beta_m)$  is the Jacobian of the margin at  $\beta_m$ ,

$$\bar{\mathbf{J}}(\beta_m) = \left\{ N^{-1} \sum_{i=1}^N w_i \delta_i(S_p) \frac{\partial f(\mathbf{x}_i, \beta_m)}{\partial \beta'_m} \right\}$$

Using (A5), we get

$$\sqrt{N}(\hat{\theta} - \theta) = w \cdot^{-1} N^{-0.5} \left[ \sum_{i=1}^N s_i(\theta, \beta) - \bar{\mathbf{J}}(\beta_m) \left\{ \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \overline{\mathbf{G}}_m \right\}^{-1} \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \left\{ \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\beta) \right\} \right]$$

$\hat{\theta}$  is asymptotically normal, and a consistent estimator of its variance is given by

$$\widehat{\text{Var}}\{\sqrt{N}(\hat{\theta} - \theta)\} = \sum_{i=1}^N w \cdot^{-2} \left[ s_i(\hat{\theta}, \hat{\beta}) - \bar{\mathbf{J}}(\hat{\beta}) \left\{ \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \overline{\mathbf{G}}(\hat{\beta}) \right\}^{-1} \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \mathbf{Z}'_i \mathbf{u}_i(\hat{\beta}) \right]^2$$

See [Wooldridge \(2010, sec 12.4 and 12.5\)](#) for details.

`gmm` returns  $N^{-1} \left\{ \overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \overline{\mathbf{G}}(\hat{\beta}) \right\}^{-1}$  as the model-based variance. The scores are  $-\overline{\mathbf{G}}(\hat{\beta})' \mathbf{W} \mathbf{Z}'_i \mathbf{u}_i(\hat{\beta})$  and may be predicted in postestimation; see [\[R\] gmm postestimation](#). These scores correspond to derivatives of the criterion function  $Q(\beta)$ , scaled by  $-1/2$ . See [Cameron and Trivedi \(2005, sec. 6.3.2\)](#) for more details.

`margins` estimates the asymptotic standard error of  $\hat{\theta}$  from the model-based variance, the scores, and its own predictions of  $s_i$  and the Jacobian  $\bar{\mathbf{J}}(\hat{\beta})$ .

## Postestimation commands

The following postestimation command is of special interest after `gmm`:

Command	Description
<code>estat overid</code>	perform test of overidentifying restrictions

The following standard postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>hausman</code>	Hausman’s specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	residuals
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, residuals, and scores.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, xb equation(#eqno | eqname) ]
```

```
predict [type] newvar [if] [in], residuals [equation(#eqno | eqname) ]
```

```
predict [type] { stub* | newvar1 ... newvarq } [if] [in] [, residuals ]
```

```
predict [type] stub* [if] [in], scores
```

Residuals are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Scores are available only for observations within the estimation sample.

You specify one new variable and (optionally) `equation()`, or you specify `stub*` or `q` or `p` new variables, where `q` is the number of moment equations and `p` is the number of parameters in the model.

## Option for predict

Main

`xb`, the default, calculates the linear prediction.

`residuals` calculates the residuals, the predicted values of the moment equations. This option requires that the length of the new variable list be equal to the number of moment equations, `q`. Otherwise, use `stub*` to have `predict` generate enumerated variables with prefix `stub`. If `equation()` is not specified, the `j`th new variable will contain the residuals for the `j`th moment equation.

`equation(#eqno | eqname)` with `xb` refers to a linear prediction in the model, whereas `equation(#eqno | eqname)` with `residuals` refers to a moment equation.

For `xb`, specifying `equation(#1)` indicates that the calculation is to be made for the first linear prediction within curly braces. Specifying `equation(xb1)` would indicate that the calculation is to be made for the linear prediction `xb1`, assuming there is a linear prediction named `xb1` in the model, for instance, `{xb1:varlist}`.

For `residuals`, specifying `equation(#1)` indicates that the calculation is to be made for the first moment equation. Specifying `equation(demand)` would indicate that the calculation is to be made for the moment equation named `demand`, assuming there is a moment equation named `demand` in the model.

If you specify one new variable name and omit `equation()`, results are the same as if you had specified `equation(#1)`.

For more information on using `predict` after multiple-equation estimation commands, see [R] [predict](#).

`scores` calculates the parameter-level score equations, the first derivatives of the GMM criterion function with respect to the parameters scaled by  $-0.5$ . This option requires that the length of the new variable list be equal to the number of parameters,  $p$ . Otherwise, use `stub*` to have `predict` generate enumerated variables with prefix `stub`. The  $j$ th new variable will contain the  $j$ th score of the model.

## margins

### Description for margins

`margins` estimates margins of response for linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>xb</code>	linear prediction; the default
<code><u>r</u>esiduals</code>	not allowed with <code>margins</code>

`xb` defaults to the first equation.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## estat

### Description for estat

`estat overid` reports Hansen's  $J$  statistic, which is used to determine the validity of the overidentifying restrictions in a GMM model. If the model is correctly specified in the sense that  $E\{\mathbf{z}_i u_i(\boldsymbol{\beta})\} = \mathbf{0}$ , then the sample analog to that condition should hold at the estimated value of  $\boldsymbol{\beta}$ . Hansen's  $J$  statistic is valid only if the weight matrix is optimal, meaning that it equals the inverse of the covariance matrix of the moment conditions. Therefore, `estat overid` only reports Hansen's  $J$  statistic after two-step or iterated estimation, or if you specified `winitial(matname)` when calling `gmm`. In the latter case, it is your responsibility to determine the validity of the  $J$  statistic.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

```
estat overid
```

`collect` is allowed with `estat overid`; see [U] 11.1.10 Prefix commands.

### Remarks and examples

As we noted in *Introduction* of [R] `gmm`, underlying generalized method of moments (GMM) estimators is a set of  $l$  moment conditions,  $E\{\mathbf{z}_i u_i(\boldsymbol{\beta})\} = \mathbf{0}$ . When  $l$  is greater than the number of parameters,  $k$ , any size- $k$  subset of the moment conditions would yield a consistent parameter estimate. We remarked that the parameter estimates we would obtain would in general depend on which  $k$  moment conditions we used. However, if all our moment conditions are indeed valid, then the parameter estimates should not differ too much regardless of which  $k$  moment conditions we used to estimate the parameters. The test of overidentifying restrictions is a model specification test based on this observation. The test of overidentifying restrictions requires that the number of moment conditions be greater than the number of parameters in the model.

Recall that the GMM criterion function is

$$Q = \left\{ \frac{1}{N} \sum_i \mathbf{z}_i u_i(\boldsymbol{\beta}) \right\}' \mathbf{W} \left\{ \frac{1}{N} \sum_i \mathbf{z}_i u_i(\boldsymbol{\beta}) \right\}$$

The test of overidentifying restrictions is remarkably simple. If  $\mathbf{W}$  is an optimal weight matrix, under the null hypothesis  $H_0: E\{\mathbf{z}_i u_i(\boldsymbol{\beta})\} = \mathbf{0}$ , the test statistic  $J = N \times Q \sim \chi^2(l - k)$ . A large test statistic casts doubt on the null hypothesis.

For the test to be valid,  $\mathbf{W}$  must be optimal, meaning that  $\mathbf{W}$  must be the inverse of the covariance matrix of the moment conditions:

$$\mathbf{W}^{-1} = E\{\mathbf{z}_i u_i(\boldsymbol{\beta}) u_i'(\boldsymbol{\beta}) \mathbf{z}_i'\}$$

Therefore, `estat overid` works only after the two-step and iterated estimators, or if you supplied your own initial weight matrix by using the `winitial(matname)` option to `gmm` and used the one-step estimator.

Often the overidentifying restrictions test is interpreted as a test of the validity of the instruments  $\mathbf{z}$ . However, other forms of model misspecification can sometimes lead to a significant test statistic. See Hall (2005, sec. 5.1) for a discussion of the overidentifying restrictions test and its behavior in correctly and misspecified models.

### ► Example 1

In [example 6](#) of [R] `gmm`, we fit an exponential regression model of the number of doctor visits based on the person's gender, income, possession of private health insurance, and presence of a chronic disease. We argued that the variable `income` may be endogenous; we used the person's age and race as additional instrumental variables. Here we refit the model and test the specification of the model. We type

```
. use https://www.stata-press.com/data/r18/docvisits
. gmm (docvis - exp({xb:private chronic female income} + {b0})),
> instruments(private chronic female age black hispanic)
(output omitted)
. estat overid
Test of overidentifying restriction:
Hansen's J chi2(2) = 9.52598 (p = 0.0085)
```

The  $J$  statistic is significant even at the 1% significance level, so we conclude that our model is misspecified. One possibility is that age and race directly affect the number of doctor visits, so we are not justified in excluding them from the model.

A simple technique to explore whether any of the instruments is invalid is to examine the statistics

$$r_j = \mathbf{W}_{jj}^{1/2} \left\{ \frac{1}{N} \sum_{i=1}^N z_{ij} u_i(\hat{\beta}) \right\}$$

for  $j = 1, \dots, k$ , where  $\mathbf{W}_{jj}$  denotes the  $j$ th diagonal element of  $\mathbf{W}$ ,  $u_i(\hat{\beta})$  denotes the sample residuals, and  $k$  is the number of instruments. If all the instruments are valid, then the scaled sample moments should at least be on the same order of magnitude. If one (or more) instrument's  $r_j$  is large in absolute value relative to the others, then that could be an indication that instrument is not valid.

In Stata, we type

```
. predict double r if e(sample), residuals // obtain residual from the model
. matrix W = e(W) // retrieve weight matrix
. local i 1
. // loop over each instrument and compute r_j
. foreach var of varlist private chronic female age black hispanic {
2. generate double r'var' = r*'var'*sqrt(W['i', 'i'])
3. local '++i'
4. }
. summarize r*
```

Variable	Obs	Mean	Std. dev.	Min	Max
r	4,412	.0344373	8.26176	-151.1847	113.059
rprivate	4,412	.007988	3.824118	-72.66254	54.33852
rchronic	4,412	.0026947	2.0707	-43.7311	32.703
rfemale	4,412	.0028168	1.566397	-12.7388	24.43621
rage	4,412	.0360978	4.752986	-89.74112	55.58143
rblack	4,412	-.0379317	1.062027	-24.39747	27.34512
rhispanic	4,412	-.017435	1.08567	-5.509386	31.53512

We notice that the  $r_j$  statistics for `age`, `black`, and `hispanic` are larger than those for the other instruments in our model, supporting our suspicion that age and race may have a direct impact on the number of doctor visits.

◀

## Stored results

`estat overid` stores the following in `r()`:

Scalars

<code>r(J)</code>	Hansen's $J$ statistic
<code>r(J_df)</code>	$J$ statistic degrees of freedom
<code>r(J_p)</code>	$J$ statistic $p$ -value

# Title

**grmeanby** — Graph means and medians by categorical variables

[Description](#)  
[Options](#)

[Quick start](#)  
[Remarks and examples](#)

[Menu](#)  
[References](#)

[Syntax](#)

## Description

`grmeanby` graphs the (optionally weighted) means or medians of *varname* according to the values of the variables in *varlist*. The variables in *varlist* may be string or numeric and, if numeric, may be labeled.

## Quick start

Graph means of *v1* for each level of categorical variables *cvar1*, *cvar2*, and *cvar3*

```
grmeanby cvar1 cvar2 cvar3, sum(v1)
```

Same as above, but graph medians

```
grmeanby cvar1 cvar2 cvar3, sum(v1) median
```

Same as above, but use + as the marker

```
grmeanby cvar1 cvar2 cvar3, sum(v1) median msymbol(+)
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Graph means/medians by groups

## Syntax

```
grmeanby varlist [if] [in] [weight] , summarize(varname) [options]
```

<i>options</i>	Description
Main	
* <u>summarize</u> ( <i>varname</i> )	graph mean (or median) of <i>varname</i>
<u>median</u>	graph medians; default is to graph means
Plot	
<i>cline_options</i>	change look of the lines
<i>marker_options</i>	change look of markers (color, size, etc.)
<i>marker_label_options</i>	add marker labels; change look or position
Y axis, X axis, Titles, Legend, Overall	
<i>twoway_options</i>	any options other than by() documented in [G-3] <i>twoway_options</i>

\*summarize(*varname*) is required.

*aweight*s and *fweight*s are allowed; see [U] 11.1.6 [weight](#).

## Options

### Main

summarize(*varname*) is required; it specifies the name of the variable whose mean or median is to be graphed.

median specifies that the graph is to be of medians, not means.

### Plot

*cline\_options* affect the rendition of the lines through the markers, including their color, pattern, and width; see [G-3] [cline\\_options](#).

*marker\_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] [marker\\_label\\_options](#).

### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] [twoway\\_options](#), excluding by(). These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

The idea of graphing means of categorical variables was shown in [Chambers and Hastie \(1992, 3\)](#). Because this was shown in the context of an S function for making such graphs, it doubtless has roots going back further than that. `grmeanby` is, in any case, another implementation of what we will assume is their idea.

## ▷ Example 1

Using a variation of our auto dataset, we graph the mean of mpg by foreign, rep77, rep78, and make:

```
. use https://www.stata-press.com/data/r18/auto1
(Automobile models)
. grmeanby foreign rep77 rep78 make, sum(mpg)
```

If we had wanted a graph of medians rather than means, we could have typed

```
. grmeanby foreign rep77 rep78 make, sum(mpg) median
```

[Methods and formulas](#)

## Description

`hausman` performs Hausman's (1978) specification test.

## Quick start

Hausman test for stored models `consistent` and `efficient`

```
hausman consistent efficient
```

Same as above, but compare fixed-effects and random-effects linear regression models

```
hausman fixed random, sigmamore
```

Endogeneity test after `ivprobit` and `probit` with estimates stored in `iv` and `noiv`

```
hausman iv noiv, equations(1:1)
```

Test of independence of irrelevant alternatives for model with all alternatives `all` and model with omitted alternative `omitted`

```
hausman omitted all, alleqs constant
```

## Menu

Statistics > Postestimation

## Syntax

```
hausman name-consistent [name-efficient] [, options]
```

*name-consistent* and *name-efficient* are names under which estimation results were stored via `estimates store`; see [R] [estimates store](#). A period (.) may be used to refer to the last estimation results, even if these were not already stored. Not specifying *name-efficient* is equivalent to specifying the last estimation results as “.”.

<i>options</i>	Description
Main	
<code>constant</code>	include estimated intercepts in comparison; default is to exclude
<code>alleqs</code>	use all equations to perform test; default is first equation only
<code>skipeqs(<i>eqlist</i>)</code>	skip specified equations when performing test
<code>equations(<i>matchlist</i>)</code>	associate/compare the specified (by number) pairs of equations
<code>force</code>	force performance of test, even though assumptions are not met
<code>df(#)</code>	use # degrees of freedom
<code>sigmamore</code>	base both (co)variance matrices on disturbance variance estimate from efficient estimator
<code>sigmaless</code>	base both (co)variance matrices on disturbance variance estimate from consistent estimator
Advanced	
<code>tconsistent(<i>string</i>)</code>	consistent estimator column header
<code>tefficient(<i>string</i>)</code>	efficient estimator column header

collect is allowed; see [U] [11.1.10 Prefix commands](#).

## Options

### Main

`constant` specifies that the estimated intercept(s) be included in the model comparison; by default, they are excluded. The default behavior is appropriate for models in which the constant does not have a common interpretation across the two models.

`alleqs` specifies that all the equations in the models be used to perform the Hausman test; by default, only the first equation is used.

`skipeqs(eqlist)` specifies in *eqlist* the names of equations to be excluded from the test. Equation numbers are not allowed in this context, because the equation names, along with the variable names, are used to identify common coefficients.

`equations(matchlist)` specifies, by number, the pairs of equations that are to be compared.

The *matchlist* in `equations()` should follow the syntax

$$\#_c:\#_e \left[ , \#_c:\#_e \left[ , \dots \right] \right]$$

where  $\#_c$  ( $\#_e$ ) is an equation number of the always-consistent (efficient under  $H_0$ ) estimator. For instance, `equations(1:1)`, `equations(1:1, 2:2)`, or `equations(1:2)`.

If `equations()` is not specified, then equations are matched on equation names.

`equations()` handles the situation in which one estimator uses equation names and the other does not. For instance, `equations(1:2)` means that equation 1 of the always-consistent estimator is to be tested against equation 2 of the efficient estimator. `equations(1:1, 2:2)` means that equation 1 is to be tested against equation 1 and that equation 2 is to be tested against equation 2. If `equations()` is specified, the `alleqs` and `skipeqs` options are ignored.

`force` specifies that the Hausman test be performed, even though the assumptions of the Hausman test seem not to be met, for example, because the estimators were `pweighted` or the data were clustered.

`df(#)` specifies the degrees of freedom for the Hausman test. The default is the matrix rank of the variance of the difference between the coefficients of the two estimators.

`sigmamore` and `sigmaless` specify that the two covariance matrices used in the test be based on a common estimate of disturbance variance ( $\sigma^2$ ).

`sigmamore` specifies that the covariance matrices be based on the estimated disturbance variance from the efficient estimator. This option provides a proper estimate of the contrast variance for so-called tests of exogeneity and overidentification in instrumental-variables regression.

`sigmaless` specifies that the covariance matrices be based on the estimated disturbance variance from the consistent estimator.

These options can be specified only when both estimators store `e(sigma)` or `e(rmse)`, or with the `xtreg` command. `e(sigma_e)` is stored after the `xtreg` command with the `fe` or `mle` option. `e(rmse)` is stored after the `xtreg` command with the `re` option.

`sigmamore` or `sigmaless` are recommended when comparing fixed-effects and random-effects linear regression because they are much less likely to produce a non-positive-definite-differenced covariance matrix (although the tests are asymptotically equivalent whether or not one of the options is specified).

#### Advanced

`tconsistent(string)` and `tefficient(string)` are formatting options. They allow you to specify the headers of the columns of coefficients that default to the names of the models. These options will be of interest primarily to programmers.

## Remarks and examples

`hausman` is a general implementation of Hausman's (1978) specification test, which compares an estimator  $\hat{\theta}_1$  that is known to be consistent with an estimator  $\hat{\theta}_2$  that is efficient under the assumption being tested. The null hypothesis is that the estimator  $\hat{\theta}_2$  is indeed an efficient (and consistent) estimator of the true parameters. If this is the case, there should be no systematic difference between the two estimators. If there exists a systematic difference in the estimates, you have reason to doubt the assumptions on which the efficient estimator is based.

The assumption of efficiency is violated if the estimator is `pweighted` or the data are clustered, so `hausman` cannot be used. The test can be forced by specifying the `force` option with `hausman`. For an alternative to using `hausman` in these cases, see [R] [suest](#).

To use `hausman`, you

```
. (compute the always-consistent estimator)
. estimates store name-consistent
. (compute the estimator that is efficient under H_0)
. hausman name-consistent .
```

Alternatively, you can turn this around:

```
. (compute the estimator that is efficient under  $H_0$ )
. estimates store name-efficient
. (fit the less-efficient model)
. (compute the always-consistent estimator)
. hausman . name-efficient
```

You can, of course, also compute and store both the always-consistent and efficient-under- $H_0$  estimators and perform the Hausman test with

```
. hausman name-consistent name-efficient
```

## ► Example 1

We are studying the factors that affect the wages of young women in the United States between 1968 and 1988, and we have a panel-data sample of individual women over that time span.

```
. use https://www.stata-press.com/data/r18/nlswork4
(National Longitudinal Survey of Young Women, 14-24 years old in 1968)
. describe
```

```
Contains data from https://www.stata-press.com/data/r18/nlswork4.dta
Observations:      28,534      National Longitudinal Survey of

Prob > chi2 = 0.0000

Under the current specification, our initial hypothesis that the individual-level effects are adequately modeled by a random-effects model is resoundingly rejected. This result is based on the rest of our model specification, and random effects might be appropriate for some alternate model of wages. ◀

Jerry Allen Hausman (1946– ) is an American economist and econometrician. He was born in West Virginia and went on to study economics at Brown and Oxford. He joined the MIT faculty in 1972 and continues to teach there. He currently researches new goods and their effects on consumer welfare and its measurement in the Consumer Price Index along with regulation and competition in the telecommunications industry.

Hausman is best known for his many contributions to econometrics. In 1978, he published his now famous paper giving the Hausman specification test. The work remains one of the most widely cited econometrics papers. He has also done extensive work in applied microeconomics pertaining to governments role in the economy, including antitrust regulation, public finance, and taxation.

In 1980, Hausman received the Frisch Medal, a biennial award from the Econometric Society recognizing exceptional applied work, for his paper with David Wise on attrition bias. In 1985, he won the John Bates Clark Award from the American Economics Association, which is given for outstanding contributions to economics by an economist under 40 years of age. In 2012, the *Advances in Econometrics* book series devoted an entire volume to Hausman and his contributions to econometrics.

## ▶ Example 2

A stringent assumption of multinomial and conditional logit models is that outcome categories for the model have the property of independence of irrelevant alternatives (IIA). Stated simply, this assumption requires that the inclusion or exclusion of categories does not affect the relative risks associated with the regressors in the remaining categories.

One classic example of a situation in which this assumption would be violated involves the choice of transportation mode; see [McFadden \(1974\)](#). For simplicity, postulate a transportation model with the four possible outcomes: rides a train to work, takes a bus to work, drives the Ford to work, and drives the Chevrolet to work. Clearly, “drives the Ford” is a closer substitute to “drives the Chevrolet” than it is to “rides a train” (at least for most people). This means that excluding “drives the Ford” from the model could be expected to affect the relative risks of the remaining options and that the model would not obey the IIA assumption.

Using the data presented in [R] [mlogit](#), we will use a simplified model to test for IIA. The choice of insurance type among indemnity, prepaid, and uninsured is modeled as a function of age and gender. The indemnity category is allowed to be the base category, and the model including all three outcomes is fit. The results are then stored under the name `allcats`.

```
. use https://www.stata-press.com/data/r18/sysdsn3
(Health insurance data)
. mlogit insure age male
Iteration 0: Log likelihood = -555.85446

```
. estimates store allcats
```

Under the IIA assumption, we would expect no systematic change in the coefficients if we excluded one of the outcomes from the model. (For an extensive discussion, see [Hausman and McFadden \[1984\]](#).) We reestimate the parameters, excluding the uninsured outcome, and perform a Hausman test against the fully efficient full model.

```
. mlogit insure age male if insure != "Uninsure":insure
Iteration 0: Log likelihood = -394.8693

b = Consistent under H0 and Ha; obtained from **mlogit**.

B = Inconsistent under Ha, efficient under H0; obtained from **mlogit**.

Test of H0: Difference in coefficients not systematic

$$\begin{aligned} \text{chi2}(3) &= (b-B)'[(V_b-V_B)^{-1}](b-B) \\ &= 0.08 \end{aligned}$$

Prob > chi2 = 0.9944

(V\_b-V\_B is not positive definite)

The syntax of the `if` condition on the `mlogit` command simply identified the "Uninsured" category with the `insure` value label; see [U] 12.6.3 Value labels. On examining the output from `hausman`, we see that there is no evidence that the IIA assumption has been violated.

Because the Hausman test is a standardized comparison of model coefficients, using it with `mlogit` requires that the base outcome be the same in both competing models. In particular, if the most-frequent category (the default base outcome) is being removed to test for IIA, you must use the `baseoutcome()` option in `mlogit` to manually set the base outcome to something else. Or you can use the `equation()` option of the `hausman` command to align the equations of the two models.

Having the missing values for the square root of the diagonal of the covariance matrix of the differences is not comforting, but it is also not surprising. This covariance matrix is guaranteed to be positive definite only asymptotically (it is a consequence of the assumption that one of the estimators is efficient), and assurances are not made about the diagonal elements. Negative values along the diagonal are possible, and the fourth column of the table is provided mainly for descriptive use.

We can also perform the Hausman IIA test against the remaining alternative in the model:

```
. mlogit insure age male if insure != "Prepaid":insure
```

```

Test of H0: Difference in coefficients not systematic

```
chi2(3) = (b-B)'[(V_b-V_B)^(-1)](b-B)
        = -0.18
```

Warning: chi2 < 0 ==> model fitted on these data  
fails to meet the asymptotic assumptions  
of the Hausman test; see **suest** for a  
generalized test.

Here the  $\chi^2$  statistic is actually negative. We might interpret this result as strong evidence that we cannot reject the null hypothesis. Such a result is not an unusual outcome for the Hausman test, particularly when the sample is relatively small—there are only 45 uninsured individuals in this dataset.

Are we surprised by the results of the Hausman test in this example? Not really. Judging from the  $z$  statistics on the original multinomial logit model, we were struggling to identify any structure in the data with the current specification. Even when we were willing to assume IIA and computed the efficient estimator under this assumption, few of the effects could be identified as statistically different from those on the base category. Trying to base a Hausman test on a contrast (difference) between two poor estimates is just asking too much of the existing data.

◀

In [example 2](#), we encountered a case in which the Hausman was not well defined. Unfortunately, in our experience this happens fairly often. Stata provides an alternative to the Hausman test that overcomes this problem through an alternative estimator of the variance of the difference between the two estimators. This other estimator is guaranteed to be positive semidefinite. This alternative estimator also allows a widening of the scope of problems to which Hausman-type tests can be applied by relaxing the assumption that one of the estimators is efficient. For instance, you can perform Hausman-type tests to clustered observations and survey estimators. See [\[R\] suest](#) for details.

## Stored results

**hausman** stores the following in `r()`:

Scalars

```
r(chi2)     $\chi^2$ 
r(df)      degrees of freedom for the statistic
r(p)        $p$ -value for the  $\chi^2$ 
r(rank)    rank of  $(V\_b-V\_B)^{-1}$ 
```

## Methods and formulas

The Hausman statistic is distributed as  $\chi^2$  and is computed as

$$H = (\beta_c - \beta_e)'(V_c - V_e)^{-1}(\beta_c - \beta_e)$$

where

$\beta_c$	is the coefficient vector from the consistent estimator
$\beta_e$	is the coefficient vector from the efficient estimator
$V_c$	is the covariance matrix of the consistent estimator
$V_e$	is the covariance matrix of the efficient estimator

When the difference in the variance matrices is not positive definite, a Moore–Penrose generalized inverse is used. As noted in [Gouriéroux and Monfort \(1995, 125–128\)](#), the choice of generalized inverse is not important asymptotically.

The number of degrees of freedom for the statistic is the rank of the difference in the variance matrices. When the difference is positive definite, this is the number of common coefficients in the models being compared.

## Acknowledgment

Portions of `hausman` are based on an early implementation by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands.

## Description

`heckman` fits regression models with selection by using either Heckman's two-step consistent estimator or full maximum likelihood.

## Quick start

Heckman model of  $y$  on  $x1$  with  $v1$  predicting selection when binary variable `selected` indicates selection status

```
heckman y x1, select(selected = v1 x1)
```

Same as above, and generate  $v2$  containing the inverse of Mills's ratio

```
heckman y x1, select(selected = v1 x1) mills(v2)
```

Same as above

```
heckman y x1, select(selected = v1 x1) nshazard(v2)
```

Fit a Heckman model using the two-step estimation method

```
heckman y x1, select(selected = v1 x1) twostep
```

Same as above, and display first-stage probit estimates

```
heckman y x1, select(selected = v1 x1) twostep first
```

## Menu

Statistics > Sample-selection models > Heckman selection model

## Syntax

### Basic syntax

```
heckman depvar [indepvars], select(varlists) [twostep]
```

or

```
heckman depvar [indepvars], select(depvars = varlists) [twostep]
```

### Full syntax for maximum likelihood estimates only

```
heckman depvar [indepvars] [if] [in] [weight],  
  select( [depvars = ] varlists [ , noconstant offset(varnameo) ] )  
  [heckman_ml_options]
```

### Full syntax for Heckman's two-step consistent estimates only

```
heckman depvar [indepvars] [if] [in], twostep  
  select( [depvars = ] varlists [ , noconstant ] ) [heckman_ts_options]
```

---

<i>heckman_ml_options</i>	Description
Model	
<u>m</u> le	use maximum likelihood estimator; the default
* <u>s</u> elect()	specify selection equation: dependent and independent variables; whether to have constant term and offset variable
<u>n</u> oconstant	suppress constant term
<u>o</u> ffset( <i>varname</i> )	include <i>varname</i> in model with coefficient constrained to 1
<u>c</u> onstraints( <i>constraints</i> )	apply specified linear constraints
SE/Robust	
vce( <i>vcetype</i> )	<i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>opg</u> , <u>bootstrap</u> , or <u>jackknife</u>
Reporting	
<u>l</u> evel(#)	set confidence level; default is level(95)
<u>f</u> irst	report first-step probit estimates
lrmodel	perform the likelihood-ratio model test instead of the default Wald test
<u>n</u> shazard( <i>newvar</i> )	generate nonselection hazard variable
<u>m</u> ills( <i>newvar</i> )	synonym for nshazard()
<u>n</u> ocnsreport	do not display constraints
<i>display_options</i>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<i>maximize_options</i>	control the maximization process; seldom used
<u>c</u> ollinear	keep collinear variables
<u>c</u> oeflegend	display legend instead of statistics

---

\*select() is required.

The full specification is `select( [depvars = ] varlist [ , noconstant offset(varnameo) ] )`.

<i>heckman_ts_options</i>	Description
Model	
* <code>twostep</code>	produce two-step consistent estimate
* <code>select()</code>	specify selection equation: dependent and independent variables; whether to have constant term
<code>noconstant</code>	suppress constant term
<code>rhosigma</code>	truncate $\rho$ to $[-1, 1]$ with consistent $\sigma$
<code>hotrunc</code>	truncate $\rho$ to $[-1, 1]$
<code>holimited</code>	truncate $\rho$ in limited cases
<code>hoforce</code>	do not truncate $\rho$
SE	
<code>vce(vctype)</code>	<i>vctype</i> may be conventional, <code>bootstrap</code> , or <code>jackknife</code>
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>first</code>	report first-step probit estimates
<code>nshazard(newvar)</code>	generate nonselection hazard variable
<code>mills(newvar)</code>	synonym for <code>nshazard()</code>
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<code>coeflegend</code>	display legend instead of statistics

\* `twostep` and `select()` are required.

The full specification is `select([depvars = ] varlists [ , noconstant ])`.

*indepvars* and *varlist<sub>s</sub>* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *indepvars*, *varlist<sub>s</sub>*, and *depvar<sub>s</sub>* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes`, `bootstrap`, `by`, `collect`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: heckman.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`twostep`, `vce()`, `first`, `lrmmodel`, and `weights` are not allowed with the `svy` prefix; see [SVY] svy.

`pweights`, `fweights`, and `iweights` are allowed with maximum likelihood estimation; see [U] 11.1.6 weight. No weights are allowed if `twostep` is specified.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options for Heckman selection model (ML)

### Model

`mle` requests that the maximum likelihood estimator be used. This is the default.

`select([depvars = ] varlists [ , noconstant offset(varnameo) ])` specifies the variables and options for the selection equation. It is an integral part of specifying a Heckman model and is required. The selection equation should contain at least one variable that is not in the outcome equation.

If `depvars` is specified, it should be coded as 0 or 1, with 0 indicating an observation not selected and 1 indicating a selected observation. If `depvars` is not specified, observations for which `depvar` is not missing are assumed selected, and those for which `depvar` is missing are assumed not selected.

`noconstant` suppresses the selection constant term (intercept).

`offset(varnameo)` specifies that selection offset `varnameo` be included in the model with the coefficient constrained to be 1.

`noconstant`, `offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

#### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

#### Reporting

`level(#)`; see [R] [Estimation options](#).

`first` specifies that the first-step probit estimates of the selection equation be displayed before estimation.

`lrmmodel`; see [R] [Estimation options](#).

`nshazard(newvar)` and `mills(newvar)` are synonyms; either will create a new variable containing the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills ratio—from the selection equation. The nonselection hazard is computed from the estimated parameters of the selection equation.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

#### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `heckman` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Options for Heckman selection model (two-step)

#### Model

`twostep` specifies that Heckman's (1979) two-step efficient estimates of the parameters, standard errors, and covariance matrix be produced.

`select( [ depvars = ] varlists [ , noconstant ] )` specifies the variables and options for the selection equation. It is an integral part of specifying a Heckman model and is required. The selection equation should contain at least one variable that is not in the outcome equation.

If *depvar*<sub>s</sub> is specified, it should be coded as 0 or 1, with 0 indicating an observation not selected and 1 indicating a selected observation. If *depvar*<sub>s</sub> is not specified, observations for which *depvar* is not missing are assumed selected, and those for which *depvar* is missing are assumed not selected.

`noconstant` suppresses the selection constant term (intercept).

`noconstant`; see [R] [Estimation options](#).

`rhosigma`, `rot trunc`, `rho limited`, and `rho force` are rarely used options to specify how the two-step estimator (option `twostep`) handles unusual cases in which the two-step estimate of  $\rho$  is outside the admissible range for a correlation,  $[-1, 1]$ . When  $\text{abs}(\rho) > 1$ , the two-step estimate of the coefficient variance–covariance matrix may not be positive definite and thus may be unusable for testing. The default is `rhosigma`.

`rhosigma` specifies that  $\rho$  be truncated, as with the `rot trunc` option, and that the estimate of  $\sigma$  be made consistent with  $\hat{\rho}$ , the truncated estimate of  $\rho$ . So,  $\hat{\sigma} = \beta_m \hat{\rho}$ ; see [Methods and formulas](#) for the definition of  $\beta_m$ . Both the truncated  $\rho$  and the new estimate of  $\hat{\sigma}$  are used in all computations to estimate the two-step covariance matrix.

`rot trunc` specifies that  $\rho$  be truncated to lie in the range  $[-1, 1]$ . If the two-step estimate is less than  $-1$ ,  $\rho$  is set to  $-1$ ; if the two-step estimate is greater than 1,  $\rho$  is set to 1. This truncated value of  $\rho$  is used in all computations to estimate the two-step covariance matrix.

`rho limited` specifies that  $\rho$  be truncated only in computing the diagonal matrix **D** as it enters  $V_{\text{twostep}}$  and **Q**; see [Methods and formulas](#). In all other computations, the untruncated estimate of  $\rho$  is used.

`rho force` specifies that the two-step estimate of  $\rho$  be retained, even if it is outside the admissible range for a correlation. This option may, in rare cases, lead to a non–positive-definite covariance matrix.

These options have no effect when estimation is by maximum likelihood, the default. They also have no effect when the two-step estimate of  $\rho$  is in the range  $[-1, 1]$ .

#### SE

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`conventional`) and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(conventional)`, the default, uses the two-step variance estimator derived by Heckman.

#### Reporting

`level(#)`; see [R] [Estimation options](#).

`first` specifies that the first-step probit estimates of the selection equation be displayed before estimation.

`nshazard(newvar)` and `mills(newvar)` are synonyms; either will create a new variable containing the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills ratio—from the selection equation. The nonselection hazard is computed from the estimated parameters of the selection equation.

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

The following option is available with `heckman` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

The Heckman selection model (Gronau 1974; Lewis 1974; Heckman 1976) assumes that there exists an underlying regression relationship,

$$y_j = \mathbf{x}_j\beta + u_{1j} \qquad \text{regression equation}$$

The dependent variable, however, is not always observed. Rather, the dependent variable for observation  $j$  is observed if

$$\mathbf{z}_j\gamma + u_{2j} > 0 \qquad \text{selection equation}$$

where

$$u_1 \sim N(0, \sigma)$$

$$u_2 \sim N(0, 1)$$

$$\text{corr}(u_1, u_2) = \rho$$

When  $\rho \neq 0$ , standard regression techniques applied to the first equation yield biased results. `heckman` provides consistent, asymptotically efficient estimates for all the parameters in such models.

In one classic example, the first equation describes the wages of women. Women choose whether to work, and thus, from our point of view as researchers, whether we observe their wages in our data. If women made this decision randomly, we could ignore that not all wages are observed and use ordinary regression to fit a wage model. Such an assumption of random participation, however, is unlikely to be true; women who would have low wages may be unlikely to choose to work, and thus the sample of observed wages is biased upward. In the jargon of economics, women choose not to work when their personal reservation wage is greater than the wage offered by employers. Thus, women who choose not to work might have even higher offer wages than those who do work—they may have high offer wages, but they have even higher reservation wages. We could tell a story that competency is related to wages, but competency is rewarded more at home than in the labor force.

In any case, in this problem—which is the paradigm for most such problems—a solution can be found if there are some variables that strongly affect the chances for observation (the reservation wage) but not the outcome under study (the offer wage). Such a variable might be the number of children in the home. (Theoretically, we do not need such identifying variables, but without them, we depend on functional form to identify the model. It would be difficult for anyone to take such results seriously because the functional form assumptions have no firm basis in theory.)

### ► Example 1

In the syntax for `heckman`, `depvar` and `indepvars` are the dependent variable and regressors for the underlying regression model to be fit ( $\mathbf{y} = \mathbf{X}\beta$ ), and `varlists` are the variables ( $\mathbf{Z}$ ) thought to determine whether `depvar` is observed or unobserved (selected or not selected). In our female wage example, the number of children at home would be included in the second list. By default, `heckman` assumes that missing values (see [U] [12.2.1 Missing values](#)) of `depvar` imply that the dependent variable is

unobserved (not selected). With some datasets, it is more convenient to specify a binary variable ( $depvar_s$ ) that identifies the observations for which the dependent is observed/selected ( $depvar_s \neq 0$ ) or not observed ( $depvar_s = 0$ ); `heckman` will accommodate either type of data. Here we have a (fictional) dataset on 2,000 women, 1,343 of whom work:

```
. use https://www.stata-press.com/data/r18/womenwk
. summarize age educ married children wage
```

Variable	Obs	Mean	Std. dev.	Min	Max
age	2,000	36.208	8.28656	20	59
education	2,000	13.084	3.045912	10	20
married	2,000	.6705	.4701492	0	1
children	2,000	1.6445	1.398963	0	5
wage	1,343	23.69217	6.305374	5.88497	45.80979

We will assume that the hourly wage is a function of education and age, whereas the likelihood of working (the likelihood of the wage being observed) is a function of marital status, the number of children at home, and (implicitly) the wage (via the inclusion of age and education, which we think determine the wage):

```
. heckman wage educ age, select(married children educ age)
Iteration 0: Log likelihood = -5178.7009
Iteration 1: Log likelihood = -5178.3049
Iteration 2: Log likelihood = -5178.3045
Heckman selection model                Number of obs    =    2,000
(regression model with sample selection) Selected         =    1,343
                                         Nonselected     =     657
                                         Wald chi2(2)    =    508.44
Log likelihood = -5178.304             Prob > chi2     =     0.0000
```

wage	Coefficient	Std. err.	z	P> z	[95% conf. interval]

`heckman` assumes that wage is the dependent variable and that the first variable list (`educ` and `age`) are the determinants of wage. The variables specified in the `select()` option (`married`, `children`, `educ`, and `age`) are assumed to determine whether the dependent variable is observed (the selection equation). Thus, we fit the model

$$\text{wage} = \beta_0 + \beta_1 \text{educ} + \beta_2 \text{age} + u_1$$

and we assumed that `wage` is observed if

$$\gamma_0 + \gamma_1\text{married} + \gamma_2\text{children} + \gamma_3\text{educ} + \gamma_4\text{age} + u_2 > 0$$

where  $u_1$  and  $u_2$  have correlation  $\rho$ .

The reported results for the wage equation are interpreted exactly as though we observed wage data for all women in the sample; the coefficients on age and education level represent the estimated marginal effects of the regressors in the underlying regression equation. The results for the two ancillary parameters require some explanation. `heckman` does not directly estimate  $\rho$ ; to constrain  $\rho$  within its valid limits, and for numerical stability during optimization, it estimates the inverse hyperbolic tangent of  $\rho$ :

$$\text{atanh } \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)$$

This estimate is reported as `/athrho`. In the bottom panel of the output, `heckman` undoes this transformation for you: the estimated value of  $\rho$  is 0.7035061. The standard error for  $\rho$  is computed using the delta method, and its confidence intervals are the transformed intervals of `/athrho`.

Similarly,  $\sigma$ , the standard error of the residual in the wage equation, is not directly estimated; for numerical stability, `heckman` instead estimates  $\ln \sigma$ . The untransformed `sigma` is reported at the end of the output: 6.004797.

Finally, some researchers—especially economists—are used to the selectivity effect summarized not by  $\rho$  but by  $\lambda = \rho\sigma$ . `heckman` reports this, too, along with an estimate of the standard error and confidence interval.

◀

## □ Technical note

If each of the equations in the model had contained many regressors, the `heckman` command could have become long. An alternate way of specifying our wage model would be to use Stata's global macros. The following lines are an equivalent way of specifying our model:

```
. global wageeq "wage educ age"
. global seleq "married children educ age"
. heckman $wageeq, select($seleq)
(output omitted)
```

□

## □ Technical note

The reported model  $\chi^2$  test is a Wald test that all coefficients in the regression model (except the constant) are 0. `heckman` is an estimation command, so you can use `test`, `testnl`, or `lrtest` to perform tests against whatever nested alternate model you choose; see [R] [test](#), [R] [testnl](#), and [R] [lrtest](#).

The estimation of  $\rho$  and  $\sigma$  in the forms  $\text{atanh } \rho$  and  $\ln \sigma$  extends the range of these parameters to infinity in both directions, thus avoiding boundary problems during the maximization. Tests of  $\rho$  must be made in the transformed units. However, because  $\text{atanh}(0) = 0$ , the reported test for  $\text{atanh } \rho = 0$  is equivalent to the test for  $\rho = 0$ .

The likelihood-ratio test reported at the bottom of the output is an equivalent test for  $\rho = 0$  and is computationally the comparison of the joint likelihood of an independent probit model for the selection equation and a regression model on the observed wage data against the Heckman model likelihood. Because  $\chi^2 = 61.20$ , this clearly justifies the Heckman selection equation with these data. □

## ▷ Example 2

This command supports the Huber/White/sandwich estimator of variance under the `vce(robust)` and `vce(cluster clustvar)` options or when `pweights` are used for population-weighted data; see [\[U\] 20.22 Obtaining robust variance estimates](#). We can obtain robust standard errors for our wage model by specifying clustering on county of residence (the `county` variable).

```
. heckman wage educ age, select(married children educ age) vce(cluster county)
Iteration 0: Log pseudolikelihood = -5178.7009
Iteration 1: Log pseudolikelihood = -5178.3049
Iteration 2: Log pseudolikelihood = -5178.3045

Heckman selection model                Number of obs    =      2,000
(regression model with sample selection) Selected         =      1,343
                                         Nonselected     =       657

                                         Wald chi2(1)    =          .
Log pseudolikelihood = -5178.304      Prob > chi2     =          .

                                         (Std. err. adjusted for 10 clusters in county)
```

```
Wald test of indep. eqns. (rho = 0): chi2(1) = 38.81      Prob > chi2 = 0.0000
```

The robust standard errors tend to be a bit larger, but we notice no systematic differences. This finding is not surprising because the data were not constructed to have any county-specific correlations or any other characteristics that would deviate from the assumptions of the Heckman model. ◀

### ▷ Example 3

Stata also produces Heckman's (1979) two-step efficient estimator of the model with the `twostep` option. Maximum likelihood estimation of the parameters can be time consuming with large datasets, and the two-step estimates may provide a good alternative in such cases. Continuing with the women's wage model, we can obtain the two-step estimates with Heckman's consistent covariance estimates by typing

```
. heckman wage educ age, select(married children educ age) twostep
Heckman selection model -- two-step estimates   Number of obs   =       2,000
(regression model with sample selection)       Selected        =       1,343
                                                Nonselected     =         657
                                                Wald chi2(2)    =       442.54
                                                Prob > chi2     =         0.0000
```

### □ Technical note

The Heckman selection model depends strongly on the model being correct, much more so than ordinary regression. Running a separate probit or logit for sample inclusion followed by a regression, referred to in the literature as the two-part model (Manning, Duan, and Rogers 1987)—not to be confused with Heckman's two-step procedure—is an especially attractive alternative if the regression part of the model arose because of taking a logarithm of zero values. When the goal is to analyze an underlying regression model or to predict the value of the dependent variable that would be observed in the absence of selection, however, the Heckman model is more appropriate. When the goal is to predict an actual response, the two-part model is usually the better choice.

The Heckman selection model can be unstable when the model is not properly specified or if a specific dataset simply does not support the model's assumptions. For example, let's examine the solution to another simulated problem.

```

The model has converged to a value of  $\rho$  that is 1.0—within machine-rounding tolerances. Given the form of the likelihood for the Heckman selection model, this implies a division by zero, and it is surprising that the model solution turns out as well as it does. Reparameterizing  $\rho$  has allowed the estimation to converge, but we clearly have problems with the estimates. Moreover, if this had occurred in a large dataset, waiting for convergence might take considerable time.

This dataset was not intentionally developed to cause problems. It is actually generated by a “Heckman process” and when generated starting from different random values can be easily estimated. The luck of the draw here merely led to data that, despite the source, did not support the assumptions of the Heckman model.

The two-step model is generally more stable when the data are problematic. It even tolerates estimates of  $\rho$  less than  $-1$  and greater than 1. For these reasons, the two-step model may be preferred when exploring a large dataset. Still, if the maximum likelihood estimates cannot converge, or converge to a value of  $\rho$  that is at the boundary of acceptable values, there is scant support for fitting a Heckman selection model on the data. Heckman (1979) discusses the implications of  $\rho$  being exactly 1 or 0, together with the implications of other possible covariance relationships among the model’s determinants.

□

## Stored results

`heckman` (maximum likelihood) stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(N_selected)</code>	number of selected observations
<code>e(N_nonselected)</code>	number of nonselected observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(N_clust)</code>	number of clusters
<code>e(lambda)</code>	$\lambda$
<code>e(selambda)</code>	standard error of $\lambda$
<code>e(sigma)</code>	$\sigma$
<code>e(chi2)</code>	$\chi^2$
<code>e(chi2_c)</code>	$\chi^2$ for comparison test
<code>e(p)</code>	$p$ -value for model test
<code>e(p_c)</code>	$p$ -value for comparison test
<code>e(rho)</code>	$\rho$
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(rank0)</code>	rank of <code>e(V)</code> for constant-only model
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

Matrices	
<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

James Joseph Heckman (1944– ) was born in Chicago in 1944 and studied mathematics at Colorado College and economics at Princeton. He has taught economics at Columbia and (since 1973) at the University of Chicago. He has worked on developing a scientific basis for economic policy evaluation, with emphasis on models of individuals or disaggregated groups and the problems and possibilities created by heterogeneity, diversity, and unobserved counterfactual states. In 2000, he shared the Nobel Prize in Economics with Daniel L. McFadden.

## Methods and formulas

Cameron and Trivedi (2022, 974–981) and Greene (2018, 950–957) provide good introductions to the Heckman selection model. Adkins and Hill (2011, sec. 16.8) describe the two-step estimator with an application using Stata. Jones (2007, 35–40) illustrates Heckman estimation with an application to health economics.

Regression estimates using the nonselection hazard (Heckman 1979) provide starting values for maximum likelihood estimation.

The regression equation is

$$y_j = \mathbf{x}_j \boldsymbol{\beta} + u_{1j}$$

The selection equation is

$$\mathbf{z}_j \boldsymbol{\gamma} + u_{2j} > 0$$

where

$$u_1 \sim N(0, \sigma)$$

$$u_2 \sim N(0, 1)$$

$$\text{corr}(u_1, u_2) = \rho$$

The log likelihood for observation  $j$ ,  $\ln L_j = l_j$ , is

$$l_j = \begin{cases} w_j \ln \Phi \left\{ \frac{\mathbf{z}_j \boldsymbol{\gamma} + (y_j - \mathbf{x}_j \boldsymbol{\beta}) \rho / \sigma}{\sqrt{1 - \rho^2}} \right\} - \frac{w_j}{2} \left( \frac{y_j - \mathbf{x}_j \boldsymbol{\beta}}{\sigma} \right)^2 - w_j \ln(\sqrt{2\pi} \sigma) & y_j \text{ observed} \\ w_j \ln \Phi(-\mathbf{z}_j \boldsymbol{\gamma}) & y_j \text{ not observed} \end{cases}$$

where  $\Phi(\cdot)$  is the standard cumulative normal and  $w_j$  is an optional weight for observation  $j$ .

In the maximum likelihood estimation,  $\sigma$  and  $\rho$  are not directly estimated. Directly estimated are  $\ln \sigma$  and  $\text{atanh } \rho$ :

$$\text{atanh } \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)$$

The standard error of  $\lambda = \rho\sigma$  is approximated through the propagation of error (delta) method; that is,

$$\text{Var}(\lambda) \approx \mathbf{D} \text{Var}\{(\text{atanh } \rho \quad \ln\sigma)\} \mathbf{D}'$$

where  $\mathbf{D}$  is the Jacobian of  $\lambda$  with respect to  $\text{atanh } \rho$  and  $\ln\sigma$ .

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly *Maximum likelihood estimators* and *Methods and formulas*.

The maximum likelihood version of heckman also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

The two-step estimates are computed using Heckman's (1979) procedure.

Probit estimates of the selection equation

$$\Pr(y_j \text{ observed} \mid \mathbf{z}_j) = \Phi(\mathbf{z}_j\boldsymbol{\gamma})$$

are obtained. From these estimates, the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills ratio,  $m_j$ —for each observation  $j$  is computed as

$$m_j = \frac{\phi(\mathbf{z}_j\hat{\boldsymbol{\gamma}})}{\Phi(\mathbf{z}_j\hat{\boldsymbol{\gamma}})}$$

where  $\phi$  is the normal density. We also define

$$\delta_j = m_j(m_j + \hat{\boldsymbol{\gamma}}\mathbf{z}_j)$$

Following Heckman, the two-step parameter estimates of  $\boldsymbol{\beta}$  are obtained by augmenting the regression equation with the nonselection hazard  $\mathbf{m}$ . Thus, the regressors become  $[\mathbf{X} \quad \mathbf{m}]$ , and we obtain the additional parameter estimate  $\boldsymbol{\beta}_m$  on the variable containing the nonselection hazard.

A consistent estimate of the regression disturbance variance is obtained using the residuals from the augmented regression and the parameter estimate on the nonselection hazard,

$$\hat{\sigma}^2 = \frac{\mathbf{e}'\mathbf{e} + \boldsymbol{\beta}_m^2 \sum_{j=1}^N \delta_j}{N}$$

The two-step estimate of  $\rho$  is then

$$\hat{\rho} = \frac{\boldsymbol{\beta}_m}{\hat{\sigma}}$$

Heckman derived consistent estimates of the coefficient covariance matrix on the basis of the augmented regression.

Let  $\mathbf{W} = [\mathbf{X} \quad \mathbf{m}]$  and  $\mathbf{R}$  be a square, diagonal matrix of dimension  $N$ , with  $(1 - \hat{\rho}^2 \delta_j)$  as the diagonal elements. The conventional VCE is

$$\mathbf{V}_{\text{twostep}} = \hat{\sigma}^2 (\mathbf{W}'\mathbf{W})^{-1} (\mathbf{W}'\mathbf{R}\mathbf{W} + \mathbf{Q}) (\mathbf{W}'\mathbf{W})^{-1}$$

where

$$\mathbf{Q} = \hat{\rho}^2 (\mathbf{W}'\mathbf{D}\mathbf{Z}) \mathbf{V}_p (\mathbf{Z}'\mathbf{D}\mathbf{W})$$

where  $\mathbf{D}$  is the square, diagonal matrix of dimension  $N$  with  $\delta_j$  as the diagonal elements;  $\mathbf{Z}$  is the data matrix of selection equation covariates; and  $\mathbf{V}_p$  is the variance–covariance estimate from the probit estimation of the selection equation.

Remarks and examples

## Postestimation commands

The following postestimation commands are available after `heckman`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
* <code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
† <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
† <code>lrtest</code>	likelihood-ratio test; not available with two-step estimator
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from <code>margins</code> (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	linear predictions and their SEs, probabilities, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
* <code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`estat ic` and `suest` are not appropriate after `heckman`, `twostep`.

†`hausman` and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, probabilities, expected values, and nonselection hazards.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

After `ML` or `twostep`

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

After `ML`

```
predict [type] stub* [if] [in], scores
```

*statistic*

Description

Main

<code>xb</code>	linear prediction; the default
<code>stdp</code>	standard error of the prediction
<code>stdf</code>	standard error of the forecast
<code>xbse1</code>	linear prediction for selection equation
<code>stdpse1</code>	standard error of the linear prediction for selection equation
<code>pr(<i>a</i>,<i>b</i>)</code>	$\Pr(y_j \mid a < y_j < b)$
<code>e(<i>a</i>,<i>b</i>)</code>	$E(y_j \mid a < y_j < b)$
<code>y<sup>*</sup>star(<i>a</i>,<i>b</i>)</code>	$E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$
<code>ycond</code>	$E(y_j \mid y_j \text{ observed})$
<code>yexpected</code>	$E(y_j^*), y_j$ taken to be 0 where unobserved
<code>nshazard</code> or <code>mills</code>	nonselection hazard (also called the inverse of Mills's ratio)
<code>psel</code>	$\Pr(y_j \text{ observed})$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where *a* and *b* may be numbers or variables; *a* missing ( $a \geq .$ ) means  $-\infty$ , and *b* missing ( $b \geq .$ ) means  $+\infty$ ; see [U] 12.2.1 Missing values.

## Options for predict

Main

`xb`, the default, calculates the linear prediction  $\mathbf{x}_j \mathbf{b}$ .

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] [regress postestimation](#).

`xbse1` calculates the linear prediction for the selection equation.

`stdpse1` calculates the standard error of the linear prediction for the selection equation.

`pr(a,b)` calculates  $\Pr(a < \mathbf{x}_j \mathbf{b} + u_1 < b)$ , the probability that  $y_j | \mathbf{x}_j$  would be observed in the interval  $(a, b)$ .

$a$  and  $b$  may be specified as numbers or variable names;  $lb$  and  $ub$  are variable names;

`pr(20,30)` calculates  $\Pr(20 < \mathbf{x}_j \mathbf{b} + u_1 < 30)$ ; `pr(lb,ub)` calculates  $\Pr(lb < \mathbf{x}_j \mathbf{b} + u_1 < ub)$ ; and `pr(20,ub)` calculates  $\Pr(20 < \mathbf{x}_j \mathbf{b} + u_1 < ub)$ .

$a$  missing ( $a \geq .$ ) means  $-\infty$ ; `pr(.,30)` calculates  $\Pr(-\infty < \mathbf{x}_j \mathbf{b} + u_j < 30)$ ;

`pr(lb,30)` calculates  $\Pr(-\infty < \mathbf{x}_j \mathbf{b} + u_j < 30)$  in observations for which  $lb \geq .$  and calculates  $\Pr(lb < \mathbf{x}_j \mathbf{b} + u_j < 30)$  elsewhere.

$b$  missing ( $b \geq .$ ) means  $+\infty$ ; `pr(20,.)` calculates  $\Pr(+\infty > \mathbf{x}_j \mathbf{b} + u_j > 20)$ ;

`pr(20,ub)` calculates  $\Pr(+\infty > \mathbf{x}_j \mathbf{b} + u_j > 20)$  in observations for which  $ub \geq .$  and calculates  $\Pr(20 < \mathbf{x}_j \mathbf{b} + u_j < ub)$  elsewhere.

`e(a,b)` calculates  $E(\mathbf{x}_j \mathbf{b} + u_1 \mid a < \mathbf{x}_j \mathbf{b} + u_1 < b)$ , the expected value of  $y_j | \mathbf{x}_j$  conditional on  $y_j | \mathbf{x}_j$  being in the interval  $(a, b)$ , meaning that  $y_j | \mathbf{x}_j$  is truncated.

$a$  and  $b$  are specified as they are for `pr()`.

`ystar(a,b)` calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j \mathbf{b} + u_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j \mathbf{b} + u_j \geq b$ , and  $y_j^* = \mathbf{x}_j \mathbf{b} + u_j$  otherwise, meaning that  $y_j^*$  is censored.  $a$  and  $b$  are specified as they are for `pr()`.

`ycond` calculates the expected value of the dependent variable conditional on the dependent variable being observed, that is, selected;  $E(y_j \mid y_j \text{ observed})$ .

`yexpected` calculates the expected value of the dependent variable ( $y_j^*$ ), where that value is taken to be 0 when it is expected to be unobserved;  $y_j^* = \Pr(y_j \text{ observed}) E(y_j \mid y_j \text{ observed})$ .

The assumption of 0 is valid for many cases where nonselection implies nonparticipation (for example, unobserved wage levels, insurance claims from those who are uninsured) but may be inappropriate for some problems (for example, unobserved disease incidence).

`nshazard` and `mills` are synonyms; both calculate the nonselection hazard—what Heckman (1979) referred to as the inverse of the Mills ratio—from the selection equation.

`pse1` calculates the probability of selection (or being observed):

$$\Pr(y_j \text{ observed}) = \Pr(\mathbf{z}_j \boldsymbol{\gamma} + u_{2j} > 0).$$

scores, not available with `twostep`, calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j \boldsymbol{\gamma})$ .

The third new variable will contain  $\partial \ln L / \partial (\operatorname{atanh} \rho)$ .

The fourth new variable will contain  $\partial \ln L / \partial (\ln \sigma)$ .

`nooffset` is relevant when you specify `offset( varname )` for `heckman`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j$ .

## margins

### Description for margins

`margins` estimates margins of response for linear predictions, probabilities, expected values, and nonselection hazards.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [ marginlist ] [ , options ]
```

```
margins [ marginlist ] , predict(statistic ...) [ predict(statistic ...) ... ] [ options ]
```

<i>statistic</i>	Description
<code>xb</code>	linear prediction; the default
<code>xbse1</code>	linear prediction for selection equation
<code>pr(<i>a,b</i>)</code>	$\Pr(y_j \mid a < y_j < b)$
<code>e(<i>a,b</i>)</code>	$E(y_j \mid a < y_j < b)$
<code>y<sup>star</sup>(<i>a,b</i>)</code>	$E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$
* <code>ycond</code>	$E(y_j \mid y_j \text{ observed})$
* <code>yexpected</code>	$E(y_j^*), y_j$ taken to be 0 where unobserved
<code>nshazard</code> or <code>mills</code>	nonselection hazard (also called the inverse of Mills's ratio)
<code>pse1</code>	$\Pr(y_j \text{ observed})$
<code>stdp</code>	not allowed with <code>margins</code>
<code>stdf</code>	not allowed with <code>margins</code>
<code>stdpsel</code>	not allowed with <code>margins</code>

\*`ycond` and `yexpected` are not allowed with `margins` after `heckman`, `twostep`.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## Remarks and examples

### ▷ Example 1

The default statistic produced by `predict` after `heckman` is the expected value of the dependent variable from the underlying distribution of the regression model. In the `wage` model of [R] [heckman](#), this is the expected wage rate among all women, regardless of whether they were observed to participate in the labor force:

```
. use https://www.stata-press.com/data/r18/womenwk
. heckman wage educ age, select(married children educ age) vce(cluster county)
  (output omitted)
. predict heckwage
  (option xb assumed; fitted values)
```

It is instructive to compare these predicted wage values from the Heckman model with an ordinary regression model—a model without the selection adjustment:

```
. regress wage educ age
```

Source	SS	df	MS	Number of obs	=	1,343
Model	13524.0337	2	6762.01687	F(2, 1340)	=	227.49
Residual	39830.8609	1,340	29.7245231	Prob > F	=	0.0000
Total	53354.8946	1,342	39.7577456	R-squared	=	0.2535
				Adj R-squared	=	0.2524
				Root MSE	=	5.452

wage	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
education	.8965829	.0498061	18.00	0.000	.7988765	.9942893
age	.1465739	.0187135	7.83	0.000	.109863	.1832848
_cons	6.084875	.8896182	6.84	0.000	4.339679	7.830071

```
. predict regwage
  (option xb assumed; fitted values)
```

```
. summarize heckwage regwage
```

Variable	Obs	Mean	Std. dev.	Min	Max
heckwage	2,000	21.15532	3.83965	14.6479	32.85949
regwage	2,000	23.12291	3.241911	17.98218	32.66439

Because this dataset was concocted, we know the true coefficients of the wage regression equation to be 1, 0.2, and 1, respectively. We can compute the true mean wage for our sample.

```
. generate truewage = 1 + .2*age + 1*educ
. summarize truewage
```

Variable	Obs	Mean	Std. dev.	Min	Max
truewage	2,000	21.3256	3.797904	15	32.8

Whereas the mean of the predictions from `heckman` is within 18 cents of the true mean wage, ordinary regression yields predictions that are on average about \$1.80 per hour too high because of the selection effect. The regression predictions also show somewhat less variation than the true wages.

The coefficients from `heckman` are so close to the true values that they are not worth testing. Conversely, the regression equation is significantly off but seems to give the right sense. Would we be led far astray if we relied on the OLS coefficients? The effect of age is off by more than 5 cents per year of age, and the coefficient on education level is off by about 10%. We can test the OLS coefficient on education level against the true value by using `test`.

```
. test educ = 1
( 1) education = 1
      F( 1, 1340) = 4.31
      Prob > F = 0.0380
```

The OLS coefficient on education is substantially lower than the true parameter; moreover, the difference from the true parameter is also statistically significant beyond the 5% level. We can perform a similar test for the OLS age coefficient:

```
. test age = .2
( 1) age = .2
      F( 1, 1340) = 8.15
      Prob > F = 0.0044
```

We find even stronger evidence that the OLS regression results are biased away from the true parameters.

◀

## ▶ Example 2

Several other interesting aspects of the Heckman model can be explored with `predict`. Continuing with our wage model, we can obtain the expected wages for women conditional on participating in the labor force with the `ycond` option. Let's get these predictions and compare them with actual wages for women participating in the labor force.

```
. use https://www.stata-press.com/data/r18/womenwk, clear
. heckman wage educ age, select(married children educ age)
  (output omitted)
. predict hcndwage, ycond
. summarize wage hcndwage if wage != .
```

Variable	Obs	Mean	Std. dev.	Min	Max
wage	1,343	23.69217	6.305374	5.88497	45.80979
hcndwage	1,343	23.68239	3.335087	16.18337	33.7567

We see that the average predictions from `heckman` are close to the observed levels but do not have the same mean. These conditional wage predictions are available for all observations in the dataset but can be directly compared only with observed wages, where individuals are participating in the labor force.

What if we were interested in making predictions about mean wages for all women? Here the expected wage is 0 for those who are not expected to participate in the labor force, with expected participation determined by the selection equation. These values can be obtained with the `yexpected` option of `predict`. For comparison, a variable can be generated where the wage is set to 0 for nonparticipants.

```
. predict hexpwage, yexpected
. generate wage0 = wage
  (657 missing values generated)
. replace wage0 = 0 if wage == .
  (657 real changes made)
```

```
. summarize hexpwage wage0
```

Variable	Obs	Mean	Std. dev.	Min	Max
hexpwage	2,000	15.92511	5.979336	2.492469	32.45858
wage0	2,000	15.90929	12.27081	0	45.80979

Again we note that the predictions from `heckman` are close to the observed mean hourly wage rate for all women. Why aren't the predictions using `ycond` and `yexpected` equal to their observed sample equivalents? For the Heckman model, unlike linear regression, the sample moments implied by the optimal solution to the model likelihood do not require that these predictions match observed data. Properly accounting for the additional variation from the selection equation requires that the model use more information than just the sample moments of the observed wages.

## Description

`heckoprobit` fits maximum-likelihood ordered probit models with sample selection.

## Quick start

Ordered probit model of `y` on `x` with selection indicated by binary variable `selected` and predicted by `v`

```
heckoprobit y x, select(selected = v x)
```

Add [indicator variables](#) for each level of categorical variable `a`

```
heckoprobit y x i.a, select(selected = v x i.a)
```

Account for complex sampling design using [svyset](#) data

```
svy: heckoprobit y x, select(selected = v x)
```

## Menu

Statistics > Sample-selection models > Ordered probit model with selection

## Syntax

```
heckoprobit depvar indepvars [if] [in] [weight],
      select( [depvars =] varlists [, noconstant offset(varnameo) ] ) [options]
```

<i>options</i>	Description
<b>Model</b>	
* <u>select</u> ()	specify selection equation: dependent and independent variables; whether to have constant term and offset variable
<u>offset</u> ( <i>varname</i> )	include <i>varname</i> in model with coefficient constrained to 1
<u>constraints</u> ( <i>constraints</i> )	apply specified linear constraints
<b>SE/Robust</b>	
<u>vce</u> ( <i>vcetype</i> )	<i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>opg</u> , <u>bootstrap</u> , or <u>jackknife</u>
<b>Reporting</b>	
<u>level</u> (#)	set confidence level; default is <u>level</u> (95)
<u>first</u>	report first-step probit estimates
<u>noheader</u>	do not display header above parameter table
<u>nofootnote</u>	do not display footnotes below parameter table
<u>nocnsreport</u>	do not display constraints
<u>display_options</u>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>Maximization</b>	
<u>maximize_options</u>	control the maximization process; seldom used
<u>collinear</u>	keep collinear variables
<u>coeflegend</u>	display legend instead of statistics

\*select() is required.

The full specification is select( [*depvar<sub>s</sub>* =] *varlist<sub>s</sub>* [, noconstant offset(*varname<sub>o</sub>*) ] ).

*indepvars* and *varlist<sub>s</sub>* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*depvar*, *indepvars*, *depvar<sub>s</sub>*, and *varlist<sub>s</sub>* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

bayes, bootstrap, by, collect, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: heckoprobit**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

vce() , first , and weights are not allowed with the svy prefix; see [SVY] **svy**.

pweights , fweights , and iweights are allowed; see [U] 11.1.6 **weight**.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

Model

select( [*depvar<sub>s</sub>* =] *varlist<sub>s</sub>* [, noconstant offset(*varname<sub>o</sub>*) ] ) specifies the variables and options for the selection equation. It is an integral part of specifying a selection model and is

required. The selection equation should contain at least one variable that is not in the outcome equation.

If *depvar<sub>s</sub>* is specified, it should be coded as 0 or 1, 0 indicating an observation not selected and 1 indicating a selected observation. If *depvar<sub>s</sub>* is not specified, observations for which *depvar* is not missing are assumed selected, and those for which *depvar* is missing are assumed not selected.

*noconstant* suppresses the selection constant term (intercept).

*offset(varname<sub>o</sub>)* specifies that selection offset *varname<sub>o</sub>* be included in the model with the coefficient constrained to be 1.

*offset(varname)*, *constraints(constraints)*; see [R] [Estimation options](#).

#### SE/Robust

*vce(vcetype)* specifies the type of standard error reported, which includes types that are derived from asymptotic theory (*oim*, *opg*), that are robust to some kinds of misspecification (*robust*), that allow for intragroup correlation (*cluster clustvar*), and that use bootstrap or jackknife methods (*bootstrap*, *jackknife*); see [R] [vce\\_option](#).

#### Reporting

*level(#)*; see [R] [Estimation options](#).

*first* specifies that the first-step probit estimates of the selection equation be displayed before estimation.

*noheader* suppresses the header above the parameter table.

*nofootnote* suppresses the footnotes displayed below the parameter table.

*nocnsreport*; see [R] [Estimation options](#).

*display\_options*: *nocl*, *nopvalues*, *noomitted*, *vsquish*, *noemptycells*, *baselevels*, *allbaselevels*, *nofvlabel*, *fvwrap(#)*, *fvwrapon(style)*, *cformat(%fmt)*, *pformat(%fmt)*, *sformat(%fmt)*, and *nolstretch*; see [R] [Estimation options](#).

#### Maximization

*maximize\_options*: *difficult*, *technique(algorithm\_spec)*, *iterate(#)*, *[no]log*, *trace*, *gradient*, *showstep*, *hessian*, *showtolerance*, *tolerance(#)*, *ltolerance(#)*, *nrtolerance(#)*, *nonrtolerance*, and *from(init\_specs)*; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to *technique(bhhh)* resets the default *vcetype* to *vce(opg)*.

The following options are available with *heckoprobit* but are not shown in the dialog box:

*collinear*, *coeflegend*; see [R] [Estimation options](#).

## Remarks and examples

*heckoprobit* estimates the parameters of a regression model for an ordered categorical outcome from a nonrandom sample known as a selected sample. Selected samples suffer from “selection on unobservables” because the errors that determine whether a case is missing are correlated with the errors that determine the outcome.

For ordered categorical regression from samples that do not suffer from selection on unobservables, see [R] **oprobit** or [R] **ologit**. For regression of a continuous outcome variable from a selected sample, see [R] **heckman**.

Even though we are interested in modeling a single ordinal outcome, there are two dependent variables in the ordered probit sample-selection model because we must also model the sample-selection process. First, there is the ordinal outcome  $y_j$ . Second, there is a binary variable that indicates whether each case in the sample is observed or unobserved. To handle the sample-selection problem, we model both dependent variables jointly. Both variables are categorical. Their categorical values are determined by the values of linear combinations of covariates and normally distributed error terms relative to certain cutpoints that partition the real line. The error terms used in the determination of selection and the ordinal outcome value may be correlated.

The probability that the ordinal outcome  $y_j$  is equal to the value  $v_h$  is given by the probability that  $\mathbf{x}_j\boldsymbol{\beta} + u_{1j}$  falls within the cutpoints  $\kappa_{h-1}$  and  $\kappa_h$ ,

$$\Pr(y_j = v_h) = \Pr(\kappa_{h-1} < \mathbf{x}_j\boldsymbol{\beta} + u_{1j} \leq \kappa_h)$$

where  $\mathbf{x}_j$  is the outcome covariates,  $\boldsymbol{\beta}$  is the coefficients, and  $u_{1j}$  is a random-error term. The observed outcome values  $v_1, \dots, v_H$  are integers such that  $v_i < v_m$  for  $i < m$ .  $\kappa_0$  is taken as  $-\infty$  and  $\kappa_H$  is taken as  $+\infty$ .

We model the selection process for the outcome by

$$s_j = \mathbf{1}(z_j\boldsymbol{\gamma} + u_{2j} > 0)$$

where  $s_j = 1$  if we observed  $y_j$  and 0 otherwise,  $z_j$  is the covariates used to model the selection process,  $\boldsymbol{\gamma}$  is the coefficients for the selection process,  $\mathbf{1}(\cdot)$  denotes the indicator function, and  $u_{2j}$  is a random-error term.

$(u_{1j}, u_{2j})$  have bivariate normal distribution with mean zero and variance matrix

$$\begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix}$$

When  $\rho \neq 0$ , standard ordered probit techniques applied to the outcome equation yield inconsistent results. **heckoprobit** provides consistent, asymptotically efficient estimates for all the parameters in such models.

De Luca and Perotti (2011) describe the maximum likelihood estimator used in **heckoprobit**.

## ► Example 1

We have a simulated dataset containing a sample of 5,000 women, 3,480 of whom work. The outcome of interest is a woman's job satisfaction, and we suspect that unobservables that determine job satisfaction and the unobservables that increase the likelihood of employment are correlated. Women may make a decision to work based on how satisfying their job would be. We estimate the parameters of an ordered probit sample-selection model for the outcome of job satisfaction (**satisfaction**) with selection on employment (**work**). Age (**age**) and years of education (**education**) are used as outcome covariates, and we also expect that they affect selection. Additional covariates for selection are marital status (**married**) and the number of children at home (**children**).

Here we estimate the parameters of the model with **heckoprobit**. We use the factorial interaction of **married** and **children** in **select()**. This specifies that the number of children and marital status affect selection, and it allows the effect of the number of children to differ among married and nonmarried women. The factorial interaction is specified using factor-variable notation, which is described in [U] 11.4.3 **Factor variables**.

```
. use https://www.stata-press.com/data/r18/womensat
(Job satisfaction, female)
. heckoprobit satisfaction education age,
> select(work=education age i.married##c.children)

rho	.6310096	.0470026			.5299093	.7144252

LR test of indep. eqns. (rho = 0): chi2(1) = 88.10      Prob > chi2 = 0.0000

The output shows several iteration logs. The first iteration log corresponds to running the ordered probit model for those observations in the sample where we have observed the outcome. The second iteration log corresponds to running the selection probit model, which models whether we observe

our outcome of interest. If  $\rho = 0$ , the sum of the log likelihoods from these two models will equal the log likelihood of the ordered probit sample-selection model; this sum is printed in the iteration log as the comparison log likelihood. The final iteration log is for fitting the full ordered probit sample-selection model.

The Wald test in the header is highly significant, indicating a good model fit. All the covariates are statistically significant. The likelihood-ratio test in the footer indicates that we can reject the null hypothesis that the errors for outcome and selection are uncorrelated. This means that we should use the ordered probit sample-selection model instead of the simple ordered probit model.

The positive estimate of 0.63 for  $\rho$  indicates that unobservables that increase job satisfaction tend to occur with unobservables that increase the chance of having a job.

◀

## Stored results

`heckprobit` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(N_selected)</code>	number of selected observations
<code>e(N_nonselected)</code>	number of nonselected observations
<code>e(N_cd)</code>	number of completely determined observations
<code>e(k_cat)</code>	number of categories
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(ll_c)</code>	log likelihood, comparison model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(chi2_c)</code>	$\chi^2$ for comparison test
<code>e(p)</code>	$p$ -value for model test
<code>e(p_c)</code>	$p$ -value for comparison test
<code>e(rho)</code>	$\rho$
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

## Macros

<code>e(cmd)</code>	<code>heckprobit</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	names of dependent variables
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset1)</code>	offset for regression equation
<code>e(offset2)</code>	offset for selection equation
<code>e(chi2type)</code>	Wald or LR; type of model $\chi^2$ test
<code>e(chi2_ct)</code>	type of comparison $\chi^2$ test
<code>e(vce)</code>	<i>vctype</i> specified in <code>vce()</code>
<code>e(vctype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(marginsnotok)</code>	predictions disallowed by <code>margins</code>
<code>e(marginsdefault)</code>	default <code>predict()</code> specification for <code>margins</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

## Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(cat)</code>	category values
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

## Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

## Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals
-----------------------	--

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

De Luca and Perotti (2011) provide an introduction to this model.

The ordinal outcome equation is

$$y_j = \sum_{h=1}^H v_h 1(\kappa_{h-1} < \mathbf{x}_j \boldsymbol{\beta} + u_{1j} \leq \kappa_h)$$

where  $\mathbf{x}_j$  is the outcome covariates,  $\boldsymbol{\beta}$  is the coefficients, and  $u_{1j}$  is a random-error term. The observed outcome values  $v_1, \dots, v_H$  are integers such that  $v_i < v_m$  for  $i < m$ .  $\kappa_1, \dots, \kappa_{H-1}$  are real numbers such that  $\kappa_i < \kappa_m$  for  $i < m$ .  $\kappa_0$  is taken as  $-\infty$  and  $\kappa_H$  is taken as  $+\infty$ .

The selection equation is

$$s_j = \mathbf{1}(z_j\gamma + u_{2j} > 0)$$

where  $s_j = 1$  if we observed  $y_j$  and 0 otherwise,  $z_j$  is the covariates used to model the selection process,  $\gamma$  is the coefficients for the selection process, and  $u_{2j}$  is a random-error term.

$(u_{1j}, u_{2j})$  have bivariate normal distribution with mean zero and variance matrix

$$\begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix}$$

Let  $a_j = z_j\gamma + \text{offset}_j^\gamma$  and  $b_j = x_j\beta + \text{offset}_j^\beta$ . This yields the log likelihood

$$\ln L = \sum_{j \notin S} w_j \ln \{\Phi(-a_j)\} + \sum_{h=1}^H \sum_{\substack{j \in S \\ y_j = v_h}} w_j \ln \{\Phi_2(a_j, \kappa_h - b_j, -\rho) - \Phi_2(a_j, \kappa_{h-1} - b_j, -\rho)\}$$

where  $S$  is the set of observations for which  $y_j$  is observed,  $\Phi_2(\cdot)$  is the cumulative bivariate normal distribution function (with mean  $[0 \ 0]'$ ),  $\Phi(\cdot)$  is the standard cumulative normal, and  $w_j$  is an optional weight for observation  $j$ .

In the maximum likelihood estimation,  $\rho$  is not directly estimated. Directly estimated is  $\text{atanh } \rho$ :

$$\text{atanh } \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)$$

From the form of the likelihood, it is clear that if  $\rho = 0$ , the log likelihood for the ordered probit sample-selection model is equal to the sum of the ordered probit model for the outcome  $y$  and the selection model. We can perform a likelihood-ratio test by comparing the log likelihood of the full model with the sum of the log likelihoods for the ordered probit and selection models.

## Postestimation commands

The following postestimation commands are available after `heckoprobit`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	probabilities, linear predictions and their SEs, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`hausman` and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

## Menu for predict

## Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
    outcome(outcome) nooffset ]
```

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

Main	
<code>pmargin</code>	marginal probabilities; the default
<code>p1</code>	bivariate probabilities of levels with selection
<code>p0</code>	bivariate probabilities of levels with no selection
<code>pcond1</code>	probabilities of levels conditional on selection
<code>pcond0</code>	probabilities of levels conditional on no selection
<code>pselect</code>	selection probability
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the linear prediction
<code>xbselect</code>	linear prediction for selection equation
<code>stdpselect</code>	standard error of the linear prediction for selection equation

If you do not specify `outcome()`, `pmargin` (with one new variable specified) assumes `outcome(#1)`.

You specify one or  $k$  new variables with `pmargin`, where  $k$  is the number of outcomes.

You specify one new variable with `pselect`, `xb`, `stdp`, `xbselect`, and `stdpselect`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pmargin`, the default, calculates the predicted marginal probabilities.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the marginal probability that  $y_j$  is equal to the level `outcome()` is calculated. When `outcome()` is not specified, the marginal probabilities for each outcome level are calculated.

`p1` calculates the predicted bivariate probabilities of outcome levels with selection.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the bivariate probability that  $y_j$  is equal to the level `outcome()` and that  $y_j$  is observed is calculated. When `outcome()` is not specified, the bivariate probabilities for each outcome level and selection are calculated.

`p0` calculates the predicted bivariate probabilities of outcome levels with no selection.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the bivariate probability that  $y_j$  is equal to the level `outcome()` and that  $y_j$  is not observed is calculated. When `outcome()` is not specified, the bivariate probabilities for each outcome level and no selection are calculated.

`pcond1` calculates the predicted probabilities of outcome levels conditional on selection.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the probability that  $y_j$  is equal to the level `outcome()` given that  $y_j$  is observed is calculated. When `outcome()` is not specified, the probabilities for each outcome level conditional on selection are calculated.

`pcond0` calculates the predicted probabilities of outcome levels conditional on no selection.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the probability that  $y_j$  is equal to the level `outcome()` given that  $y_j$  is not observed is calculated. When `outcome()` is not specified, the probabilities for each outcome level conditional on no selection are calculated.

`pse1` calculates the predicted univariate (marginal) probability of selection.

`xb` calculates the linear prediction for the outcome variable, which is  $\mathbf{x}_j\boldsymbol{\beta}$  if `offset()` was not specified and  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta$  if `offset()` was specified.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`xbse1` calculates the linear prediction for the selection equation, which is  $\mathbf{z}_j\boldsymbol{\gamma}$  if `offset()` was not specified in `select()` and  $\mathbf{z}_j\boldsymbol{\gamma} + \text{offset}_j^\gamma$  if `offset()` was specified in `select()`.

`stdpse1` calculates the standard error of the linear prediction for the selection equation.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc.

`nooffset` is relevant only if you specified `offset(varname)` for `heckoprobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\mathbf{b}$  rather than as  $\mathbf{x}_j\mathbf{b} + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\boldsymbol{\gamma})$ .

When the dependent variable takes  $k$  different values, new variables three through  $k + 1$  will contain  $\partial \ln L / \partial (\kappa_{j-2})$ .

The last new variable will contain  $\partial \ln L / \partial (\text{atanh } \rho)$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
default	marginal probabilities for each outcome
<u>p</u> margin	marginal probabilities
<u>p</u> 1	bivariate probabilities of levels with selection
<u>p</u> 0	bivariate probabilities of levels with no selection
<u>p</u> cond1	probabilities of levels conditional on selection
<u>p</u> cond0	probabilities of levels conditional on no selection
<u>p</u> sel	selection probability
<u>x</u> b	linear prediction
<u>x</u> bsel	linear prediction for selection equation
stdp	not allowed with <code>margins</code>
stdpsel	not allowed with <code>margins</code>

`pmargin`, `p1`, `p0`, `pcond1`, and `pcond0` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $\mathbf{e}(\mathbf{b})$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

### ► Example 1

In [example 1](#) of [\[R\] heckoprobit](#), we examined a simulated dataset of 5,000 women, 3,480 of whom work and can thus report job satisfaction. Using job satisfaction (`satisfaction`) as the outcome variable and employment (`work`) as the selection variable, we estimated the parameters of an ordered probit sample-selection model. Covariates `age` (`age`), years of education (`education`), number of children (`children`), and marital status (`married`) are expected to affect selection. The outcome, job satisfaction, is affected by `age` and `education`.

We first reestimate the parameters of the regression, but this time we request a robust variance estimator:

```
. use https://www.stata-press.com/data/r18/womensat
(Job satisfaction, female)
. heckoprobit satisfaction education age,
> select(work=education age i.married##c.children) vce(robust)
(output omitted)
```

We then use `margins` (see [\[R\] margins](#)) to estimate the average marginal effect of education on the probability of having low job satisfaction.

```
. margins, dydx(education) vce(unconditional)
Average marginal effects          Number of obs = 5,000
dy/dx wrt: education
1._predict: Pr(satisfaction=1), predict(pmarginal outcome(1))
2._predict: Pr(satisfaction=2), predict(pmarginal outcome(2))
3._predict: Pr(satisfaction=3), predict(pmarginal outcome(3))
4._predict: Pr(satisfaction=4), predict(pmarginal outcome(4))
```

	Unconditional				
	dy/dx	std. err.	z	P> z	[95% conf. interval]

The estimated average marginal effect of education on the probability of having low job satisfaction is approximately  $-0.023$ .

◀

## Methods and formulas

The ordinal outcome equation is

$$y_j = \sum_{h=1}^H v_h 1(\kappa_{h-1} < \mathbf{x}_j \boldsymbol{\beta} + u_{1j} \leq \kappa_h)$$

where  $\mathbf{x}_j$  is the outcome covariates,  $\beta$  is the coefficients, and  $u_{1j}$  is a random-error term. The observed outcome values  $v_1, \dots, v_H$  are integers such that  $v_i < v_m$  for  $i < m$ .  $\kappa_1, \dots, \kappa_{H-1}$  are real numbers such that  $\kappa_i < \kappa_m$  for  $i < m$ .  $\kappa_0$  is taken as  $-\infty$  and  $\kappa_H$  is taken as  $+\infty$ .

The selection equation is

$$s_j = 1(\mathbf{z}_j\gamma + u_{2j} > 0)$$

where  $s_j = 1$  if we observed  $y_j$  and 0 otherwise,  $\mathbf{z}_j$  is the covariates used to model the selection process,  $\gamma$  is the coefficients for the selection process, and  $u_{2j}$  is a random-error term.

$(u_{1j}, u_{2j})$  have bivariate normal distribution with mean zero and variance matrix

$$\begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix}$$

The probability of selection is

$$\Pr(s_j = 1) = \Phi(\mathbf{z}_j\gamma + \text{offset}_j^\gamma)$$

$\Phi(\cdot)$  is the standard cumulative normal distribution function.

The probability of selection and the outcome  $y_j = v_h$  is

$$\begin{aligned} \Pr(y_j = v_h, s_j = 1) &= \Phi_2\left(\mathbf{z}_j\gamma + \text{offset}_j^\gamma, \kappa_h - x_j\beta - \text{offset}_j^\beta, -\rho\right) \\ &\quad - \Phi_2\left(\mathbf{z}_j\gamma + \text{offset}_j^\gamma, \kappa_{h-1} - \mathbf{x}_j\beta - \text{offset}_j^\beta, -\rho\right) \end{aligned}$$

$\Phi_2(\cdot)$  is the cumulative bivariate normal distribution function (with mean  $[0 \ 0]'$ ).

The probability of  $y_j$  not being selected and the outcome  $y_j = v_h$  is

$$\begin{aligned} \Pr(y_j = v_h, s_j = 0) &= \Phi_2\left(-\mathbf{z}_j\gamma - \text{offset}_j^\gamma, \kappa_h - x_j\beta - \text{offset}_j^\beta, \rho\right) \\ &\quad - \Phi_2\left(-\mathbf{z}_j\gamma - \text{offset}_j^\gamma, \kappa_{h-1} - \mathbf{x}_j\beta - \text{offset}_j^\beta, \rho\right) \end{aligned}$$

The probability of outcome  $y_j = v_h$  given selection is

$$\Pr(y_j = v_h | s_j = 1) = \frac{\Pr(y_j = v_h, s_j = 1)}{\Pr(s_j = 1)}$$

The probability of outcome  $y_j = v_h$  given  $y_j$  is not selected is

$$\Pr(y_j = v_h | s_j = 0) = \frac{\Pr(y_j = v_h, s_j = 0)}{\Pr(s_j = 0)}$$

The marginal probabilities of the outcome  $y_j$  are

$$\begin{aligned} \Pr(y_j = v_1) &= \Phi(\kappa_1 - x_j\beta - \text{offset}_j^\beta) \\ \Pr(y_j = v_H) &= 1 - \Phi(\kappa_{H-1} - x_j\beta - \text{offset}_j^\beta) \\ \Pr(y_j = v_h) &= \Phi(\kappa_h - x_j\beta - \text{offset}_j^\beta) - \Phi(\kappa_{h-1} - x_j\beta - \text{offset}_j^\beta) \end{aligned}$$

## Description

`heckpoisson` fits a Poisson regression model with endogenous sample selection. This is sometimes called nonignorability of selection, missing not at random, or selection bias. Unlike the standard Poisson model, there is no assumption of equidispersion.

## Quick start

Poisson model of `y` on `x1` with `z1` predicting selection when binary variable `selected` indicates selection status

```
heckpoisson y x1, select(selected = z1)
```

Add categorical variable `a` using [factor-variables](#) syntax

```
heckpoisson y x1 i.a, select(selected = z1 i.a)
```

Report results as incidence-rate ratios

```
heckpoisson y x1 i.a, select(selected = z1 i.a) irr
```

Add robust standard errors

```
heckpoisson y x1 i.a, select(selected = z1 i.a) vce(robust)
```

Include exposure variable `expose` to account for different exposure levels

```
heckpoisson y x1 i.a, select(selected = z1 i.a) exposure(expose)
```

## Menu

Statistics > Sample-selection models > Poisson model with sample selection

## Syntax

```
heckpoisson depvar indepvars [if] [in] [weight],
      select( [depvars =] indepvarss [, noconstant offset(varnameos) ] ) [options]
```

<i>options</i>	Description
<b>Model</b>	
* <u>select</u> ()	specify selection equation: dependent and independent variables; whether to have constant term and offset variable
<u>noconstant</u>	suppress constant term
<u>exposure</u> ( <i>varname<sub>e</sub></i> )	include $\ln(\text{varname}_e)$ in model with coefficient constrained to 1
<u>offset</u> ( <i>varname<sub>o</sub></i> )	include <i>varname<sub>o</sub></i> in model with coefficient constrained to 1
<u>constraints</u> ( <i>constraints</i> )	apply specified linear constraints
<b>SE/Robust</b>	
<u>vce</u> ( <i>vcetype</i> )	<i>vcetype</i> may be oim, <u>robust</u> , <u>cluster</u> <i>clustvar</i> , opg, <u>bootstrap</u> , or <u>jackknife</u>
<b>Reporting</b>	
<u>level</u> (#)	set confidence level; default is level(95)
<u>irr</u>	report incidence-rate ratios
<u>nocnsreport</u>	do not display constraints
<u>display_options</u>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>Integration</b>	
<u>intpoints</u> (#)	set the number of integration (quadrature) points; default is intpoints(25)
<b>Maximization</b>	
<u>maximize_options</u>	control the maximization process; seldom used
<u>collinear</u>	keep collinear variables
<u>coeflegend</u>	display legend instead of statistics

\*select() is required.

The full specification is select( [*depvar<sub>s</sub>* =] *indepvars<sub>s</sub>* [, noconstant offset(*varname<sub>os</sub>*) ] ).

*indepvars* and *indepvars<sub>s</sub>* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*indepvars* and *indepvars<sub>s</sub>* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

bootstrap, by, collect, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 **Prefix commands**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

vce() and weights are not allowed with the svy prefix; see [SVY] **svy**.

fweights, iwweights, and pweights are allowed; see [U] 11.1.6 **weight**.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`select([depcvars = ] indepvarss [ , noconstant offset(varnameos) ])` specifies the variables and options for the selection equation. It is an integral part of specifying a sample-selection model and is required.

If *depcvar*<sub>s</sub> is specified, it should be coded as 0 or 1, with 0 indicating an observation not selected and 1 indicating a selected observation. If *depcvar*<sub>s</sub> is not specified, then observations for which *depcvar* is not missing are assumed selected and those for which *depcvar* is missing are assumed not selected.

`noconstant` suppresses the selection constant term (intercept).

`offset`(*varname*<sub>os</sub>) specifies that selection offset *varname*<sub>os</sub> be included in the model with the coefficient constrained to be 1.

`noconstant`, `exposure`(*varname*<sub>e</sub>), `offset`(*varname*<sub>o</sub>), `constraints`(*constraints*); see [R] [Estimation options](#).

### SE/Robust

`vce`(*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster` *clustvar*), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level`(#); see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap`(#), `fvwrapon`(*style*), `cformat`(%*fmt*), `pformat`(%*fmt*), `sformat`(%*fmt*), and `nolstretch`; see [R] [Estimation options](#).

### Integration

`intpoints`(#) specifies the number of integration points to use for quadrature. The default is `intpoints`(25), which means that 25 quadrature points are used. The maximum number of allowed integration points is 128.

The more integration points, the more accurate the approximation to the log likelihood. However, computation time increases with the number of quadrature points and is roughly proportional to the number of points used.

### Maximization

*maximize\_options*: `difficult`, `technique`(*algorithm\_spec*), `iterate`(#), `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance`(#), `ltolerance`(#), `nrtolerance`(#), `nonrntolerance`, and `from`(*init\_specs*); see [R] [Maximize](#). These options are seldom used.

The following options are available with `heckpoisson` but are not shown in the dialog box: `collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

When analyzing observational data, we must consider the possibility that we cannot treat the observations for which we have data as if they were selected at random. Suppose we are interested in the number of after-school tutoring sessions a child attends. If unobservable variables that affect which students attend the sessions, for example, family stability, also affect the number of visits we observe, then a condition known as endogenous sample selection is present. This phenomenon is sometimes simply referred to as sample selection or called missing not at random, nonignorability of selection, or selection bias. When endogenous sample selection occurs, conventional estimation techniques are not appropriate. [Cameron and Trivedi \(2022, 974–981\)](#) and [Greene \(2018, 950–957\)](#) provide good introductions to the concept of endogenous sample selection.

The venerable Heckman estimator handles endogenous sample selection when the outcome of interest is modeled by linear regression; see [R] [heckman](#). However, the Heckman estimator is not appropriate for count outcomes because its linear model for the outcome could produce negative predicted values and does not restrict the predicted values to integers.

There are different methods for estimating the parameters of a count-data model with endogenous sample selection. `heckpoisson` implements the maximum likelihood estimator derived in [Terza \(1998\)](#); see also [Cameron and Trivedi \(2013, chap. 10\)](#) for a discussion of this estimator.

The model consists of one equation for the count outcome,  $y$ , and one equation for a binary selection indicator,  $s$ . The indicator  $s$  is always observed and takes values of 0 or 1. But the outcome  $y$  is observed only if  $s = 1$ , that is, we have complete information about the covariates of interest and selection status. However, the value of the primary outcome of interest,  $y$ , is sometimes unknown.

More formally, the count outcome  $y$  is assumed to have a Poisson distribution, conditional on the covariates, with conditional mean

$$E(y_j | \mathbf{x}_j, \epsilon_{1j}) = \exp(\mathbf{x}_j \boldsymbol{\beta} + \epsilon_{1j}) \quad \text{Poisson regression equation}$$

However, we only observe  $y$  for observation  $j$  if  $s_j = 1$ :

$$s_j = \begin{cases} 1, & \text{if } \mathbf{w}_j \boldsymbol{\gamma} + \epsilon_{2j} > 0 \\ 0, & \text{otherwise} \end{cases} \quad \text{selection equation}$$

where

$$\epsilon_1 \sim N(0, \sigma)$$

$$\epsilon_2 \sim N(0, 1)$$

$$\text{corr}(\epsilon_1, \epsilon_2) = \rho$$

When  $\rho \neq 0$ , standard Poisson regression based on the observed  $y$  yields biased estimates. `heckpoisson` provides consistent, asymptotically efficient estimates for the parameters in such models.

Unlike the standard Poisson regression, the Poisson model with sample selection allows underdispersion and overdispersion.

### ▷ Example 1: Poisson model with sample selection

Suppose we want to know the effect of research and development (R&D) expenditures on the number of patents obtained by a firm in the last two years. The `patent` dataset contains fictional data on the number of patents (`npatents`) of 10,000 firms in different sectors. After reading in the data, we tabulate the frequencies of `npatents` against an indicator for whether a firm applied for patents (`applied`).

```
. use https://www.stata-press.com/data/r18/patent
(Fictional data on patents and R&D)
. tabulate npatents applied, missing
```

Number of patents (last 2 yrs)	Applied for patent		Total
	Not apply	Apply	
0	0	1,127	1,127
1	0	1,455	1,455
2	0	1,131	1,131
3	0	710	710
4	0	479	479
5	0	266	266
6	0	126	126
7	0	98	98
8	0	66	66
9	0	42	42
10	0	19	19
11	0	24	24
12	0	5	5
13	0	7	7
14	0	5	5
15	0	10	10
17	0	1	1
18	0	1	1
19	0	2	2
22	0	1	1
.	4,425	0	4,425
Total	4,425	5,575	10,000

The output shows that `npatents` is missing for about half of the sample because some firms did not apply for any patents. Some firms prefer to keep their discoveries as trade secrets instead of applying for patents. The sample selection will be endogenous if the unobservable variables that affect which firms apply for patents also affect the number of patents obtained. Therefore, we do not want to use a standard Poisson model for these data.

We model `npatents` as a function of R&D expenditures (`expenditure`) and a categorical variable indicating whether the firm is in the information technology (IT) sector (`tech`). We model the selection indicator `applied` as a function of `expenditure`, `tech`, and firm size (`size`), which is excluded from the outcome model.

```

. heckpoisson npatents expenditure i.tech,

Wald test of indep. eqns. (rho = 0): chi2(1) = 16.64 Prob > chi2 = 0.0000

The coefficient estimates reported by `heckpoisson` can be interpreted similarly to those reported by `poisson`. For example, the positive coefficient on `expenditure` tells us that increasing R&D expenditures is associated with an increasing number of patents. However, the magnitude of the effect cannot be directly determined by the coefficients. The best way to obtain interpretable effects is by using `margins`. See [example 1](#) in [\[R\] heckpoisson postestimation](#) for more information.

The estimated correlation between the selection errors and outcome errors is 0.8, and the Wald test in the footer indicates that we can reject the null hypothesis of zero correlation. This positive and significant correlation estimate implies that unobservable factors that increase the number of patents a firm is awarded tend to occur with unobservable factors that also increase the chance of a firm being willing to apply for patents.

□ Technical note

In practice, we rely on the strength of the relationship between size and applied and the fact that size does not appear in the model for `npatents` to pin down the parameter estimates. Technically, we do not need this exclusion restriction, but identification from the functional form alone tends to be weak. For a discussion of this point, see [Cameron and Trivedi \(2022, 977–981\)](#). □

▷ Example 2: Obtaining incidence-rate ratios

In some cases, we may wish to view the parameters as incidence-rate ratios (IRRs). That is, we want to hold all the  $x$ 's in the model constant except one, say, the  $i$ th. The IRR for a one-unit change in  $x_i$  is

$$\frac{e^{\ln(E)+\beta_1x_1+\dots+\beta_i(x_i+1)+\dots+\beta_kx_k+e_1}}{e^{\ln(E)+\beta_1x_1+\dots+\beta_ix_i+\dots+\beta_kx_k+e_1}} = e^{\beta_i}$$

For instance, we may want to know the relative incidence rate of patents as the expenditure changes or the relative incidence rate of patents as sectors change from non-IT to IT.

We can use option `irr` to display the coefficient estimates transformed to IRRs. This option may be specified when we originally fit our model or on replay. Because we have already fit the model, we specify `irr` below using the replay syntax.

```
. heckpoisson, irr
Poisson regression with endogenous selection      Number of obs   =   10,000
(25 quadrature points)                          Selected        =    5,575
                                                Nonselected     =    4,425
                                                Wald chi2(2)    =    443.90
Log likelihood = -17440.44                       Prob > chi2     =    0.0000
```

Matrices	
e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance
Functions	
e(sample)	marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices	
r(table)	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

`heckpoisson` implements [Terza's](#) maximum likelihood estimator for the parameters of a count-data model with endogenous sample selection ([Terza 1998](#)).

Suppose that the count outcome  $y_j$  has covariates  $\mathbf{x}_j$  and that  $y_j$  has a Poisson distribution, conditional on  $\mathbf{x}_j$ , with conditional mean

$$E(y_j | \mathbf{x}_j, \epsilon_{1j}) = \mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \epsilon_{1j})$$

and

$$\Pr(Y = y_j | \mathbf{x}_j, \epsilon_{1j}) = \frac{\mu_j^{y_j} e^{-\mu_j}}{y_j!}$$

We only observe  $y_j$  when  $s_j$ , the selection outcome, which is the binary outcome from a latent-variable model with covariates  $\mathbf{w}_j$ , is equal to 1.

$$s_j = \begin{cases} 1, & \text{if } \mathbf{w}_j \boldsymbol{\gamma} + \epsilon_{2j} > 0 \\ 0, & \text{otherwise} \end{cases}$$

The error terms  $\epsilon_1$  and  $\epsilon_2$  are assumed to have bivariate normal distribution with zero mean and covariance matrix

$$\begin{bmatrix} \sigma^2 & \sigma\rho \\ \sigma\rho & 1 \end{bmatrix}$$

where  $\sigma$  and  $\rho$  have their usual interpretation for the bivariate normal distribution. A nonzero  $\rho$  implies that the selected sample is not representative of the whole population and therefore that inference based on standard Poisson regression using the observed sample is incorrect.

In maximum likelihood estimation,  $\ln \sigma$  and  $\operatorname{atanh} \rho$  are estimated rather than directly estimating  $\sigma$  and  $\rho$ .

$$\operatorname{atanh} \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)$$

The joint log likelihood is given by

$$\ln L(\boldsymbol{\theta}) = \sum_{i=1}^N [s_j \times \ln\{\Pr(y_j, s_j = 1) | \mathbf{x}_j, \mathbf{w}_j, \boldsymbol{\theta}\} + (1 - s_j) \times \ln\{\Pr(s_j = 0 | \mathbf{w}_j, \boldsymbol{\theta})\}]$$

where  $\boldsymbol{\theta}$  denotes  $(\boldsymbol{\beta}, \boldsymbol{\gamma}, \rho, \sigma)$  for notational simplicity.

The joint probability  $\Pr(y_j, s_j = 1 | \mathbf{x}_j, \mathbf{w}_j, \boldsymbol{\theta})$  can be obtained by integrating the conditional probability  $\Pr(y_j, s_j = 1 | \mathbf{x}_j, \mathbf{w}_j, \boldsymbol{\theta}, \epsilon_1)$  over  $\epsilon_1$ . More precisely,

$$\Pr(y_j, s_j = 1 | \mathbf{x}_j, \mathbf{w}_j, \boldsymbol{\theta}) = \int_{-\infty}^{\infty} \Pr(y_j | \mathbf{x}_j, \epsilon_1) \Phi \left( \frac{\mathbf{w}_j \boldsymbol{\gamma} + \rho / \sigma \epsilon_1}{\sqrt{1 - \rho^2}} \right) \phi(\epsilon_1 / \sigma) d\epsilon_1 \quad (1)$$

where  $\phi(\cdot)$  is the standard normal density function and  $\Phi(\cdot)$  is the standard normal cumulative density function.  $\Pr(s_j = 0 | \mathbf{w}_j, \boldsymbol{\theta})$  is similarly derived.

$$\Pr(s_j = 0 | \mathbf{w}_j, \boldsymbol{\theta}) = \int_{-\infty}^{\infty} \Phi \left( -\frac{\mathbf{w}_j \boldsymbol{\gamma} + \rho / \sigma \epsilon_1}{\sqrt{1 - \rho^2}} \right) \phi(\epsilon_1 / \sigma) d\epsilon_1 \quad (2)$$

The integrations in (1) and (2) have no closed form and must be approximated using Gauss–Hermite quadrature.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`heckpoisson` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

Remarks and examples

## Postestimation commands

The following postestimation commands are available after `heckpoisson`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	number of events, incidence rates, probabilities, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates new variables containing predictions such as number of events, incidence rates, conditional predicted number of events, probabilities, linear predictions, and equation-level scores.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>n</code>	number of events; the default
<code>ir</code>	incidence rate
<code>ncond</code>	predicted number of events conditional on $y_j$ being observed
<code>pr(<math>n</math>)</code>	$\Pr(y_j = n)$
<code>pr(<math>a, b</math>)</code>	$\Pr(a \leq y_j \leq b)$
<code>pselect</code>	$\Pr(y_j \text{ observed})$
<code>xb</code>	linear prediction
<code>xbselect</code>	linear prediction for selection equation

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`n`, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta + \sigma^2/2)$  if neither `offset()` nor `exposure()` was specified when the model was fit; is  $\exp(\mathbf{x}_j\beta + \sigma^2/2 + \text{offset}_j)$  if `offset()` was specified; or is  $\exp(\mathbf{x}_j\beta + \sigma^2/2) \times \text{exposure}_i$  if `exposure()` was specified.

`ir` calculates the incidence rate  $\exp(\mathbf{x}_j\beta + \sigma^2/2)$ , which is the predicted number of events when exposure is 1. Specifying `ir` is equivalent to specifying `n` when neither `offset()` nor `exposure()` was specified when the model was fit.

`ncond` calculates the predicted number of events conditional on  $y_j$  being observed, which is  $\exp(\mathbf{x}_j\beta + \sigma^2/2)\Phi(\mathbf{w}_j\gamma + \rho\sigma)/\Phi(\mathbf{w}_j\gamma)$ .

`pr( $n$ )` calculates the probability  $\Pr(y_j = n)$ , where  $n$  is a nonnegative integer that may be specified as a number or a variable.

`pr(a,b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where  $a$  and  $b$  are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20,.)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20,b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates

$\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(.,b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a,b)`.

`pselect` calculates the probability of selection (or being observed):

$$\Pr(y_j \text{ observed}) = \Pr(\mathbf{w}_j\gamma + \epsilon_{2j} > 0)$$

`xb` calculates the linear prediction for the dependent count variable, which is  $\mathbf{x}_j\beta$  if neither `offset()` nor `exposure()` was specified;  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  if `offset()` was specified; or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$  if `exposure()` was specified.

`xbselect` calculates the linear prediction for the selection equation, which is  $\mathbf{w}_j\gamma$  if `offset()` was not specified in `select()` and is  $\mathbf{w}_j\gamma + \text{offset}_j^\gamma$  if `offset()` was specified in `select()`.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j$  or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{w}_j\gamma)$ .

The third new variable will contain  $\partial \ln L / \partial \text{atanh } \rho$ .

The fourth new variable will contain  $\partial \ln L / \partial \ln \sigma$ .

# margins

## Description for margins

`margins` estimates margins of response for number of events, incidence rates, conditional predicted number of events, probabilities, and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>n</code>	number of events; the default
<code>ir</code>	incidence rate
<code>ncond</code>	predicted number of events conditional on $y_j$ being observed
<code>pr(<math>n</math>)</code>	$\Pr(y_j = n)$
<code>pr(<math>a, b</math>)</code>	$\Pr(a \leq y_j \leq b)$
<code>p<u>sel</u></code>	$\Pr(y_j \text{ observed})$
<code>x<u>b</u></code>	linear prediction
<code>x<u>b</u>sel</code>	linear prediction for selection equation

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## Remarks and examples

### ▷ Example 1: Obtaining margins for a count model with selection

In [example 1](#) of [R] [heckpoisson](#), we fit a model for the number of patents. In that example, we are interested in the effect of R&D expenditures on the number of patents received by a firm. We continue that example to determine the magnitude of the effect of R&D expenditures on the number of patents and compare this effect for IT and non-IT sectors.

After reading in the data and fitting the model, we use `margins` to estimate the effect of an increase of a million dollars in R&D expenditures (`expenditure`) on the number of patents (`npatents`) for firms in the IT and non-IT sectors (`tech`).

To do this, we use the `at()` option of `margins`. We use the observed values in our first scenario, so we tell `margins` to set `expenditure` equal to itself. For our second scenario, we tell `margins` to set `expenditure` equal to the observed value plus 1 because expenditures are measured in millions of dollars. We include the `post` option so that we can perform additional calculations later.

```

. use https://www.stata-press.com/data/r18/patent
(Fictional data on patents and R&D)
. quietly heckpoisson npatents expenditure i.tech,
> select(applied = expenditure size i.tech)
. margins i.tech, at(expenditure = generate(expenditure))
> at(expenditure = generate(expenditure+1)) post
Predictive margins                                Number of obs = 10,000
Model VCE: OIM
Expression: Predicted number of events, predict()
1._at: expenditure = expenditure
2._at: expenditure = expenditure+1

```

	Delta-method			z	P> z	[95% conf. interval]
	Margin	std. err.				
<hr/>						
_at#tech						
1 #						
Non-IT se..	1.276213	.0556644	22.93	0.000	1.167112	1.385313
1#IT sector	2.287013	.080119	28.55	0.000	2.129983	2.444044
2 #						
Non-IT se..	2.099539	.131364	15.98	0.000	1.84207	2.357007
2#IT sector	3.76244	.2226221	16.90	0.000	3.326109	4.198771

The output indicates that the expected number of patents for non-IT firms is about 1.28 compared with 2.29 for firms in the IT sector.

The second scenario shows the expected number of patents after our hypothetical increase in R&D expenditures. In the non-IT sector, the expected number of patents received would be about 2.10 compared with 3.76 in the IT sector. It appears that increasing expenditures may have a larger effect for IT firms—the difference between the two scenarios is 1.47 for IT firms and only 0.82 for non-IT firms. We can test whether the effect of increasing expenditures is different for IT and non-IT firms. We use `lincom` to obtain an estimate of the difference in the differences between scenarios for the two sectors and a test of its significance. We ask for the differences by referring to the scenarios as 1.\_at and 2.\_at and by referring to the sector using the value that corresponds to the IT sector indicator, 1.tech for IT firms and 0.tech otherwise.

```

. lincom (_b[2._at#1.tech] - _b[1._at#1.tech]) -
> (_b[2._at#0.tech] - _b[1._at#0.tech])
( 1) 1bn._at#0bn.tech - 1bn._at#1.tech - 2._at#0bn.tech + 2._at#1.tech = 0

```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]
(1)	.6521006	.0917299	7.11	0.000	.4723134 .8318878

We find that the expected effect of increasing R&D expenditures by one million dollars is 0.65 patents larger for IT firms than for non-IT firms, and this difference is significantly different from 0. ◀

## Methods and formulas

Suppose that the count outcome  $y_j$  has covariates  $\mathbf{x}_j$  and the selection outcome  $s_j$  has covariates  $\mathbf{w}_j$ .  $y_j$  is assumed to have a Poisson distribution, conditional on  $\mathbf{x}_j$ , with conditional mean

$$E(y_j | \mathbf{x}_j, \epsilon_{1j}) = \mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \epsilon_{1j})$$

$s_j$  is a binary outcome from a latent-variable model:

$$s_j = \begin{cases} 1, & \text{if } \mathbf{w}_j\gamma + \epsilon_{2j} > 0 \\ 0, & \text{otherwise} \end{cases}$$

The expectation of  $y_j$  conditional on covariates  $\mathbf{x}_j$  for the whole population is

$$E(y_j|\mathbf{x}_j) = \exp(\mathbf{x}_j\boldsymbol{\beta} + \sigma^2/2)$$

Furthermore, if we want the expectation of  $y_j$  only if it was observed, then the formula is

$$E(y_j|\mathbf{x}_j, \mathbf{w}_j, s_j = 1) = \exp(\mathbf{x}_j\boldsymbol{\beta} + \sigma^2/2) \frac{\Phi(\mathbf{w}_j\gamma + \rho\sigma)}{\Phi(\mathbf{w}_j\gamma)}$$

We note that if  $\rho = 0$ , this expectation is the same as its population version.

We can also predict the probability of  $y_j$  conditional on  $\mathbf{x}_j$ . Note that although  $y_j$  is Poisson-distributed conditional on  $\epsilon_1$  and  $\mathbf{x}_j$ , the distribution of  $y_j$  is unknown unconditional on  $\epsilon_1$ .

$$\Pr(y_j = n|\mathbf{x}_j) = \int_{-\infty}^{\infty} \Pr(y_j = n|\mathbf{x}_j, \epsilon_1) \phi(\epsilon_1/\sigma) d\epsilon_1$$

As in the implementation of log likelihood, we approximate this integral by Gauss–Hermite quadrature.

## Description

`heckprobit` fits maximum-likelihood probit models with sample selection.

## Quick start

Probit model of  $y$  on  $x$  with sample selection indicated by binary variable `selected` and predicted by  $v$

```
heckprobit y x, select(selected = v x)
```

Suppress iteration log

```
heckprobit y x, select(selected = v x) nolog
```

With cluster-robust standard errors for clustering by levels of `cvar`

```
heckprobit y x, select(selected = v x) vce(cluster cvar)
```

## Menu

Statistics > Sample-selection models > Probit model with sample selection

## Syntax

```
heckprobit depvar indepvars [if] [in] [weight],
      select( [depvars =] varlists [, noconstant offset(varnameo) ] ) [options]
```

<i>options</i>	Description
Model	
* <u>select</u> ()	specify selection equation: dependent and independent variables; whether to have constant term and offset variable
<u>noconstant</u>	suppress constant term
<u>offset</u> ( <i>varname</i> )	include <i>varname</i> in model with coefficient constrained to 1
<u>constraints</u> ( <i>constraints</i> )	apply specified linear constraints
SE/Robust	
<u>vce</u> ( <i>vcetype</i> )	<i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>opg</u> , <u>bootstrap</u> , or <u>jackknife</u>
Reporting	
<u>level</u> (#)	set confidence level; default is <u>level</u> (95)
<u>first</u>	report first-step probit estimates
<u>lrmodel</u>	perform the likelihood-ratio model test instead of the default Wald test
<u>nocnsreport</u>	do not display constraints
<u>display_options</u>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<u>maximize_options</u>	control the maximization process; seldom used
<u>collinear</u>	keep collinear variables
<u>coeflegend</u>	display legend instead of statistics

\*select() is required.

The full specification is select( [*depvar<sub>s</sub>* =] *varlist<sub>s</sub>* [, noconstant offset(*varname<sub>o</sub>*) ] ).

*indepvars* and *varlist<sub>s</sub>* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*depvar*, *indepvars*, *depvar<sub>s</sub>*, and *varlist<sub>s</sub>* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

bayes, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: heckprobit**.

Weights are not allowed with the bootstrap prefix; see [R] **bootstrap**.

vce(), first, lrmodel, and weights are not allowed with the svy prefix; see [SVY] **svy**.

pweights, fweights, and iweights are allowed; see [U] 11.1.6 **weight**.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

Model

select( [*depvar<sub>s</sub>* =] *varlist<sub>s</sub>* [, noconstant offset(*varname<sub>o</sub>*) ] ) specifies the variables and options for the selection equation. It is an integral part of specifying a selection model and is

required. The selection equation should contain at least one variable that is not in the outcome equation.

If `depvars` is specified, it should be coded as 0 or 1, 0 indicating an observation not selected and 1 indicating a selected observation. If `depvars` is not specified, observations for which `depvar` is not missing are assumed selected, and those for which `depvar` is missing are assumed not selected.

`noconstant` suppresses the selection constant term (intercept).

`offset(varnameo)` specifies that selection offset `varnameo` be included in the model with the coefficient constrained to be 1.

`noconstant`, `offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

---

#### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

---

#### Reporting

`level(#)`; see [R] [Estimation options](#).

`first` specifies that the first-step probit estimates of the selection equation be displayed before estimation.

`lrmmodel`, `nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

---

#### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `heckprobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

The probit model with sample selection (Van de Ven and Van Pragg 1981) assumes that there exists an underlying relationship

$$y_j^* = \mathbf{x}_j\boldsymbol{\beta} + u_{1j} \quad \textit{latent equation}$$

such that we observe only the binary outcome

$$y_j^{\text{probit}} = (y_j^* > 0) \quad \textit{probit equation}$$

The dependent variable, however, is not always observed. Rather, the dependent variable for observation  $j$  is observed if

$$y_j^{\text{select}} = (\mathbf{z}_j\boldsymbol{\gamma} + u_{2j} > 0) \quad \textit{selection equation}$$

where

$$u_1 \sim N(0, 1)$$

$$u_2 \sim N(0, 1)$$

$$\text{corr}(u_1, u_2) = \rho$$

When  $\rho \neq 0$ , standard probit techniques applied to the first equation yield biased results. `heckprobit` provides consistent, asymptotically efficient estimates for all the parameters in such models.

For the model to be well identified, the selection equation should have at least one variable that is not in the probit equation. Otherwise, the model is identified only by functional form, and the coefficients have no structural interpretation.

### ► Example 1

We use the data from Pindyck and Rubinfeld (1998). In this dataset, the variables are whether children attend private school (`private`), number of years the family has been at the present residence (`years`), log of property tax (`logptax`), log of income (`loginc`), and whether one voted for an increase in property taxes (`vote`).

In this example, we alter the meaning of the data. Here we assume that we observe whether children attend private school only if the family votes for increasing the property taxes. This assumption is not true in the dataset, and we make it only to illustrate the use of this command.

We observe whether children attend private school only if the head of household voted for an increase in property taxes. We assume that the vote is affected by the number of years in residence, the current property taxes paid, and the household income. We wish to model whether children are sent to private school on the basis of the number of years spent in the current residence and the current property taxes paid.

```

LR test of indep. eqns. (rho = 0): chi2(1) = 0.27          Prob > chi2 = 0.6020

```

The output shows several iteration logs. The first iteration log corresponds to running the probit model for those observations in the sample where we have observed the outcome. The second iteration log corresponds to running the selection probit model, which models whether we observe our outcome of interest. If  $\rho = 0$ , the sum of the log likelihoods from these two models will equal the log likelihood of the probit model with sample selection; this sum is printed in the iteration log as the comparison log likelihood. The third iteration log shows starting values for the iterations.

The final iteration log is for fitting the full probit model with sample selection. A likelihood-ratio test of the log likelihood for this model and the comparison log likelihood is presented at the end of the output. If we had specified the `vce(robust)` option, this test would be presented as a Wald test instead of as a likelihood-ratio test.

◀

## ▷ Example 2

In [example 1](#), we could have obtained robust standard errors by specifying the `vce(robust)` option. We do this here and also eliminate the iteration logs by using the `nolog` option:

```
. heckprobit private years logptax, sel(vote=years loginc logptax) vce(robust)
> nolog
```

```
Probit model with sample selection          Number of obs   =       95
                                           Selected       =       59
                                           Nonselected    =       36
                                           Wald chi2(2)   =        2.55
                                           Prob > chi2    =       0.2798

Log pseudolikelihood = -74.24497
```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
<b>private</b>						
years	-.1142596	.1113968	-1.03	0.305	-.3325934	.1040741
logptax	.3516101	.7358211	0.48	0.633	-1.090573	1.793793
_cons	-2.780667	4.786652	-0.58	0.561	-12.16233	6.600998
<b>vote</b>						
years	-.0167511	.0173344	-0.97	0.334	-.0507259	.0172237
loginc	.9923023	.4228042	2.35	0.019	.1636213	1.820983
logptax	-1.278783	.5095156	-2.51	0.012	-2.277415	-.2801506
_cons	-.5458205	4.54389	-0.12	0.904	-9.451682	8.360041
/athrho	-.8663164	1.63062	-0.53	0.595	-4.062272	2.329639
rho	-.6994978	.8327621			-.9994078	.9812312

```
Wald test of indep. eqns. (rho = 0): chi2(1) = 0.28      Prob > chi2 = 0.5952
```

Regardless of whether we specify the `vce(robust)` option, the outcome is not significantly different from the outcome obtained by fitting the probit and selection models separately. This result is not surprising because the selection mechanism estimated was invented for the example rather than borne from any economic theory.

◀

## Stored results

heckprobit stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(N_selected)</code>	number of selected observations
<code>e(N_nonselected)</code>	number of nonselected observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(ll_c)</code>	log likelihood, comparison model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(chi2_c)</code>	$\chi^2$ for comparison test
<code>e(p)</code>	$p$ -value for model test
<code>e(p_c)</code>	$p$ -value for comparison test
<code>e(rho)</code>	$\rho$
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(rank0)</code>	rank of <code>e(V)</code> for constant-only model
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>heckprobit</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	names of dependent variables
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset1)</code>	offset for regression equation
<code>e(offset2)</code>	offset for selection equation
<code>e(chi2type)</code>	Wald or LR; type of model $\chi^2$ test
<code>e(chi2_ct)</code>	type of comparison $\chi^2$ test
<code>e(vce)</code>	<i>vce</i> type specified in <code>vce()</code>
<code>e(vctype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance-covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices	
<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Van de Ven and Van Pragg (1981) provide an introduction and an explanation of this model.

The probit equation is

$$y_j = (\mathbf{x}_j\boldsymbol{\beta} + u_{1j} > 0)$$

The selection equation is

$$\mathbf{z}_j\boldsymbol{\gamma} + u_{2j} > 0$$

where

$$u_1 \sim N(0, 1)$$

$$u_2 \sim N(0, 1)$$

$$\text{corr}(u_1, u_2) = \rho$$

The log likelihood is

$$\begin{aligned} \ln L = & \sum_{\substack{j \in S \\ y_j \neq 0}} w_j \ln \left\{ \Phi_2 \left( x_j\boldsymbol{\beta} + \text{offset}_j^\beta, z_j\boldsymbol{\gamma} + \text{offset}_j^\gamma, \rho \right) \right\} \\ & + \sum_{\substack{j \in S \\ y_j = 0}} w_j \ln \left\{ \Phi_2 \left( -x_j\boldsymbol{\beta} + \text{offset}_j^\beta, z_j\boldsymbol{\gamma} + \text{offset}_j^\gamma, -\rho \right) \right\} \\ & + \sum_{j \notin S} w_j \ln \left\{ 1 - \Phi \left( z_j\boldsymbol{\gamma} + \text{offset}_j^\gamma \right) \right\} \end{aligned}$$

where  $S$  is the set of observations for which  $y_j$  is observed,  $\Phi_2(\cdot)$  is the cumulative bivariate normal distribution function (with mean  $[0 \ 0]'$ ),  $\Phi(\cdot)$  is the standard cumulative normal, and  $w_j$  is an optional weight for observation  $j$ .

In the maximum likelihood estimation,  $\rho$  is not directly estimated. Directly estimated is  $\text{atanh } \rho$ :

$$\text{atanh } \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)$$

From the form of the likelihood, it is clear that if  $\rho = 0$ , the log likelihood for the probit model with sample selection is equal to the sum of the probit model for the outcome  $y$  and the selection model. We can perform a likelihood-ratio test by comparing the likelihood of the full model with the sum of the log likelihoods for the probit and selection models.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

heckprobit also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `heckprobit`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICC, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	probabilities, linear predictions and their SEs, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`hausman` and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
Main	
<code>pmargin</code>	$\Phi(\mathbf{x}_j \mathbf{b})$ , success probability; the default
<code>p11</code>	$\Phi_2(\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, \rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)$
<code>p10</code>	$\Phi_2(\mathbf{x}_j \mathbf{b}, -\mathbf{z}_j \mathbf{g}, -\rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 0)$
<code>p01</code>	$\Phi_2(-\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, -\rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 1)$
<code>p00</code>	$\Phi_2(-\mathbf{x}_j \mathbf{b}, -\mathbf{z}_j \mathbf{g}, \rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 0)$
<code>pselect</code>	$\Phi(\mathbf{z}_j \mathbf{g})$ , selection probability
<code>pcond</code>	$\Phi_2(\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, \rho) / \Phi(\mathbf{z}_j \mathbf{g})$ , probability of success conditional on selection
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the linear prediction
<code>xbselect</code>	linear prediction for selection equation
<code>stdpselect</code>	standard error of the linear prediction for selection equation

$\Phi(\cdot)$  is the standard normal distribution function, and  $\Phi_2(\cdot)$  is the bivariate normal distribution function.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

Main

`pmargin`, the default, calculates the univariate (marginal) predicted probability of success  $\Pr(y_j^{\text{probit}} = 1)$ .

`p11` calculates the bivariate predicted probability  $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)$ .

`p10` calculates the bivariate predicted probability  $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 0)$ .

`p01` calculates the bivariate predicted probability  $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 1)$ .

`p00` calculates the bivariate predicted probability  $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 0)$ .

`pse1` calculates the univariate (marginal) predicted probability of selection  $\Pr(y_j^{\text{select}} = 1)$ .

`pcond` calculates the conditional (on selection) predicted probability of success

$$\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1) / \Pr(y_j^{\text{select}} = 1).$$

`xb` calculates the probit linear prediction  $\mathbf{x}_j\mathbf{b}$ .

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`xbse1` calculates the linear prediction for the selection equation.

`stdpse1` calculates the standard error of the linear prediction for the selection equation.

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\boldsymbol{\gamma})$ .

The third new variable will contain  $\partial \ln L / \partial (\text{atanh } \rho)$ .

`nooffset` is relevant only if you specified `offset(varname)` for `heckprobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\mathbf{b}$  rather than as  $\mathbf{x}_j\mathbf{b} + \text{offset}_j$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>pmargin</code>	$\Phi(\mathbf{x}_j \mathbf{b})$ , success probability; the default
<code>p11</code>	$\Phi_2(\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, \rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)$
<code>p10</code>	$\Phi_2(\mathbf{x}_j \mathbf{b}, -\mathbf{z}_j \mathbf{g}, -\rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 0)$
<code>p01</code>	$\Phi_2(-\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, -\rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 1)$
<code>p00</code>	$\Phi_2(-\mathbf{x}_j \mathbf{b}, -\mathbf{z}_j \mathbf{g}, \rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 0)$
<code>pselect</code>	$\Phi(\mathbf{z}_j \mathbf{g})$ , selection probability
<code>pcond</code>	$\Phi_2(\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, \rho) / \Phi(\mathbf{z}_j \mathbf{g})$ , probability of success conditional on selection
<code>xb</code>	linear prediction
<code>xbselect</code>	linear prediction for selection equation
<code>stdp</code>	not allowed with <code>margins</code>
<code>stdpselect</code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than  $\mathbf{e}(\mathbf{b})$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

### ▷ Example 1

It is instructive to compare the marginal predicted probabilities with the predicted probabilities that we would obtain by ignoring the selection mechanism. To compare the two approaches, we will synthesize data so that we know the “true” predicted probabilities.

First, we need to generate correlated error terms, which we can do using a standard Cholesky decomposition approach. For our example, we will clear any data from memory and then generate errors that have a correlation of 0.5 by using the following commands. We set the seed so that interested readers can type in these same commands and obtain the same results.

```
. set seed 12309
. set obs 5000
Number of observations (_N) was 0, now 5,000.
. generate c1 = rnormal()
. generate c2 = rnormal()
. matrix P = (1, .5 \ .5, 1)
. matrix A = cholesky(P)
. local fac1 = A[2,1]
. local fac2 = A[2,2]
. generate u1 = c1
. generate u2 = 'fac1'*c1 + 'fac2'*c2
```

We can check that the errors have the correct correlation by using the `correlate` command. We will also normalize the errors so that they have a standard deviation of one, so we can generate a bivariate probit model with known coefficients. We do that with the following commands:

```
. correlate u1 u2
(obs=5,000)
```

	u1	u2
u1	1.0000	
u2	0.5012	1.0000

```
. summarize u1
(output omitted)
. replace u1 = u1/r(sd)
(5,000 real changes made)
. summarize u2
(output omitted)
. replace u2 = u2/r(sd)
(5,000 real changes made)
. drop c1 c2
. generate x1 = runiform()-.5
. generate x2 = runiform()+1/3
. generate y1s = 0.5 + 4*x1 + u1
. generate y2s = 3 - 3*x2 + .5*x1 + u2
. generate y1 = (y1s>0)
. generate y2 = (y2s>0)
```

We have now created two dependent variables, `y1` and `y2`, which are defined by our specified coefficients. We also included error terms for each equation, and the error terms are correlated. We run `heckprobit` to verify that the data have been correctly generated according to the model

$$y_1 = .5 + 4x_1 + u_1$$

$$y_2 = 3 + .5x_1 - 3x_2 + u_2$$

where we assume that  $y_1$  is observed only if  $y_2 = 1$ .

```
. heckprobit y1 x1, sel(y2 = x1 x2) nolog
Probit model with sample selection          Number of obs    =      5,000
                                           Selected         =      3,182
                                           Nonselected      =      1,818
                                           Wald chi2(1)    =      947.76
                                           Prob > chi2     =      0.0000
Log likelihood = -3612.401
```

x1	.5361114	.0711951	7.53	0.000	.3965715	.6756513
x2	-3.017537	.0817541	-36.91	0.000	-3.177772	-2.857302
_cons	2.990145	.0765942	39.04	0.000	2.840024	3.140267
/athrho	.5339516	.0854577	6.25	0.000	.3664575	.7014457
rho	.4883959	.0650735			.3508892	.6052846

```
LR test of indep. eqns. (rho = 0): chi2(1) = 41.36      Prob > chi2 = 0.0000
```

Now that we have verified that we have generated data according to a known model, we can obtain and then compare predicted probabilities from the probit model with sample selection and a (usual) probit model.

```
. predict pmarg
(option pmargin assumed; Pr(y1=1))
. probit y1 x1 if y2==1
(output omitted)
. predict phat
(option pr assumed; Pr(y1))
```

Using the (marginal) predicted probabilities from the probit model with sample selection (`pmarg`) and the predicted probabilities from the (usual) probit model (`phat`), we can also generate the “true” predicted probabilities from the synthesized `y1s` variable and then compare the predicted probabilities:

```
. generate ptrue = normal(y1s)
. summarize pmarg ptrue phat
```

Variable	Obs	Mean	Std. dev.	Min	Max
pmarg	5,000	.6089004	.3249993	.0632337	.99354
ptrue	5,000	.5967872	.3534232	2.78e-07	1
phat	5,000	.6588519	.3113716	.0910951	.997021

Here we see that ignoring the selection mechanism (comparing the `phat` variable with the true `ptrue` variable) results in predicted probabilities that are much higher than the true values. Looking at the marginal predicted probabilities from the model with sample selection, however, results in more accurate predictions.

# Title

**help** — Display help in Stata

[Description](#)      [Menu](#)      [Syntax](#)      [Options](#)  
[Remarks and examples](#)      [Also see](#)

## Description

The `help` command displays help information about the specified command or topic. `help` launches a new Viewer to display help for the specified command or topic or displays help on the console in Stata for Unix(console). If `help` is not followed by a command or a topic name, Stata displays advice for using the help system and documentation.

## Menu

Help > Stata command...

## Syntax

```
help [ command_or_topic_name ] [ , new name(viewername) marker(markername) ]
```

## Options

`new` specifies that a new Viewer window not be opened for the help topic if a Viewer window is already open. The default is for a new Viewer window to be opened each time `help` is typed so that multiple help files may be viewed at once. `new` causes the help file to be displayed in the topmost open Viewer.

`name`(*viewername*) specifies that help be displayed in a Viewer window named *viewername*. If the named window already exists, its contents will be replaced. If the named window does not exist, it will be created.

`marker`(*markername*) specifies that the help file be opened to the position of *markername* within the help file.

## Remarks and examples

To obtain help for any Stata command, type `help` *command* or select **Help > Stata command...** and fill in *command*.

`help` is best explained by examples.

To obtain help for ...	type
<code>regress</code>	<code>help regress</code>
postestimation tools for <code>regress</code>	<code>help regress postestimation</code> or <code>help regress post</code>
graph option <code>xlabel()</code>	<code>help graph xlabel()</code>
Stata function <code>strpos()</code>	<code>help strpos()</code>
Mata function <code>optimize()</code>	<code>help mata optimize()</code>

Tips:

- `help` displays advice for using the help system and documentation.
- `help guide` displays a table of contents for basic Stata concepts.
- `help estimation commands` displays an alphabetical listing of all Stata estimation commands.
- `help functions` displays help on Stata functions by category.
- `help mata functions` displays a subject table of contents for Mata's functions.
- `help ts glossary` displays the glossary for the time-series manual, and similarly for the other Stata specialty manuals.

If you type `help topic` and help for *topic* is not found, Stata will automatically perform a search for *topic*.

For instance, try typing `help forecasting`. A forecasting help file is not found, so Stata executes `search forecasting` and displays the results in the Viewer.

See [U] 4 **Stata's help and search facilities** for a complete description of how to use `help`.

## □ Technical note

When you type `help topic`, Stata first looks along the `adopath` for `topic.sthlp`; see [U] 17.5 **Where does Stata look for ado-files?** □

# Title

**hetoprobit** — Heteroskedastic ordered probit regression

[Description](#)  
[Options](#)  
[References](#)

[Quick start](#)  
[Remarks and examples](#)  
[Also see](#)

[Menu](#)  
[Stored results](#)

[Syntax](#)  
[Methods and formulas](#)

## Description

`hetoprobit` fits a heteroskedastic ordered probit model for an ordinal dependent variable. `hetoprobit` is a generalization of `oprobit` that allows the variance to be modeled as a function of independent variables and to differ between subjects or groups in the population.

## Quick start

Heteroskedastic ordinal probit model of `y` on `x1`, using `x2` to model the variance

```
hetoprobit y x1, het(x2)
```

With robust standard errors

```
hetoprobit y x1, het(x2) vce(robust)
```

Perform a Wald test on the variance instead of a likelihood-ratio (LR) test

```
hetoprobit y x1, het(x2) waldhet
```

## Menu

Statistics > Ordinal outcomes > Heteroskedastic ordered probit regression

## Syntax

```
hetoprobit depvar [indepvars] [if] [in] [weight],
      het(varlist [, offset(varnameo)] [options])
```

<i>options</i>	Description
<b>Model</b>	
* <b>het</b> ( <i>varlist</i> [...])	independent variables to model the variance and optional offset variable
<u>offset</u> ( <i>varname</i> )	include <i>varname</i> in model with coefficient constrained to 1
<u>constraints</u> ( <i>constraints</i> )	apply specified linear constraints
<b>SE/Robust</b>	
<u>vce</u> ( <i>vcetype</i> )	<i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>opg</u> , <u>bootstrap</u> , or <u>jackknife</u>
<b>Reporting</b>	
<u>level</u> (#)	set confidence level; default is <u>level</u> (95)
<u>waldhet</u>	perform Wald test on variance instead of LR test
<u>nocnsreport</u>	do not display constraints
<u>display_options</u>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>Maximization</b>	
<u>maximize_options</u>	control the maximization process; seldom used
<u>noheader</u>	do not display header above coefficient table
<u>notable</u>	do not display coefficient table
<u>collinear</u>	keep collinear variables
<u>coeflegend</u>	display legend instead of statistics

\***het**() is required. The full specification is **het**(*varlist* [, offset(*varname<sub>o</sub>*)]).

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*depvar*, *indepvars*, and *varlist* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

**bayes**, **bootstrap**, **by**, **collect**, **fp**, **jackknife**, **rolling**, **statsby**, and **svy** are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: hetoprobit**.

Weights are not allowed with the **bootstrap** prefix; see [R] **bootstrap**.

**vce**() and weights are not allowed with the **svy** prefix; see [SVY] **svy**.

**fweights**, **iwweights**, and **pweights** are allowed; see [U] 11.1.6 **weight**.

**noheader**, **notable**, **collinear**, and **coeflegend** do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`het(varlist [ , offset(varnameo) ])` specifies the independent variables and, optionally, the offset variable in the variance function. `het()` is required.

`offset(varnameo)` specifies that offset `varnameo` be included in the variance model with the coefficient constrained to be 1.

`offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`; see [R] [Estimation options](#).

`waldhet` specifies that a Wald test of whether  $\ln\sigma = 0$  be performed instead of the LR test.

`nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `hetoprobit` but are not shown in the dialog box:

`noheader` suppresses the header above the coefficient table.

`notable` suppresses the display of the coefficient table.

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

`hetoprobit` fits a maximum-likelihood heteroskedastic ordered probit model, which is a generalization of the ordered probit model (see [R] [oprobit](#)).

In ordinal regression models, the outcome is an ordinal variable—a variable that is categorical and ordered, for instance, “poor”, “good”, and “excellent”. The specific values of the ordinal variable are irrelevant. It matters only that larger values are assumed to correspond to “higher” outcomes. To simplify the discussion in this entry, we assume without loss of generality that the dependent variable takes on the integer values  $0, 1, \dots, H$ , for some value  $H > 1$ .

In ordered probit models, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome  $y_j = h$ , where  $h = 0, 1, \dots, H$ , corresponds to the probability that the value of the linear function, plus random error, is within the range of the cutpoints associated with the outcome

$$\begin{aligned}\Pr(y_j = h) &= \Pr(\kappa_h < \beta_1 x_{1j} + \beta_2 x_{2j} + \dots + \beta_k x_{kj} + u_j \leq \kappa_{h+1}) \\ &= \Phi(\kappa_{h+1} - \mathbf{x}_j \boldsymbol{\beta}) - \Phi(\kappa_h - \mathbf{x}_j \boldsymbol{\beta})\end{aligned}$$

where  $\mathbf{x}_j = (x_{1j}, x_{2j}, \dots, x_{kj})$  are the  $k$  independent variables that model the mean function;  $\boldsymbol{\beta}$  is a column vector of unknown parameters in the mean function;  $u_j$ , where  $j = 1, \dots, N$ , are normally distributed error terms;  $\kappa_h$ , where  $h = 1, \dots, H$ , are the unknown cutpoints that separate the different possible values of  $h$ ; and  $\Phi(\cdot)$  is the cumulative distribution function of the standard normal distribution. Also, by convention, to complete the intervals for the lowest and highest values of the outcome,  $\kappa_0 = -\infty$  and  $\kappa_{H+1} = \infty$ .

In conventional ordinal probit models, the error term is assumed i.i.d. normal with unit variance for all observations. **hetoprobit** generalizes the ordered probit model by representing the variance of the error term  $u_j$  as a multiplicative function of explanatory variables  $\mathbf{z}_j = (z_{1j}, z_{2j}, \dots, z_{mj})$ . This approach was introduced by [Harvey \(1976\)](#), though we depart from Harvey slightly by modeling standard deviation rather than variance. More specifically, we model the natural logarithm of the standard deviation as a linear combination of the explanatory variables,

$$\ln \sigma_j = \mathbf{z}_j \boldsymbol{\gamma}$$

where  $\boldsymbol{\gamma}$  is a column vector of unknown parameters in the variance function.

With this generalization, the error variance may differ between subjects or between groups in the population, and

$$\Pr(y_j = h) = \Phi \left\{ \frac{\kappa_{h+1} - \mathbf{x}_j \boldsymbol{\beta}}{\exp(\mathbf{z}_j \boldsymbol{\gamma})} \right\} - \Phi \left\{ \frac{\kappa_h - \mathbf{x}_j \boldsymbol{\beta}}{\exp(\mathbf{z}_j \boldsymbol{\gamma})} \right\}$$

For the model to be identifiable, there can be no constant term in  $\mathbf{z}_j \boldsymbol{\gamma}$ . Also, as with [\[R\] oprobbit](#), there is no constant term in  $\mathbf{x}_j \boldsymbol{\beta}$ . The role of the constant is subsumed by the cutpoints.

We estimate the coefficients  $\beta_1, \beta_2, \dots, \beta_k$  and  $\gamma_1, \gamma_2, \dots, \gamma_m$  together with the cutpoints  $\kappa_1, \kappa_2, \dots, \kappa_H$ . If the model has no independent variables in  $\mathbf{x}_j$ , only the cutpoints and the  $\boldsymbol{\gamma}$  parameters are estimated.

Modeling of heteroskedastic variance has both constructive and defensive uses. It is known that differences in variance between subjects or between groups in the population can cause biased coefficient estimates and can complicate comparison of distinct groups. Thus, incorporating a model for variance can be necessary for proper inference, even if the variance function itself is not a topic of interest to the researcher. For discussion, see [Williams \(2010\)](#) and the references cited therein. There are also cases where modeling the differences between variances of different subjects or different groups in the population is one of the principal purposes of the study. We will discuss such a scenario in the examples below. See [Reardon et al. \(2017\)](#) and [Alvarez and Brehm \(1995\)](#) for additional examples.

## ▷ Example 1: Modeling heteroskedasticity of reported health status

In this example, we will use a slightly modified subset of data from the 2015 Eating & Health Module of the American Time Use Survey (ATUS), conducted by the U.S. Bureau of Labor Statistics. Our analysis will not account for the survey design. The ATUS measures the amount of time people spend doing various activities, such as working, caring for children, volunteering, and socializing. Of interest to us is an ordinal response variable, `health`, which contains individuals' self-assessments of their overall health status on a five-point scale: 1 for “poor”, 2 for “fair”, 3 for “good”, 4 for “very good”, and 5 for “excellent”.

We want to examine the role that age and other factors play in an individual's self-assessment of health. Age is a natural variable to include when modeling mean or typical health status. But we also suspect that the variation in health status is greater in an older population, as compared with a youthful population, which consists mainly of healthy individuals. If our suspicion is true, quantifying the relationship between variation in health status and age may have value, for example, in planning a healthcare strategy that is appropriately tailored both for the older Medicare population and for a younger cohort.

Thus, we will use `hetoprobit` to model heteroskedasticity induced by age. In modeling the variance term, in addition to age, we will include a factor variable, `exercise`, which indicates whether or not an individual exercised during the previous week. For purposes of illustration, imagine that we are not interested in exercise as a topic in its own right, but we are concerned that health variability among those who exercise may differ from the variability among those who do not. Therefore, we include `exercise` in the variance term to help insulate our estimation results against a possible hidden bias.

Our model will include three explanatory variables for the mean function: `age`, `bmi` (body mass index), and `exercise`.

```
. use https://www.stata-press.com/data/r18/eathealth15
(2015 ATUS Eating & Health Module extract)
. hetoprobit health age bmi i.exercise, het(age i.exercise)
(output omitted)
```

Fitting ordered probit model:

```
Iteration 0: Log likelihood = -2905.7943
Iteration 1: Log likelihood = -2717.2752
Iteration 2: Log likelihood = -2716.9679
Iteration 3: Log likelihood = -2716.9679
```

Fitting full model:

```
Iteration 0: Log likelihood = -2716.9679
Iteration 1: Log likelihood = -2708.6752
Iteration 2: Log likelihood = -2708.5492
Iteration 3: Log likelihood = -2708.5491
```

Heteroskedastic ordered probit regression

Number of obs = 2,009

LR chi2(3) = 366.91

Log likelihood = -2708.5491

Prob > chi2 = 0.0000

health	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
<b>health</b>						
age	-.0083348	.0015969	-5.22	0.000	-.0114646	-.005205

/cut4	-.4189882	.1524084			-.7177031	-.1202733

LR test of lnsigma=0: chi2(2) = 16.84

Prob > chi2 = 0.0002

The LR test at the bottom of the output is a test of homogeneity of the variance function. The  $\chi^2(2)$  statistic of 16.84 is significant, indicating that heteroskedasticity is present. If you prefer the Wald test for heteroskedasticity, you can specify the `waldhet` option. The coefficients for the variance function are reported in the section of the table labeled `lnsigma`. Our results indicate that `age` is a significant contributor to the variance function but that `exercise` is not significant at a 0.05 level.

The LR test for the model that appears above the coefficient table is a joint test for inclusion of `age`, `bmi`, and `exercise` in the mean function. The null model for this test is the model consisting only of cutpoints and the heteroskedastic term. Coefficients for the mean function are reported in the section of the table labeled `health`. In this example, `age`, `bmi`, and `exercise` are significant components of the linear predictor of the mean.

The signs of the coefficients in the fitted model are directly interpretable. For example, the negative value for the coefficient of `bmi` implies that higher values of `bmi` predict lower values of health status. However, because of the probit link and the fact that we estimate variance with a log transformation, the numerical relationships between the coefficients of the model and the outcome variables are nonlinear. Postestimation commands recognize and account for these nonlinearities.

### ▷ Example 2: Predict the probability of a poor health rating

Ordered probit models allow us to look at the probabilities of different outcomes of interest. Suppose we are interested in predictions of a reported health status of "poor" (`health = 1`) and how it differs across levels of `bmi`. First, we obtain the predicted probability of poor health.

```
. predict pr1, pr outcome(1)
```

We can now visualize how the predicted probability of poor health status differs across the range of `bmi` values in our sample.

```
. twoway scatter pr1 bmi, ytitle("Pr(poor health)")
> title("Effect of BMI on probability of poor health")
```

We see that predicted probabilities of poor health increase as body mass index increases.

### ▷ Example 3: Predictive margins and average marginal effect

The graph [above](#) plots the predicted probability of poor health for each individual in our dataset. We may also want to evaluate how the average predicted probability changes across levels of the covariates in the model. For instance, we can use the `margins` command to obtain the expected probability of having poor health across a range of ages.

```

. margins, at(age = (30(10)70)) predict(outcome(1))
Predictive margins                                Number of obs = 2,009
Model VCE: OIM
Expression: Pr(health==1), predict(outcome(1))
1._at: age = 30
2._at: age = 40
3._at: age = 50
4._at: age = 60
5._at: age = 70

```

	Margin	Delta-method std. err.	z	P> z	[95% conf. interval]	
_at						
1	.0225765	.0037522	6.02	0.000	.0152224	.0299306
2	.0299079	.0038887	7.69	0.000	.0222862	.0375297
3	.0388244	.0041936	9.26	0.000	.0306051	.0470438
4	.0494246	.0049748	9.93	0.000	.0396742	.0591751
5	.0617532	.0064443	9.58	0.000	.0491226	.0743839

Based on our model, what would we expect if everyone was 30 years old but had the same distributions of `bmi` and `exercise` that we observed in our data? The first line in this table reports that the average predicted probability of poor health is 0.0226 in this case. The second line shows the average predicted probability of poor health if we set `age = 40`, and so on. We find that for `age = 70`, the average probability of reporting a poor health status has increased to 0.0618. We can visualize this by typing `marginsplot` after `margins`.

```

. marginsplot
Variables that uniquely identify margins: age

```

We have focused on the prediction of poor health. We could instead simultaneously obtain average predicted probabilities of poor, fair, good, very good, and excellent health status and plot them across our requested age range. In that case, we would type

```

. margins, at(age = (30(10)70))
. marginsplot

```

We might also be interested in characterizing the relationship between `bmi` and the probability of reporting poor health. The coefficients and cutpoints reported in `hetoprobit` are not easily interpreted. We can, however, use `margins` to estimate the average marginal effect of `bmi` on the probability of

reporting poor health. Because the average marginal effect depends on the value of `bmi`, we estimate it across a range of `bmi` values by typing

```
. margins, dydx(bmi) at(bmi = (20(5)35)) predict(outcome(1))
Average marginal effects                               Number of obs = 2,009
Model VCE: OIM
Expression: Pr(health==1), predict(outcome(1))
dy/dx wrt: bmi
1._at: bmi = 20
2._at: bmi = 25
3._at: bmi = 30
4._at: bmi = 35
```

		Delta-method		z	P> z	[95% conf. interval]	
		dy/dx	std. err.				
bmi							
	_at						
	1	.0015875	.0001721	9.23	0.000	.0012503	.0019248
	2	.0024512	.0002665	9.20	0.000	.0019288	.0029736
	3	.0036447	.0004377	8.33	0.000	.0027868	.0045027
	4	.0052124	.0007013	7.43	0.000	.0038379	.006587

The average marginal effect of `bmi` on the probability of reporting poor health increases as `bmi` itself increases.

► Example 4: Interpreting the variance function

From the output of our `hetoprobit` command, we determined that variance of health status is affected by age. Let's consider to what extent. In this example, we assess the effect of age on the variance by using the `margins` command. We use the `predict(sigma)` option to obtain the average predicted standard deviation of the errors. We will look at ages 15 and 85, which are the youngest and oldest ages, respectively, in our dataset.

```
. margins, predict(sigma) at(age = (15,85)) noatlegend
Predictive margins                               Number of obs = 2,009
Model VCE: OIM
Expression: Heteroskedastic standard deviation, predict(sigma)
```

		Delta-method		z	P> z	[95% conf. interval]	
		Margin	std. err.				
	_at						
	1	1.014732	.0320905	31.62	0.000	.9518354	1.077628
	2	1.355853	.1398144	9.70	0.000	1.081822	1.629884

Variation increases with age. The expected standard deviation of the error term changes from 1.015 at age 15 to 1.356 at age 85.

## Stored results

`hetoprobit` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(k_cat)</code>	number of categories
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom ( $\alpha\beta$ term)
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, cutpoint-only (heteroskedastic) model
<code>e(ll_c)</code>	log likelihood, comparison (homoskedastic) model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(chi2_c)</code>	$\chi^2$ for heteroskedasticity test
<code>e(p)</code>	$p$ -value for model test
<code>e(p_c)</code>	$p$ -value for heteroskedasticity test
<code>e(df_m_c)</code>	degrees of freedom for heteroskedasticity test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>hetoprobit</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset1)</code>	offset for ordered probit equation
<code>e(offset2)</code>	offset for variance equation
<code>e(chi2type)</code>	LR; type of model $\chi^2$ test
<code>e(chi2_ct)</code>	LR or Wald; type of heteroskedasticity test corresponding to <code>e(chi2_c)</code>
<code>e(vce)</code>	<i>vcetype</i> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	b V
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(marginsnotok)</code>	predictions disallowed by <code>margins</code>
<code>e(marginsdefault)</code>	default <code>predict()</code> specification for <code>margins</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(cat)</code>	category values
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices	
<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

`hetoprobit` fits a cumulative probit model with heteroskedastic variance using maximum likelihood estimation. Namely, the model is that, for a subject with explanatory variables  $\mathbf{x}$  and  $\mathbf{z}$ ,

$$\Pr(Y \leq h) = \Phi \left\{ \frac{\kappa_{h+1} - \mathbf{x}\beta}{\exp(\mathbf{z}\gamma)} \right\}$$

where  $Y$  is an ordinal outcome taking on values  $h = 0, 1, \dots, H$ , and  $\Phi(\cdot)$  is the cdf of the standard normal distribution. The value  $\kappa_{h+1}$  is a cutpoint that separates the region corresponding to  $Y = h$  from regions for higher-valued categories. The effects  $\beta$  and the effects  $\gamma$  are the same for each cumulative probability.

The log-likelihood function is

$$\ln L = \sum_{j=1}^N w_j \sum_{h=0}^H I_h(y_j) \ln \left[ \Phi \left\{ \frac{\kappa_{h+1} - \mathbf{x}_j\beta}{\exp(\mathbf{z}_j\gamma)} \right\} - \Phi \left\{ \frac{\kappa_h - \mathbf{x}_j\beta}{\exp(\mathbf{z}_j\gamma)} \right\} \right]$$

where

$$I_h(y_j) = \begin{cases} 1 & \text{if } y_j = h \\ 0 & \text{otherwise} \end{cases}$$

and  $y_j$ , where  $j = 1, \dots, N$ , is an observed value of  $Y$ ;  $w_j$  are optional weights;  $\kappa_0 = -\infty$  and  $\kappa_{H+1} = \infty$ ; and all other terminology is defined in [Remarks and examples](#) above.

The log-likelihood function is maximized as described in [R] [Maximize](#).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`hetoprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

Remarks and examples

## Postestimation commands

The following postestimation commands are available after `hetoprobit`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>linktest</code>	link test for model specification
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	probabilities, linear predictions, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard deviations.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
    outcome(outcome) nooffset]
```

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>pr</code>	predicted probabilities; the default
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the linear prediction
<code>sigma</code>	standard deviation of the error term

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb`, `stdp`, or `sigma`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction. The linear prediction is defined by ignoring the contribution of the estimated cutpoints.

`stdp` calculates the standard error of the linear prediction.

`sigma` calculates the standard deviation of the error term.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is available only with the default `pr` option.

`nooffset` is relevant only if you specified `offset(varname)` for `hetoprobit` or within the `het()` option. `nooffset` modifies the calculations made by `predict` so that they ignore the offset variable: the linear prediction is treated as  $\mathbf{x}_j\mathbf{b}$  rather than as  $\mathbf{x}_j\mathbf{b} + \text{offset}_j^b$ , and the prediction of  $\ln(\sigma)$  is treated as  $\mathbf{z}_j\mathbf{g}$  rather than as  $\mathbf{z}_j\mathbf{g} + \text{offset}_j^g$ . `nooffset` is not allowed with `scores`.

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The next new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\boldsymbol{\gamma})$ .

The next new variable will contain  $\partial \ln L / \partial \kappa_1$ .

The next new variable (if any) will contain  $\partial \ln L / \partial \kappa_2$ .

...

The last new variable will contain  $\partial \ln L / \partial \kappa_H$ , where  $\kappa_h$  for  $h = 1, 2, \dots, H$  refers to the  $h$ th cutpoint. If the linear predictor had no *indepvars*, the first new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\boldsymbol{\gamma})$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities, linear predictions, and standard deviations.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
------------------	-------------

---

Main

<code>default</code>	probabilities for each outcome
<code>pr</code>	probability for a specified outcome
<code>xb</code>	linear prediction
<code>stdp</code>	not allowed with <code>margins</code>
<code>sigma</code>	standard deviation of the error term

---

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

### Remarks and examples

See [U] [20 Estimation and postestimation commands](#) for an overview of postestimation commands, including information on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests.

Once you have fit a model with `hetoprobit`, you may use the `predict` command to obtain the predicted probabilities for both the estimation sample and other samples. With the `pr` option, `predict` calculates the predicted probability of one or all ordinal value outcomes. With the `xb` option, `predict` calculates the linear prediction,  $\mathbf{x}_j\mathbf{b}$ , where  $\mathbf{x}_j$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector. The linear prediction is defined ignoring the contribution of the cutpoints. With the `sigma` option, `predict` calculates the predicted standard deviations of the error term,  $\sigma_j = \exp(\mathbf{z}_j\mathbf{g})$ , where  $\mathbf{g}$  is the estimated coefficient vector for the variance model.

See [example 2](#) in [R] [hetoprobit](#) for an example of `predict` after `hetoprobit`. In [example 3](#) and [example 4](#), we demonstrate how to use `margins` to obtain marginal effects, to compute expected probabilities of outcome levels across values of covariates, and to characterize the variance as a function of covariates.

## Methods and formulas

For definitions of the terminology used in this section, see *Remarks and examples* in [R] [hetoprobit](#).

For outcome  $h$ , the statistic `pr` is the estimated predicted probability

$$\widehat{\Pr}(y_j = h) = \Phi \left\{ \frac{\widehat{\kappa}_{h+1} - \mathbf{x}_j \mathbf{b}}{\exp(\mathbf{z}_j \mathbf{g})} \right\} - \Phi \left\{ \frac{\widehat{\kappa}_h - \mathbf{x}_j \mathbf{b}}{\exp(\mathbf{z}_j \mathbf{g})} \right\}$$

where  $\mathbf{x}_j \mathbf{b}$  and  $\mathbf{z}_j \mathbf{g}$  are the linear predictions of the regression and variance models, respectively, for the  $j$ th subject.

The statistic `sigma` is the estimated standard deviation of the modeled heteroskedastic error, namely,

$$\widehat{\sigma}_j = \exp(\mathbf{z}_j \mathbf{g})$$

If you specified `offset(varname)` with `hetoprobit` or within the `het()` option (and if you do not specify option `nooffset` with `predict`), then the specified offsets are applied by `predict`. Namely, the linear prediction is computed as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j^b$ ; the prediction of  $\ln(\sigma)$  is computed as  $\mathbf{z}_j \mathbf{g} + \text{offset}_j^g$ ; and all other statistics are based on the resulting predictions. If you specify `nooffset` with `predict`, then the linear prediction is  $\mathbf{x}_j \mathbf{b}$  and the prediction of  $\ln(\sigma)$  is  $\mathbf{z}_j \mathbf{g}$ , regardless of whether you specified the `offset()` option with `hetoprobit` or within `het()`.

## Description

`hetprobit` fits a maximum-likelihood heteroskedastic probit model.

## Quick start

Heteroskedastic probit model of  $y$  on  $x1$ , using  $x2$  to model the variance

```
hetprobit y x1, het(x2)
```

With robust standard errors

```
hetprobit y x1, het(x2) vce(robust)
```

After fitting a model, reprint the table as a coefficient legend

```
hetprobit, coeflegend
```

## Menu

Statistics > Binary outcomes > Heteroskedastic probit regression

## Syntax

```
hetprobit depvar [indepvars] [if] [in] [weight],
      het(varlist [, offset(varnameo)] [options])
```

<i>options</i>	Description
<b>Model</b>	
* <b>het</b> ( <i>varlist</i> [...])	independent variables to model the variance and optional offset variable
<b>noconstant</b>	suppress constant term
<b>offset</b> ( <i>varname</i> )	include <i>varname</i> in model with coefficient constrained to 1
<b>asis</b>	retain perfect predictor variables
<b>constraints</b> ( <i>constraints</i> )	apply specified linear constraints
<b>SE/Robust</b>	
<b>vce</b> ( <i>vcetype</i> )	<i>vcetype</i> may be <code>oim</code> , <code>robust</code> , <code>cluster</code> <i>clustvar</i> , <code>opg</code> , <code>bootstrap</code> , or <code>jackknife</code>
<b>Reporting</b>	
<b>level</b> (#)	set confidence level; default is <code>level(95)</code>
<b>lrmodel</b>	perform the likelihood-ratio model test instead of the default Wald test
<b>waldhet</b>	perform Wald test on variance instead of LR test
<b>nocnsreport</b>	do not display constraints
<b>display_options</b>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>Maximization</b>	
<b>maximize_options</b>	control the maximization process; seldom used
<b>collinear</b>	keep collinear variables
<b>coeflegend</b>	display legend instead of statistics

\***het**() is required. The full specification is `het(varlist [, offset(varnameo)])`.

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *indepvars*, and *varlist* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes`, `bootstrap`, `by`, `collect`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: hetprobit.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`vce()`, `lrmodel`, and weights are not allowed with the `svy` prefix; see [SVY] svy.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

Model

`het(varlist [, offset(varnameo)])` specifies the independent variables and, optionally, the offset variable in the variance function. `het()` is required.

`offset(varnameo)` specifies that selection offset `varnameo` be included in the model with the coefficient constrained to be 1.

`noconstant`, `offset(varname)`; see [R] [Estimation options](#).

`asis` forces the retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] [probit](#).

`constraints(constraints)`; see [R] [Estimation options](#).

#### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

#### Reporting

`level(#)`, `lrmodel`; see [R] [Estimation options](#).

`waldhet` specifies that a Wald test of whether  $\ln\sigma = 0$  be performed instead of the LR test.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

#### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `hetprobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)  
[Robust standard errors](#)

## Introduction

`hetprobit` fits a maximum-likelihood heteroskedastic probit model, which is a generalization of the probit model. Let  $y_j, j = 1, \dots, N$ , be a binary outcome variable taking on the value 0 (failure) or 1 (success). In the probit model, the probability that  $y_j$  takes on the value 1 is modeled as a nonlinear function of a linear combination of the  $k$  independent variables  $\mathbf{x}_j = (x_{1j}, x_{2j}, \dots, x_{kj})$ ,

$$\Pr(y_j = 1) = \Phi(\mathbf{x}_j \mathbf{b})$$

in which  $\Phi(\cdot)$  is the cumulative distribution function (CDF) of a standard normal random variable, that is, a normally distributed (Gaussian) random variable with mean 0 and variance 1. The linear combination of the independent variables,  $\mathbf{x}_j \mathbf{b}$ , is commonly called the *index function*, or *index*. Heteroskedastic probit generalizes the probit model by generalizing  $\Phi(\cdot)$  to a normal CDF with a variance that is no longer fixed at 1 but can vary as a function of the independent variables. `hetprobit` models the variance as a multiplicative function of these  $m$  variables  $\mathbf{z}_j = (z_{1j}, z_{2j}, \dots, z_{mj})$ , following Harvey (1976):

$$\sigma_j^2 = \{ \exp(\mathbf{z}_j \boldsymbol{\gamma}) \}^2$$

Thus, the probability of success as a function of all the independent variables is

$$\Pr(y_j = 1) = \Phi \left\{ \mathbf{x}_j \mathbf{b} / \exp(\mathbf{z}_j \boldsymbol{\gamma}) \right\}$$

From this expression, it is clear that, unlike the index  $\mathbf{x}_j \mathbf{b}$ , no constant term can be present in  $\mathbf{z}_j \boldsymbol{\gamma}$  if the model is to be identifiable.

Suppose that the binary outcomes  $y_j$  are generated by thresholding an unobserved random variable,  $w$ , which is normally distributed with mean  $\mathbf{x}_j \mathbf{b}$  and variance 1 such that

$$y_j = \begin{cases} 1 & \text{if } w_j > 0 \\ 0 & \text{if } w_j \leq 0 \end{cases}$$

This process gives the probit model:

$$\Pr(y_j = 1) = \Pr(w_j > 0) = \Phi(\mathbf{x}_j \mathbf{b})$$

Now, suppose that the unobserved  $w_j$  are heteroskedastic with variance

$$\sigma_j^2 = \{ \exp(\mathbf{z}_j \boldsymbol{\gamma}) \}^2$$

Relaxing the homoskedastic assumption of the probit model in this manner yields our multiplicative heteroskedastic probit model:

$$\Pr(y_j = 1) = \Phi \left\{ \mathbf{x}_j \mathbf{b} / \exp(\mathbf{z}_j \boldsymbol{\gamma}) \right\}$$

## ▷ Example 1

For this example, we generate simulated data for a simple heteroskedastic probit model and then estimate the coefficients with `hetprobit`:

```
. set obs 1000
Number of observations (_N) was 0, now 1,000.
. set seed 1234567
. generate x = 1-2*runiform()
. generate xhet = runiform()
. generate sigma = exp(1.5*xhet)
. generate p = normal((0.3+2*x)/sigma)
. generate y = cond(runiform()<=p,1,0)
. hetprobit y x, het(xhet)
Fitting probit model:
Iteration 0: Log likelihood = -688.33746
Iteration 1: Log likelihood = -610.48362
Iteration 2: Log likelihood = -610.3626
Iteration 3: Log likelihood = -610.3626
Fitting full model:
Iteration 0: Log likelihood = -610.3626
Iteration 1: Log likelihood = -600.8767
Iteration 2: Log likelihood = -600.10154
Iteration 3: Log likelihood = -600.01544
Iteration 4: Log likelihood = -600.01521
Iteration 5: Log likelihood = -600.01521
Heteroskedastic probit model
```

	Number of obs	=	1,000
	Zero outcomes	=	451
	Nonzero outcomes	=	549
	Wald chi2(1)	=	54.20
	Prob > chi2	=	0.0000

```
Log likelihood = -600.0152
```

	y	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
y	x	1.782479	.2421117	7.36	0.000	1.307949	2.257009
	_cons	.3140616	.0871121	3.61	0.000	.1433249	.4847982
lnsigma	xhet	1.31152	.3011689	4.35	0.000	.7212402	1.901801
			LR test of lnsigma=0: chi2(1) = 20.69		Prob > chi2 = 0.0000		

Above, we created two variables, `x` and `xhet`, and then simulated the model

$$\Pr(y = 1) = F\left\{\frac{\beta_0 + \beta_1 x}{\exp(\gamma_1 xhet)}\right\}$$

for  $\beta_0 = 0.3$ ,  $\beta_1 = 2$ , and  $\gamma_1 = 1.5$ . According to `hetprobit`'s output, all coefficients are significant, and, as we would expect, the Wald test of the full model versus the constant-only model—for example, the index consisting of  $\beta_0 + \beta_1 x$  versus that of just  $\beta_0$ —is significant with  $\chi^2(1) = 54$ . Likewise, the likelihood-ratio test of heteroskedasticity, which tests the full model with heteroskedasticity against the full model without, is significant with  $\chi^2(1) = 21$ . See [R] [Maximize](#) for more explanation of the output. For this simple model, `hetprobit` took five iterations to converge. As stated elsewhere (Greene 2018, 764), this is a difficult model to fit, and it is not uncommon for it to require many iterations or for the optimizer to print out warnings and informative messages during the optimization. Slow convergence is especially common for models in which one or more of the independent variables appear in both the index and variance functions. ◀

## □ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes. □

## Robust standard errors

If you specify the `vce(robust)` option, `hetprobit` reports robust standard errors as described in [U] 20.22 [Obtaining robust variance estimates](#). To illustrate the effect of this option, we will reestimate our coefficients by using the same model and data in our example, this time adding `vce(robust)` to our `hetprobit` command.

## ▷ Example 2

```
. hetprobit y x, het(xhet) vce(robust) nolog
Heteroskedastic probit model           Number of obs   =       1,000
                                         Zero outcomes   =         451
                                         Nonzero outcomes =         549
                                         Wald chi2(1)    =        50.49
                                         Prob > chi2     =         0.0000

Log pseudolikelihood = -600.0152
```

		Robust				
y	Coefficient	std. err.	z	P> z	[95% conf. interval]	
y						
x	1.782479	.2508447	7.11	0.000	1.290832	2.274126
_cons	.3140616	.087195	3.60	0.000	.1431625	.4849607
lnsigma						
xhet	1.31152	.3059137	4.29	0.000	.7119406	1.9111

```
Wald test of lnsigma=0: chi2(1) = 18.38           Prob > chi2 = 0.0000
```

The `vce(robust)` standard errors for two of the three parameters are larger than the previously reported conventional standard errors. This is to be expected, even though (by construction) we have perfect model specification because this option trades off efficient estimation of the coefficient variance–covariance matrix for robustness against misspecification. ◀

Specifying the `vce(cluster clustvar)` option relaxes the usual assumption of independence between observations to the weaker assumption of independence just between clusters; that is, `hetprobit, vce(cluster clustvar)` is robust with respect to within-cluster correlation. This option is less efficient than the `xtgee` population-averaged models because `hetprobit` inefficiently sums within cluster for the standard error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation.

## Stored results

`hetprobit` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(N_f)</code>	number of zero outcomes
<code>e(N_s)</code>	number of nonzero outcomes
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(ll_c)</code>	log likelihood, comparison model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(chi2_c)</code>	$\chi^2$ for heteroskedasticity test
<code>e(p_c)</code>	<i>p</i> -value for heteroskedasticity test
<code>e(df_m_c)</code>	degrees of freedom for heteroskedasticity test
<code>e(p)</code>	<i>p</i> -value for model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(rank0)</code>	rank of <code>e(V)</code> for constant-only model
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>hetprobit</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset1)</code>	offset for probit equation
<code>e(offset2)</code>	offset for variance equation
<code>e(chi2type)</code>	Wald or LR; type of model $\chi^2$ test
<code>e(chi2_ct)</code>	Wald or LR; type of model $\chi^2$ test corresponding to <code>e(chi2_c)</code>
<code>e(vce)</code>	<i>vce</i> type specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(method)</code>	<code>ml</code>
<code>e(ml_method)</code>	type of <code>ml</code> method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices

`r(table)` matrix containing the coefficients with their standard errors, test statistics,  $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

The heteroskedastic probit model is a generalization of the probit model because it allows the scale of the inverse link function to vary from observation to observation as a function of the independent variables.

The log-likelihood function for the heteroskedastic probit model is

$$\ln L = \sum_{j \in S} w_j \ln \Phi\{\mathbf{x}_j \boldsymbol{\beta} / \exp(\mathbf{z}_j \boldsymbol{\gamma})\} + \sum_{j \notin S} w_j \ln [1 - \Phi\{\mathbf{x}_j \boldsymbol{\beta} / \exp(\mathbf{z}_j \boldsymbol{\gamma})\}]$$

where  $S$  is the set of all observations  $j$  such that  $y_j \neq 0$  and  $w_j$  denotes the optional weights.  $\ln L$  is maximized as described in [R] [Maximize](#).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`hetprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `hetprobit`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>linktest</code>	link test for model specification
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	probabilities, linear predictions, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard deviations.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>pr</code>	probability of a positive outcome; the default
<code>xb</code>	linear prediction
<code>sigma</code>	standard deviation of the error term

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`sigma` calculates the standard deviation of the error term.

`nooffset` is relevant only if you specified `offset(varname)` for `hetprobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\mathbf{b}$  rather than as  $\mathbf{x}_j\mathbf{b} + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\boldsymbol{\gamma})$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities, linear predictions, and standard deviations.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>pr</code>	probability of a positive outcome; the default
<code>xb</code>	linear prediction
<code>sigma</code>	standard deviation of the error term

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(\mathbf{b})$ .

For the full syntax, see [\[R\] margins](#).

### Remarks and examples

Once you have fit a model, you can use the `predict` command to obtain the predicted probabilities for both the estimation sample and other samples; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#). `predict` without arguments calculates the predicted probability of a positive outcome. With the `xb` option, `predict` calculates the index function combination,  $\mathbf{x}_j\mathbf{b}$ , where  $\mathbf{x}_j$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector. With the `sigma` option, `predict` calculates the predicted standard deviation,  $\sigma_j = \exp(\mathbf{z}_j\boldsymbol{\gamma})$ .

## ▷ Example 1

We use `predict` to compute the predicted probabilities and standard deviations based on the model in [example 2](#) in [\[R\] hetprobit](#) to compare these with the actual values:

```
. predict phat
(option pr assumed; Pr(y))
. generate diff_p = phat - p
. summarize diff_p
```

Variable	Obs	Mean	Std. dev.	Min	Max
diff_p	1,000	.0082805	.0103027	-.0169849	.0396469

```
. predict sigmahat, sigma
. generate diff_s = sigmahat - sigma
. summarize diff_s
```

Variable	Obs	Mean	Std. dev.	Min	Max
diff_s	1,000	-.2579493	.2126614	-.7661171	-.000025

## Description

`hetregress` fits a multiplicative heteroskedastic linear regression by modeling the variance as an exponential function of the specified variables using either maximum likelihood (ML; the default) or Harvey's two-step generalized least-squares (GLS) method.

## Quick start

Heteroskedastic regression model of  $y$  on  $x1$ , using  $x2$  to model the variance

```
hetregress y x1, het(x2)
```

Using Harvey's two-step GLS estimator instead of the default ML

```
hetregress y x1, het(x2) twostep
```

With robust standard errors

```
hetregress y x1, het(x2) vce(robust)
```

Perform a Wald test on the variance instead of a likelihood-ratio (LR) test

```
hetregress y x1, het(x2) waldhet
```

## Menu

Statistics > Linear models and related > Heteroskedastic linear regression

## Syntax

### Maximum likelihood estimation

```
hetregress depvar [indepvars] [if] [in] [weight] [, ml_options]
```

### Two-step GLS estimation

```
hetregress depvar [indepvars] [if] [in], twostep het(varlist) [ts_options]
```

<i>ml_options</i>	Description
<b>Model</b>

**bayes**, **bootstrap**, **by**, **collect**, **fp**, **jackknife**, **rolling**, **statsby**, and **svy** are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: hetregress**.

Weights are not allowed with the **bootstrap** prefix; see [R] **bootstrap**.

**aweight**s are not allowed with the **jackknife** prefix; see [R] **jackknife**.

**vce**(), **lrmmodel**, **twostep**, and **weights** are not allowed with the **svy** prefix; see [SVY] **svy**.

**aweight**s, **fweight**s, **iweight**s, and **pweight**s are allowed with maximum likelihood estimation; see [U] 11.1.6 **weight**. **collinear** and **coeflegend** do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options for maximum likelihood estimation

### Model

**mle** requests that the maximum likelihood estimator be used. This is the default.

**het**(*varlist*) specifies the independent variables in the variance function. When the **het**() option is not specified, homoskedasticity is assumed and the **waldhet** option is not allowed.

**noconstant**, **constraints**(*constraints*); see [R] **Estimation options**.

### SE/Robust

**vce**(*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (**oim**, **opg**), that are robust to some kinds of misspecification (**robust**), that allow for intragroup correlation (**cluster** *clustvar*), and that use bootstrap or jackknife methods (**bootstrap**, **jackknife**); see [R] **vce\_option**.

### Reporting

**level**(#), **lrmmodel**; see [R] **Estimation options**.

**waldhet** specifies that the Wald test of whether  $\ln\sigma^2 = 0$  be performed instead of the LR test.

nocnsreport; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

#### Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `hetregress` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Options for two-step GLS estimation

#### Model

`twostep` specifies that the model be fit using Harvey's two-step GLS estimator. This option requires that the independent variables be specified in the `het()` option to model the variance.

`het(varlist)` specifies the independent variables in the variance function.

`noconstant`; see [R] [Estimation options](#).

#### SE

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`conventional`) and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(conventional)`, the default, uses the two-step variance estimator derived by Heckman.

#### Reporting

`level(#)`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

The following option is available with `hetregress` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Introduction*

*Maximum likelihood estimation*

*Two-step GLS estimation*

## Introduction

**hetregress** fits a multiplicative heteroskedastic linear regression model using either ML or Harvey's two-step GLS method. Multiplicative heteroskedasticity occurs when the variances of the error terms are assumed to be a multiplicative function of one or more variables. When variables are not specified in the `het()` option, **hetregress** fits a homoskedastic linear regression model.

Heteroskedasticity arises in a regression when the variances of the error terms are not constant across observations. For example, wages may be heteroskedastic when predicted by age group. While there is little variability in wages among workers in their teens and early 20s, wages among workers in their 50s may vary greatly because of a variety of factors. Heteroskedasticity is often found in time-series data and cross-sectional measurements and is a common issue in econometrics, social science, and many other fields. For more detailed information on how to detect the presence of heteroskedasticity, see *Tests for violation of assumptions* in [R] **regress postestimation**.

We can use **hetregress** when the variance is assumed to have a form that is an exponential function of a linear combination of one or more variables. This is known as multiplicative heteroskedasticity and includes most of the useful formulations for variance as special cases. For example, in the special case of groupwise heteroskedasticity, the sample can be divided into groups where each group has a different variance.

A model with multiplicative heteroskedasticity can be written as

$$y_i = \mathbf{x}_i\boldsymbol{\beta} + \epsilon_i; \quad \sigma_i^2 = \exp(\mathbf{z}_i\boldsymbol{\alpha}) \quad (1)$$

where  $y_i$ ,  $i = 1, \dots, n$ , is the dependent variable;  $\mathbf{x}_i = (x_{1i}, x_{2i}, \dots, x_{ki})$  are the  $k$  independent variables that model the mean function; and  $\mathbf{z}_i = (z_{1i}, z_{2i}, \dots, z_{mi})$  are the  $m$  variables that model the variance function.  $\boldsymbol{\beta}$ 's are unknown parameters in the mean function, and  $\boldsymbol{\alpha}$ 's are unknown parameters in the variance function.  $\epsilon_i$ 's are errors that are independent and identically distributed with mean 0 and variance  $\sigma_i^2$ . Groupwise heteroskedasticity is modeled using (1) but where the  $\mathbf{z}_i$ 's are all indicator (dummy) variables for groups.

Harvey (1976) introduced two methods for dealing with multiplicative heteroskedasticity: ML estimation and two-step GLS estimation. By default, **hetregress** fits the multiplicative heteroskedastic regression model using ML. If the `twostep` option is specified, **hetregress** fits the model using the two-step GLS method. The ML estimates are more efficient than those obtained by the GLS estimator if the mean and variance function are correctly specified and the errors are normally distributed. By contrast, the two-step GLS estimates are more robust if the variance function is incorrect or the errors are nonnormal.

If the form of the variance is completely unknown, we may be better off using the OLS estimator instead of the ML and GLS estimators because it remains unbiased. However, we should then use the robust standard errors to correct for heteroskedasticity. Using robust standard errors for the OLS estimator allows us to make appropriate inferences without specifying any form for the variance. We discuss three modifications of the robust variance calculation in *Robust standard errors* of [R] **regress**.

If the form of the variance is known and does not contain any unknown parameters, we can use the weighted least-squares estimator, also called the generalized least-squares estimator. For example, we can use weighted least squares to correct for heteroskedasticity if the variance is proportional to one of the regressors. See section 9.5.2 of [Greene \(2018\)](#) for details, and also see [Weighted regression in \[R\] regress](#).

[Greene \(2018\)](#) and [Hill, Griffiths, and Lim \(2018\)](#) compare the ML estimator and the GLS estimator with the robust OLS estimator. If the form of the heteroskedasticity is specified correctly, the ML and GLS estimators are more efficient than the robust OLS estimator. However, if the form of the heteroskedasticity is misspecified, the robust OLS estimator may be more efficient than the ML and GLS estimators.

## Maximum likelihood estimation

### ► Example 1: Multiplicative heteroskedasticity

Consider the following dataset from a study of household expenditure on food described in [Hill, Griffiths, and Lim \(2018, chap. 8\)](#). We want to investigate the relationship between average household expenditure on food and household income by fitting a model of weekly food expenditure (`food_exp`) on weekly income (`income`) using OLS.

```
. use https://www.stata-press.com/data/r18/foodexp
(Household expenditure on food)
. regress food_exp income
(output omitted)
```

However, we suspect that the variance for low-income families may be lower than that for high-income families, because low-income families usually have less money to spend on food, while high-income families can choose to spend more or less on food. We plot the least-squares residuals against the value of `income` by using the `rvpplot` command after `regress`.

```
. rvpplot income, yline(0)
```

The graph confirms our suspicions about a relationship between income and the residuals. We believe that the variance is some power function of `income`. Therefore, we fit a multiplicative heteroskedastic regression model. The model for each observation is

$$\text{food\_exp}_i = \beta_0 + \beta_1 \times \text{income}_i + \epsilon_i$$

and the variance function can be written as

$$\sigma_i^2 = \sigma^2 \times \text{income}_i^\gamma$$

where  $\gamma$  is an unknown parameter of the variance function. To ensure that we will get positive values for the variance  $\sigma_i^2$  for all possible values of the unknown parameter  $\gamma$ , we rewrite this function so that  $\sigma_i^2$  is an exponential function of a linear combination of  $\ln(\text{income}_i)$  and a constant term:

$$\sigma_i^2 = \exp\{\alpha_0 + \alpha_1 \times \ln(\text{income}_i)\}$$

where  $\alpha_0 = \ln(\sigma^2)$  and  $\alpha_1 = \gamma$ .

To fit this model using **hetregress**, we first create a variable that contains the logarithm of **income** (**logincome**) and use it in the **het()** option to model the variance function. The constant term in the variance function is always assumed.

```
. generate double logincome = ln(income)
. hetregress food_exp income, het(logincome)
Fitting full model:
Iteration 0: Log likelihood = -227.889
Iteration 1: Log likelihood = -226.61039
Iteration 2: Log likelihood = -225.72188
Iteration 3: Log likelihood = -225.71519
Iteration 4: Log likelihood = -225.71519
Heteroskedastic linear regression      Number of obs      =           40
ML estimation                          Wald chi2(1)       =          135.11
Log likelihood = -225.7152             Prob > chi2        =           0.0000
```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
<b>food_exp</b>						
income	10.63444	.9148876	11.62	0.000	8.841295	12.42759
_cons	76.07294	7.369143	10.32	0.000	61.62969	90.5162
<b>lnsigma2</b>						
logincome	2.769762	.4481606	6.18	0.000	1.891383	3.648141
_cons	.4684052	1.310337	0.36	0.721	-2.099809	3.036619

```
LR test of lnsigma2=0: chi2(1) = 19.59      Prob > chi2 = 0.0000
```

The LR test at the bottom of the output is a test for the parameters of the variance function. The  $\chi^2(1)$  statistic of 19.59 is significant, indicating that heteroskedasticity is present. If we had preferred the Wald test for heteroskedasticity instead of the LR test, we would have specified the **waldhet** option.

In addition to the estimated parameters for the mean function (under **food\_exp**), **hetregress** reports estimated parameters and test statistics for the variance function. The significant  $z$  statistic for **logincome** also suggests the presence of heteroskedasticity. Relating the output back to our model,  $\exp(0.47) \approx 1.60$  is our estimate of  $\sigma^2$ . The coefficient for **logincome** is 2.77. This is our estimate of  $\gamma$ , and it can be interpreted as the multiplicative factor of the variance associated with income.

We can obtain more formal results by using `nlcom`:

```
. nlcom (sigma2: exp(_b[lnsigma2:_cons]))
      sigma2: exp(_b[lnsigma2:_cons])
```

food_exp	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
sigma2	1.597445	2.093191	0.76	0.445	-2.505135	5.700024

Here `sigma2` refers to  $\sigma^2$  in the variance function given [above](#).

◀

## Two-step GLS estimation

### ▷ Example 2: Groupwise heteroskedasticity

Here we will use a dataset of 725 faculty members' salaries described in [DeMaris \(2004\)](#) to determine whether there is evidence of a difference in salaries between male faculty and female faculty. In addition to `sex` (`female`), other variables that might affect the salaries are prior experience (`priorex`), years in rank (`yrrank`), years at the university (`yrbg`), and marketability of discipline (`salfac`). We will treat `female` as a factor variable and all other variables as continuous variables.

We could fit this model with `regress` by including main effects and the interaction terms between `female` and all other variables (by using [factor-variable notation](#)).

```
. use https://www.stata-press.com/data/r18/salary, clear
(DeMaris (2004) - Faculty salaries)
. regress salary i.female##(c.priorexp c.yrrank c.yrbg c.salfac)
```

Source	SS	df	MS	Number of obs		
Model	8.9287e+10	9	9.9207e+09	F(9, 715)	=	135.23
Residual	5.2453e+10	715	73360978.8	Prob > F	=	0.0000
				R-squared	=	0.6299
				Adj R-squared	=	0.6253
Total	1.4174e+11	724	195773163	Root MSE	=	8565.1

salary	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
1.female	5735.113	4987.433	1.15	0.251	-4056.65	15526.88
priorexp	1042.845	82.62092	12.62	0.000	880.6366	1205.054
yrrank	-47.80904	99.85936	-0.48	0.632	-243.8617	148.2436
yrbg	1009.12	75.5161	13.36	0.000	860.8607	1157.38
salfac	33601.3	2531.61	13.27	0.000	28631.02	38571.58
female# c.priorexp 1	-662.7972	159.6171	-4.15	0.000	-976.1715	-349.4228
female# c.yrrank 1	-447.8621	218.8695	-2.05	0.041	-877.5659	-18.15833
female#c.yrbg 1	115.4784	157.9372	0.73	0.465	-194.5976	425.5545
female# c.salfac 1	-7618.157	5142.204	-1.48	0.139	-17713.78	2477.467
_cons	2137.718	2634.266	0.81	0.417	-3034.103	7309.539

However, we believe that the variances differ between female faculty and male faculty. In this case, we will use `estat hettest` to perform the [Breusch and Pagan \(1979\)](#) test for heteroskedasticity. See [Tests for violation of assumptions](#) in [\[R\] regress postestimation](#) for more detailed information.

```
. estat hettest i.female
Breusch-Pagan/Cook-Weisberg test for heteroskedasticity
Assumption: Normal error terms
Variable: i.female
H0: Constant variance
      chi2(1) = 11.80
      Prob > chi2 = 0.0006
```

The results above suggest the presence of heteroskedasticity with respect to sex. This is a case of groupwise heteroskedasticity and can be modeled using `hetregress` by treating the sex variable (`female`) as a factor variable (`i.female`) in the `het()` option.

We add the twostep option to obtain two-step GLS estimates instead of ML estimates.

```
. hetregress salary i.female##(c.priorexp c.yrrank c.yrbg c.salfac),
> het(i.female) twostep
```

```
Heteroskedastic linear regression      Number of obs      =      725
Two-step GLS estimation                Wald chi2(9)        =     1270.02
                                       Prob > chi2          =      0.0000
```

salary	Coefficient	Std. err.	z	P> z	[95% conf. interval]

_cons	2137.718	2840.48	0.75	0.452	-3429.52	7704.956
lnsigma2						
1.female	-.5676939	.1808783	-3.14	0.002	-.9222088	-.2131789
_cons	17.90879	.0982708	182.24	0.000	17.71618	18.1014

```
Wald test of lnsigma2=0: chi2(1) = 9.85      Prob > chi2 = 0.0017
```

The Wald test for heteroskedasticity is reported at the bottom of the coefficient table instead of the LR test because there is no likelihood computed for the two-step GLS estimation.

Compared with the OLS results obtained using `regress`, the estimated coefficients for the mean function are not affected by heteroskedasticity, but their standard errors are. Also, the estimated variance in salaries for female faculty is about  $\exp(-0.6) \approx 0.5$  times the estimated variance in salaries for male faculty.

The results above suggest that `priorexp`, `yrbg`, and `salfac` have significant effects on the salary of male faculty. We see also that the effects of `priorexp` and `yrrank` on salaries are significantly different between males and females. For example, each additional year of experience for male faculty increases their salary by \$1,042.85, and the estimated difference in effect is \$662.80 less for female faculty than for male faculty.

To obtain an estimate for female faculty of the effect of experience on salary, we can use `lincom`.

```
. lincom priorexp + 1.female#c.priorexp
(1) [salary]priorexp + [salary]1.female#c.priorexp = 0
```

salary	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
(1)	380.0481	110.8702	3.43	0.001	162.7465	597.3497

We see that each additional year of experience increases salary by only \$380.05 and that this effect is significant.

We can estimate the effect of each of the other variables on the salaries of female faculty if we wish.

```
. lincom yrrank + 1.female#c.yrrank
(1) [salary]yrrank + [salary]1.female#c.yrrank = 0
```

salary	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
(1)	-495.6711	158.1108	-3.13	0.002	-805.5627	-185.7796

The effect of `yrrank` is associated with a decrease in salary. The effect is significant for female faculty but not for male faculty.

◀

## Stored results

`hetregress` (ML) stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood, full model
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(ll_c)</code>	log likelihood, comparison model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$ for mean model test
<code>e(chi2_c)</code>	$\chi^2$ for heteroskedasticity test
<code>e(p_c)</code>	<i>p</i> -value for heteroskedasticity test
<code>e(df_m_c)</code>	degrees of freedom for heteroskedasticity test
<code>e(p)</code>	<i>p</i> -value for the mean model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(rank0)</code>	rank of <code>e(V)</code> for constant-only model
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

## Methods and formulas

Methods and formulas are presented under the following headings:

*Maximum likelihood estimation*

*Two-step GLS estimation*

## Maximum likelihood estimation

By default, `hetregress` fits a multiplicative heteroskedastic regression using ML estimation. The log-likelihood function is

$$\ln L = \sum_{i=1}^n \frac{w_i}{2} \left\{ \frac{(y_i - \mathbf{x}_i \boldsymbol{\beta})^2}{\exp(\mathbf{z}_i \boldsymbol{\alpha})} - \ln(2\pi) - \mathbf{z}_i \boldsymbol{\alpha} \right\}$$

where  $y_i$ ,  $i = 1, \dots, n$ , is the dependent variable;  $\mathbf{x}_i = (x_{1i}, x_{2i}, \dots, x_{ki})$  are the  $k$  independent variables that model the mean function;  $\mathbf{z}_i = (z_{1i}, z_{2i}, \dots, z_{mi})$  are the  $m$  variables that model the variance function; and  $w_i$  are the weights.  $\boldsymbol{\beta}$  is a column vector of unknown parameters in the mean function, and  $\boldsymbol{\alpha}$  is a column vector of unknown parameters in the variance function. The GLS estimates  $\hat{\boldsymbol{\beta}}_{\text{GLS}}$  and  $\hat{\boldsymbol{\alpha}}_{\text{GLS}}$  (described below) are used as the initial values in ML estimation. The  $\ln L$  function is maximized as described in [R] **Maximize**.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`hetregress` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Two-step GLS estimation

`hetregress` uses two-step GLS estimation when the `twostep` option is specified. Harvey (1976) describes the procedure in detail, but here are the main steps.

1. Use OLS to estimate regression coefficients  $\beta$  and compute residuals  $\mathbf{e}_i$ ,  $i = 1, \dots, n$ .
2. Use OLS to regress the log-squared residuals,  $\ln(\mathbf{e}_i^2)$ , on  $\mathbf{z}$  and estimate  $\alpha$ .
3. Perform correction for the OLS estimates of  $\alpha$  to obtain  $\hat{\alpha}_c$  and their covariance matrix based on Harvey (1976).
4. Compute  $\hat{\sigma}_i^2 = \exp(\mathbf{z}_i \hat{\alpha}_c)$ ,  $i = 1, \dots, n$ .
5. Refit the original regression model using  $\hat{\sigma}_i^2$ 's as weights to obtain the GLS estimates  $\hat{\alpha}_{\text{GLS}}$  and  $\hat{\beta}_{\text{GLS}}$ .

## Postestimation commands

The following postestimation commands are available after `hetregress`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
* <code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICC, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
* <code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
† <code>forecast</code>	dynamic forecasts and simulations
† <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>linktest</code>	link test for model specification
* † <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	linear predictions and their SEs, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
* <code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\* `estat ic`, `estat (svy)`, `lrtest`, and `suest` are not appropriate after `hetregress`, `twostep`.

† `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, and standard deviations.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

After *ML* or two-step

```
predict [type] newvar [if] [in] [, statistic]
```

After *ML*

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
Main	
<code>xb</code>	linear prediction; the default
<code>stdp</code>	standard error of the linear prediction
<code>sigma</code>	standard deviation of the error term

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard errors of the linear prediction.

`sigma` calculates the standard deviations of the error term.

`scores` calculates equation-level score variables.

The first new variable will contain the derivative of the log likelihood with respect to the regression equation,  $\partial \ln L / \partial (\mathbf{x}_i \beta)$ .

The second new variable will contain the derivative of the log likelihood with respect to the scale equation (`lnsigma2`),  $\partial \ln L / \partial (\mathbf{z}_i \alpha)$ .

## margins

### Description for margins

`margins` estimates margins of response for linear predictions and of standard deviations.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>xb</code>	linear prediction; the default
<code>stdp</code>	not allowed with <code>margins</code>
<code>sigma</code>	standard deviation of the error term

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(\mathbf{b})$ .

For the full syntax, see [\[R\] margins](#).

### Remarks and examples

Once you have fit a heteroskedastic regression model, you can use the `predict` command to obtain the predicted values both for the estimation sample and for other samples; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#). `predict` without arguments calculates the linear prediction from the fitted model  $\mathbf{x}_i\mathbf{b}$ , where  $\mathbf{x}_i$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector for the mean model. With the `stdp` option, `predict` calculates the standard error of the linear prediction. With the `sigma` option, `predict` calculates the predicted standard deviations of the error term,  $\hat{\sigma}_j = \exp(0.5 \times \mathbf{z}_i\mathbf{a})$ , where  $\mathbf{g}$  is the estimated parameter vector for the variance model.

▷ Example 1: Predicting heteroskedastic standard deviation

We can use `predict` to compute the predicted values of the standard deviations for female and male faculty based on the model from [example 2](#) in [R] `hetregress`.

```
. use https://www.stata-press.com/data/r18/salary
(DeMaris (2004) - Faculty salaries)
. hetregress salary i.female##(c.priorexp c.yrrank c.yrbg c.salfac),
> het(i.female) twostep
(output omitted)
. predict sigma, sigma
. tabulate female, summarize(sigma)
```

		Summary of Heteroskedastic standard deviation		
1 = female; 0 = male		Mean	Std. dev.	Freq.
0		7741.8481	0	511
1		5828.6973	0	214
Total		7177.1388	873.22924	725

The predicted standard deviation for male faculty is approximately  $7742/5829 \approx 1.3$  times the size for female faculty. We could have obtained the same results using `margins` with the `predict(sigma)` option.

▷ Example 2: Marginal means

We can use `margins` to compute the adjusted mean salary for male and female faculty when other factors are fixed at their means:

```
. margins female, atmeans
Adjusted predictions                                Number of obs = 725
Model VCE: Conventional
Expression: Linear prediction, predict()
At: 0.female = .7048276 (mean)
    1.female = .2951724 (mean)
    priorexp = 2.89931 (mean)
    yrrank   = 7.397241 (mean)
    yrbg     = 12.52966 (mean)
    salfac   = .9399862 (mean)
```

		Delta-method			[95% conf. interval]	
		Margin	std. err.	z	P> z	
female						
0		49036.29	420.3711	116.65	0.000	48212.37 49860.2
1		43822.74	569.9368	76.89	0.000	42705.69 44939.8

If everyone in the population were male faculty while holding all other factors at their mean values, the average salary would be \$49,036. If, instead, everyone were female faculty, the average salary would be \$43,823.

## Description

`histogram` draws histograms of *varname*, which is assumed to be the name of a continuous variable unless the `discrete` option is specified.

`hist` is a synonym for `histogram`.

## Quick start

Histogram of `v1`

```
histogram v1
```

Add a normal density curve to the graph

```
histogram v1, normal
```

Add a kernel density estimate to the graph

```
histogram v1, normal kdensity
```

Add "My Title" as the title of the graph

```
histogram v1, normal kdensity title("My Title")
```

Specify the number of bins as 10

```
histogram v1, bins(10)
```

Specify the width of the bins as 2

```
histogram v1, width(2)
```

Specify that `v2` should be treated as discrete

```
histogram v2, discrete
```

Same as above, but with narrower bars and space between the bars

```
histogram v2, discrete barwidth(.8)
```

Add labels to the bars on the *x* axis

```
histogram v2, discrete barwidth(.8) xlabel(1 "Category 1" ///
2 "Category 2" 3 "Category 3" 4 "Category 4")
```

Show frequencies on the *y* axis

```
histogram v1, frequency
```

Show percentages on the *y* axis

```
histogram v1, percent
```

Produce histograms for each value of categorical variable `catvar`

```
histogram v1, by(catvar)
```

Same as above, but with histograms arranged in a single column

```
histogram v1, by(cvar, cols(1))
```

# Menu

Graphics &gt; Histogram

# Syntax

```
histogram varname [if] [in] [weight] [, [continuous_opts | discrete_opts] options ]
```

## *continuous\_opts*

## Description

### Main

<code>bins(#)</code>	set number of bins to #
<code>width(#)</code>	set width of bins to #
<code>start(#)</code>	set lower limit of first bin to #

## *discrete\_opts*

## Description

### Main

<code>discrete</code>	specify that data are discrete
<code>width(#)</code>	set width of bins to #
<code>start(#)</code>	set theoretical minimum value to #

## *options*

## Description

### Main

<code>density</code>	draw as density; the default
<code>fraction</code>	draw as fractions
<code>frequency</code>	draw as frequencies
<code>percent</code>	draw as percentages
<code>bar_options</code>	rendition of bars
<code>binrescale</code>	recalculate bin sizes when <code>by()</code> is specified
<code>addlabels</code>	add height labels to bars
<code>addlabopts(<i>marker_label_options</i>)</code>	affect rendition of labels

### Density plots

<code>normal</code>	add a normal density to the graph
<code>normopts(<i>line_options</i>)</code>	affect rendition of normal density
<code>kdensity</code>	add a kernel density estimate to the graph
<code>kdenopts(<i>kdensity_options</i>)</code>	affect rendition of kernel density

### Add plots

<code>addplot(<i>plot</i>)</code>	add other plots to the histogram
-----------------------------------	----------------------------------

### Y axis, X axis, Titles, Legend, Overall, By

<code>twoway_options</code>	any options documented in [G-3] <code>twoway_options</code>
-----------------------------	---

---

`fweights` are allowed; see [U] 11.1.6 `weight`.

## Options

Options are presented under the following headings:

*Options for use in the continuous case*

*Options for use in the discrete case*

*Options for use in the continuous and discrete cases*

### Options for use in the continuous case

Main

`bins(#)` and `width(#)` are alternatives. They specify how the data are to be aggregated into bins: `bins()` by specifying the number of bins (from which the width can be derived) and `width()` by specifying the bin width (from which the number of bins can be derived).

If neither option is specified, results are the same as if `bins(k)` had been specified, where

$$k = \min\left\{\sqrt{N}, 10 \ln(N)/\ln(10)\right\}$$

and where  $N$  is the (weighted) number of observations.

`start(#)` specifies the theoretical minimum of *varname*. The default is `start(m)`, where  $m$  is the observed minimum value of *varname*.

Specify `start()` when you are concerned about sparse data, for instance, if you know that *varname* can have a value of 0, but you are concerned that 0 may not be observed.

`start(#)`, if specified, must be less than or equal to  $m$ , or else an error will be issued.

### Options for use in the discrete case

Main

`discrete` specifies that *varname* is discrete and that you want each unique value of *varname* to have its own bin (bar of histogram).

`width(#)` is rarely specified in the discrete case; it specifies the width of the bins. The default is `width(d)`, where  $d$  is the observed minimum difference between the unique values of *varname*.

Specify `width()` if you are concerned that your data are sparse. For example, in theory *varname* could take on the values, say, 1, 2, 3, ..., 9, but because of the sparseness, perhaps only the values 2, 4, 7, and 8 are observed. Here the default width calculation would produce `width(2)`, and you would want to specify `width(1)`.

`start(#)` is also rarely specified in the discrete case; it specifies the theoretical minimum value of *varname*. The default is `start(m)`, where  $m$  is the observed minimum value.

As with `width()`, specify `start(#)` if you are concerned that your data are sparse. In the previous example, you might also want to specify `start(1)`. `start()` does nothing more than add white space to the left side of the graph.

The value of  $\#$  in `start()` must be less than or equal to  $m$ , or an error will be issued.

**Options for use in the continuous and discrete cases**

## Main

`density`, `fraction`, `frequency`, and `percent` specify whether you want the histogram scaled to density units, fractional units, frequencies, or percentages. `density` is the default.

`density` scales the height of the bars so that the sum of their areas equals 1.

`fraction` scales the height of the bars so that the sum of their heights equals 1.

`frequency` scales the height of the bars so that each bar's height is equal to the number of observations in the category. Thus the sum of the heights is equal to the total number of observations.

`percent` scales the height of the bars so that the sum of their heights equals 100.

*bar\_options* are any of the options allowed by `graph twoway bar`; see [G-2] **graph twoway bar**.

One of the most useful *bar\_options* is `barwidth(#)`, which specifies the width of the bars in *varname* units. By default, `histogram` draws the bars so that adjacent bars just touch. If you want gaps between the bars, do not specify `histogram`'s `width()` option—which would change how the histogram is calculated—but specify the *bar\_option* `barwidth()` or the `histogram` option `gap`, both of which affect only how the bar is rendered.

The *bar\_option* `horizontal` cannot be used with the `addlabels` option.

`binrescale` specifies that bin size and plot range be recalculated for each group when `by()` is specified. If `normal` is specified, the mean and standard deviation of each overlaid normal density plot are recalculated in each group. Similarly, if `kdensity` is specified, the scaling of the overlaid kernel density plot is recalculated in each group.

`addlabels` specifies that the top of each bar be labeled with the density, fraction, or frequency, as determined by the `density`, `fraction`, and `frequency` options.

`addlabopts(marker_label_options)` specifies how to render the labels atop the bars. See [G-3] **marker\_label\_options**. Do not specify the *marker\_label\_option* `mlabel(varname)`, which specifies the variable to be used; this is specified for you by `histogram`.

`addlabopts()` will accept more options than those documented in [G-3] **marker\_label\_options**. All options allowed by `twoway scatter` are also allowed by `addlabopts()`; see [G-2] **graph twoway scatter**. One particularly useful option is `yvarformat()`; see [G-3] **advanced\_options**.

## Density plots

`normal` specifies that the histogram be overlaid with an appropriately scaled normal density. The normal will have the same mean and standard deviation as the data.

`normopts(line_options)` specifies details about the rendition of the normal curve, such as the color and style of line used. See [G-2] **graph twoway line**.

`kdensity` specifies that the histogram be overlaid with an appropriately scaled kernel density estimate of the density. By default, the estimate will be produced using the Epanechnikov kernel with an “optimal” half-width. This default corresponds to the default of `kdensity`; see [R] **kdensity**. How the estimate is produced can be controlled using the `kdenopts()` option described below.

`kdenopts(kdensity_options)` specifies details about how the kernel density estimate is to be produced along with details about the rendition of the resulting curve, such as the color and style of line used; see [G-2] **graph twoway kdensity**. The kernel density estimate is described in [R] **kdensity**. As an example, if you wanted to produce kernel density estimates by using the Gaussian kernel with

optimal half-width, you would specify `kdenopts(gauss)` and if you also wanted a half-width of 5, you would specify `kdenopts(gauss width(5))`.

Add plots

`addplot(plot)` allows adding more graph twoway plots to the graph; see [G-3] [addplot\\_option](#).

Y axis, X axis, Titles, Legend, Overall, By

`tway_options` are any of the options documented in [G-3] [twoway\\_options](#). This includes, most importantly, options for titling the graph (see [G-3] [title\\_options](#)), options for saving the graph to disk (see [G-3] [saving\\_option](#)), and the `by()` option, which will allow you to simultaneously graph histograms for different subsets of the data (see [G-3] [by\\_option](#)).

## Remarks and examples

Remarks are presented under the following headings:

- [Histograms of continuous variables](#)
- [Overlaying normal and kernel density estimates](#)
- [Histograms of discrete variables](#)
- [Use with by\(\)](#)
- [Video example](#)

For an example of editing a histogram with the Graph Editor, see [Pollock \(2011, 29–31\)](#).

## Histograms of continuous variables

`histogram` assumes that the variable is continuous, so you need type only `histogram` followed by the variable name:

```
. use https://www.stata-press.com/data/r18/sp500
(S&P 500)
. histogram volume
(bin=15, start=4103, width=1280.3533)
```

The small values reported for density on the *y* axis are correct; if you added up the area of the bars, you would get 1. Nevertheless, many people are used to seeing histograms scaled so that the bar heights sum to 1,

```
. histogram volume, fraction  
(bin=15, start=4103, width=1280.3533)
```

and others are used to seeing histograms so that the bar height reflects the number of observations,

```
. histogram volume, frequency  
(bin=15, start=4103, width=1280.3533)
```

Regardless of the scale you prefer, you can specify other options to make the graph look more impressive:

```
. summarize volume
Variable | Obs      Mean      Std. dev.   Min      Max
-----|-----
volume  | 248     12320.68  2585.929   4103     23308.3

. histogram volume, freq
>   xaxis(1 2)
>   ylabel(0(10)60)
>   xlabel(12321 "mean"
>         9735 "-1 s.d."
>         14907 "+1 s.d."
>         7149 "-2 s.d."
>         17493 "+2 s.d."
>         20078 "+3 s.d."
>         22664 "+4 s.d."
>                                     , axis(2) grid)
>   xlabel(, axis(1) nogrid)
>   xtitle("", axis(2))
>   subtitle("S&P 500, January 2001 to December 2001")
>   note("Source: Yahoo! Finance and Commodity Systems, Inc.")
(bin=15, start=4103, width=1280.3533)
```

For an explanation of the `xaxis()` option—it created the upper and lower  $x$  axis—see [G-3] [axis\\_choice\\_options](#). For an explanation of the `ylabel()` and `xlabel()` options, see [G-3] [axis\\_label\\_options](#). For an explanation of the `subtitle()` and `note()` options, see [G-3] [title\\_options](#).

## Overlaying normal and kernel density estimates

Specifying `normal` will overlay a normal density over the histogram. It would be enough to type

```
. histogram volume, normal
```

but we will add the option to our more impressive rendition:

```
. summarize volume
Variable | Obs      Mean      Std. dev.   Min      Max
-----|-----
volume  | 248     12320.68  2585.929   4103     23308.3
```

```

. histogram volume, freq normal
>     xaxis(1 2)
>     ylabel(0(10)60)
>     xlabel(12321 "mean"
>           9735 "-1 s.d."
>           14907 "+1 s.d."
>           7149 "-2 s.d."
>           17493 "+2 s.d."
>           20078 "+3 s.d."
>           22664 "+4 s.d."
>
>           , axis(2) grid)
>     xlabel(, axis(1) nogrid)
>     xtitle("", axis(2))
>     subtitle("S&P 500, January 2001 to December 2001")
>     note("Source: Yahoo! Finance and Commodity Systems, Inc.")
(bin=15, start=4103, width=1280.3533)

```

If we instead wanted to overlay a kernel density estimate, we could specify `kdensity` in place of `normal`.

## Histograms of discrete variables

Specify `histogram`'s discrete option when you wish to treat the data as discrete—when you wish each unique value of the variable to be assigned its own bin. For instance, in the automobile data, `mpg` is a continuous variable, but the mileage ratings have been measured to integer precision. If we were to type

```

. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. histogram mpg
(bin=8, start=12, width=3.625)

```

`mpg` would be treated as continuous and categorized into eight bins by the default number-of-bins calculation, which is based on the number of observations, 74.

Adding the `discrete` option makes a histogram with a bin for each of the 21 unique values.

```
. histogram mpg, discrete
(start=12, width=1)
```

Just as in the continuous case, the  $y$  axis was reported in density, and we could specify the `fraction` or `frequency` options if we wanted it to be reported differently. Below, we specify `frequency`, we specify `addlabels` to add a report of frequencies printed above the bars, and we specify `xlabel(12(2)42)` to label the values 12, 14, ..., 42 on the  $x$  axis:

```
. histogram mpg, discrete freq addlabels xlabel(12(2)42)
(start=12, width=1)
```

**Use with by()**

histogram may be used with graph twoway's by(); for example,

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. histogram mpg, discrete by(foreign)
```

Here results would be easier to compare if the graphs were presented in one column:

```
. histogram mpg, discrete by(foreign, col(1))
```

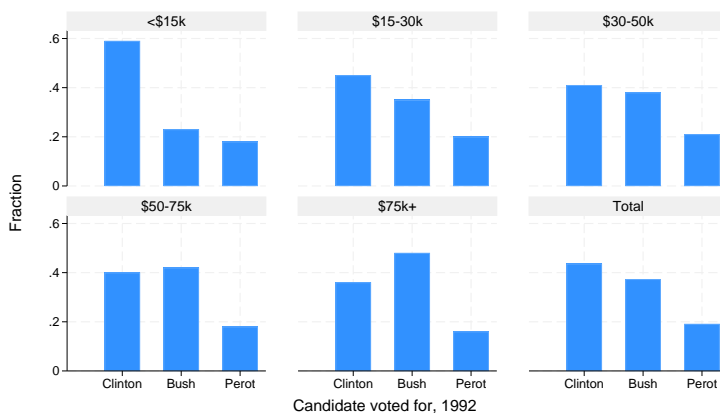

col(1) is a by() suboption—see [G-3] *by\_option*—and there are other useful suboptions, such as total, which will add an overall total histogram. total is a suboption of by(), not an option of histogram, so you would type

```
. histogram mpg, discrete by(foreign, total)
```

and not histogram mpg, discrete by(foreign) total.

As another example, [Lipset \(1993\)](#) reprinted data from the *New York Times* (November 5, 1992) collected by the Voter Research and Surveys based on questionnaires completed by 15,490 U.S. presidential voters from 300 polling places on election day in 1992.

```
. use https://www.stata-press.com/data/r18/voter
(1992 U.S. presidential voters)
. histogram candi [fweight=pop], discrete fraction by(inc, total)
> gap(40) xlabel(2 3 4, valuelabel)
```

Graphs by Family income

Candidate voted for, 1992

We specified `gap(40)` to reduce the width of the bars by 40%. We also used `xlabel()`'s `valuelabel` suboption, which caused our bars to be labeled “Clinton”, “Bush”, and “Perot”, rather than 2, 3, and 4; see [\[G-3\] axis\\_label\\_options](#).

## Description

This entry discusses a statistical issue that arises when using the Bayesian (BIC), consistent Akaike's (CAIC), and corrected Akaike's (AICc) information criteria to compare models.

Stata calculates BIC, CAIC, and AICc using  $N = e(N)$ , unless `e(N_ic)` has been set; in that instance, it uses  $N = e(N\_ic)$ . For example, choice-model `cm` commands set `e(N_ic)` to the number of cases because these commands use a data arrangement in which multiple Stata observations represent a single statistical observation, which is called a case.

Sometimes, it would be better if a different  $N$  than  $e(N)$  were used. Commands that calculate BIC, CAIC, and AICc have an `n()` option, allowing you to specify the  $N$  to be used.

In summary,

1. if you are comparing results estimated by the same estimation command, using the default BIC, CAIC, or AICc calculation is probably fine. There is an issue, but most researchers would ignore it.
2. if you are comparing results estimated by different estimation commands, you need to be on your guard.
  - a. If the different estimation commands share the same definitions of observations, independence, and the like, you are back to case 1.
  - b. If they differ in these regards, you need to think about the value of  $N$  that should be used. For example, `logit` and `xtlogit` differ in that the former assumes independent observations and the latter, independent panels.
  - c. If estimation commands differ in the events being used over which the likelihood function is calculated, the information criteria may not be comparable at all. We say information *criteria* because this would apply equally to the Akaike information criterion (AIC) and its possible extensions AICc and CAIC, as well as to the BIC. For instance, `streg` and `stcox` produce such incomparable results. The events used by `streg` are the actual survival times, whereas the events used by `stcox` are failures within risk pools, conditional on the times at which failures occurred.

## Remarks and examples

Remarks are presented under the following headings:

*Background*

*The problem of determining  $N$*

*The problem of conformable likelihoods*

*The first problem does not arise with AIC; the second problem does  
Calculating BIC, AICc, and CAIC correctly*

## Background

The AIC and the BIC are two popular measures for comparing maximum likelihood models. AIC and BIC are defined as

$$\text{AIC} = -2 \ln L + 2k$$

$$\text{BIC} = -2 \ln L + k \ln N$$

where

$\ln L$  = maximized log-likelihood

$k$  = number of parameters estimated

$N$  = number of observations

However, when sample size is small, AIC is biased, and [Burnham and Anderson \(2002\)](#) suggest to use AICc,

$$\text{AICc} = \text{AIC} + \frac{2k(k+1)}{N-k-1}$$

CAIC is a consistent version of AIC and was proposed in [Bozdogan \(1987\)](#),

$$\text{CAIC} = -2 \ln L + k(\ln N + 1)$$

All four information criteria—AIC, BIC, CAIC, and AICc—can be viewed as measures that combine fit and complexity. Fit is measured negatively by  $-2 \ln L$ ; the larger the value, the worse the fit. Complexity is measured positively, for example, by  $2k$  (AIC) or  $k \ln N$  (BIC).

Given two models fit on the same data, the model with the smaller value of the information criterion is considered to be better.

There is substantial literature on these measures: see [Akaike \(1974\)](#); [Raftery \(1995\)](#); [Sakamoto, Ishiguro, and Kitagawa \(1986\)](#); [Schwarz \(1978\)](#); [Burnham and Anderson \(2002\)](#); and [Hurvich and Tsai \(1989\)](#).

When Stata calculates the above measures, it uses the rank of  $\mathbf{e}(V)$  for  $k$ , and it uses  $\mathbf{e}(N)$  for  $N$ .  $\mathbf{e}(V)$  and  $\mathbf{e}(N)$  are Stata notation for results stored by the estimation command.  $\mathbf{e}(V)$  is the variance–covariance matrix of the estimated parameters, and  $\mathbf{e}(N)$  is the number of observations in the dataset used in calculating the result.

## The problem of determining N

The difference between AIC and the other three information criteria is that AIC uses the constant 2 to weight  $k$ , whereas the complexity term for BIC, CAIC, and AICc depends on  $N$ .

Determining what value of  $N$  should be used is problematic. Despite appearances, the definition “ $N$  is the number of observations” is not easy to make operational.  $N$  does not appear in the likelihood function itself,  $N$  is not the output of a standard statistical formula, and what is an observation is often subjective.

## ▷ Example 1

Often what is meant by  $N$  is obvious. Consider a simple logit model. What is meant by  $N$  is the number of observations that is statistically independent and that corresponds to  $M$ , the number of observations in the dataset used in the calculation. We will write  $N = M$ .

But now assume that the same dataset has a grouping variable and the data are thought to be clustered within group. To keep the problem simple, let's pretend that there are  $G$  groups and  $m$  observations within group, so that  $M = G \times m$ . Because you are worried about intragroup correlation, you fit your model with `xtlogit`, grouping on the grouping variable. Now, you wish to calculate BIC. What is the  $N$  that should be used?  $N = M$  or  $N = G$ ?

That is a deep question. If the observations really are independent, then you should use  $N = M$ . If the observations within group are not just correlated but are duplicates of one another, and they had to be so, then you should use  $N = G$  (Kass and Raftery 1995). Between those two extremes, you should probably use a number between  $N$  and  $G$ , but determining what that number should be from measured correlations is difficult. Using  $N = M$  is conservative in that, if anything, it overweights complexity. Conservativeness, however, is subjective, too: using  $N = G$  could be considered more conservative in that fewer constraints are being placed on the data.

When the estimated correlation is high, our reaction would be that using  $N = G$  is probably more reasonable. Our first reaction, however, would be that using BIC to compare models is probably a misuse of the measure.

Stata uses  $N = M$ . An informal survey of web-based literature suggests that  $N = M$  is the popular choice.

There is another reason, not so good, to choose  $N = M$ . It makes across-model comparisons more likely to be valid when performed without thinking about the issue. Say that you wish to compare the `logit` and `xtlogit` results. Thus, you need to calculate

$$\text{BIC}_p = -2 \ln L_p + k \ln N_p$$

$$\text{BIC}_x = -2 \ln L_x + k \ln N_x$$

Whatever  $N$  you use, you must use the same  $N$  in both formulas. Stata's choice of  $N = M$  at least meets that test.

◀

## ▷ Example 2

In the above example, using  $N = M$  is reasonable. Now, let's look at when using  $N = M$  is wrong, even if popular.

Consider a model fit by `stcox`. Using  $N = M$  is certainly wrong if for no other reason than  $M$  is not even a well-defined number. The same data can be represented by different datasets with different numbers of observations. For example, in one dataset, there might be one observation per subject. In another, the same subjects could have two records each, the first recording the first half of the time at risk and the second recording the remaining part. All statistics calculated by Stata on either dataset would be the same, but  $M$  would be different.

Deciding on the right definition, however, is difficult. Viewed one way,  $N$  in the Cox regression case should be the number of risk pools,  $R$ , because the Cox regression calculation is made on the basis of the independent risk pools. Viewed another way,  $N$  should be the number of subjects,  $N_{\text{subj}}$ , because, even though the likelihood function is based on risk pools, the parameters estimated are at the subject level.

You can decide which argument you prefer.

For parametric survival models, in single-record data,  $N = M$  is unambiguously correct. For multirecord data, there is an argument for  $N = M$  and for  $N = N_{\text{subj}}$ .

◀

## The problem of conformable likelihoods

The problem of conformable likelihoods does not concern  $N$ . Researchers sometimes use information criteria such as BIC and AIC to make comparisons across models. For that to be valid, the likelihoods must be conformable; that is, the likelihoods must all measure the same thing.

It is common to think of the likelihood function as the  $\text{Pr}(\text{data} \mid \text{parameters})$ , but in fact, the likelihood is

$$\text{Pr}(\text{particular events in the data} \mid \text{parameters})$$

You must ensure that the events are the same.

For instance, they are not the same in the semiparametric Cox regression and the various parametric survival models. In Cox regression, the events are, at each failure time, that the subjects observed to fail in fact failed, given that failures occurred at those times. In the parametric models, the events are that each subject failed exactly when the subject was observed to fail.

The formula for AIC, AICc, CAIC, and BIC can be written as

$$\text{measure} = -2 \ln L + \text{complexity}$$

When you are comparing models, if the likelihoods are measuring different events, even if the models obtain estimates of the same parameters, differences in the information measures are irrelevant.

## The first problem does not arise with AIC; the second problem does

Regardless of model, the problem of defining  $N$  never arises with AIC because  $N$  is not used in the AIC calculation. AIC uses a constant 2 to weight complexity as measured by  $k$ , rather than  $\ln N$ .

However, for all four information criteria—AIC, AICc, CAIC, and BIC—the likelihood functions must be conformable; that is, they must be measuring the same event.

## Calculating BIC, AICc, and CAIC correctly

When using BIC, AICc, or CAIC to compare results, and especially when using them to compare results from different models, you should think carefully about how  $N$  should be defined. Then, specify that number by using the `n()` option:

```
. estimates stats full sub, all n(74)
```

```
Information criteria
```

Model	N	ll(null)	ll(model)	df
full	74	-45.03321	-20.59083	4
sub	74	-45.03321	-27.17516	3

Model	AIC	BIC	AICc	CAIC
full	49.18167	58.39793	49.76138	62.39793
sub	60.35031	67.26251	60.69317	70.26251

Legend: AIC is Akaike's information criterion.

BIC is Bayesian information criterion.

AICc is corrected Akaike's information criterion.

CAIC is consistent Akaike's information criterion.

Both `estimates stats` and `estat ic` allow the `n()` option; see [\[R\] estimates stats](#) and [\[R\] estat ic](#).

## Methods and formulas

AIC, BIC, CAIC, and AICc are defined as

$$\text{AIC} = -2 \ln L + 2k$$

$$\text{BIC} = -2 \ln L + k \ln N$$

$$\text{CAIC} = -2 \ln L + k(\ln N + 1)$$

$$\text{AICc} = \text{AIC} + \frac{2k(k+1)}{N-k-1}$$

where  $\ln L$  is the maximized log-likelihood of the model;  $k$  is the model degrees of freedom calculated as the rank of variance-covariance matrix of the parameters  $e(V)$ , unless the `df()` option is specified; and  $N$  is the number of observations used in estimation or, more precisely, the number of independent terms in the likelihood. Operationally,  $N$  is defined as  $e(N)$ , unless the estimation command returns `e(N_ic)` or the `n()` option is specified with `estimates stats` or `estat ic`.

## Description

`icc` estimates intraclass correlations for one-way random-effects models, two-way random-effects models, or two-way mixed-effects models for both individual and average measurements. Intraclass correlations measuring consistency of agreement or absolute agreement of the measurements may be estimated.

## Quick start

Individual and average absolute-agreement intraclass correlation coefficients (ICCs) for ratings `y` of targets identified by `tid` in a one-way random-effects model

```
icc y tid
```

Same as above, but test that the individual and average ICCs are equal to 0.5

```
icc y tid, testvalue(.5)
```

Absolute-agreement ICCs for targets identified by `tid` and raters identified by `rid` in a two-way random-effects model

```
icc y tid rid
```

Same as above, but estimate consistency-of-agreement ICCs

```
icc y tid rid, consistency
```

Consistency-of-agreement ICCs when estimating random effects for targets and fixed effects for raters in a mixed-effects model

```
icc y tid rid, mixed
```

Same as above, but estimate absolute-agreement ICCs

```
icc y tid rid, mixed absolute
```

Same as above, but report 90% confidence intervals and test that ICCs are equal to 0.3

```
icc y tid rid, mixed absolute level(90) testvalue(.3)
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Intraclass correlations

## Syntax

Calculate intraclass correlations for one-way random-effects model

```
icc depvar target [if] [in] [, oneway_options]
```

Calculate intraclass correlations for two-way random-effects model

```
icc depvar target rater [if] [in] [, twoway_re_options]
```

Calculate intraclass correlations for two-way mixed-effects model

```
icc depvar target rater [if] [in], mixed [twoway_me_options]
```

<i>oneway_options</i>	Description
Main	
<u>absolute</u>	estimate absolute agreement; the default
<u>testvalue</u> (#)	test whether intraclass correlations equal #; default is <code>testvalue(0)</code>
Reporting	
<u>level</u> (#)	set confidence level; default is <code>level(95)</code>
<u>format</u> (% <i>fmt</i> )	display format for statistics and confidence intervals; default is <code>format(%9.0g)</code>

<i>twoway_re_options</i>	Description
Main	
<u>absolute</u>	estimate absolute agreement; the default
<u>consistency</u>	estimate consistency of agreement
<u>testvalue</u> (#)	test whether intraclass correlations equal #; default is <code>testvalue(0)</code>
Reporting	
<u>level</u> (#)	set confidence level; default is <code>level(95)</code>
<u>format</u> (% <i>fmt</i> )	display format for statistics and confidence intervals; default is <code>format(%9.0g)</code>

<i>twoway_me_options</i>	Description
Main	
* <b>mixed</b>	estimate intraclass correlations for a mixed-effects model
<b>consistency</b>	estimate consistency of agreement; the default
<b>absolute</b>	estimate absolute agreement
<b>testvalue</b> (#)	test whether intraclass correlations equal #; default is <b>testvalue</b> (0)
Reporting	
<b>level</b> (#)	set confidence level; default is <b>level</b> (95)
<b>format</b> (% <i>fmt</i> )	display format for statistics and confidence intervals; default is <b>format</b> (%9.0g)

\* **mixed** is required.

**bootstrap**, **by**, **collect**, **jackknife**, and **statsby** are allowed; see [U] 11.1.10 **Prefix commands**.

## Options for one-way RE model

### Main

**absolute** specifies that intraclass correlations measuring absolute agreement of the measurements be estimated. This is the default for random-effects models.

**testvalue**(#) tests whether intraclass correlations equal #. The default is **testvalue**(0).

### Reporting

**level**(#) specifies the confidence level, as a percentage, for confidence intervals. The default is **level**(95) or as set by **set level**; see [R] **level**.

**format**(%*fmt*) specifies how the intraclass correlation estimates and confidence intervals are to be formatted. The default is **format**(%9.0g).

## Options for two-way RE and ME models

### Main

**mixed** is required to calculate two-way mixed-effects models. **mixed** specifies that intraclass correlations for a mixed-effects model be estimated.

**absolute** specifies that intraclass correlations measuring absolute agreement of the measurements be estimated. This is the default for random-effects models. Only one of **absolute** or **consistency** may be specified.

**consistency** specifies that intraclass correlations measuring consistency of agreement of the measurements be estimated. This is the default for mixed-effects models. Only one of **absolute** or **consistency** may be specified.

**testvalue**(#) tests whether intraclass correlations equal #. The default is **testvalue**(0).

## Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [R] [level](#).

`format(%fmt)` specifies how the intraclass correlation estimates and confidence intervals are to be formatted. The default is `format(%9.0g)`.

## Remarks and examples

Remarks are presented under the following headings:

*Introduction*

*One-way random effects*

*Two-way random effects*

*Two-way mixed effects*

*Adoption study*

*Relationship between ICCs*

*Tests against nonzero values*

## Introduction

In some disciplines, such as psychology and sociology, data are often measured with error that can seriously affect statistical interpretation of the results. Thus, it is important to assess the amount of measurement error by evaluating the consistency or reliability of measurements. The intraclass correlation coefficient (ICC) is often used to measure the consistency or homogeneity of measurements.

Several versions of ICCs are introduced in the literature depending on the experimental design and goals of the study (see, for example, [Shrout and Fleiss \[1979\]](#) and [McGraw and Wong \[1996a\]](#)). Following [Shrout and Fleiss \(1979\)](#), we describe various forms of ICCs in the context of a reliability study of ratings of different targets (or objects of measurements) by several raters.

Consider  $n$  targets (for example, students, patients, athletes) that are randomly sampled from a population of interest. Each target is rated independently by a set of  $k$  raters (for example, teachers, doctors, judges). One rating per target and rater is obtained. It is of interest to determine the extent of the agreement of the ratings.

As noted by [Shrout and Fleiss \(1979\)](#) and [McGraw and Wong \(1996a\)](#), you need to answer several questions to decide what version of ICC is appropriate to measure the agreement in your study:

1. Is a one-way or two-way analysis-of-variance model appropriate for your study?
2. Are differences between raters' mean ratings relevant to the reliability of interest?
3. Is the unit of analysis an individual rating or the mean rating over several raters?
4. Is the consistency of agreement or the absolute agreement of ratings of interest?

Three types of analysis-of-variance models are considered for the reliability study: one-way random effects, two-way random effects, and two-way mixed effects. Mixed models contain both fixed effects and random effects. In the one-way random-effects model, each target is rated by a different set of  $k$  independent raters, who are randomly drawn from the population of raters. The target is the only random effect in this model; the effects due to raters and possibly due to rater-and-target interaction cannot be separated from random error. In the two-way random-effects model, each target is rated by the same set of  $k$  independent raters, who are randomly drawn from the population of raters. The random effects in this model are target and rater and possibly their interaction, although in the absence of repeated measurements for each rater on each target, the effect of an interaction cannot be separated from random error. In the two-way mixed-effects model, each target is rated by the

same set of  $k$  independent raters. Because they are the only raters of interest, rater is a fixed effect. The random effects are target and possibly target-and-rater interaction, but again the interaction effect cannot be separated from random error without repeated measurements for each rater and target. The definition of ICC depends on the chosen random-effects model; see *Methods and formulas* for details.

In summary, use a one-way model if there are no systematic differences in measurements due to raters and use a two-way model otherwise. If you want to generalize your results to a population of raters from which the observed raters are sampled, use a two-way random-effects model, treating raters as random. If you are interested only in the effects of the observed  $k$  raters, use a two-way mixed-effects model, treating raters as fixed. For example, suppose you compare judges' ratings of targets from different groups. If you use the combined data from  $k$  judges to compare the groups, the random-effects model is appropriate. If you compare groups separately for each judge and then pool the differences, the mixed-effects model is appropriate.

The definition of ICC also depends on the unit of analysis in a study—whether the agreement is measured between individual ratings (individual ICC) or between the averages of ratings over several raters (average ICC). The data on individual ratings are more common. The data on average ratings are typically used when individual ratings are deemed unreliable. The average ICC can also be used when teams of raters are used to rate a target. For example, the ratings of teams of physicians may be evaluated in this manner. When the unit of analysis is an average rating, you should remember that the interpretation of ICC pertains to average ratings and not individual ratings.

Finally, depending on whether consistency of agreement or absolute agreement is of interest, two types of ICC are used: consistency-of-agreement ICC (CA-ICC) and absolute-agreement ICC (AA-ICC). Under consistency of agreement, the scores are considered consistent if the scores from any two raters differ by the same constant value for all targets. This implies that raters give the same ranking to all targets. Under absolute agreement, the scores are considered in absolute agreement if the scores from all raters match exactly.

For example, suppose we observe three targets and two raters. The ratings are (2,4), (4,6), and (6,8), with rater 1 giving the scores (2,4,6) and rater 2 giving the scores (4,6,8), two points higher than rater 1. The CA-ICC between individual ratings is 1 because the scores from rater 1 and rater 2 differ by a constant value (two points) for all targets. That rater 1 gives lower scores than rater 2 is deemed irrelevant under the consistency measure of agreement. The raters have the same difference of opinion on every target, and the variation between raters that is caused by this difference is not relevant. On the other hand, the AA-ICC between individual ratings is  $8/12 = 0.67$ , where 8 is the estimated between-target variance and 12 is the estimated total variance of ratings.

Either CA-ICC or AA-ICC can serve as a useful measure of agreement depending on whether rater variability is relevant for determining the degree of agreement. As McGraw and Wong (1996a) point out, CA-ICC is useful when comparative judgments are made about objects of measurement. The CA-ICC represents correlation when the rater is fixed; the AA-ICC represents correlation when the rater is random.

See Shrout and Fleiss (1979) and McGraw and Wong (1996a) for more detailed guidelines about the choice of appropriate ICC.

Shrout and Fleiss (1979) and McGraw and Wong (1996a) describe 10 versions of ICCs based on the concepts above: individual and average AA-ICCs for a one-way model (consistency of agreement is not defined for this model); individual and average AA-ICCs and CA-ICCs for a two-way random-effects model; and individual and average AA-ICCs and CA-ICCs for a two-way mixed-effects model. Although each of these ICCs has its own definition and interpretation, the estimators for some are identical, leading to the same estimates of those ICCs; see *Relationship between ICCs* and *Methods and formulas* for details.

The `icc` command calculates ICCs for each of the three analysis-of-variance models. You can use option `absolute` to compute AA-ICCs or option `consistency` to compute CA-ICCs. By default, `icc` computes ICCs corresponding to the correlation between ratings and between average ratings made on the same target: AA-ICC for a random-effects model and CA-ICC for a mixed-effects model. As pointed out by [Shrout and Fleiss \(1979\)](#), although the data on average ratings might be needed for reliability, the generalization of interest might be individuals. For this reason, `icc` reports ICCs for both units, individual and average, for each model.

In addition to estimates of ICCs, `icc` provides confidence intervals and one-sided  $F$  tests. The  $F$  test of  $H_0: \rho = 0$  versus  $H_a: \rho > 0$  is the same for the individual and average ICCs, so `icc` reports one test. This is not true, however, for nonzero null hypotheses (see [Tests against nonzero values](#) for details), so `icc` reports a separate test in this case.

The `icc` command requires data in long form; see [\[D\] reshape](#) for how to convert data in wide form to long form. The data must also be balanced and contain one observation per target and rater. For unbalanced data, `icc` omits all targets with fewer than  $k$  ratings from computation. Under one-way models,  $k$  is determined as the largest number of observed ratings for a target. Under two-way models,  $k$  is the number of unique raters. If multiple observations per target and rater are detected, `icc` issues an error.

We demonstrate the use of `icc` using datasets from [Shrout and Fleiss \(1979\)](#) and [McGraw and Wong \(1996a\)](#). In the next three sections, we use an example from table 2 of [Shrout and Fleiss \(1979\)](#) with six targets and four judges. For instructional purposes, we analyze these data under each of the three different models: one-way random effects, two-way random effects, and two-way mixed effects.

## One-way random effects

In the one-way random-effects model, we assume that the  $n$  targets being rated are randomly selected from the population of potential targets. Each is rated by a different set of  $k$  raters randomly drawn from the population of potential raters. [McGraw and Wong \(1996a\)](#) describe an example of this setting, where behavioral genetics data are used to assess familial resemblance. Family units can be viewed as “targets”, and children can be viewed as “raters”. By taking a measurement on a child of the family unit, we obtain the “rating” of the family unit by the “child-rater”. In this case, we can use ICC to assess similarity between children within a family or, in other words, assess if there is a family effect in these data.

As we mentioned in the introduction, only AA-ICC is defined for a one-way model. The consistency of agreement is not defined in this case, as each target is evaluated by a different set of raters. Thus, there is no between-rater variability in this model.

In a one-way model, the AA-ICC corresponds to the correlation coefficient between ratings within a target. It is also a ratio of the between-target variance of ratings to the total variance of ratings, the sum of the between-target and error variances.

### ► Example 1: One-way random-effects ICCs

Consider data from table 2 of [Shrout and Fleiss \(1979\)](#) stored in `judges.dta`. The data contain 24 ratings of  $n = 6$  targets by  $k = 4$  judges. We list the first eight observations:

```
. use https://www.stata-press.com/data/r18/judges
(Ratings of targets by judges)
. list in 1/8, sepby(target)
```

	rating	target	judge
1.	9	1	1
2.	2	1	2
3.	5	1	3
4.	8	1	4
5.	6	2	1
6.	1	2	2
7.	3	2	3
8.	2	2	4

For a moment, let's ignore that targets are rated by the same set of judges. Instead, we assume that a different set of four judges is used to rate each target. In this case, the only systematic variation in the data is due to targets, so the one-way random-effects model is appropriate.

We use `icc` to estimate the intraclass correlations for these data. To compute ICCs for a one-way model, we specify the dependent variable `rating` followed by the target variable `target`:

```
. icc rating target
Intraclass correlations
One-way random-effects model
Absolute agreement
Random effects: target          Number of targets =      6
                                Number of raters   =      4
```

	rating	ICC	[95% conf. interval]	
Individual		.1657418	-.1329323	.7225601
Average		.4427971	-.8844422	.9124154

```
F test that
ICC=0.00: F(5.0, 18.0) = 1.79          Prob > F = 0.165
```

```
Note: ICCs estimate correlations between individual measurements
and between average measurements made on the same target.
```

`icc` reports the AA-ICCs for both individual and average ratings. The individual AA-ICC corresponds to  $ICC(1)$  in McGraw and Wong (1996a) or  $ICC(1,1)$  in Shrout and Fleiss (1979). The average AA-ICC corresponds to  $ICC(k)$  in McGraw and Wong (1996a) or  $ICC(1,k)$  in Shrout and Fleiss (1979).

The estimated correlation between individual ratings is 0.17, indicating little similarity between ratings within a target, low reliability of individual target ratings, or no target effect. The estimated intraclass correlation between ratings averaged over  $k = 4$  judges is higher, 0.44. (The average ICC will typically be higher than the individual ICC.) The estimated intraclass correlation measures the similarity or reliability of mean ratings from groups of four judges. We do not have statistical evidence that either ICC is different from zero based on reported confidence intervals and the one-sided  $F$  test.

Note that although the estimates of ICCs cannot be negative in this setting, the lower bound of the computed confidence interval may be negative. A common ad-hoc way of handling this is to truncate the lower bound at zero.

The estimates of both the individual and the average AA-ICC are also computed by the `loneaway` command (see [R] [loneaway](#)), which performs a one-way analysis of variance.

## □ Technical note

Mean rating is commonly used when individual rating is unreliable because the reliability of a mean rating is always higher than the reliability of the individual rating when the individual reliability is positive.

In the [previous example](#), we estimated low reliability of the individual ratings of a target, 0.17. The reliability increased to 0.44 for the ratings averaged over four judges. What if we had more judges?

We can use the Spearman–Brown formula ([Spearman 1910](#); [Brown 1910](#)) to compute the  $m$ -average ICC based on the individual ICC:

$$\text{ICC}(m) = \frac{m\text{ICC}(1)}{1 + (m - 1)\text{ICC}(1)}$$

Using this formula for the previous example, we find that the mean reliability over, say, 10 judges is  $10 \times 0.17 / (1 + 9 \times 0.17) = 0.67$ .

Alternatively, we can invert the Spearman–Brown formula to determine the number of judges (or the number of ratings of a target) we need to achieve the desired reliability. Suppose we would like an average reliability of 0.9, then

$$m = \frac{\text{ICC}(m)\{1 - \text{ICC}(1)\}}{\text{ICC}(1)\{1 - \text{ICC}(m)\}} = \frac{0.9(1 - 0.17)}{0.17(1 - 0.9)} = 44$$

See, for example, [Bliese \(2000\)](#) for other examples.

□

## Two-way random effects

As before, we assume that the targets being rated are randomly selected from the population of potential targets. We now also assume that each target is evaluated by the same set of  $k$  raters, who have been randomly sampled from the population of raters. In this scenario, we want to generalize our findings to the population of raters from which the observed  $k$  raters were sampled. For example, suppose we want to estimate the reliability of doctors' evaluations of patients with a certain condition. Unless the reliability at a specific hospital is of interest, the doctors may be interchanged with others in the relevant population of doctors.

As for a one-way model, the AA-ICC corresponds to the correlation between measurements on the same target and is also a ratio of the between-target variance to the total variance of measurements in a two-way random-effects model. The total variance is now the sum of the between-target, between-rater, and error variances. Unlike a one-way model, the CA-ICC can be computed for a two-way random-effects model when the consistency of agreement is of interest rather than the absolute agreement. The CA-ICC is also the ratio of the between-target variance to the total variance, but the total variance does not include the between-rater variance because the between-rater variability is irrelevant for the consistency of agreement.

Again, the two versions, individual and average, are available for each ICC.

## ▷ Example 2: Two-way random-effects ICCs

Continuing with [example 1](#), recall that we previously ignored that each target is rated by the same set of four judges and instead assumed different sets of judges. We return to the original data setting. We want to evaluate the agreement between judges' ratings of targets in a population represented by the observed set of four judges.

In a two-way model, we must specify both the target and the rater variables. In `icc`, we now additionally specify the rater variable `judge` following the target variable `target`; the random-effects model is assumed by default.

```
. icc rating target judge
Intraclass correlations
Two-way random-effects model
Absolute agreement
Random effects: target      Number of targets =      6
Random effects: judge      Number of raters =      4
```

rating	ICC	[95% conf. interval]	
Individual	.2897638	.0187865	.7610844
Average	.6200505	.0711368	.927232

```
F test that
ICC=0.00: F(5.0, 15.0) = 11.03      Prob > F = 0.000
```

```
Note: ICCs estimate correlations between individual measurements
and between average measurements made on the same target.
```

As for a one-way random-effects model, `icc` by default reports AA-ICCs that correspond to the correlation between ratings on a target. Notice that both individual and average ICCs are larger in the two-way random-effects model than in the previous one-way model—0.29 versus 0.17 and 0.62 versus 0.44, respectively. We also have statistical evidence to reject the null hypothesis that neither ICC is zero based on confidence intervals and the  $F$  test. If a one-way model is used when a two-way model is appropriate, the true ICC will generally be underestimated.

The individual AA-ICC corresponds to  $ICC(A,1)$  in [McGraw and Wong \(1996a\)](#) or  $ICC(2,1)$  in [Shrout and Fleiss \(1979\)](#). The average AA-ICC corresponds to  $ICC(A,k)$  in [McGraw and Wong \(1996a\)](#) or  $ICC(2,k)$  in [Shrout and Fleiss \(1979\)](#).

Instead of the absolute agreement, we can also assess the consistency of agreement. The individual and average CA-ICCs are considered in [McGraw and Wong \(1996a\)](#) and denoted as  $ICC(C,1)$  and  $ICC(C,k)$ , respectively. These ICCs are not considered in [Shrout and Fleiss \(1979\)](#) because they are not correlations in the strict sense. Although CA-ICCs do not estimate correlation, they can provide useful information about the reliability of the raters. [McGraw and Wong \(1996a\)](#) note that the practical value of the individual and average CA-ICCs in the two-way random-effects model setting is well documented in measurement theory, citing [Hartmann \(1982\)](#) and [Suen \(1988\)](#).

To estimate the individual and average CA-ICCs, we specify the consistency option:

```
. icc rating target judge, consistency
Intraclass correlations
Two-way random-effects model
Consistency of agreement
Random effects: target      Number of targets =      6
Random effects: judge      Number of raters   =      4
```

rating	ICC	[95% conf. interval]	
Individual	.7148407	.3424648	.9458583
Average	.9093155	.6756747	.9858917

```
F test that
ICC=0.00: F(5.0, 15.0) = 11.03      Prob > F = 0.000
```

We estimate that the consistency of agreement of ratings in the considered population of raters is high, 0.71, based on the individual CA-ICC. On the other hand, the absolute agreement of ratings is low, 0.29, based on the individual AA-ICC from the previous output.

◀

The measure of consistency of agreement among means, the average CA-ICC, is equivalent to Cronbach's alpha (Cronbach 1951); see [MV] [alpha](#). The individual CA-ICC can also be equivalent to the Pearson's correlation coefficient between raters when  $k = 2$ ; see McGraw and Wong (1996a) for details.

In the next example, we will see that the actual estimates of the individual and average AA-ICCs and CA-ICCs are the same whether we examine a random-effects model or a mixed-effects model. The differences between these ICCs are in their definitions and interpretations.

## Two-way mixed effects

As in a two-way random-effects model, we assume that the targets are randomly selected from the population of potential targets and that each is evaluated by the same set of  $k$  raters. In a mixed-effects model, however, we assume that these raters are the only raters of interest. So as before, the targets are random, but now the raters are fixed.

In the two-way mixed-effects model, the fixed effect of the rater does not contribute to the between-rater random variance component to the total variance. As such, the definitions and interpretations of ICCs are different in a mixed-effects model than in a random-effects model. However, the estimates of ICCs as well as test statistics and confidence intervals are the same. The only exceptions are average AA-ICCs and CA-ICCs. These are not estimable in a two-way mixed-effects model including an interaction term between target and rater; see [Relationship between ICCs](#) and [Methods and formulas](#) for details.

In a two-way mixed-effects model, the CA-ICC corresponds to the correlation between measurements on the same target. As pointed out by Shrout and Fleiss (1979), when the rater variance is ignored, the correlation coefficient is interpreted in terms of rater consistency rather than rater absolute agreement. Formally, the CA-ICC is the ratio of the covariance between measurements on the target to the total variance of the measurements. The AA-ICC corresponds to the same ratio, but includes a variance of the fixed factor, rater, in its denominator.

### ▶ Example 3: Two-way mixed-effects ICCs

Continuing with [example 2](#), suppose that we are now interested in assessing the agreement of ratings from only the observed four judges. The judges are now fixed effects, and the appropriate model is a two-way mixed-effects model.

To estimate ICCs for a two-way mixed-effects model, we specify the mixed option with `icc`:

```
. icc rating target judge, mixed
Intraclass correlations
Two-way mixed-effects model
Consistency of agreement
Random effects: target      Number of targets =      6
Fixed effects: judge       Number of raters   =      4
```

rating	ICC	[95% conf. interval]	
Individual	.7148407	.3424648	.9458583
Average	.9093155	.6756747	.9858917

```
F test that
ICC=0.00: F(5.0, 15.0) = 11.03          Prob > F = 0.000
```

Note: ICCs estimate correlations between individual measurements and between average measurements made on the same target.

As we described in the introduction, `icc` by default reports ICCs corresponding to the correlations. So, for a mixed-effects model, `icc` reports CA-ICCs by default. The individual and average CA-ICCs are denoted as  $ICC(3,1)$  and  $ICC(3,k)$  in [Shrout and Fleiss \(1979\)](#) and  $ICC(C,1)$  and  $ICC(C,k)$  in [McGraw and Wong \(1996a\)](#).

Our estimates of the individual and average CA-ICCs are identical to the CA-ICC estimates obtained under the two-way random-effects model in [example 2](#), but our interpretation of the results is different. Under a mixed-effects model, 0.71 and 0.91 are the estimates, respectively, of the correlation between individual measurements and the correlation between average measurements made on the same target.

We can also estimate the AA-ICCs in this setting by specifying the `absolute` option:

```
. icc rating target judge, mixed absolute
Intraclass correlations
Two-way mixed-effects model
Absolute agreement
Random effects: target      Number of targets =      6
Fixed effects: judge       Number of raters   =      4
```

rating	ICC	[95% conf. interval]	
Individual	.2897638	.0187865	.7610844
Average	.6200505	.0711368	.927232

```
F test that
ICC=0.00: F(5.0, 15.0) = 11.03          Prob > F = 0.000
```

The intraclass correlation estimates match the individual and average AA-ICCs obtained under the two-way random-effects model in [example 2](#); but in a mixed-effects model, they do not represent correlations. We demonstrate the use of an individual AA-ICC in a mixed-effects setting in the next example.

The AA-ICCs under a mixed-effects model are not considered by [Shrout and Fleiss \(1979\)](#). They are denoted as  $ICC(A,1)$  and  $ICC(A,k)$  in [McGraw and Wong \(1996a\)](#).

## Adoption study

In this section, we consider the adoption study described in [McGraw and Wong \(1996a\)](#). Adoption studies commonly include two effects of interest. One is the mean difference between the adopted child and its biological parents. It is used to determine if characteristics of adopted children differ on average from those of their biological parents. Another effect of interest is the correlation between genetically paired individuals and genetically unrelated individuals who live together. This effect is used to evaluate the impact of genetic differences on individual differences.

As discussed in [McGraw and Wong \(1996a\)](#), a consistent finding from adoption research using IQ as a trait characteristic is that while adopted children typically have higher IQs than their biological parents, their IQs correlate better with those of their biological parents than with those of their adoptive parents. Both effects are important, and there is additional need to reconcile the two findings. [McGraw and Wong \(1996a\)](#) propose to use the individual AA-ICC for this purpose.

### ► Example 4: Absolute-agreement ICC in a mixed-effects model

The `adoption.dta` dataset contains the data from table 6 of [McGraw and Wong \(1996a\)](#) on IQ scores:

```
. use https://www.stata-press.com/data/r18/adoption
(Biological mother and adopted child IQ scores)
. describe
Contains data from https://www.stata-press.com/data/r18/adoption.dta
Observations:      20          Biological mother and adopted
                    child IQ scores
Variables:         5           15 May 2022 13:50
                               (_dta has notes)
```

Variable name	Storage type	Display format	Value label	Variable label
family	byte	%9.0g		Adoptive family ID
mc	byte	%9.0g	mcvalues	Whether mother or child
iq3	int	%9.0g		IQ scores, mother-child difference of 3 pts
iq9	int	%9.0g		IQ scores, mother-child difference of 9 pts
iq15	int	%9.0g		IQ scores, mother-child difference of 15 pts

Sorted by:

The `family` variable contains adoptive family identifiers, the `mc` variable records a mother or a child, and the `iq3`, `iq9`, and `iq15` variables record IQ scores with differences between mother and child mean IQ scores of 3, 9, and 15 points, respectively.

```
. by mc, sort: summarize iq*
```

```
-> mc = Mother
```

Variable	Obs	Mean	Std. dev.	Min	Max
iq3	10	97	15.0037	62	116
iq9	10	91	15.0037	56	110
iq15	10	85	15.0037	50	104

```
-> mc = Child
```

Variable	Obs	Mean	Std. dev.	Min	Max
iq3	10	100	15.0037	65	119
iq9	10	100	15.0037	65	119
iq15	10	100	15.0037	65	119

The variances of the mother and child IQ scores are the same.

Children are fixed effects, so the mixed-effects model is appropriate for these data. We want to compare individual CA-ICC with individual AA-ICC for each of the three IQ variables. We could issue a separate `icc` command for each of the three IQ variables to obtain the intraclass correlations. Instead, we use `reshape` to convert our data to long form with one `iq` variable and the new `diff` variable recording mean differences:

```
. reshape long iq, i(family mc) j(diff)
(j = 3 9 15)
```

Data	Wide	->	Long
Number of observations	20	->	60
Number of variables	5	->	4
j variable (3 values)		->	diff
xij variables:	iq3 iq9 iq15	->	iq

We can now use the `by` prefix with `icc` to estimate intraclass correlations for the three groups of interest:

```
. by diff, sort: icc iq family mc, mixed
```

```
-> diff = 3
```

```
Intraclass correlations
Two-way mixed-effects model
Consistency of agreement
```

```
Random effects: family      Number of targets =      10
Fixed effects: mc           Number of raters   =      2
```

iq	ICC	[95% conf. interval]	
Individual	.7142152	.1967504	.920474
Average	.8332853	.3288078	.9585904

```
F test that
```

```
ICC=0.00: F(9.0, 9.0) = 6.00          Prob > F = 0.007
```

```
Note: ICCs estimate correlations between individual measurements
and between average measurements made on the same target.
```

```
-> diff = 9
```

```
Intraclass correlations
Two-way mixed-effects model
Consistency of agreement
```

```
Random effects: family      Number of targets =      10
Fixed effects: mc           Number of raters   =      2
```

iq	ICC	[95% conf. interval]	
Individual	.7142152	.1967504	.920474
Average	.8332853	.3288078	.9585904

```
F test that
```

```
ICC=0.00: F(9.0, 9.0) = 6.00          Prob > F = 0.007
```

```
Note: ICCs estimate correlations between individual measurements
and between average measurements made on the same target.
```

```
-> diff = 15
```

```
(output omitted)
```

The estimated CA-ICCs are the same in all three groups and are equal to the corresponding estimates of the Pearson's correlation coefficients because mothers' and childrens' IQ scores have the same variability. The scores differ only in means, and mean differences are irrelevant when measuring the consistency of agreement.

## Relationship between ICCs

In examples 2 and 3, we saw that the estimates of AA-ICCs and CA-ICCs are the same for two-way random-effects and two-way mixed-effects models. In this section, we consider the relationship between various forms of ICCs in more detail; also see [Methods and formulas](#).

There are 10 different versions of ICCs, but only 6 different estimators are needed to compute them. These estimators include the two estimators for the individual and average AA-ICCs in a one-way model, the two estimators for the individual and average AA-ICCs in two-way models, and the two estimators for the individual and average CA-ICCs in two-way models.

Only individual and average AA-ICCs are defined for the one-way model. The estimates of AA-ICCs based on the one-way model will typically be smaller than individual and average estimates of AA-ICCs and CA-ICCs based on two-way models. The estimates of individual and average CA-ICCs will typically be larger than the estimates of individual and average AA-ICCs.

Although AA-ICCs and CA-ICCs have the same respective estimators in two-way random-effects and mixed-effects models, their definitions and interpretations are different. The AA-ICCs based on a random-effects model contain the between-rater variance component in the denominator of the variance ratio. The AA-ICCs based on a mixed-effects model contain the variance of the fixed-factor rater instead of the random between-rater variability. The AA-ICCs in a random-effects model represent correlations between any two measurements made on a target. The AA-ICCs in a mixed-effects model measure absolute agreement of measurements treating raters as fixed. The CA-ICCs for random-effects and mixed-effects models have the same definition but different interpretations. The CA-ICCs represent correlations between any two measurements made on a target in a mixed-effects model but estimate the degree of consistency among measurements treating raters as random in a random-effects model. The difference in the definitions of AA-ICCs and CA-ICCs is that CA-ICCs do not contain the between-rater variance in the denominator of the variance ratio.

For two-way models, the definitions and interpretations (but not the estimators) of ICCs also depend on whether the model contains an interaction between target and rater. For two-way models with interaction, ICCs include an additional variance component for the target-rater interaction in the denominator of the variance ratio. This component cannot be separated from random error because there is only one observation per target and rater.

Also, under a two-way mixed-effects model including interaction, the interaction components are not mutually independent, as they are in a two-way random-effects model. The considered version of the mixed-effects model places a constraint on the interaction effects—the sum of the interaction effects over levels of the fixed factor is zero; see, for example, chapter 7 in [Kuehl \(2000\)](#) for an introductory discussion of mixed models. In this version of the model, there is a correlation between the interaction effects. Specifically, the two interaction effects for the same target and two different raters are negatively correlated. As a result, the estimated intraclass correlation can be negative under a two-way mixed-effects model with interaction. Also, average AA-ICC and average CA-ICC cannot be estimated in a two-way mixed-effects model including interaction; see [Methods and formulas](#) and [McGraw and Wong \(1996a\)](#) for details.

## Tests against nonzero values

It may be of interest to test whether the intraclass correlation is equal to a value other than zero. `icc` supports testing against positive values through the use of the `testvalue()` option. Specifying `testvalue(#)` provides a one-sided hypothesis test of  $H_0: \rho = \#$  versus  $H_a: \rho > \#$ . The test is provided separately for both individual and average ICCs.

## ▷ Example 5: Testing ICC against a nonzero value

We return to the two-way random-effects model for the judge and target data from [Shrout and Fleiss \(1979\)](#). Suppose we want to test whether the individual and average AA-ICCs are each equal to 0.2. We specify the `testvalue(0.2)` option with `icc`:

```
. use https://www.stata-press.com/data/r18/judges, clear
(Ratings of targets by judges)
. icc rating target judge, testvalue(0.2)

Intraclass correlations
Two-way random-effects model
Absolute agreement
Random effects: target      Number of targets =      6
Random effects: judge      Number of raters   =      4
```

rating	ICC	[95% conf. interval]	
Individual	.2897638	.0187865	.7610844
Average	.6200505	.0711368	.927232

```
F test that
ICC(1)=0.20: F(5.0, 5.3) = 1.54          Prob > F = 0.317
ICC(k)=0.20: F(5.0, 9.4) = 4.35        Prob > F = 0.026
```

Note: ICCs estimate correlations between individual measurements and between average measurements made on the same target.

We reject the null hypothesis that the average AA-ICC, labeled as  $ICC(k)$  in the output, is equal to 0.2, but we do not have statistical evidence to reject the null hypothesis that the individual AA-ICC, labeled as  $ICC(1)$ , is equal to 0.2. ◀

## Stored results

`icc` stores the following in `r()`:

### Scalars

<code>r(N_target)</code>	number of targets
<code>r(N_rater)</code>	number of raters
<code>r(icc_i)</code>	intraclass correlation for individual measurements
<code>r(icc_i_F)</code>	$F$ test statistic for individual ICC
<code>r(icc_i_df1)</code>	numerator degrees of freedom for <code>r(icc_i_F)</code>
<code>r(icc_i_df2)</code>	denominator degrees of freedom for <code>r(icc_i_F)</code>
<code>r(icc_i_p)</code>	$p$ -value for $F$ test of individual ICC
<code>r(icc_i_lb)</code>	lower endpoint for confidence intervals of individual ICC
<code>r(icc_i_ub)</code>	upper endpoint for confidence intervals of individual ICC
<code>r(icc_avg)</code>	intraclass correlation for average measurements
<code>r(icc_avg_F)</code>	$F$ test statistic for average ICC
<code>r(icc_avg_df1)</code>	numerator degrees of freedom for <code>r(icc_avg_F)</code>
<code>r(icc_avg_df2)</code>	denominator degrees of freedom for <code>r(icc_avg_F)</code>
<code>r(icc_avg_p)</code>	$p$ -value for $F$ test of average ICC
<code>r(icc_avg_lb)</code>	lower endpoint for confidence intervals of average ICC
<code>r(icc_avg_ub)</code>	upper endpoint for confidence intervals of average ICC
<code>r(testvalue)</code>	null hypothesis value
<code>r(level)</code>	confidence level

### Macros

<code>r(model)</code>	analysis-of-variance model
<code>r(depvar)</code>	name of dependent variable
<code>r(target)</code>	target variable
<code>r(rater)</code>	rater variable
<code>r(ttype)</code>	type of ICC estimated (absolute or consistency)

## Methods and formulas

We observe  $y_{ij}$ , where  $i = 1, \dots, n$  and  $j = 1, \dots, k$ .  $y_{ij}$  is the  $j$ th rating on the  $i$ th target. Let  $\alpha = 1 - l/100$ , where  $l$  is the significance level specified by the user.

Methods and formulas are presented under the following headings:

*Mean squares*  
*One-way random effects*  
*Two-way random effects*  
*Two-way mixed effects*

## Mean squares

The mean squares within targets are

$$\text{WMS} = \sum_i \sum_j \frac{(y_{ij} - \bar{y}_{i.})^2}{n(k-1)}$$

where  $\bar{y}_{i.} = \sum_j y_{ij}/k$ .

The mean squares between targets are

$$\text{BMS} = \sum_i \frac{(\bar{y}_{i.} - \bar{y}_{..})^2}{n-1}$$

where  $\bar{y}_{..} = \sum_i \bar{y}_{i.}/n$ .

These are the only mean squares needed to estimate ICC in the one-way random-effects model. For the two-way models, we need two additional mean squares.

The mean squares between raters are

$$\text{JMS} = \sum_j \frac{(\bar{y}_{.j} - \bar{y}_{..})^2}{k-1}$$

where  $\bar{y}_{.j} = \sum_i y_{ij}/n$  and  $\bar{y}_{..} = \sum_j \bar{y}_{.j}/k$ .

The residual or error mean square is

$$\text{EMS} = \frac{\sum_i \sum_j (y_{ij} - \bar{y})^2 - (k-1)\text{JMS} - (n-1)\text{BMS}}{(n-1)(k-1)}$$

## One-way random effects

Under the one-way random-effects model, we observe

$$y_{ij} = \mu + r_i + \epsilon_{ij} \quad (\text{M1})$$

where  $\mu$  is the mean rating,  $r_i$  is the target random effect, and  $\epsilon_{ij}$  is random error. The  $r_i$ s are i.i.d.  $N(0, \sigma_r^2)$ ;  $\epsilon_{ij}$ s are i.i.d.  $N(0, \sigma_\epsilon^2)$  and are independent of  $r_i$ s. There is no rater effect separate from the residual error because each target is evaluated by a different set of raters.

The individual AA-ICC is the correlation between individual measurements on the same target:

$$\rho_1 = \text{ICC}(1) = \text{Corr}(y_{ij}, y_{ij'}) = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_\epsilon^2}$$

The average AA-ICC is the correlation between average measurements of size  $k$  made on the same target:

$$\rho_k = \text{ICC}(k) = \text{Corr}(\bar{y}_i, \bar{y}'_i) = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_\epsilon^2/k}$$

They are estimated by

$$\hat{\rho}_1 = \widehat{\text{ICC}}(1) = \frac{\text{BMS} - \text{WMS}}{\text{BMS} + (k-1)\text{WMS}}$$

$$\hat{\rho}_k = \widehat{\text{ICC}}(k) = \frac{\text{BMS} - \text{WMS}}{\text{BMS}}$$

**Confidence intervals.** Let  $F_{\text{obs}} = \text{BMS}/\text{WMS}$ , let  $F_l$  be the  $(1 - \alpha/2) \times 100$ th percentile of the  $F_{n-1, n(k-1)}$  distribution, and let  $F_u$  be the  $(1 - \alpha/2) \times 100$ th percentile of the  $F_{n(k-1), n-1}$  distribution. Let  $F_L = F_{\text{obs}}/F_l$  and  $F_U = F_{\text{obs}}F_u$ .

A  $(1 - \alpha) \times 100\%$  confidence interval for  $\rho_1$  is

$$\left( \frac{F_L - 1}{F_l + k - 1}, \frac{F_U - 1}{F_U + k - 1} \right) \quad (1)$$

A  $(1 - \alpha) \times 100\%$  confidence interval for  $\rho_k$  is

$$\left( 1 - \frac{1}{F_L}, 1 - \frac{1}{F_U} \right) \quad (2)$$

**Hypothesis tests.** Consider a one-sided hypothesis test of  $H_0: \text{ICC} = \rho_0$  versus  $H_a: \text{ICC} > \rho_0$ .

The test statistic for  $\rho_1$  is

$$F_{\rho_1} = \frac{\text{BMS}}{\text{WMS}} \frac{1 - \rho_0}{1 + (k-1)\rho_0} \quad (3)$$

The test statistic for  $\rho_k$  is

$$F_{\rho_k} = \frac{\text{BMS}}{\text{WMS}} (1 - \rho_0) \quad (4)$$

Under the null hypothesis, both  $F_{\rho_1}$  and  $F_{\rho_k}$  have the  $F_{n-1, n(k-1)}$  distribution. When  $\rho_0 = 0$ , the two test statistics coincide.

## Two-way random effects

In this setting, the target is evaluated by the same set of raters, who are randomly drawn from the population of raters. The underlying models with and without interaction are

$$y_{ij} = \mu + r_i + c_j + (rc)_{ij} + \epsilon_{ij} \quad (\text{M2})$$

$$y_{ij} = \mu + r_i + c_j + \epsilon_{ij} \quad (\text{M2A})$$

where  $y_{ij}$  is the rating of the  $i$ th target by the  $j$ th rater,  $\mu$  is the mean rating,  $r_i$  is the target random effect,  $c_j$  is the rater random effect,  $(rc)_{ij}$  is the target-rater random effect, and  $\epsilon_{ij}$  is random error. The  $r_i$ s are i.i.d.  $N(0, \sigma_r^2)$ ,  $c_j$ s are i.i.d.  $N(0, \sigma_c^2)$ ,  $(rc)_{ij}$ s are i.i.d.  $N(0, \sigma_{rc}^2)$ , and  $\epsilon_{ij}$ s are i.i.d.  $N(0, \sigma_\epsilon^2)$ . Each effect is mutually independent of the others.

Below, we provide formulas for ICCs for model (M2). The corresponding ICCs for model (M2A) can be obtained by setting  $\sigma_{rc}^2 = 0$ .

The individual AA-ICC is the correlation between individual measurements on the same target:

$$\rho_{A,1} = \text{ICC}(A,1) = \text{Corr}(y_{ij}, y_{ij'}) = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_c^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)}$$

The average AA-ICC is the correlation between average measurements of size  $k$  made on the same target:

$$\rho_{A,k} = \text{ICC}(A,k) = \text{Corr}(\bar{y}_i, \bar{y}'_i) = \frac{\sigma_r^2}{\sigma_r^2 + (\sigma_c^2 + \sigma_{rc}^2 + \sigma_\epsilon^2)/k}$$

The consistency-of-agreement intraclass correlation for individual measurements, individual CA-ICC, is

$$\rho_{C,1} = \text{ICC}(C,1) = \frac{\sigma_r^2}{\sigma_r^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)}$$

The consistency-of-agreement intraclass correlation for average measurements of size  $k$ , average CA-ICC, is

$$\rho_{C,k} = \text{ICC}(C,k) = \frac{\sigma_r^2}{\sigma_r^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)/k}$$

With one observation per target and rater,  $\sigma_{rc}^2$  and  $\sigma_\epsilon^2$  cannot be estimated separately.

The estimators of intraclass correlations, confidence intervals, and test statistics are the same for models (M2) and (M2A). The estimators of ICCs are

$$\begin{aligned}\widehat{\rho}_{A,1} &= \widehat{\text{ICC}}(\widehat{A},1) = \frac{\text{BMS} - \text{EMS}}{\text{BMS} + (k-1)\text{EMS} + \frac{k}{n}(\text{JMS} - \text{EMS})} \\ \widehat{\rho}_{A,k} &= \widehat{\text{ICC}}(\widehat{A},k) = \frac{\text{BMS} - \text{EMS}}{\text{BMS} + \frac{1}{n}(\text{JMS} - \text{EMS})} \\ \widehat{\rho}_{C,1} &= \widehat{\text{ICC}}(\widehat{C},1) = \frac{\text{BMS} - \text{EMS}}{\text{BMS} + (k-1)\text{EMS}} \\ \widehat{\rho}_{C,k} &= \widehat{\text{ICC}}(\widehat{C},k) = \frac{\text{BMS} - \text{EMS}}{\text{BMS}}\end{aligned}$$

**Confidence intervals.** Let  $a = k\widehat{\rho}_{A,1}/\{n(1 - \widehat{\rho}_{A,1})\}$ ,  $b = 1 + k\widehat{\rho}_{A,1}(n-1)/\{n(1 - \widehat{\rho}_{A,1})\}$ , and

$$v = \frac{(a\text{JMS} + b\text{EMS})^2}{\frac{a^2\text{JMS}^2}{k-1} + \frac{b^2\text{EMS}^2}{(n-1)(k-1)}} \quad (5)$$

Let  $F_l$  be the  $(1-\alpha/2) \times 100$ th percentile of the  $F_{n-1,v}$  distribution and  $F_u$  be the  $(1-\alpha/2) \times 100$ th percentile of the  $F_{v,n-1}$  distribution.

A  $(1-\alpha) \times 100\%$  confidence interval for  $\rho_{A,1}$  is given by  $(L, U)$ , where

$$\begin{aligned}L &= \frac{n(\text{BMS} - F_l\text{EMS})}{F_l \{k\text{JMS} + (kn - k - n)\text{EMS}\} + n\text{BMS}} \\ U &= \frac{n(F_u\text{BMS} - \text{EMS})}{k\text{JMS} + (kn - k - n)\text{EMS} + nF_u\text{BMS}}\end{aligned} \quad (6)$$

A  $(1-\alpha) \times 100\%$  confidence intervals for  $\rho_{A,k}$  is a special case of (6) with  $k = 1$ , where  $a = \widehat{\rho}_{A,k}/\{n(1 - \widehat{\rho}_{A,k})\}$ ,  $b = 1 + \widehat{\rho}_{A,k}(n-1)/\{n(1 - \widehat{\rho}_{A,k})\}$ , and  $v$  is defined in (5).

To define confidence intervals for  $\rho_{C,1}$  and  $\rho_{C,k}$ , let  $F_{\text{obs}} = \text{BMS}/\text{EMS}$ ,  $F_l$  be the  $(1-\alpha/2) \times 100$ th percentile of the  $F_{n-1,(n-1)(k-1)}$  distribution, and  $F_u$  be the  $(1-\alpha/2) \times 100$ th percentile of the  $F_{(n-1)(k-1),n-1}$  distribution. Let  $F_L = F_{\text{obs}}/F_l$  and  $F_U = F_{\text{obs}}F_u$ .

A  $(1-\alpha) \times 100\%$  confidence intervals for  $\rho_{C,1}$  and  $\rho_{C,k}$  are then as given by (1) and (2) for model (M1).

**Hypothesis tests.** Consider a one-sided hypothesis test of  $H_o: \text{ICC} = \rho_0$  versus  $H_a: \text{ICC} > \rho_0$ . Let  $a = k\rho_0/\{n(1 - \rho_0)\}$  and  $b = 1 + k\rho_0(n-1)/\{n(1 - \rho_0)\}$ .

The test statistic for  $\rho_{A,1}$  is

$$F_{\rho_{A,1}} = \frac{\text{BMS}}{a\text{JMS} + b\text{EMS}}$$

Under the null hypothesis,  $F_{\rho_{A,1}}$  has the  $F_{n-1,v}$  distribution, where  $v$  is defined in (5).

The test statistic for  $\rho_{A,k}$  is defined similarly, except  $a = \rho_0/\{n(1 - \rho_0)\}$  and  $b = 1 + \rho_0(n-1)/\{n(1 - \rho_0)\}$ . Under the null hypothesis,  $F_{\rho_{A,k}}$  has the  $F_{n-1,v}$  distribution, where  $v$  is defined in (5). When  $\rho_0 = 0$ , then  $a = 0$ ,  $b = 1$ , and the two test statistics coincide.

The test statistics for  $\rho_{C,1}$  and  $\rho_{C,k}$  are defined by (3) and (4), respectively, with WMS replaced by EMS. Under the null hypothesis, both  $F_{\rho_{C,1}}$  and  $F_{\rho_{C,k}}$  have the  $F_{n-1,(n-1)(k-1)}$  distribution. They also both have the same value when  $\rho_0 = 0$ .

## Two-way mixed effects

In this setting, every target is evaluated by the same set of judges, who are the only judges of interest. The underlying models with and without interaction are

$$y_{ij} = \mu + r_i + c_j + (rc)_{ij} + \epsilon_{ij} \quad (\text{M3})$$

$$y_{ij} = \mu + r_i + c_j + \epsilon_{ij} \quad (\text{M3A})$$

where  $y_{ij}$  is the rating of the  $i$ th target by the  $j$ th rater,  $\mu$  is the mean rating,  $r_i$  is the target random effect,  $c_j$  is the rater random effect,  $(rc)_{ij}$  is an interaction effect between target and rater, and  $\epsilon_{ij}$  is random error. The  $r_i$ s are i.i.d.  $N(0, \sigma_r^2)$ ,  $(rc)_{ij}$ s are  $N(0, \sigma_{rc}^2)$ , and  $\epsilon_{ij}$ s are i.i.d.  $N(0, \sigma_\epsilon^2)$ . Each random effect is mutually independent of the others. The  $c_j$ s are fixed such that  $\sum_j c_j = 0$ . The variance of  $c_j$ s is  $\theta_c^2 = \sum c_j^2 / (k - 1)$ .

In the presence of an interaction, two versions of a mixed-effects model may be considered. One assumes that  $(rc)_{ij}$ s are i.i.d.  $N(0, \sigma_{rc}^2)$ . Another assumes that  $(rc)_{ij}$ s are  $N(0, \sigma_{rc}^2)$  with an additional constraint that  $\sum_j (rc)_{ij} = 0$  (for example, [Kuehl \[2000\]](#)), so only interaction terms involving different targets are independent. The latter model is considered here.

We now define the intraclass correlations for individual measurements for model (M3).

The individual CA-ICC, the correlation between individual measurements on the same target, is

$$\rho_{C,1} = \text{ICC}(C,1) = \text{Corr}(y_{ij}, y_{ij'}) = \frac{\sigma_r^2 - \sigma_{rc}^2 / (k - 1)}{\sigma_r^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)}$$

The absolute-agreement intraclass correlation for individual measurements, individual AA-ICC, is

$$\rho_{A,1} = \text{ICC}(A,1) = \frac{\sigma_r^2 - \sigma_{rc}^2 / (k - 1)}{\sigma_r^2 + \theta_c^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)}$$

[Shrout and Fleiss \(1979\)](#) show that the individual ICC could be negative in this case—a phenomenon first pointed out by [Sitgreaves \(1960\)](#). This can happen when the interaction term has a high variance relative to the targets and there are not many raters.

The individual intraclass correlations for model (M3A) have similar definitions with  $\sigma_{rc}^2 = 0$ . The individual CA-ICC is the correlation between individual measurements on the same target,  $\text{Corr}(y_{ij}, y_{ij'})$ .

We now discuss the intraclass correlations that correspond to average measurements. Neither average AA-ICC,  $\rho_{A,k}$ , nor average CA-ICC,  $\rho_{C,k}$ , can be estimated under model (M3) ([Shrout and Fleiss 1979](#); [McGraw and Wong 1996a](#)). The problem is that in this model,  $\sigma_r^2$ , which is the covariance between two means based on  $k$  raters, cannot be estimated.

Specifically, the parameter  $\sigma_r^2$  appears only in the expectation of the between-target mean squares BMS. Under the restriction  $\sum_j (rc)_{ij} = 0$ ,

$$E(\text{BMS}) = k\sigma_r^2 + \sigma_\epsilon^2$$

Note that  $\sigma_{rc}^2$  does not appear in the expectation of between-target mean squares. With one observation per target and rater,  $\sigma_{rc}^2$  and  $\sigma_\epsilon^2$  cannot be estimated separately (only their sum  $\sigma_{rc}^2 + \sigma_\epsilon^2$  can be estimated), so BMS alone cannot be used to estimate  $\sigma_r^2$ .

Under model (M3A), however, there is no interaction (and thus no interaction variance component  $\sigma_{rc}^2$ ), so  $\rho_{A,k}$  or  $\rho_{C,k}$  can be estimated.

The average AA-ICC, the absolute-agreement intraclass correlation for average measurements of size  $k$ , is

$$\rho_{A,k} = \text{ICC}(A,k) = \frac{\sigma_r^2}{\sigma_r^2 + (\theta_c^2 + \sigma_\epsilon^2)/k}$$

The average CA-ICC, the correlation between average measurements of size  $k$  made on the same target, is

$$\rho_{C,k} = \text{ICC}(C,k) = \text{Corr}(\bar{y}_i, \bar{y}'_i) = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_\epsilon^2/k}$$

The estimators of ICCs, their confidence intervals, and hypothesis tests are as described for two-way random-effects models, except  $\rho_{A,k}$  and  $\rho_{C,k}$  are not defined under model (M3).

## Description

There are different approaches for measuring inequality and poverty, and different methods for summarizing the distribution of earnings, income, and wealth. Stata has some official features for these types of analyses. For example, the `roctab` command has an option to report Gini and Pietra indices, which are measures of income inequality; see [R] [roctab](#). With the `cumul` command, you can obtain the cumulative distribution function of, for example, household expenditures; see [R] [cumul](#). Additionally, you may want to look at the shape of income distributions; see [R] [kdensity](#) and [R] [histogram](#).

However, you might also be interested in the generalized Lorenz curve or a welfare index, which cannot be obtained from any official Stata commands. Fortunately, Stata users have developed an excellent suite of commands that create these graphs and report these types of indices, along with many other related measures. In this entry, we demonstrate how to find and install community-contributed commands related to inequality, poverty, and distributional summaries of earnings, income, and wealth.

## Remarks and examples

Suppose you are in search of a command to report inequality indices; you could type the following:

```
. search inequality
```

First, you will see official resources related to this keyword, including frequently asked questions (FAQs) and *Stata Journal* articles. Then, you will see community-contributed additions to Stata that are available from the Internet, which typically include additions published in the *Stata Journal* and those posted on the Statistical Software Components (SSC) Archive, provided by <http://repec.org>. For example, in the output from `search`, we find `ineqdec0`, which calculates inequality indices with decomposition by subgroup.

### Search of web resources from Stata and other users

(output omitted)

```
ineqdec0 from http://fmwww.bc.edu/RePEc/bocode/i
'INEQDECO': module to calculate inequality indices with decomposition by
subgroup / ineqdec0 is a stripped-down version of ineqdeco (q.v.). /
Unlike the latter, it will provide estimates using samples /containing
zero or negative values for the variable of / interest. But as a result
ineqdecgini from http://fmwww.bc.edu/RePEc/bocode/i
'INEQDECGINI': module to estimate Gini coefficient with optional
decomposition by subgroups / ineqdecgini estimates the Gini coefficient
(a.k.a. Gini index) / of inequality plus, optionally, a decomposition by
population / subgroup into components representing inequality within /
```

(output omitted)

(end of search)

Let's take a closer look at this package:

1. Click on *ineqdec0* from <http://fmwww.bc.edu/RePEc/bocode/i>.
2. Click on *ineqdec0.hlp*.

This leads us to the help file, where we could learn more about which indices are computed with this package. This particular command supports `fweights` and `awweights`, but not all community-contributed commands do; it is important to look at the help file and confirm whether the command is a good fit for the analysis you want to perform. If it is, you can install it:

3. Click on the back button.
4. Click on *click here to install*.

Once you see a message indicating that the installation is complete, you may now use this command.

Another thing to keep in mind when installing packages is whether they are designed to work with complex survey data. This particular command is not. We can click on the back button once to return to the description of `ineqdec0` and then once more to return to the search results. Scrolling up, we come across

**Search of official help files, FAQs, Examples, and Stata Journals**

(output omitted)

```
SJ-16-2 st0427_1 . . . . . Software update for conindex
. . . . . O. O'Donnell, S. O'Neill, T. Van Ourti, and B. Walsh
(help conindex if installed)
Q2/16 SJ 16(2):521--522
program can now be used on data from complex survey designs
```

(output omitted)

(end of search)

This is an update for a package called `conindex`; this updated version of the command can be used with data from complex survey designs. The original version of the package was introduced in *Stata Journal* Volume 16 Number 1 (March 2016), and this update was published the following quarter. If we scroll up a bit more in the search results, we will find an even more recent update:

**Search of official help files, FAQs, Examples, and Stata Journals**

(output omitted)

```
SJ-18-3 st0427_2 . . . . . Software update for conindex
. . . . . O. O'Donnell, S. O'Neill, T. Van Ourti, and B. Walsh
(help conindex if installed)
Q3/18 SJ 18(3):758--759
uses the community-contributed lorenz command and fix a small bug
in the graph option
```

(output omitted)

(end of search)

It is best to install the most recent version, which we can do as follows:

1. Click on *st0427\_2*.
2. Click on *click here to install*.

The examples above demonstrate how to install community-contributed commands related to measures of inequality, but you would follow the same steps to find and install commands related to poverty measures, indices of social welfare, and the like.

For example, type the following:

```
. search poverty
```

In the list of results, you will find `glcurve`, which can be used to draw Lorenz curves, concentration curves, and other related curves. We can install this command as follows:

1. Click on `glcurve` from <http://fmwww.bc.edu/RePEc/bocode/g>.
2. Click on *click here to install*.

These are just a few examples of the many community-contributed commands that are available. You can use `search` to find more community-contributed commands used to obtain other measures of inequality and poverty, and distributional summaries of earnings, income, and wealth.

**Max Otto Lorenz** (1876–1959) was born in Burlington, Iowa. He did his undergraduate studies at the University of Iowa and received his PhD from the University of Wisconsin–Madison in 1906. In 1905, he published his only article, “Methods of measuring the concentration of wealth”, in a scientific journal. In the article, he introduces what we now call the Lorenz curve, a term first introduced in a statistics textbook in 1912.

Lorenz worked his whole life in governmental statistical institutions. He was the Deputy Commissioner of Labor and Industrial Statistics for Wisconsin, worked for the U.S. Bureau of the Census and the Bureau of Railway Economics, and was the Director of the Bureau of Statistics and the Bureau of Transport and Economic Statistics.

His hobbies included calendar reform and Interlingua, a proposed international language.

# Title

**intreg** — Interval regression

[Description](#)  
[Options](#)  
[References](#)

[Quick start](#)  
[Remarks and examples](#)  
[Also see](#)

[Menu](#)  
[Stored results](#)

[Syntax](#)  
[Methods and formulas](#)

## Description

`intreg` fits a linear model with an outcome measured as point data, interval data, left-censored data, or right-censored data. As such, it is a generalization of the model fit by `tobit`.

## Quick start

Regression on `x1` and `x2` of an interval-measured dependent variable with lower endpoint `y_lower` and upper endpoint `y_upper`

```
intreg y_lower y_upper x1 x2
```

With robust standard errors

```
intreg y_lower y_upper x1 x2, vce(robust)
```

Model heteroskedasticity in the conditional variance as a function of `x3`

```
intreg y_lower y_upper x1 x2, het(x3)
```

Adjust for complex survey design using `svyset` data

```
svy: intreg y_lower y_upper x1 x2
```

## Menu

Statistics > Linear models and related > Censored regression > Interval regression

## Syntax

```
intreg depvar1 depvar2 [indepvars] [if] [in] [weight] [, options]
```

*depvar*<sub>1</sub> and *depvar*<sub>2</sub> should have the following form:

Type of data		<i>depvar</i> <sub>1</sub>	<i>depvar</i> <sub>2</sub>
point data	$a = [a, a]$	<i>a</i>	<i>a</i>
interval data	$[a, b]$	<i>a</i>	<i>b</i>
left-censored data	$(-\infty, b]$	.	<i>b</i>
right-censored data	$[a, +\infty)$	<i>a</i>	.
missing		.	.

<i>options</i>	Description
<b>Model</b>	
<code>noconstant</code>	suppress constant term
<code>het(<i>varlist</i> [, <code>noconstant</code>])</code>	independent variables to model the variance; use <code>noconstant</code> to suppress constant term
<code>offset(<i>varname</i>)</code>	include <i>varname</i> in model with coefficient constrained to 1
<code>constraints(<i>constraints</i>)</code>	apply specified linear constraints
<b>SE/Robust</b>	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>opg</code> , <code>bootstrap</code> , or <code>jackknife</code>
<b>Reporting</b>	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>nocnsreport</code>	do not display constraints
<code>display_*</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>Maximization</b>	
<code>maximize_*</code>	control the maximization process; seldom used
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*depvar*<sub>1</sub>, *depvar*<sub>2</sub>, *indepvars*, and *varlist* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `mfp`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: intreg** and [FMM] **fmm: intreg**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`aweight`s are not allowed with the `jackknife` prefix; see [R] **jackknife**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`aweight`s, `fweight`s, `iweight`s, and `pweight`s are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`noconstant`; see [R] [Estimation options](#).

`het(varlist [, noconstant])` specifies that the logarithm of the standard deviation be modeled as a linear combination of *varlist*. The constant is included unless `noconstant` is specified.

`offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `intreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

`intreg` fits a linear model to an outcome that may be either observed exactly or unobserved but known to fall within some interval. The values of the outcome variable may be observed (point data), unobserved but known to fall within an interval with fixed endpoints (interval-censored data), unobserved but known to fall within an interval that has a fixed upper endpoint (left-censored data), or unobserved but known to fall within an interval that has a fixed lower endpoint (right-censored data). Such censored data arise naturally in many contexts, such as wage data. Often, you know only that, for example, a person's salary is between \$30,000 and \$40,000.

The interval regression model fit by `intreg` is a generalization of the models fit by `tobit` because it extends censoring beyond left-censored data or right-censored data; see [Cameron and Trivedi \(2022, 965–967\)](#) for additional discussion of these data types. See [Wooldridge \(2020, sec. 17.4\)](#) for an introduction to censored and truncated regression models.

Regardless of the type of censoring, `intreg` requires the outcome to be stored in the dataset as interval data. That is, two dependent variables, `depvar1` and `depvar2`, are used to hold the endpoints of the interval. If the data are left-censored, the lower endpoint is  $-\infty$  and is represented by a missing value in `depvar1`. If the data are right-censored, the upper endpoint is  $+\infty$  and is represented by a missing value in `depvar2`. Point data are represented by the two endpoints being equal. Truly missing values of the dependent variable must be represented by missing values in both `depvar1` and `depvar2`.

### ▷ Example 1: Interval regression

`womenwage2.dta` contains the yearly wages of working women in interval form. Women were asked to indicate a category for their yearly income from employment. The categories were \$5,000 or less, \$5,001–\$10,000, . . . , \$25,001–\$30,000, \$30,001–\$40,000, \$40,001–\$50,000, and more than \$50,000. The lower and upper endpoints of the wage categories (in \$1,000s) are recorded in variables `wage1` and `wage2`. Below, we list the first 10 observations in `wage1` and `wage2`.

```
. use https://www.stata-press.com/data/r18/womenwage2
(Wages of women, fictional data)
. list wage1 wage2 in 1/10
```

	wage1	wage2
1.	.	5
2.	5	10
3.	5	10
4.	10	15
5.	15	20
6.	20	25
7.	25	30
8.	30	40
9.	40	50
10.	50	.

We see, for example, that the first respondent made \$5,000 or less in a year, that the second respondent made between \$5,001 and \$10,000 in a year, and so on. The tenth respondent made at least \$50,000 a year.

We now fit an interval regression model of women’s wages using social and demographic characteristics as explanatory variables. The variables include the subject’s age (`age`), years of schooling (`school`), job tenure (`tenure`), a dummy for living in a rural area (`rural1`), and a dummy for never being married (`nev_mar`).

```
. intreg wage1 wage2 age c.age#c.age i.nev_mar i.rural school tenure
```

```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
age	.7914438	.4433604	1.79	0.074	-.0775265	1.660414
c.age#c.age	-.0132624	.0073028	-1.82	0.069	-.0275757	.0010509
1.nev_mar	-.2075022	.8119581	-0.26	0.798	-1.798911	1.383906
1.rural	-3.043044	.7757324	-3.92	0.000	-4.563452	-1.522637
school	1.334721	.1357873	9.83	0.000	1.068583	1.600859
tenure	.8000664	.1045077	7.66	0.000	.5952351	1.004898
_cons	-12.70238	6.367117	-1.99	0.046	-25.1817	-.2230583
/lnsigma	1.987823	.0346543	57.36	0.000	1.919902	2.055744
sigma	7.299626	.2529634			6.82029	7.81265

Because the conditional mean modeled by interval regression is linear, the coefficients are interpreted the same way they are in ordinary least-squares regression; see [R] [regress](#). For example, residing in a rural area lowers the expected income by \$3,043 and each additional year of schooling raises the expected income by \$1,335.

## □ Technical note

Instead of using intervals to record wages, we could treat the outcome as categorical with a higher category corresponding to a higher wage. Here we fit an ordered probit model for `wagecat`, created based on groups defined by the intervals, by using `oprobit` (see [R] [oprobit](#)) with the same covariates:

```
. oprobit wagecat age c.age#c.age i.nev_mar i.rural school tenure
Iteration 0:  Log likelihood = -881.1491
Iteration 1:  Log likelihood = -764.31729
Iteration 2:  Log likelihood = -763.31191
Iteration 3:  Log likelihood = -763.31049
Iteration 4:  Log likelihood = -763.31049

Ordered probit regression                                Number of obs =   488
LR chi2(6)      = 235.68
Prob > chi2     = 0.0000
Pseudo R2      = 0.1337

Log likelihood = -763.31049
```

wagecat	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
age	.1674519	.0620333	2.70	0.007	.0458689	.289035
c.age#c.age	-.0027983	.0010214	-2.74	0.006	-.0048001	-.0007964

/cut2	3.941018	.8979167			2.181134	5.700903
/cut3	5.085205	.9056582			3.310148	6.860263
/cut4	5.875534	.9120933			4.087864	7.663204
/cut5	6.468723	.918117			4.669247	8.268199
/cut6	6.922726	.9215455			5.11653	8.728922
/cut7	7.34471	.9237628			5.534168	9.155252
/cut8	7.963441	.9338881			6.133054	9.793828

We can directly compare the log likelihoods for the `intreg` and `oprobit` models because both likelihoods are discrete. If we had point data in our `intreg` estimation, the likelihood would be a mixture of discrete and continuous terms, and we could not compare it directly with the `oprobit` likelihood.

Here the `oprobit` log likelihood is significantly larger (that is, less negative), so it fits better than the `intreg` model. The `intreg` model assumes normality, but the distribution of wages is skewed and definitely nonnormal. Normality is more closely approximated if we model the log of wages.

```

. generate logwage1 = log(wage1)
(14 missing values generated)
. generate logwage2 = log(wage2)
(6 missing values generated)
. intreg logwage1 logwage2 age c.age#c.age i.nev_mar i.rural school tenure
Fitting constant-only model:

sigma	.4037381	.0143838			.3765081	.4329373

The log likelihood of this intreg model is close to the oprobit log likelihood, and the  $z$  statistics for both models are similar. □

## Stored results

`intreg` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(N_unc)</code>	number of uncensored observations
<code>e(N_lrc)</code>	number of left-censored observations
<code>e(N_rlc)</code>	number of right-censored observations
<code>e(N_int)</code>	number of interval observations
<code>e(k)</code>	number of parameters
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(p)</code>	$p$ -value for model $\chi^2$ test
<code>e(sigma)</code>	sigma
<code>e(se_sigma)</code>	standard error of sigma
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(rank0)</code>	rank of <code>e(V)</code> for constant-only model
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>intreg</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	names of dependent variables
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset)</code>	linear offset variable
<code>e(chi2type)</code>	Wald or LR; type of model $\chi^2$ test
<code>e(vce)</code>	<code>vctype</code> specified in <code>vce()</code>
<code>e(vctype)</code>	title used to label Std. err.
<code>e(het)</code>	heteroskedasticity, if <code>het()</code> specified
<code>e(ml_score)</code>	program used to implement <code>scores</code>
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	b V
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance-covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices	
<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

The regression equation of interest is

$$y_j = \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j$$

where  $y_j$  is a continuous outcome for the  $j$ th observation—either observed or unobserved—with covariates  $\mathbf{x}_j$  and corresponding coefficients  $\boldsymbol{\beta}$ . The model assumes that the error term is normally distributed;  $\epsilon \sim N(0, \sigma^2)$ .

For observations  $j \in \mathcal{C}$ , we observe  $y_j$ , that is, point data. Observations  $j \in \mathcal{I}$  are intervals; we know only that the unobserved  $y_j$  is in the interval  $[y_{1j}, y_{2j}]$ . For these observations, the likelihood contribution is  $\Pr(y_{1j} \leq Y_j \leq y_{2j})$ , where  $Y_j$  denotes the random variable representing the dependent variable in the model. Observations  $j \in \mathcal{L}$  are left-censored; we know only that the unobserved  $y_j$  is less than or equal to  $y_{\mathcal{L}j}$ , a censoring value that we do know. Similarly, observations  $j \in \mathcal{R}$  are right-censored; we know only that the unobserved  $y_j$  is greater than or equal to  $y_{\mathcal{R}j}$ . The likelihoods for these censored observations contain terms of the form  $\Pr(Y_j \leq y_{\mathcal{L}j})$  for left-censored data and  $\Pr(Y_j \geq y_{\mathcal{R}j})$  for right-censored data.

The log likelihood is

$$\begin{aligned} \ln L = & -\frac{1}{2} \sum_{j \in \mathcal{C}} w_j \left\{ \left( \frac{y_j - \mathbf{x}_j\boldsymbol{\beta}}{\sigma} \right)^2 + \log 2\pi\sigma^2 \right\} \\ & + \sum_{j \in \mathcal{L}} w_j \log \Phi \left( \frac{y_{\mathcal{L}j} - \mathbf{x}_j\boldsymbol{\beta}}{\sigma} \right) \\ & + \sum_{j \in \mathcal{R}} w_j \log \left\{ 1 - \Phi \left( \frac{y_{\mathcal{R}j} - \mathbf{x}_j\boldsymbol{\beta}}{\sigma} \right) \right\} \\ & + \sum_{j \in \mathcal{I}} w_j \log \left\{ \Phi \left( \frac{y_{2j} - \mathbf{x}_j\boldsymbol{\beta}}{\sigma} \right) - \Phi \left( \frac{y_{1j} - \mathbf{x}_j\boldsymbol{\beta}}{\sigma} \right) \right\} \end{aligned}$$

where  $\Phi()$  is the cumulative standard normal distribution and  $w_j$  is the weight for the  $j$ th observation. If no weights are specified,  $w_j = 1$ . If `aweight`s are specified,  $w_j = 1$ , and  $\sigma$  is replaced by  $\sigma/\sqrt{a_j}$  in the above, where  $a_j$  are the `aweight`s normalized to sum to  $N$ .

When the `het()` option is specified,  $\sigma$  is modeled as  $\ln(\sigma) = z'_j\boldsymbol{\gamma}$ , where  $z$  represents the variables in `het()` and  $\boldsymbol{\gamma}$  is a vector of the estimated parameters to model the variance.

Note that the likelihood for `intreg` subsumes that of the `tobit` models; see [\[R\] tobit](#).

Maximization is as described in [\[R\] Maximize](#). `intreg` stores the estimated  $\sigma$  in `e(b)` in the log metric; therefore, if you want to provide an initial value for  $\sigma$  or to specify a constraint on it, ensure you do so on the log scale.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`intreg` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `intreg`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	linear, censored, and truncated predictions
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`hausman` and `lrtest` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>xb</code>	linear prediction; the default
<code>stdp</code>	standard error of the prediction
<code>stdf</code>	standard error of the forecast
<code>pr(<i>a</i>,<i>b</i>)</code>	$\Pr(a < y_j < b)$
<code>e(<i>a</i>,<i>b</i>)</code>	$E(y_j   a < y_j < b)$
<code>ystar(<i>a</i>,<i>b</i>)</code>	$E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where *a* and *b* may be numbers or variables; *a* missing (*a* ≥ .) means  $-\infty$ , and *b* missing (*b* ≥ .) means  $+\infty$ ; see [\[U\] 12.2.1 Missing values](#).

## Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see [Methods and formulas](#) in [\[R\] regress postestimation](#).

`pr(a,b)` calculates  $\Pr(a < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < b)$ , the probability that  $y_j | \mathbf{x}_j$  would be observed in the interval (*a*, *b*).

$a$  and  $b$  may be specified as numbers or variable names;  $lb$  and  $ub$  are variable names;

`pr(20,30)` calculates  $\Pr(20 < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$ ;

`pr(lb,ub)` calculates  $\Pr(lb < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < ub)$ ; and

`pr(20,ub)` calculates  $\Pr(20 < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < ub)$ .

$a$  missing ( $a \geq .$ ) means  $-\infty$ ; `pr(.,30)` calculates  $\Pr(-\infty < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$ ;

`pr(lb,30)` calculates  $\Pr(-\infty < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$  in observations for which  $lb \geq .$

and calculates  $\Pr(lb < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$  elsewhere.

$b$  missing ( $b \geq .$ ) means  $+\infty$ ; `pr(20,.)` calculates  $\Pr(+\infty > \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j > 20)$ ;

`pr(20,ub)` calculates  $\Pr(+\infty > \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j > 20)$  in observations for which  $ub \geq .$

and calculates  $\Pr(20 < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < ub)$  elsewhere.

`e(a,b)` calculates  $E(\mathbf{x}_j\boldsymbol{\beta} + \epsilon_j \mid a < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < b)$ , the expected value of  $y_j \mid \mathbf{x}_j$  conditional on  $y_j \mid \mathbf{x}_j$  being in the interval  $(a, b)$ , meaning that  $y_j \mid \mathbf{x}_j$  is truncated.

$a$  and  $b$  are specified as they are for `pr()`.

`ystar(a,b)` calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j\boldsymbol{\beta} + \epsilon_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j\boldsymbol{\beta} + \epsilon_j \geq b$ , and  $y_j^* = \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j$  otherwise, meaning that  $y_j^*$  is censored.  $a$  and  $b$  are specified as they are for `pr()`.

`nooffset` is relevant only if you specified `offset(varname)`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\boldsymbol{\beta}$  rather than as  $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial \ln \sigma$ .

# margins

## Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>xb</code>	linear prediction; the default
<code>pr(<i>a,b</i>)</code>	$\Pr(a < y_j < b)$
<code>e(<i>a,b</i>)</code>	$E(y_j   a < y_j < b)$
<code><u>y</u>star(<i>a,b</i>)</code>	$E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$
<code>stdp</code>	not allowed with <code>margins</code>
<code>stdf</code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

### ► Example 1: Marginal predictions

Continuing with [example 1](#) of [R] `intreg`, we compute women's expected wages conditional on a woman's wage being higher than \$5,000. To do this, we can use the `e(a,b)` option.

```
. use https://www.stata-press.com/data/r18/womenwage2
(Wages of women, fictional data)
. intreg wage1 wage2 age c.age#c.age i.nev_mar i.rural school tenure
(output omitted)
. predict w1, e(5,.)
. summarize w1
```

Variable	Obs	Mean	Std. dev.	Min	Max
w1	488	18.02362	4.583738	8.717687	35.31161

The predicted wages range from \$8,718 to \$35,312.

We can also examine whether the probability of earning more than \$5,000 varies with age. We can use `margins` to compute the marginal means of the predicted probabilities at different ages.

```
. margins, predict(pr(5,)) at(age=(20(5)50))
Predictive margins                                Number of obs = 488
Model VCE: OIM
Expression: Pr(y>5), predict(pr(5,))
1._at: age = 20
2._at: age = 25
3._at: age = 30
4._at: age = 35
5._at: age = 40
6._at: age = 45
7._at: age = 50
```

	Delta-method				
	Margin	std. err.	z	P> z	[95% conf. interval]
_at					
1	.8912598	.0151773	58.72	0.000	.8615127 .9210068
2	.9104568	.0103467	87.99	0.000	.8901775 .930736
3	.9160005	.0120025	76.32	0.000	.892476 .9395251
4	.9096667	.0136693	66.55	0.000	.8828753 .9364581
5	.8894289	.0206992	42.97	0.000	.8488593 .9299985
6	.8491103	.0447429	18.98	0.000	.7614159 .9368048
7	.7781644	.0970557	8.02	0.000	.5879387 .9683902

We can visualize these results by using `marginsplot`:

```
. marginsplot
Variables that uniquely identify margins: age
```

The probability increases until age 30 and decreases thereafter.

## Description

`ivfprobit` fits a model for a fractional dependent variable, such as a rate or proportion, where one or more of the covariates are endogenous. The dependent variable must be greater than or equal to 0 and less than or equal to 1. `ivfprobit` assumes all endogenous covariates are continuous.

## Quick start

Fractional probit regression of  $y_1$  on  $x$  and endogenous regressor  $y_2$  that is instrumented using  $z$

```
ivfprobit y1 x (y2 = z)
```

Same as above, but with endogenous regressors  $y_2$  and  $y_3$ , using  $z_1$ ,  $z_2$ , and  $z_3$  as instruments

```
ivfprobit y1 x (y2 y3 = z1 z2 z3)
```

## Menu

Statistics > Endogenous covariates > Fractional probit with endogenous covariates

## Syntax

```
ivfprobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight] [, options]
```

*varlist*<sub>1</sub> is the list of exogenous variables.

*varlist*<sub>2</sub> is the list of endogenous variables.

*varlist*<sub>iv</sub> is the list of exogenous variables used with *varlist*<sub>1</sub> as instruments for *varlist*<sub>2</sub>.

<i>options</i>	Description
Model	
<b>noconstant</b>	suppress constant term
<b>constraints</b> ( <i>numlist</i> )	apply specified linear constraints
SE/Robust	
<b>vce</b> ( <i>vcetype</i> )	<i>vcetype</i> may be <b>robust</b> , <b>cluster</b> <i>clustvar</i> , <b>bootstrap</b> , or <b>jackknife</b>
Reporting	
<b>level</b> (#)	set confidence level; default is level(95)
<b>first</b>	report first-stage regression
<b>nocnsreport</b>	do not display constraints
<b>display_options</b>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<b>maximize_options</b>	control the maximization process
<b>coeflegend</b>	display legend instead of statistics

*varlist*<sub>1</sub> and *varlist*<sub>iv</sub> may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *varlist*<sub>1</sub>, *varlist*<sub>2</sub>, and *varlist*<sub>iv</sub> may contain time-series operators; see [U] 11.4.4 Time-series varlists.

**bootstrap**, **by**, **collect**, **fp**, **jackknife**, **rolling**, **statsby**, and **svy** are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the **bootstrap** prefix; see [R] **bootstrap**.

**vce**() and weights are not allowed with the **svy** prefix; see [SVY] **svy**.

**fweights**, **iwweights**, and **pweights** are allowed. See [U] 11.1.6 **weight**.

**coeflegend** does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`noconstant`, `constraints(numlist)`; see [R] [Estimation options](#).

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`; see [R] [Estimation options](#).

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. The default is not to show these parameter estimates.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#).

The following option is available with `ivfprobit` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[Model setup](#)  
[Model identification](#)

### Model setup

`ivfprobit` fits models for fractional dependent variables when one or more of the covariates is endogenous. Fractional variables can take any value in the interval  $[0, 1]$ ; thus, `ivfprobit` is useful for modeling outcomes such as rates and proportions.

Formally, we can write the model fit by `ivfprobit` as

$$E(y_{1i} | \mathbf{x}_{1i}, \mathbf{x}_{2i}, \mathbf{y}_{2i}, u_i) = \Phi(\mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i) \quad (1)$$

$$\mathbf{y}_{2i} = \mathbf{x}_{i1}\boldsymbol{\Pi}_1 + \mathbf{x}_{i2}\boldsymbol{\Pi}_2 + v_i$$

where subscript  $i$  denotes the observation,  $\mathbf{y}_{2i}$  is a  $1 \times p$  vector of continuous endogenous variables,  $\mathbf{x}_{1i}$  is a  $1 \times k_1$  vector of exogenous covariates, and  $\mathbf{x}_{2i}$  is a  $1 \times k_2$  vector of excluded instruments. Endogeneity arises from the possible correlation between  $u_i$  and  $v_i$ . The coefficients in vectors  $\beta$  and  $\gamma$  are the parameters of interest. Matrices  $\Pi_1$  and  $\Pi_2$  contain the coefficients of the first stage for the reduced-form equation.

To obtain parameter estimates, `ivfprobit` maximizes the same likelihood as `ivprobit` but does not require a binary dependent variable and does not require the joint density of the errors in the model to be specified correctly; see [R] [ivprobit](#) for more information. `ivfprobit` fits the model via quasilielihood estimation rather than maximum likelihood estimation. The key insight behind quasilielihood estimation is that we do not need to know the true distribution of the entire model to obtain consistent parameter estimates. In fact, the only requirement is the correct specification of the conditional mean given in (1) after integrating over  $u_i$ . Specifying the full distribution of the model correctly is required only if we want to obtain asymptotically efficient standard errors from maximum likelihood estimation.

`ivfprobit` does not assume that the true model is a probit model that accounts for endogeneity, such as the one fit by `ivprobit`. Therefore, the standard errors provided by maximum likelihood estimation are not appropriate. Instead, `ivfprobit` takes the maximum quasilielihood approach and reports robust standard errors by default.

For further discussion on quasilielihood estimation in the context of fractional regression, see [Papke and Wooldridge \(1996\)](#) and [Wooldridge \(2010\)](#).

## ▷ Example 1

We use a corporate 401(k) participation dataset and fit a fractional probit regression of the 401(k) participation rate (`prate`), on corporate employment size (`ltotemp`) and its square, an indicator of whether the 401(k) is the sole pension plan (`sole`), and plan matching rate (`mrate`). The plan matching rate is endogenous and is instrumented using the age of the plan (`age`) and its square.

Our outcome variable `prate` has values between 0 and 1, including 1,351 firms with participation rates of 1. We assume that the functional form of the expected participation rate, after integrating over  $u_i$ , is a cumulative normal density as in (1).

We use `ivfprobit` to fit the fractional probit model, accounting for endogeneity of `mrate`.

```
. use https://www.stata-press.com/data/r18/401k
(Firm-level data on 401k participation)
. ivfprobit prate c.ltotemp##c.ltotemp i.sole (mrate = c.age##c.age)
Fitting exogenous fractional probit model:
Iteration 0: Log pseudolikelihood = -1769.7046
Iteration 1: Log pseudolikelihood = -1675.4223
Iteration 2: Log pseudolikelihood = -1674.7663
Iteration 3: Log pseudolikelihood = -1674.7661
Iteration 4: Log pseudolikelihood = -1674.7661
Fitting full model:
Iteration 0: Log pseudolikelihood = -3712.498
Iteration 1: Log pseudolikelihood = -3712.4767
Iteration 2: Log pseudolikelihood = -3712.4767
Fractional probit model with endogenous regressors
Number of obs = 4,075
Wald chi2(4) = 907.06
Prob > chi2 = 0.0000
Log pseudolikelihood = -3712.4767
```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
mrate	1.907922	.0946094	20.17	0.000	1.722491	2.093353
ltotemp	-.4229273	.0744177	-5.68	0.000	-.5687833	-.2770713
c.ltotemp#						
c.ltotemp	.0217492	.0046476	4.68	0.000	.01264	.0308583
sole						
Only plan	-.1733119	.0366136	-4.73	0.000	-.2450733	-.1015504
_cons	1.904103	.3199032	5.95	0.000	1.277104	2.531102
corr(e.mrate, e.prate)	-.5690386	.0431738			-.6476498	-.4784406
sd(e.mrate)	.3989664	.0061807			.3870345	.4112661

```
Wald test of exogeneity: chi2(1) = 102.40 Prob > chi2 = 0.0000
Endogenous: mrate
Exogenous: ltotemp c.ltotemp##c.ltotemp i.sole age c.age##c.age
```

We find a positive effect of `mrate` on the participation rate. Additionally, we see that the correlation between the unobservables, `corr(e.mrate, e.prate)`, is different from zero. This means there is evidence to support our endogeneity conjecture.

◀

## Model identification

As in the basic linear instrumental-variables model, the order condition for identification requires that the number of excluded exogenous variables (that is, the additional instruments) be at least as great as the number of included endogenous variables ( $k_2 \geq p$ ). `ivfprobit` checks this for you and issues an error message if the order condition is not met.

`ivfprobit`, like `probit` and `ivprobit`, checks the exogenous and endogenous variables to see if any of them predict the outcome variable perfectly. It will drop any offending variables and observations and then fit the model on the remaining data. Instruments that are perfect predictors do not affect estimation, so they are not checked. See [Model identification](#) in [R] [probit](#) for more information.

## Stored results

`ivfprobit` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(N_clust)</code>	number of clusters
<code>e(endog_ct)</code>	number of endogenous covariates
<code>e(p)</code>	model Wald $p$ -value
<code>e(p_exog)</code>	exogeneity test Wald $p$ -value
<code>e(chi2)</code>	model Wald $\chi^2$
<code>e(chi2_exog)</code>	Wald $\chi^2$ test of exogeneity
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>ivfprobit</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(endog)</code>	names of endogenous variables
<code>e(exog)</code>	names of exogenous variables
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(chi2type)</code>	Wald; type of model $\chi^2$ test
<code>e(vce)</code>	<i>vce</i> type specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(footnote)</code>	program used to implement the footnote display
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(Sigma)</code>	$\widehat{\Sigma}$
<code>e(V)</code>	variance-covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices	
<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Postestimation commands

The following postestimation commands are of special interest after `ivfprobit`:

Command	Description
<code>estat correlation</code>	report the correlation matrix of the errors of the dependent variable and the endogenous variables
<code>estat covariance</code>	report the covariance matrix of the errors of the dependent variable and the endogenous variables

These commands are not appropriate after the `svy` prefix.

The following standard postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	conditional means, linear predictions, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`forecast` is not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as conditional means, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic asfmethod]
```

```
predict [type] {stub*|newvarlist} [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>cm</code>	conditional mean; the default
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the linear prediction

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

<i>asfmethod</i>	Description
------------------	-------------

Main

<code>asf</code>	average structural function; the default
<code>fixedasf</code>	fixed average structural function

## Options for predict

Main

`cm`, the default, calculates the conditional mean.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`asf` and `fixedasf` determine how the average structural function (ASF) of the conditional mean is computed. These options are not allowed with `xb` or `stdp`.

`asf` is the default estimator when the `cm` statistic is specified. `asf` computes the ASF of the conditional mean. It is the prediction conditional on the errors of the endogenous variable equations. Put another way, it is the conditional mean accounting for the correlation of the endogenous covariates with the errors of the main equation. Derivatives and contrasts based on `asf` have a structural interpretation. See [margins](#) below for computing derivatives and contrasts.

`fixedasf` calculates a fixed ASF. It is the prediction using only the coefficients and variables of the outcome equation. `fixedasf` does not condition on the errors of the endogenous variable equations. Contrasts between two fixed counterfactuals averaged over the whole sample have a potential-outcome interpretation. Intuitively, it is as if the values of the covariates were fixed at a value exogenously by fiat. See `margins` below for computing derivatives and contrasts.

To be clear, derivatives and contrasts between two fixed counterfactuals using the default `asf` option also have a potential-outcome interpretation. And, unlike `fixedasf`, they retain that interpretation when computed over subpopulations for both linear and nonlinear models.

`scores` calculates the equation-level score variables.

For models with one endogenous regressor, four new variables are created.

The first new variable will contain  $\partial \ln L / \partial (z_i \delta)$ .

The second new variable will contain  $\partial \ln L / \partial (x_i \mathbf{\Pi})$ .

The third new variable will contain  $\partial \ln L / \partial \operatorname{atanh} \rho$ .

The fourth new variable will contain  $\partial \ln L / \partial \ln \sigma$ .

For models with  $p$  endogenous regressors,  $p + \{(p + 1)(p + 2)\} / 2$  new variables are created.

The first new variable will contain  $\partial \ln L / \partial (z_i \delta)$ .

The second through  $(p + 1)$ th new variables will contain  $\partial \ln L / \partial (x_i \mathbf{\Pi}_k)$ ,  $k = 1, \dots, p$ , where  $\mathbf{\Pi}_k$  is the  $k$ th column of  $\mathbf{\Pi}$ .

The remaining score variables will contain the partial derivatives of  $\ln L$  with respect to  $s_{21}$ ,  $s_{31}$ ,  $\dots$ ,  $s_{p+1,1}$ ,  $s_{22}$ ,  $\dots$ ,  $s_{p+1,2}$ ,  $\dots$ ,  $s_{p+1,p+1}$ , where  $s_{m,n}$  denotes the  $(m, n)$  element of the Cholesky decomposition of the error covariance matrix.

# margins

## Description for margins

`margins` estimates margins of response for linear predictions and probabilities.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
------------------	-------------

---

Main

<code>cm</code>	conditional mean; the default
<code>xb</code>	linear prediction
<code>stdp</code>	not allowed with <code>margins</code>

---

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## estat

### Description for estat

`estat correlation` displays the correlation matrix of the errors of the dependent variable and the endogenous variables.

`estat covariance` displays the covariance matrix of the errors of the dependent variable and the endogenous variables.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

*Correlation matrix*

```
estat correlation [ , border(bspec) left(#) format(%fmt) ]
```

*Covariance matrix*

```
estat covariance [ , border(bspec) left(#) format(%fmt) ]
```

### Options for estat

Main

---

`border`(*bspec*) sets the border style of the matrix display. The default is `border(all)`.

`left`(#) sets the left indent of the matrix display. The default is `left(2)`.

`format`(%*fmt*) specifies the format for displaying the individual elements of the matrix. The default is `format(%9.0g)`.

## Remarks and examples

Remarks are presented under the following headings:

*Marginal effects*  
*Obtaining predicted values*

### Marginal effects

#### ▷ Example 1

We can obtain marginal effects by using the `margins` command after `ivfprobit`. We will calculate average marginal effects by using the 401(k) participation model of [example 1](#) in [\[R\] ivfprobit](#).

```
. use https://www.stata-press.com/data/r18/401k
(Firm-level data on 401k participation)
. ivfprobit prate c.ltotemp##c.ltotemp i.sole (mrate = c.age##c.age)
(output omitted)
. margins, dydx(mrate) predict(cm)

Average marginal effects                Number of obs = 4,075
Model VCE: Robust
Expression: Conditional mean of prate, predict(cm)
dy/dx wrt:  mrate
```

	Delta-method		z	P> z	[95% conf. interval]	
	dy/dx	std. err.				
mrate	.5288314	.0442438	11.95	0.000	.4421152	.6155477

The marginal effect from `ivfprobit` suggests that a \$1 increase in the matching rate (per dollar) given by employers can increase participation by approximately 50%.

◀

### Obtaining predicted values

After fitting your model with `ivfprobit`, you can obtain the conditional mean, or the linear prediction and its standard error for both the estimation sample and other samples, by using the `predict` command; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#).

### Stored results

`estat correlation` stores the following results in `r()`:

Matrices  
`r(corr)`      correlation matrix of the errors

`estat covariance` stores the following results in `r()`:

Matrices  
`r(cov)`      covariance matrix of the errors

## Methods and formulas

Recall that the model fit by `ivfprobit` is given by two equations:

$$E[y_{1i} | \mathbf{x}_{1i}, \mathbf{x}_{2i}, y_{2i}, u_i] = \Phi(\mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i)$$

$$y_{2i} = \mathbf{x}_{i1}\boldsymbol{\Pi}_1 + \mathbf{x}_{i2}\boldsymbol{\Pi}_2 + v_i$$

The linear prediction for observation  $i$  is calculated as  $\mathbf{y}_{2i}\hat{\boldsymbol{\beta}} + \mathbf{x}_{1i}\hat{\boldsymbol{\gamma}}$ . The predicted conditional mean is given by  $\Phi(\hat{m}_i)$ , where  $\Phi(\cdot)$  is the standard normal distribution function and  $\hat{m}_i$  is the plugin estimator of

$$m_i = \frac{\mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + \rho v_i / \sigma}{\sqrt{1 - \rho^2}}$$

where  $\sigma$  is the standard deviation of  $v_i$  and  $\rho$  is the correlation coefficient between  $u_i$  and  $v_i$ . The ASF uses  $\hat{m}_i$  instead of  $\mathbf{y}_{2i}\hat{\boldsymbol{\beta}} + \mathbf{x}_{1i}\hat{\boldsymbol{\gamma}}$  to evaluate  $\Phi(\cdot)$  and account for endogeneity in the model. The fixed ASF is evaluated at  $\mathbf{y}_{2i}\hat{\boldsymbol{\beta}} + \mathbf{x}_{1i}\hat{\boldsymbol{\gamma}}$ .

## Description

`ivpoisson` estimates the parameters of a Poisson regression model in which some of the covariates are endogenous. The model is also known as an exponential conditional mean model in which some of the covariates are endogenous. The model may be specified using either additive or multiplicative error terms. The model is frequently used to model count outcomes and is also used to model nonnegative outcome variables.

## Quick start

Two-step GMM estimation of the Poisson regression of  $y_1$  on  $x$  and endogenous regressor  $y_2$  that is instrumented using  $z$

```
ivpoisson gmm y1 x (y2 = z)
```

Same as above, but specify multiplicative errors rather than additive

```
ivpoisson gmm y1 x (y2 = z), multiplicative
```

Use iterative GMM estimation

```
ivpoisson gmm y1 x (y2 = z), igmm
```

Specify a weight matrix that allows for correlation within clusters identified by `cvar`

```
ivpoisson gmm y1 x (y2 = z), wmatrix(cluster cvar)
```

Use the control-function estimator

```
ivpoisson cfunction y1 x (y2 = z)
```

## Menu

Statistics > Endogenous covariates > Poisson model with endogenous covariates

## Syntax

*Generalized method of moments estimator*

```
ivpoisson gmm depvar [varlist1] [(varlist2 = varlistiv)] [if] [in] [weight]  
[ , reg_err_opt options]
```

*Control-function estimator*

```
ivpoisson cfunction depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight]  
[ , options]
```

*reg\_err\_opt*

Description

---

Model

additive

add regression errors to the conditional mean term; the default

multiplicative

multiply regression errors by the conditional mean term

---

<i>options</i>	Description
Model	
<u>noconstant</u>	suppress constant term
<u>exposure</u> ( <i>varname<sub>e</sub></i> )	include $\ln(\text{varname}_e)$ in model with coefficient constrained to 1
<u>offset</u> ( <i>varname<sub>o</sub></i> )	include <i>varname<sub>o</sub></i> in model with coefficient constrained to 1
* <u>twostep</u>	use two-step GMM estimator; the default for <code>ivpoisson gmm</code>
* <u>onestep</u>	use one-step GMM estimator; the default for <code>ivpoisson cfunction</code>
* <u>igmm</u>	use iterative GMM estimator
Weight matrix	
<u>wmatrix</u> ( <i>wmtype</i> )	specify weight matrix; <i>wmtype</i> may be <u>robust</u> , <u>cluster</u> <i>clustvar</i> , or <u>unadjusted</u>
<u>center</u>	center moments in weight-matrix computation
<u>winitial</u> ( <i>iwtype</i> [, <u>independent</u> ])	specify initial weight matrix; <i>iwtype</i> may be <u>unadjusted</u> , <u>identity</u> , or the name of a Stata matrix ( <u>independent</u> may not be specified with <code>ivpoisson gmm</code> )
SE/Robust	
<u>vce</u> ( <i>vcetype</i> )	<i>vcetype</i> may be <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>bootstrap</u> , <u>jackknife</u> , or <u>unadjusted</u>
Reporting	
<u>level</u> (#)	set confidence level; default is <code>level(95)</code>
<u>irr</u>	report incidence-rate ratios
<u>display_options</u>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Optimization	
<u>from</u> ( <i>initial_values</i> )	specify initial values for parameters
‡ <u>igmmiterate</u> (#)	specify maximum number of iterations for iterated GMM estimator
‡ <u>igmmeps</u> (#)	specify # for iterated GMM parameter convergence criterion; default is <code>igmmeps(1e-6)</code>
‡ <u>igmmweps</u> (#)	specify # for iterated GMM weight-matrix convergence criterion; default is <code>igmmweps(1e-6)</code>
<u>optimization_options</u>	control the optimization process; seldom used

\*You can specify at most one of these options.

‡These options may be specified only when `igmm` is specified.

*varlist<sub>1</sub>* and *varlist<sub>iv</sub>* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *varlist<sub>1</sub>*, *varlist<sub>2</sub>*, and *varlist<sub>iv</sub>* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bootstrap`, `by`, `collect`, `jackknife`, `rolling`, and `statsby` are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`aweight`s are not allowed with the `jackknife` prefix; see [R] `jackknife`.

`aweight`s, `fweight`s, `iweight`s, and `pweight`s are allowed; see [U] 11.1.6 weight.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`noconstant`, `exposure(varnamee)`, `offset(varnameo)`; see [R] [Estimation options](#).

`additive`, the default, specifies that the regression errors be added to the conditional mean term and have mean 0.

`multiplicative` specifies that the regression errors be multiplied by the conditional mean term and have mean 1.

`twostep`, `onestep`, and `igmm` specify which estimator is to be used.

`twostep` requests the two-step GMM estimator. `gmm` obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, and then reestimates the parameters based on that weight matrix. `twostep` is the default for `ivpoisson gmm`.

`onestep` requests the one-step GMM estimator. The parameters are estimated based on an initial weight matrix, and no updating of the weight matrix is performed except when calculating the appropriate variance–covariance (VCE) matrix. `onestep` is the default for `ivpoisson cfunction`.

`igmm` requests the iterative GMM estimator. `gmm` obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, reestimates the parameters based on that weight matrix, computes a new weight matrix, and so on, to convergence. Convergence is declared when the relative change in the parameter vector is less than `igmmeps()`, the relative change in the weight matrix is less than `igmmweps()`, or `igmmiterate()` iterations have been completed. Hall (2005, sec. 2.4 and 3.6) mentions that there may be gains to finite-sample efficiency from using the iterative estimator.

### Weight matrix

`wmatrix(wmtype)` specifies the type of weight matrix to be used in conjunction with the two-step and iterated GMM estimators.

Specifying `wmatrix(robust)` requests a weight matrix that is appropriate when the errors are independent but not necessarily identically distributed. `wmatrix(robust)` is the default.

Specifying `wmatrix(cluster clustvar)` requests a weight matrix that accounts for arbitrary correlation among observations within clusters identified by `clustvar`.

Specifying `wmatrix(unadjusted)` requests a weight matrix that is suitable when the errors are homoskedastic.

`wmatrix()` cannot be specified if `onestep` is also specified.

`center` requests that the sample moments be centered (demeaned) when computing GMM weight matrices. By default, centering is not done.

`winitial(wmtype[, independent])` specifies the weight matrix to use to obtain the first-step parameter estimates.

Specifying `winitial(unadjusted)` requests a weighting matrix that assumes the error functions are independent and identically distributed. This matrix is of the form  $(\mathbf{Z}'\mathbf{Z})^{-1}$ , where  $\mathbf{Z}$  represents all the exogenous regressors and instrumental variables.

`winitial(identity)` requests that the identity matrix be used.

`winitial(matname)` requests that Stata matrix `matname` be used.

Including the independent suboption creates a weight matrix that assumes error functions are independent. Elements of the weight matrix corresponding to covariances between any two error functions are set equal to zero. This suboption only applies to `ivpoisson cfunction`.

`winitial(unadjusted)` is the default for `ivpoisson gmm`.

`winitial(unadjusted, independent)` is the default for `ivpoisson cfunction`.

#### SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(unadjusted)` specifies that an unadjusted (nonrobust) VCE matrix be used; this, along with the `twostep` option, results in the “optimal two-step GMM” estimates often discussed in textbooks. `vce(unadjusted)` may not be set in `ivpoisson cfunction`.

The default `vctype` is based on the `wmtype` specified in the `wmatrix()` option. If `wmatrix()` is specified but `vce()` is not, then `vctype` is set equal to `wmtype`. To override this behavior in `ivpoisson gmm` and obtain an unadjusted (nonrobust) VCE matrix, specify `vce(unadjusted)`. The default `vctype` for `ivpoisson cfunction` is `robust`.

Specifying `vce(bootstrap)` or `vce(jackknife)` results in standard errors based on the bootstrap or jackknife, respectively. See [R] [vce\\_option](#), [R] [bootstrap](#), and [R] [jackknife](#) for more information on these VCEs.

The syntax for `vctypes` is identical to those for `wmatrix()`.

#### Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ .

Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results. `irr` is not allowed with `additive`.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

#### Optimization

`from(initial_values)` specifies the initial values to begin the estimation. You can specify a  $1 \times k$  matrix, where  $k$  is the number of parameters in the model, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize the coefficient for `male` to 1.23 and the constant `_cons` to 4.57, you would type

```
ivpoisson ..., from(male 1.23 _cons 4.57) ...
```

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, `ivpoisson` exits with error code 480. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model. `ivpoisson` ignores the row and column names of the matrix.

`igmmiterate(#)`, `igmmeps(#)`, and `igmmweps(#)` control the iterative process for the iterative GMM estimator for `ivpoisson`. These options can be specified only if you also specify `igmm`.

`igmmiterate(#)` specifies the maximum number of iterations to perform with the iterative GMM estimator. The default is the number set using `set maxiter`, which is 300 by default.

`igmmeps(#)` specifies the convergence criterion used for successive parameter estimates when the iterative GMM estimator is used. The default is `igmmeps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `igmmeps()` and the relative difference between successive estimates of the weight matrix is less than `igmmweps()`.

`igmmweps(#)` specifies the convergence criterion used for successive estimates of the weight matrix when the iterative GMM estimator is used. The default is `igmmweps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `igmmeps()` and the relative difference between successive estimates of the weight matrix is less than `igmmweps()`.

*optimization\_options*: `technique()`, `conv_maxiter()`, `conv_ptol()`, `conv_vtol()`, `conv_nrtol()`, and `tracelevel()`. `technique()` specifies the optimization technique to use; `gn` (the default), `nr`, `dfp`, and `bfgs` are allowed. `conv_maxiter()` specifies the maximum number of iterations; `conv_ptol()`, `conv_vtol()`, and `conv_nrtol()` specify the convergence criteria for the parameters, gradient, and scaled Hessian, respectively. `tracelevel()` allows you to obtain additional details during the iterative process. See [M-5] [optimize\(\)](#).

## Remarks and examples

`ivpoisson` estimates the parameters of a Poisson regression model in which some of the covariates are endogenous. A regressor is endogenous if it is related to the unobserved error term. The model is also known as an exponential conditional mean model in which some of the covariates are endogenous. The model may be specified using either additive or multiplicative error terms.

The model is frequently used to model count outcomes and is also used to model nonnegative outcome variables. Poisson regression is a special exponential conditional mean model. See [R] [poisson](#) for more information on Poisson regression.

The exponential conditional mean model has an error form representation in which the dependent variable  $y$  is a function of the exogenous covariates  $\mathbf{x}$ , endogenous covariates  $\mathbf{y}_2$ , and an error  $\epsilon$ . The covariates  $\mathbf{x}$  are independent of  $\epsilon$ , while  $\mathbf{y}_2$  are not.

`ivpoisson` allows  $\epsilon$  to enter either additively,

$$y_i = \exp(\mathbf{x}'_i\boldsymbol{\beta}_1 + \mathbf{y}'_{2,i}\boldsymbol{\beta}_2) + \epsilon_i$$

or multiplicatively,

$$y_i = \exp(\mathbf{x}'_i\boldsymbol{\beta}_1 + \mathbf{y}'_{2,i}\boldsymbol{\beta}_2)\epsilon_i$$

Mullahy (1997), Cameron and Trivedi (2013), Windmeijer and Santos Silva (1997), and Wooldridge (2010) discuss the generalized method of moments (GMM) estimators implemented in `ivpoisson`. GMM is frequently used in modern econometrics. Many econometric and statistical models can be expressed as conditions on the population moments. The parameter estimates produced by GMM estimators make the sample-moment conditions as true as possible given the data. See [R] [gmm](#) for further information on GMM estimation and how Stata performs it.

The rest of the discussion is presented under the following headings:

*GMM estimator for additive model*

*GMM estimator for multiplicative model*

*CF estimator for multiplicative model*

## GMM estimator for additive model

The GMM estimator uses additional variables, known as instruments and denoted by  $\mathbf{z}_i$ , to specify moment conditions that hold in the population. The GMM parameter estimates make the sample versions of these population-moment conditions as close to true as possible. The instrumental variables are assumed to be correlated with the endogenous covariates  $\mathbf{y}_{2,i}$  but independent of the errors  $\epsilon_i$ .

Under additive errors, the dependent variable  $y_i$  is determined by exogenous covariates  $\mathbf{x}_i$ , endogenous covariates  $\mathbf{y}_{2,i}$ , and zero-mean error  $\epsilon_i$  as

$$y_i = \exp(\mathbf{x}'_i\boldsymbol{\beta}_1 + \mathbf{y}'_{2,i}\boldsymbol{\beta}_2) + \epsilon_i$$

This leads to the following error function

$$u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2) = y_i - \exp(\mathbf{x}'_i\boldsymbol{\beta}_1 + \mathbf{y}'_{2,i}\boldsymbol{\beta}_2)$$

The population-moment conditions for GMM estimation are  $E\{\tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2)\} = \mathbf{0}$ , where the vector  $\tilde{\mathbf{z}}_i$  is partitioned as  $(\mathbf{x}'_i, \mathbf{z}'_i)$ . The sample-moment conditions are formed by replacing the expectation with the corresponding sample mean. The GMM estimator solves a minimization problem to make the sample-moment conditions as close to zero as possible. Details on how estimation is performed are given in [Methods and formulas](#).

Now, we will demonstrate how `ivpoisson gmm` works in the additive error setting with an example.

### ► Example 1: ivpoisson gmm with additive errors

This example uses simulated data based on the following story. A news website randomly samples 500 young adults in a major city. The website wants to model the number of times the sampled individuals visit its website (`visits`) based on their overall time spent on the Internet (`time`) and the number of times they receive an ad for the website through email or viewing another website (`ad`). The website also suspects the gender of the individual may matter, so an exogenous dummy variable, `female`, is included in the model.

We suspect time spent on the Internet is correlated with unobserved factors that additively affect the number of times an individual visits the website. So we treat `time` as an endogenous regressor. Two instruments are used for this variable. The time spent on the phone (`phone`) is one instrument. The other instrument is the time spent interacting with friends and family that live out of town (`frfam`).

We model the number of visits the website receives using an exponential conditional mean model with additive errors and use `ivpoisson gmm` to estimate the parameters of the regression in the output below. To allow for heteroskedasticity of the errors, we use robust standard errors, which is the default; see [Obtaining standard errors](#) in [R] `gmm` for a discussion of why robust standard errors is the default.

```
. use https://www.stata-press.com/data/r18/website
(Visits to website)
. ivpoisson gmm visits ad female (time = phone frfam)

Step 1
Iteration 0: GMM criterion Q(b) = .33829416
Iteration 1: GMM criterion Q(b) = .00362656
Iteration 2: GMM criterion Q(b) = .00131886
Iteration 3: GMM criterion Q(b) = .00131876

Step 2
Iteration 0: GMM criterion Q(b) = .00027102
Iteration 1: GMM criterion Q(b) = .00025811
Iteration 2: GMM criterion Q(b) = .00025811
```

In the output below, we estimate the parameters of the regression with `ivpoisson gmm`. To allow for heteroskedasticity of the errors, we use robust standard errors, which is the default.

```
. use https://www.stata-press.com/data/r18/trip
(Household trips)
. ivpoisson gmm trips cbd ptn worker weekend (tcost = pt), multiplicative

Step 1
Iteration 0: GMM criterion Q(b) = .04949852
Iteration 1: GMM criterion Q(b) = .00011194
Iteration 2: GMM criterion Q(b) = 1.563e-08
Iteration 3: GMM criterion Q(b) = 3.685e-16

Step 2
Iteration 0: GMM criterion Q(b) = 2.287e-16
Iteration 1: GMM criterion Q(b) = 1.275e-31

note: model is exactly identified.

Endogenous: tcost

Exogenous: cbd ptn worker weekend pt

We find that all coefficients are significant. At fixed values of the other covariates, we see that additional mileage from the central business district and public transit nodes reduces the expected number of trips taken. Individuals who live farther away from the central business district may still be out of the house the same amount of time, but they will take fewer trips because the transit time has increased. The situation is similar for those who live farther from public transit.

To interpret the other parameters, we will look at the partial effects of their respective independent variables. The partial effects of a change in an independent variable on the modeled conditional expectation function vary over the data because the model is nonlinear. However, under the multiplicative error model, the ratio of the new value to the old value after a discrete change in an independent variable is constant over the data.

Let  $\mathbf{w} = (\mathbf{x}', \mathbf{y}'_2)'$ . If we add 1 to the  $j$ th independent variable in  $\mathbf{w}$ , the functional form of the model implies that

$$\frac{E(y|\mathbf{w}, w_j + 1, \epsilon)}{E(y|\mathbf{w}, w_j, \epsilon)} = \frac{E(y|w_1, \dots, w_j + 1, \dots, w_k, \epsilon)}{E(y|w_1, \dots, w_j, \dots, w_k, \epsilon)} = e^{\beta_j}$$

When  $y$  is a count variable, this normalized effect is called the incidence-rate ratio (IRR) for a one-unit change in  $w_j$ .

More generally, the IRR for a  $\Delta w_j$  change in  $w_j$  is  $e^{\beta_j \Delta w_j}$  under a multiplicative-error exponential conditional mean model. We can calculate incidence-rate ratios for different changes in the covariates by using `lincom`; see [R] [lincom](#).

Here we replay the `ivpoisson` results by typing the command name and we specify the `irr` option to get the incidence-rate ratios. Each significance test for a coefficient equaling zero becomes a test for the incidence-rate ratio equaling one.

Note: `_cons` estimates baseline incidence rate.

Endogenous: `tcost`

Exogenous: `cbd ptn worker weekend pt`

Holding other covariates and the error constant, the expected number of trips made from houses with a full-time worker is nearly twice that of those houses without a full-time worker. Similarly, the expected number of trips made during a weekend day is close to 35% higher than the expected number of trips made on other days. For each additional dollar of weekly transportation cost, the expected number of household trips is increased by approximately 3.6%.

◀

## CF estimator for multiplicative model

Control-function (CF) estimators can be used to account for endogenous covariates. As [Wooldridge \(2010, sec. 18.5\)](#) describes, CF estimators assume a certain structural relationship between the endogenous covariates and the exogenous covariates and use functions of first-stage parameter estimates to control for the endogeneity in the second stage.

Wooldridge (2010, sec. 18.5) notes that the VCE of the second-stage estimator must be adjusted to account for estimates from the first stage. `ivpoisson cfunction` solves this problem by stacking the moment conditions that define each stage and applying a single GMM estimator. See Newey (1984) and Wooldridge (2010, sec. 14.2) for a description of this technique. No adjustment to the VCE is necessary because there is only one stage.

The CF estimator augments the original multiplicative model with an estimated term that controls for the endogeneity of  $\mathbf{y}_{2,i}$ . When  $\mathbf{y}_{2,i}$  is exogenous, the coefficient on this control term is zero. Let  $\mathbf{z}$  be instrumental variables, and the vector  $\tilde{\mathbf{z}}_i$  be  $(\mathbf{x}'_i, \mathbf{z}'_i)$ .

The augmented model is

$$y_i = \exp(\mathbf{x}'_i\boldsymbol{\beta}_1 + \mathbf{y}'_{2,i}\boldsymbol{\beta}_2 + \mathbf{v}'_i\boldsymbol{\rho} + c_i)$$

where

$$\mathbf{y}_{2,i} = \mathbf{B}\tilde{\mathbf{z}}'_i + \mathbf{v}_i$$

The term  $\mathbf{v}'_i\boldsymbol{\rho}$  controls for the endogeneity of  $\mathbf{y}_{2,i}$ , and we normalize  $E\{\exp(c_i)\} = 1$ . The coefficient vector  $\boldsymbol{\rho}$  measures the strength of the endogeneity of  $\mathbf{y}_{2,i}$ ;  $\mathbf{y}_{2,i}$  is exogenous when  $\boldsymbol{\rho} = \mathbf{0}$ .

`ivpoisson cfunction` estimates  $\boldsymbol{\beta}_1$  and  $\boldsymbol{\beta}_2$  and the auxiliary parameters  $\boldsymbol{\rho}$  and  $\mathbf{B}$  by GMM; see *Methods and formulas* for details.

### ► Example 3: Control-function estimator

We return to the [previous example](#), where we estimated the parameters of an exponential conditional mean model for the number of trips taken by a household in a 24-hour period. We will estimate the parameters of the regression with the CF estimator method and compare our results with those obtained with the GMM estimator in [example 2](#).

In the output below, we estimate the parameters of the regression with the `ivpoisson cfunction` command.

```

. ivpoisson cfunction trips cbd ptn worker weekend (tcost = pt)
Step 1
Iteration 0: GMM criterion Q(b) = .00056156
Iteration 1: GMM criterion Q(b) = 2.366e-07
Iteration 2: GMM criterion Q(b) = 5.552e-14
Iteration 3: GMM criterion Q(b) = 9.760e-27
note: model is exactly identified.

Endogenous: tcost

Exogenous: cbd ptn worker weekend pt

The output table presents results for the estimated coefficients in each of three equations. First, in the `trips` equation, we see the results for the estimated coefficients in the equation for the dependent variable `trips`. Second, in the `tcost` equation, we see the estimated coefficients in the regression of `tcost` on the instrumental and exogenous variables. Third, the `/c_tcost` ancillary parameter corresponds to the estimate of  $\rho$ , the coefficient on the residual variable included to control for the endogeneity of `tcost`.

We find that all coefficients are significant in the exponential conditional mean equation, `trips`. The coefficient estimates in the `trips` equation are similar to the estimates obtained by the GMM estimator in [example 2](#). That the estimated coefficient on the `tcost` control variable is significantly different from zero suggests that `tcost` is endogenous.

## Stored results

`ivpoisson` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_dv)</code>	number of dependent variables
<code>e(Q)</code>	criterion function
<code>e(J)</code>	Hansen $J$ $\chi^2$ statistic
<code>e(J_df)</code>	$J$ statistic degrees of freedom
<code>e(N_clust)</code>	number of clusters
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations used by iterative GMM estimator
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(V)</code>	variance-covariance matrix
<code>e(init)</code>	initial values of the estimators
<code>e(Wuser)</code>	user-supplied initial weight matrix
<code>e(W)</code>	weight matrix used for final round of estimation
<code>e(S)</code>	moment covariance matrix used in robust VCE computations
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in  $\mathbf{r}()$ :

Matrices	
$\mathbf{r}(\text{table})$	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in  $\mathbf{r}()$  are updated when the command is replayed and will be replaced when any  $\mathbf{r}$ -class command is run after the estimation command.

## Methods and formulas

The estimators in `ivpoisson` are GMM estimators that can be expressed in terms of error functions and the instruments that are used to form the moment conditions. When offsets  $o_j^\beta$  are used in the outcome variable equation, the following formulas apply with  $\mathbf{x}'_j\beta_1$  changed to  $\mathbf{x}'_j\beta_1 + o_j^\beta$ .

The error functions for the GMM estimators are given in the text.

Here we provide some details about the form of the error function used by the CF estimator.

Recall that the multiplicative model is

$$y_i = \exp(\mathbf{x}'_i\beta_1 + \mathbf{y}'_{2,i}\beta_2)\epsilon_i$$

We parameterize the endogenous variables in the form

$$\mathbf{y}_{2,i} = \mathbf{B}\tilde{\mathbf{z}}'_i + \mathbf{v}_i$$

This allows us to decompose  $\epsilon_i$  as

$$\epsilon_i = \exp(\mathbf{v}'_i\rho + c_i)$$

Given this setup, we obtain the following conditional mean:

$$E(y|\mathbf{x}_i, \mathbf{z}_i, \mathbf{y}_{2,i}, \mathbf{v}_i) = \exp(\mathbf{x}'_i\beta_1 + \mathbf{y}'_{2,i}\beta_2 + \mathbf{v}'_i\rho)$$

We estimate  $\mathbf{v}_i$  as the residuals of the linear regression of  $\mathbf{y}_{2,i}$  on  $\tilde{\mathbf{z}}_i$ . The estimates of  $\mathbf{v}_i$  are used as additional covariates in the exponential conditional mean model for  $y$  to estimate  $\beta_1$ ,  $\beta_2$ , and  $\rho$ . In essence, the estimates of  $\mathbf{v}_i$  control for the endogeneity.

The error functions for the endogenous covariates are defined as

$$\mathbf{u}_{en,i}(\mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i, \mathbf{B}) = \mathbf{y}_{2,i} - \mathbf{B}\tilde{\mathbf{z}}'_i$$

Now, we define the error function for the dependent variable as

$$u_y(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \mathbf{u}_{en,i}, \beta_1, \beta_2, \rho) = y_i / \exp(\mathbf{x}'_i\beta_1 + \mathbf{y}'_{2,i}\beta_2 + \mathbf{u}'_{en,i}\rho) - 1$$

$\mathbf{u}_{en,i}$  will be vector valued if we have multiple endogenous covariates  $\mathbf{y}_{2,i}$ . Call the dimension of  $\mathbf{y}_{2,i}$   $g$ .  $\mathbf{u}_{en,i}$  and  $u_{y,i}$  define  $g + 1$  separate error functions. We will use variables  $\tilde{\mathbf{z}}_i$  to instrument each error function in  $\mathbf{u}_{en,i}$ . So for error function  $j = 1, \dots, g$ , we have the error function  $u_{en,i,j}$  and the population-moment conditions  $E(\tilde{\mathbf{z}}_i u_{en,i,j}) = \mathbf{0}$ .

We calculate  $\widehat{\mathbf{v}}_{oi}$  previous to estimation as the residuals of the linear regression of  $\mathbf{y}_{2,i}$  on  $\widetilde{\mathbf{z}}_i$ . We use variables  $\mathbf{x}_i$ ,  $\mathbf{y}_{2,i}$ , and  $\widehat{\mathbf{v}}_{oi}$  to instrument the error function  $u_y$ . This leads to the population-moment conditions  $E \left\{ (\mathbf{x}'_i, \mathbf{y}'_{2,i}, \widehat{\mathbf{v}}'_{oi}) u_{y,i} \right\} = \mathbf{0}$

Details of GMM estimation can be found in *Methods and formulas* of [R] **gmm**. Determination of the weight matrix  $\mathbf{W}_N$  is discussed there.

Under the GMM estimation, the GMM estimators  $\widehat{\beta}_1$  and  $\widehat{\beta}_2$  are the values of  $\beta_1$  and  $\beta_2$  that minimize

$$Q(\beta_1, \beta_2) = \left\{ \frac{1}{N} \sum_i \widetilde{\mathbf{z}}_i u_i(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \beta_1, \beta_2) \right\}' \mathbf{W}_N \left\{ \frac{1}{N} \sum_i \widetilde{\mathbf{z}}_i u_i(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \beta_1, \beta_2) \right\} \quad (1)$$

for  $q \times q$  weight matrix  $\mathbf{W}_N$ , where  $q$  is the dimension of  $\widetilde{\mathbf{z}}_i$ . The error functions  $u_i$  were defined in the text.

In the CF method, we have multiple error functions as defined above. We can stack the moment conditions and write them more compactly as  $\mathbf{Z}'_i \mathbf{u}_i(\mathbf{B}, \beta_1, \beta_2, \rho)$ , where

$$\mathbf{Z}_i = \begin{bmatrix} \mathbf{x}'_i & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{y}'_{2,i} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \widetilde{\mathbf{z}}_i & \cdots & \mathbf{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \widetilde{\mathbf{z}}_i \end{bmatrix}$$

and

$$\mathbf{u}_i(\mathbf{B}, \beta_1, \beta_2, \rho) = \begin{bmatrix} u_y(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \mathbf{u}_{en,i}, \beta_1, \beta_2, \rho) \\ \mathbf{u}_{en}(\mathbf{y}_{2,i}, \widetilde{\mathbf{z}}_i, \mathbf{B}) \end{bmatrix}$$

The matrix  $\mathbf{Z}_i$  has  $g + 1$  rows and  $k + gz$  columns, where  $k$  is the number of covariates for  $y_i$  and  $z$  is the number of exogenous covariates in  $\widetilde{\mathbf{z}}_i$ .

The GMM estimators  $\widehat{\mathbf{B}}$ ,  $\widehat{\beta}_1$ ,  $\widehat{\beta}_2$ , and  $\widehat{\rho}$  are the values of  $\mathbf{B}$ ,  $\beta_1$ ,  $\beta_2$ , and  $\rho$  that minimize

$$Q(\mathbf{B}, \beta_1, \beta_2, \rho) = \left\{ N^{-1} \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\mathbf{B}, \beta_1, \beta_2, \rho) \right\}' \mathbf{W}_N \left\{ N^{-1} \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\mathbf{B}, \beta_1, \beta_2, \rho) \right\} \quad (2)$$

for  $(k + gz) \times (k + gz)$  weight matrix  $\mathbf{W}_N$ .

By default, `ivpoisson` minimizes (1) and (2) using the Gauss–Newton method. See Hayashi (2000, 498) for a derivation. This technique is typically faster than quasi-Newton methods and does not require second-order derivatives.

## Postestimation commands

The following postestimation command is of special interest after `ivpoisson`:

Command	Description
<code>estat overid</code>	perform test of overidentifying restrictions

The following standard postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>forecast</code>	dynamic forecasts and simulations
<code>hausman</code>	Hausman’s specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	number of events, linear predictions, residuals, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

# predict

## Description for predict

`predict` creates a new variable containing predictions such as numbers of events, linear predictions, and residuals.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset ]
```

<i>statistic</i>	Description
------------------	-------------

Main	
<code>n</code>	number of events; the default
<code>xbtotal</code>	linear prediction, using residual estimates for <code>ivpoisson cfunction</code>
<code>xb</code>	linear prediction
<code>residuals</code>	residuals

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`n`, the default, calculates the predicted number of events via the exponential-form estimate. This is  $\exp(\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2)$  if neither `offset()` nor `exposure()` was specified,  $\exp(\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2 + \text{offset}_j)$  if `offset()` was specified, or  $\exp(\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2) \times \text{exposure}_j$  if `exposure()` was specified.

After generalized method of moments estimation, the exponential-form estimate is not a consistent estimate of the conditional mean of  $y_j$ , because it is not corrected for  $E(\epsilon_j | \mathbf{y}_{2,j})$ . More details are found in [Methods and formulas](#).

After control-function estimation, we correct the exponential-form estimate for  $E(\epsilon_j | \mathbf{y}_{2,j})$  by using the estimated residuals of  $\mathbf{y}_{2,j}$  and the `c_*` auxiliary parameters. This supplements the direct effect of  $\mathbf{y}_{2,j}$  and  $\mathbf{x}_j$  through  $\beta_1$  and  $\beta_2$  with the indirect effects of  $\mathbf{y}_{2,j}$ ,  $\mathbf{x}_j$ , and the instruments  $\mathbf{z}_j$  through the endogenous error  $\epsilon_j$ . Thus, the exponential-form estimate consistently estimates the conditional mean of  $y_j$ .

`xbtotal` calculates the linear prediction, which is  $\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2$  if neither `offset()` nor `exposure()` was specified,  $\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2 + \text{offset}_j$  if `offset()` was specified, or  $\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2 + \ln(\text{exposure}_j)$  if `exposure()` was specified.

After control-function estimation, the estimate of the linear form  $\mathbf{x}'_j\beta_1$  includes the estimated residuals of the endogenous regressors with coefficients from the `c_*` auxiliary parameters.

`xb` calculates the linear prediction, which is  $\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2$  if neither `offset()` nor `exposure()` was specified,  $\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2 + \text{offset}_j$  if `offset()` was specified, or  $\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2 + \ln(\text{exposure}_j)$  if `exposure()` was specified. See `nooffset` below.

`residuals` calculates the residuals. Under additive errors, these are calculated as  $y_j - \exp(\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2)$ . Under multiplicative errors, they are calculated as  $y_j / \exp(\mathbf{x}'_j\beta_1 + \mathbf{y}'_{2,j}\beta_2) - 1$ .

When `offset()` or `exposure()` is specified,  $\mathbf{x}'_j\beta_1$  is not used directly in the residuals.  $\mathbf{x}'_j\beta_1 + \text{offset}_j$  is used if `offset()` was specified.  $\mathbf{x}'_j\beta_1 + \ln(\text{exposure}_j)$  is used if `exposure()` was specified. See `nooffset` below.

After control-function estimation, the estimate of the linear form  $\mathbf{x}'_j\beta_1$  includes the estimated residuals of the endogenous regressors with coefficients from the `c_*` auxiliary parameters.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable. `nooffset` removes the offset from calculations involving both the `treat()` equation and the dependent count variable.

## margins

### Description for margins

`margins` estimates margins of response for numbers of events and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>n</code>	number of events; the default
<code>xbtotal</code>	linear prediction, using residual estimates for <code>ivpoisson cfunction</code>
<code>xb</code>	linear prediction
<code>residuals</code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## estat

### Description for estat

`estat overid` reports Hansen's  $J$  statistic, which is used to determine the validity of the overidentifying restrictions in a GMM model. `ivpoisson gmm` uses GMM estimation to obtain parameter estimates. Under additive and multiplicative errors, Hansen's  $J$  statistic can be accurately reported when more instruments than endogenous regressors are specified. It is not appropriate to report the  $J$  statistic after `ivpoisson cfunction`, because a just-identified model is fit.

If the model is correctly specified in the sense that  $E\{\tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta})\} = 0$ , then the sample analog to that condition should hold at the estimated value of  $\beta_1$  and  $\beta_2$ . The  $\tilde{\mathbf{z}}_i$  variables are the exogenous regressors  $\mathbf{x}_i$  and instrumental variables  $\mathbf{z}_i$  used in `ivpoisson gmm`. The  $\mathbf{y}_{2,i}$  are the endogenous regressors. The  $u$  function is the error function, which will have a different form for multiplicative and additive errors in the regression.

Hansen's  $J$  statistic is valid only if the weight matrix is optimal, meaning that it equals the inverse of the covariance matrix of the moment conditions. Therefore, `estat overid` only reports Hansen's  $J$  statistic after two-step or iterated estimation or if you specified `winitial(matname)` when calling `ivpoisson gmm`. In the latter case, it is your responsibility to determine the validity of the  $J$  statistic.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

```
estat overid
```

### Remarks and examples

`estat overid` reports Hansen's  $J$  statistic, which is used to determine the validity of the overidentifying restrictions in a GMM model. It is not appropriate to use it after `ivpoisson cfunction`, because a just-identified model is fit.

Recall that the GMM criterion function is

$$Q(\boldsymbol{\beta}) = \left\{ \frac{1}{N} \sum_i \tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2) \right\}' \mathbf{W}_N \left\{ \frac{1}{N} \sum_i \tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2) \right\} \quad (\text{A1})$$

Our  $u$  function within this formula will change depending on whether we use additive or multiplicative errors. The  $\tilde{\mathbf{z}}$  vector contains the exogenous regressors and instrumental variables used. `ivpoisson gmm` estimates regression coefficients to minimize  $Q$ .

Let  $l$  be the dimension of  $\tilde{\mathbf{z}}$  and  $k$  the number of regressors. If  $\mathbf{W}_N$  is an optimal weight matrix, under the null hypothesis  $H_0: E\{\tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2)\} = \mathbf{0}$ , the test statistic  $J = N \times Q \sim \chi^2(l - k)$ . A large test statistic casts doubt on the null hypothesis.

Because the weight matrix  $\mathbf{W}_N$  must be optimal, `estat overid` works only after the two-step and iterated estimation or if you supplied your own initial weight matrix by using the `winitial(matname)` option of `ivpoisson gmm` and used the one-step estimator.

Often, the overidentifying restrictions test is interpreted as a test of the validity of the instruments  $\mathbf{z}$ . However, other forms of model misspecification can sometimes lead to a significant test statistic. See Hall (2005, sec. 5.1) for a discussion of the overidentifying restrictions test and its behavior in correctly specified and misspecified models.

Note that `ivpoisson gmm` defaults to the two-step estimator when other options are not specified to override the default. Thus, it is appropriate to perform the  $J$  test after the regression of [example 1](#) in [\[R\] ivpoisson](#).

### ▷ Example 1: Specification test

Recall [example 1](#) of [\[R\] ivpoisson](#). We estimated the parameters of an exponential conditional mean model for the number of visits to a website. Additive errors were used. Exogenous regressors included the gender of an individual and the number of ads received from the website.

An endogenous regressor, time spent on the Internet, was also included in the model. Two instruments were used. One of the instruments measured the time spent interacting with friends and out-of-town family. The other measured the time spent on the phone.

We will reestimate the parameters of the regression here and then test the specification.

```
. use https://www.stata-press.com/data/r18/website
(Visits to website)
. ivpoisson gmm visits ad female (time = phone frfam)
(output omitted)
. estat overid
Test of overidentifying restriction:
Hansen's J chi2(1) = .129055 (p = 0.7194)
```

We have two instruments for one endogenous variable, so the  $J$  statistic has one degree of freedom. The  $J$  statistic is not significant. We fail to reject the null hypothesis that the model is correctly specified.

◀

## Stored results

`estat overid` stores the following in `r()`:

Scalars

<code>r(J)</code>	Hansen's $J$ statistic
<code>r(J_df)</code>	$J$ statistic degrees of freedom
<code>r(J_p)</code>	$J$ statistic $p$ -value

## Methods and formulas

The vector  $\mathbf{x}_i$  contains the exogenous regressors, and  $\mathbf{z}_i$  the instruments. The vector  $\tilde{\mathbf{z}}_i$  is partitioned as  $(\mathbf{x}_i, \mathbf{z}_i)$ . The vector  $\mathbf{y}_{2,i}$  contains the endogenous regressors.

Under multiplicative errors, the conditional mean of  $y_i$  is

$$\begin{aligned} E(y_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) &= E\{E(y_i | \mathbf{x}_i, \mathbf{y}_{2,i}, \epsilon_i) | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i\} \\ &= E\{\exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2) \epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i\} \\ &= \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2) E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) \end{aligned}$$

Under the CF estimator,

$$\begin{aligned} E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) &= E \{ E(\epsilon_i | \mathbf{v}_i, c_i) | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i \} \\ &= E \{ \exp(\mathbf{v}'_i \boldsymbol{\rho} + c_i) | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i \} \\ &= \exp \{ (\mathbf{y}_{2,i} - \mathbf{B}\tilde{\mathbf{z}}'_i)' \boldsymbol{\rho} \} E(c_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) \\ &= \exp \{ (\mathbf{y}_{2,i} - \mathbf{B}\tilde{\mathbf{z}}'_i)' \boldsymbol{\rho} \} \end{aligned}$$

Thus under the CF estimator, we estimate the conditional mean of  $y_i$  as

$$E(y_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) = \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2 + (\mathbf{y}_{2,i} - \mathbf{B}\tilde{\mathbf{z}}'_i)' \boldsymbol{\rho})$$

The CF estimator explicitly models the functional form of the endogeneity of  $\mathbf{y}_{2,i}$  and  $\epsilon_i$  with the instruments and exogenous regressors  $\tilde{\mathbf{z}}_i$ . This allows it to correct the exponential-form estimator for the  $E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i)$  term.

In contrast, the GMM estimator does not model the functional form of the endogeneity of  $\mathbf{y}_{2,i}$  and  $\epsilon_i$ . Therefore,  $E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i)$  is not estimated, and the exponential-form estimator under GMM estimation simply ignores this term. Noting that because  $\tilde{\mathbf{z}}_i$  and  $\epsilon_i$  are independent,  $E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) = E(\epsilon_i | \mathbf{y}_{2,i})$ , we can obviously see that ignoring the term will lead to inconsistent estimation of the conditional mean of  $y_i$ .  $y_{2,i}$  and  $\epsilon_i$  are not independent, so  $E(\epsilon_i | y_{2,i})$  may vary based on  $y_{2,i}$ .

In the additive errors setting, a similar derivation will show that the exponential-form estimator obtained from GMM estimation is inconsistent for the conditional mean of  $y_i$ .

## Description

`ivprobit` fits models for binary dependent variables where one or more of the covariates are endogenous and errors are normally distributed. By default, `ivprobit` uses maximum likelihood, but Newey's (1987) minimum  $\chi^2$  (two-step) estimator can be requested. Both estimators assume that the endogenous covariates are continuous and so are not appropriate for use with discrete endogenous covariates.

## Quick start

Probit regression of `y1` on `x` and endogenous regressor `y2` that is instrumented using `z`

```
ivprobit y1 x (y2 = z)
```

With robust standard errors

```
ivprobit y1 x (y2 = z), vce(robust)
```

Use Newey's two-step estimator

```
ivprobit y1 x (y2 = z), twostep
```

Same as above, and show first-stage regression results

```
ivprobit y1 x (y2 = z), twostep first
```

## Menu

Statistics > Endogenous covariates > Probit model with endogenous covariates

## Syntax

*Maximum likelihood estimator*

```
ivprobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight] [, mle_options]
```

*Two-step estimator*

```
ivprobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight], twostep  
[tse_options]
```

*varlist*<sub>1</sub> is the list of exogenous variables.

*varlist*<sub>2</sub> is the list of endogenous variables.

*varlist*<sub>iv</sub> is the list of exogenous variables used with *varlist*<sub>1</sub> as instruments for *varlist*<sub>2</sub>.

<i>mle_options</i>	Description

*varlist*<sub>1</sub> and *varlist*<sub>iv</sub> may contain factor variables; see [U] 11.4.3 **Factor variables**.

*devar*, *varlist*<sub>1</sub>, *varlist*<sub>2</sub>, and *varlist*<sub>iv</sub> may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bootstrap`, `by`, `collect`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. `fp` is allowed with the maximum likelihood estimator.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()`, `first`, `twostep`, and `weights` are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed with the maximum likelihood estimator. `fweights` are allowed with Newey's two-step estimator. See [U] 11.1.6 **weight**.

`coeflegend` does not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options for ML estimator

### Model

`mle` requests that the conditional maximum-likelihood estimator be used. This is the default.

`asis` requests that all specified variables and observations be retained in the maximization process.

This option is typically not used and may introduce numerical instability. Normally, `ivprobit` omits any endogenous or exogenous variables that perfectly predict success or failure in the dependent variable. The associated observations are also excluded. For more information, see *Model identification* in [R] **probit**.

`constraints(constraints)`; see [R] **Estimation options**.

### SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] *vce\_option*.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the probit equation. The default is not to show these parameter estimates.

`nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#).

The following option is available with `ivprobit` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Options for two-step estimator

## Model

`twostep` is required and requests that Newey's (1987) efficient two-step estimator be used to obtain the coefficient estimates.

`asis` requests that all specified variables and observations be retained in the maximization process. This option is typically not used and may introduce numerical instability. Normally, `ivprobit` omits any endogenous or exogenous variables that perfectly predict success or failure in the dependent variable. The associated observations are also excluded. For more information, see [Model identification](#) in [R] [probit](#).

## SE

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`twostep`) and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the probit equation. The default is not to show these parameter estimates.

*display\_options*: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

The following option is available with `ivprobit` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Model setup*

*Model identification*

### Model setup

`ivprobit` fits models with dichotomous dependent variables and endogenous covariates. You can use it to fit a probit model when you suspect that one or more of the covariates are correlated with the error term. `ivprobit` is to probit modeling what `ivregress` is to linear regression analysis; see [R] [ivregress](#) for more information.

Formally, the model is

$$\begin{aligned}y_{1i}^* &= \mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i \\ \mathbf{y}_{2i} &= \mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2 + \mathbf{v}_i\end{aligned}$$

where  $i = 1, \dots, N$ ,  $\mathbf{y}_{2i}$  is a  $1 \times p$  vector of endogenous variables,  $\mathbf{x}_{1i}$  is a  $1 \times k_1$  vector of exogenous variables,  $\mathbf{x}_{2i}$  is a  $1 \times k_2$  vector of additional instruments, and the equation for  $\mathbf{y}_{2i}$  is written in reduced form. By assumption,  $(u_i, \mathbf{v}_i) \sim N(\mathbf{0}, \boldsymbol{\Sigma})$ , where  $\sigma_{11}$  is normalized to one to identify the model.  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$  are vectors of structural parameters, and  $\boldsymbol{\Pi}_1$  and  $\boldsymbol{\Pi}_2$  are matrices of reduced-form parameters. This is a recursive model:  $\mathbf{y}_{2i}$  appears in the equation for  $y_{1i}^*$ , but  $y_{1i}^*$  does not appear in the equation for  $\mathbf{y}_{2i}$ . We do not observe  $y_{1i}^*$ ; instead, we observe

$$y_{1i} = \begin{cases} 0 & y_{1i}^* < 0 \\ 1 & y_{1i}^* \geq 0 \end{cases}$$

The order condition for identification of the structural parameters requires that  $k_2 \geq p$ . Presumably,  $\boldsymbol{\Sigma}$  is not block diagonal between  $u_i$  and  $\mathbf{v}_i$ ; otherwise,  $\mathbf{y}_{2i}$  would not be endogenous.

### □ Technical note

This model is derived under the assumption that  $(u_i, \mathbf{v}_i)$  is independent and identically distributed multivariate normal for all  $i$ . The `vce(cluster clustvar)` option can be used to control for a lack of independence. As with most probit models, if  $u_i$  is heteroskedastic, point estimates will be inconsistent. □

## ▷ Example 1

We have hypothetical data on 500 two-parent households, and we wish to model whether the woman is employed. We have a variable, `fem_work`, that is equal to 1 if she has a job and 0 otherwise. Her decision to work is a function of the number of children at home (`kids`), number of years of schooling completed (`fem_educ`), and other household income measured in thousands of dollars (`other_inc`). We suspect that unobservable shocks affecting the woman's decision to hold a job also affect the household's other income. Therefore, we treat `other_inc` as endogenous. As an instrument, we use the number of years of schooling completed by the man (`male_educ`).

The syntax for specifying the exogenous, endogenous, and instrumental variables is identical to that used in `ivregress`; see [R] [ivregress](#) for details.

```
. use https://www.stata-press.com/data/r18/laborsup
. ivprobit fem_work fem_educ kids (other_inc = male_educ)

Endogenous: <code>other_inc</code>						
Exogenous: <code>fem_educ kids male_educ</code>						

`ivprobit` used the default maximum likelihood estimator. The header of the output contains the sample size as well as a Wald statistic and  $p$ -value for the test of the hypothesis that all the slope coefficients are jointly zero. Below, the table of coefficients, Stata reminds us that the endogenous variable is `other_inc` and that `fem_educ`, `kids`, and `male_educ` were used as instruments.

At the bottom of the output is a Wald test of the exogeneity of the endogenous variables. We reject the null hypothesis of no endogeneity. If there is no endogeneity, a standard probit regression would be preferable (see [R] [probit](#)).

Below we fit our model with Newey's (1987) minimum  $\chi^2$  estimator using the `twostep` option.

## ▷ Example 2

Refitting our labor-supply model with the two-step estimator yields

```
. ivprobit fem_work fem_educ kids (other_inc = male_educ), twostep
Checking reduced-form model...
Two-step probit with endogenous regressors      Number of obs   =       500
                                                Wald chi2(3)    =       93.97
                                                Prob > chi2     =       0.0000
```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
other_inc	-.058473	.0093364	-6.26	0.000	-.0767719	-.040174
fem_educ	.227437	.0281628	8.08	0.000	.1722389	.282635
kids	-.1961748	.0496323	-3.95	0.000	-.2934522	-.0988973
_cons	.3956061	.4982649	0.79	0.427	-.5809752	1.372187

```
Wald test of exogeneity: chi2(1) = 6.50                Prob > chi2 = 0.0108
Endogenous: other_inc
Exogenous: fem_educ kids male_educ
```

All the coefficients have the same signs as their counterparts in the maximum likelihood model. The Wald test at the bottom of the output confirms our earlier finding of endogeneity.

◀

## □ Technical note

In a standard probit model, the error is assumed to have a variance of 1. In the probit model with endogenous covariates, we assume that  $(u_i, \mathbf{v}_i)$  is multivariate normal with covariance matrix

$$\text{Var}(u_i, \mathbf{v}_i) = \Sigma = \begin{bmatrix} 1 & \Sigma'_{21} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}$$

From the properties of the multivariate normal distribution, it follows that  $\text{Var}(u_i | \mathbf{v}_i) = 1 - \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21}$ . Newey's estimator and other two-step probit estimators yield estimates of  $\beta/\sigma$  and  $\gamma/\sigma$ , where  $\sigma$  is the square root of  $\text{Var}(u_i | \mathbf{v}_i)$ , instead of estimates of  $\beta$  and  $\gamma$ . Hence, we cannot directly compare the estimates obtained from Newey's estimator with those obtained from maximum likelihood, which estimate  $\beta$ ,  $\gamma$ , and  $\sigma$  separately. See Wooldridge (2010, 585–594) for a discussion about the interpretation of the estimates and the computation of marginal effects of two-step probit estimators under endogeneity.

□

## Model identification

As in the linear simultaneous-equation model, the order condition for identification requires that the number of excluded exogenous variables (that is, the additional instruments) be at least as great as the number of included endogenous variables. `ivprobit` checks this for you and issues an error message if the order condition is not met.

Like `probit`, `logit`, and `logistic`, `ivprobit` checks the exogenous and endogenous variables to see if any of them predict the outcome variable perfectly. It will then omit offending variables and observations and fit the model on the remaining data. Instruments that are perfect predictors do not affect estimation, so they are not checked. See *Model identification* in [R] **probit** for more information.

`ivprobit` will also occasionally display messages such as

```
Note: 4 failures and 0 successes completely determined.
```

For an explanation of this message, see [R] **logit**.

## Stored results

`ivprobit`, `mle` stores the following in `e()`:

e(asobserved)	factor variables fvset as asobserved

## Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(rules)	information about perfect predictors
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(Sigma)	$\hat{\Sigma}$
e(V)	variance-covariance matrix of the estimators
e(V_modelbased)	model-based variance

## Functions

e(sample)	marks estimation sample
-----------	-------------------------

In addition to the above, the following is stored in `r()`:

## Matrices

r(table)	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals
----------	---

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

`ivprobit`, `twostep` stores the following in `e()`:

## Scalars

e(N)	number of observations
e(N_cds)	number of completely determined successes
e(N_cdf)	number of completely determined failures
e(df_m)	model degrees of freedom
e(df_exog)	degrees of freedom for $\chi^2$ test of exogeneity
e(p)	model Wald $p$ -value
e(p_exog)	exogeneity test Wald $p$ -value
e(chi2)	model Wald $\chi^2$
e(chi2_exog)	Wald $\chi^2$ test of exogeneity
e(rank)	rank of <code>e(V)</code>

## Macros

e(cmd)	<code>ivprobit</code>
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(endog)	names of endogenous variables
e(exog)	names of exogenous variables
e(wtype)	weight type
e(wexp)	weight expression
e(chi2type)	Wald; type of model $\chi^2$ test
e(vce)	<code>vce</code> type specified in <code>vce()</code>
e(asis)	<code>asis</code> , if specified
e(method)	<code>twostep</code>
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(predict)	program used to implement predict

e(footnote)	program used to implement the footnote display
e(marginsok)	predictions allowed by margins
e(marginsprop)	signals to the margins command
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved
Matrices	
e(b)	coefficient vector
e(rules)	information about perfect predictors
e(V)	variance–covariance matrix of the estimators
Functions	
e(sample)	marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices	
r(table)	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

Fitting limited-dependent variable models with endogenous covariates has received considerable attention in the econometrics literature. Building on the results of Amemiya (1978, 1979), Newey (1987) developed an efficient method of estimation that encompasses both Rivers and Vuong's (1988) simultaneous-equations probit model and Smith and Blundell's (1986) simultaneous-equations tobit model. An efficient alternative to two-step estimation, and `ivprobit`'s default, is to use maximum likelihood. For compactness, we write the model as

$$y_{1i}^* = \mathbf{z}_i \boldsymbol{\delta} + u_i \quad (1a)$$

$$\mathbf{y}_{2i} = \mathbf{x}_i \boldsymbol{\Pi} + v_i \quad (1b)$$

where  $\mathbf{z}_i = (\mathbf{y}_{2i}, \mathbf{x}_{1i})$ ,  $\mathbf{x}_i = (\mathbf{x}_{1i}, \mathbf{x}_{2i})$ ,  $\boldsymbol{\delta} = (\boldsymbol{\beta}', \boldsymbol{\gamma}')'$ , and  $\boldsymbol{\Pi} = (\boldsymbol{\Pi}'_1, \boldsymbol{\Pi}'_2)'$ .

Deriving the likelihood function is straightforward because we can write the joint density  $f(y_{1i}, \mathbf{y}_{2i} | \mathbf{x}_i)$  as  $f(y_{1i} | \mathbf{y}_{2i}, \mathbf{x}_i) f(\mathbf{y}_{2i} | \mathbf{x}_i)$ . When there is an endogenous regressor, the log likelihood for observation  $i$  is

$$\ln L_i = w_i \left[ y_{1i} \ln \Phi(m_i) + (1 - y_{1i}) \ln \{1 - \Phi(m_i)\} + \ln \phi \left( \frac{y_{2i} - \mathbf{x}_i \boldsymbol{\Pi}}{\sigma} \right) - \ln \sigma \right]$$

where

$$m_i = \frac{\mathbf{z}_i \boldsymbol{\delta} + \rho (y_{2i} - \mathbf{x}_i \boldsymbol{\Pi}) / \sigma}{(1 - \rho^2)^{\frac{1}{2}}}$$

$\Phi(\cdot)$  and  $\phi(\cdot)$  are the standard normal distribution and density functions, respectively;  $\sigma$  is the standard deviation of  $v_i$ ;  $\rho$  is the correlation coefficient between  $u_i$  and  $v_i$ ; and  $w_i$  is the weight for observation  $i$  or one if no weights were specified. Instead of estimating  $\sigma$  and  $\rho$ , we estimate  $\ln \sigma$  and  $\text{atanh } \rho$ , where

$$\text{atanh } \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)$$

For multiple endogenous covariates, let

$$\text{Var}(u_i, \mathbf{v}_i) = \Sigma = \begin{bmatrix} 1 & \Sigma'_{21} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}$$

As in any probit model, we have imposed the normalization  $\text{Var}(u_i) = 1$  to identify the model. The log likelihood for observation  $i$  is

$$\ln L_i = w_i \left[ y_{1i} \ln \Phi(m_i) + (1 - y_{1i}) \ln \{1 - \Phi(m_i)\} + \ln f(\mathbf{y}_{2i} | \mathbf{x}_i) \right]$$

where

$$\ln f(\mathbf{y}_{2i} | \mathbf{x}_i) = -\frac{p}{2} \ln 2\pi - \frac{1}{2} \ln |\Sigma_{22}| - \frac{1}{2} (\mathbf{y}_{2i} - \mathbf{x}_i \mathbf{\Pi}) \Sigma_{22}^{-1} (\mathbf{y}_{2i} - \mathbf{x}_i \mathbf{\Pi})'$$

and

$$m_i = (1 - \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21})^{-\frac{1}{2}} \{z_i \delta + (\mathbf{y}_{2i} - \mathbf{x}_i \mathbf{\Pi}) \Sigma_{22}^{-1} \Sigma_{21}\}$$

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

The maximum likelihood version of `ivprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

The two-step estimates are obtained using Newey's (1987) minimum  $\chi^2$  estimator. The reduced-form equation for  $y_{1i}^*$  is

$$\begin{aligned} y_{1i}^* &= (\mathbf{x}_i \mathbf{\Pi} + \mathbf{v}_i) \beta + \mathbf{x}_{1i} \gamma + u_i \\ &= \mathbf{x}_i \alpha + \mathbf{v}_i \beta + u_i \\ &= \mathbf{x}_i \alpha + \nu_i \end{aligned}$$

where  $\nu_i = \mathbf{v}_i \beta + u_i$ . Because  $u_i$  and  $\mathbf{v}_i$  are jointly normal,  $\nu_i$  is also normal. Note that

$$\alpha = \begin{bmatrix} \mathbf{\Pi}_1 \\ \mathbf{\Pi}_2 \end{bmatrix} \beta + \begin{bmatrix} \mathbf{I} \\ \mathbf{0} \end{bmatrix} \gamma = D(\mathbf{\Pi}) \delta$$

where  $D(\mathbf{\Pi}) = (\mathbf{\Pi}, \mathbf{I}_1)$  and  $\mathbf{I}_1$  is defined such that  $\mathbf{x}_i \mathbf{I}_1 = \mathbf{x}_{1i}$ . Letting  $\hat{z}_i = (\mathbf{x}_i \hat{\mathbf{\Pi}}, \mathbf{x}_{1i})$ ,  $\hat{z}_i \delta = \mathbf{x}_i D(\hat{\mathbf{\Pi}}) \delta$ , where  $D(\hat{\mathbf{\Pi}}) = (\hat{\mathbf{\Pi}}, \mathbf{I}_1)$ . Thus, one estimator of  $\alpha$  is  $D(\hat{\mathbf{\Pi}}) \delta$ ; denote this estimator by  $\hat{D} \delta$ .

$\alpha$  could also be estimated directly as the solution to

$$\max_{\alpha, \lambda} \sum_{i=1}^N l(y_{1i}, \mathbf{x}_i \alpha + \hat{\mathbf{v}}_i \lambda) \quad (2)$$

where  $l(\cdot)$  is the log likelihood for probit. Denote this estimator by  $\tilde{\alpha}$ . The inclusion of the  $\hat{\mathbf{v}}_i \lambda$  term follows because the multivariate normality of  $(u_i, \mathbf{v}_i)$  implies that, conditional on  $\mathbf{y}_{2i}$ , the expected value of  $u_i$  is nonzero. Because  $\mathbf{v}_i$  is unobservable, the least-squares residuals from fitting (1b) are used.

Amemiya (1978) shows that the estimator of  $\delta$  defined by

$$\max_{\delta} (\tilde{\alpha} - \hat{D} \delta)' \hat{\Omega}^{-1} (\tilde{\alpha} - \hat{D} \delta)$$

where  $\widehat{\Omega}$  is a consistent estimator of the covariance of  $\sqrt{N}(\tilde{\alpha} - \widehat{D}\delta)$ , is asymptotically efficient relative to all other estimators that minimize the distance between  $\tilde{\alpha}$  and  $D(\widehat{\Pi})\delta$ . Thus, an efficient estimator of  $\delta$  is

$$\widehat{\delta} = (\widehat{D}'\widehat{\Omega}^{-1}\widehat{D})^{-1}\widehat{D}'\widehat{\Omega}^{-1}\tilde{\alpha} \tag{3}$$

and

$$\text{Var}(\widehat{\delta}) = (\widehat{D}'\widehat{\Omega}^{-1}\widehat{D})^{-1} \tag{4}$$

To implement this estimator, we need  $\widehat{\Omega}^{-1}$ .

Consider the two-step maximum likelihood estimator that results from first fitting (1b) by OLS and computing the residuals  $\widehat{v}_i = y_{2i} - x_i\widehat{\Pi}$ . The estimator is then obtained by solving

$$\max_{\delta, \lambda} \sum_{i=1}^N l(y_{1i}, z_i\delta + \widehat{v}_i\lambda)$$

This is the two-step instrumental-variables (2SIV) estimator proposed by Rivers and Vuong (1988), and its role will become apparent shortly.

From Proposition 5 of Newey (1987),  $\sqrt{N}(\tilde{\alpha} - \widehat{D}\delta) \xrightarrow{d} N(\mathbf{0}, \Omega)$ , where

$$\Omega = J_{\alpha\alpha}^{-1} + (\lambda - \beta)' \Sigma_{22} (\lambda - \beta) Q^{-1}$$

and  $\Sigma_{22} = E\{v_i'v_i\}$ .  $J_{\alpha\alpha}^{-1}$  is simply the covariance matrix of  $\tilde{\alpha}$ , ignoring that  $\widehat{\Pi}$  is an estimated parameter matrix. Moreover, Newey shows that the covariance matrix from an OLS regression of  $y_{2i}(\widehat{\lambda} - \widehat{\beta})$  on  $x_i$  is a consistent estimator of the second term.  $\widehat{\lambda}$  can be obtained from solving (2), and the 2SIV estimator yields a consistent estimate,  $\widehat{\beta}$ .

Mechanically, estimation proceeds in several steps.

1. Each of the endogenous right-hand-side variables is regressed on all the exogenous variables, and the fitted values and residuals are calculated. The matrix  $\widehat{D} = D(\widehat{\Pi})$  is assembled from the estimated coefficients.
2. `probit` is used to solve (2) and obtain  $\tilde{\alpha}$  and  $\widehat{\lambda}$ . The portion of the covariance matrix corresponding to  $\alpha$ ,  $J_{\alpha\alpha}^{-1}$ , is also saved.
3. The 2SIV estimator is evaluated, and the parameters  $\widehat{\beta}$  corresponding to  $y_{2i}$  are collected.
4.  $y_{2i}(\widehat{\lambda} - \widehat{\beta})$  is regressed on  $x_i$ . The covariance matrix of the parameters from this regression is added to  $J_{\alpha\alpha}^{-1}$ , yielding  $\widehat{\Omega}$ .
5. Evaluating (3) and (4) yields the estimates  $\widehat{\delta}$  and  $\text{Var}(\widehat{\delta})$ .
6. A Wald test of the null hypothesis  $H_0: \lambda = \mathbf{0}$ , using the 2SIV estimates, serves as our test of exogeneity.

The two-step estimates are not directly comparable with those obtained from the maximum likelihood estimator or from `probit`. The argument is the same for Newey's efficient estimator as for Rivers and Vuong's (1988) 2SIV estimator, so we consider the simpler 2SIV estimator. From the properties of the normal distribution,

$$E(u_i|v_i) = v_i\Sigma_{22}^{-1}\Sigma_{21} \quad \text{and} \quad \text{Var}(u_i|v_i) = 1 - \Sigma_{21}'\Sigma_{22}^{-1}\Sigma_{21}$$

We write  $u_i$  as  $u_i = \mathbf{v}_i \Sigma_{22}^{-1} \Sigma_{21} + e_i = \mathbf{v}_i \boldsymbol{\lambda} + e_i$ , where  $e_i \sim N(0, 1 - \rho^2)$ ,  $\rho^2 = \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21}$ , and  $e_i$  is independent of  $\mathbf{v}_i$ . In the second stage of 2SIV, we use a probit regression to estimate the parameters of

$$y_{1i} = \mathbf{z}_i \boldsymbol{\delta} + \mathbf{v}_i \boldsymbol{\lambda} + e_i$$

Because  $\mathbf{v}_i$  is unobservable, we use the sample residuals from the first-stage regressions.

$$\Pr(y_{1i} = 1 | \mathbf{z}_i, \mathbf{v}_i) = \Pr(\mathbf{z}_i \boldsymbol{\delta} + \mathbf{v}_i \boldsymbol{\lambda} + e_i > 0 | \mathbf{z}_i, \mathbf{v}_i) = \Phi \left\{ (1 - \rho^2)^{-\frac{1}{2}} (\mathbf{z}_i \boldsymbol{\delta} + \mathbf{v}_i \boldsymbol{\lambda}) \right\}$$

Hence, as mentioned previously, 2SIV and Newey's estimator do not estimate  $\boldsymbol{\delta}$  and  $\boldsymbol{\lambda}$  but rather

$$\boldsymbol{\delta}_\rho = \frac{1}{(1 - \rho^2)^{\frac{1}{2}}} \boldsymbol{\delta} \quad \text{and} \quad \boldsymbol{\lambda}_\rho = \frac{1}{(1 - \rho^2)^{\frac{1}{2}}} \boldsymbol{\lambda}$$

## Acknowledgments

The two-step estimator is based on the `probitiv` command written by Jonah Gelbach of the University of California at Berkeley Law School and the `ivprob` command written by Joe Harkness of the University of Connecticut.

## Postestimation commands

The following postestimation commands are of special interest after `ivprobit`:

Command	Description
<code>estat classification</code>	report various summary statistics, including the classification table
<code>estat correlation</code>	report the correlation matrix of the errors of the dependent variable and the endogenous variables
<code>estat covariance</code>	report the covariance matrix of the errors of the dependent variable and the endogenous variables
<code>lroc</code>	compute area under ROC curve and graph the curve
<code>lsens</code>	graph sensitivity and specificity versus probability cutoff

These commands are not appropriate after the two-step estimator or the `svy` prefix.

The following standard postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
* <code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
*† <code>forecast</code>	dynamic forecasts and simulations
† <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
† <code>lrtest</code>	likelihood-ratio test; not available with two-step estimator
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	linear predictions and their SEs, probabilities, etc.

<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
* <code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\* `estat ic`, `forecast`, and `suest` are not appropriate after `ivprobit`, `twostep`.

† `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as structural functions, linear predictions, standard errors, and probabilities.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

After *ML*

```
predict [type] newvar [if] [in] [, statistic asfmethod rules asif]
```

```
predict [type] { stub* | newvarlist } [if] [in] , scores
```

After *twostep*

```
predict [type] newvar [if] [in] [, twostep_statistic]
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>xb</code>	linear prediction excluding endogeneity; the default
<code>pr</code>	probability of a positive outcome
<code>stdp</code>	standard error of the linear prediction

<i>asfmethod</i>	Description
------------------	-------------

Main

<code>asf</code>	average structural function; the default
<code>fixedasf</code>	fixed average structural function

*twostep\_statistic* Description

Main

<b>xb</b>	linear prediction; the default
<b>stdp</b>	standard error of the linear prediction

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Options for `predict`

Main

**xb**, the default, calculates the linear prediction.

**pr** calculates the probability of a positive outcome. Results depend on how the endogeneity complication is handled, which is determined by the **asf** or **fixedasf** option. **pr** is not available with the two-step estimator.

**stdp** calculates the standard error of the linear prediction.

**asf** and **fixedasf** determine how the average structural function (ASF) of the specified statistic is computed. These options are not allowed with **xb** or **stdp**.

**asf** is the default for the ML estimator when the **pr** statistic is specified. **asf** computes the ASF of the specified statistic. It is the statistic conditional on the errors of the endogenous variable equations. Put another way, it is the statistic accounting for the correlation of the endogenous covariates with the errors of the main equation. Derivatives and contrasts based on **asf** have a structural interpretation. See [margins](#) for computing derivatives and contrasts.

**fixedasf** calculates a fixed ASF. It is the specified statistic using only the coefficients and variables of the outcome equation. **fixedasf** does not condition on the errors of the endogenous variable equations. Contrasts between two fixed counterfactuals averaged over the whole sample have a potential-outcome interpretation. Intuitively, it is as if the values of the covariates were fixed at a value exogenously by fiat. See [margins](#) for computing derivatives and contrasts.

To be clear, derivatives and contrasts between two fixed counterfactuals using the default **asf** option also have a potential-outcome interpretation. And, unlike **fixedasf**, they retain that interpretation when computed over subpopulations for both linear and nonlinear models.

**rules** requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations. **rules** is not available with the two-step estimator.

**asif** requests that Stata ignore the rules and the exclusion criteria and calculate predictions for all observations possible using the estimated parameters from the model. **asif** is not available with the two-step estimator.

**scores**, not available with **twostep**, calculates equation-level score variables.

For models with one endogenous regressor, four new variables are created.

The first new variable will contain  $\partial \ln L / \partial (z_i \delta)$ .

The second new variable will contain  $\partial \ln L / \partial (x_i \Pi)$ .

The third new variable will contain  $\partial \ln L / \partial \operatorname{atanh} \rho$ .

The fourth new variable will contain  $\partial \ln L / \partial \ln \sigma$ .

For models with  $p$  endogenous regressors,  $p + \{(p + 1)(p + 2)\}/2$  new variables are created.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{z}_i \boldsymbol{\delta})$ .

The second through  $(p + 1)$ th new score variables will contain  $\partial \ln L / \partial (\mathbf{x}_i \boldsymbol{\Pi}_k)$ ,  $k = 1, \dots, p$ , where  $\boldsymbol{\Pi}_k$  is the  $k$ th column of  $\boldsymbol{\Pi}$ .

The remaining score variables will contain the partial derivatives of  $\ln L$  with respect to  $s_{21}$ ,  $s_{31}$ ,  $\dots$ ,  $s_{p+1,1}$ ,  $s_{22}$ ,  $\dots$ ,  $s_{p+1,2}$ ,  $\dots$ ,  $s_{p+1,p+1}$ , where  $s_{m,n}$  denotes the  $(m, n)$  element of the Cholesky decomposition of the error covariance matrix.

## margins

### Description for margins

`margins` estimates margins of response for linear predictions and probabilities.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

After ML

<i>statistic</i>	Description
------------------	-------------

Main

<code>xb</code>	linear prediction excluding endogeneity; the default
<code>pr</code>	probability of a positive outcome
<code>stdp</code>	not allowed with <code>margins</code>

After twostep

<i>statistic</i>	Description
------------------	-------------

Main

<code>xb</code>	linear prediction; the default
<code>stdp</code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than  $\mathbf{e}(\mathbf{b})$ .

For the full syntax, see [R] [margins](#).

## estat

### Description for estat

`estat correlation` displays the correlation matrix of the errors of the dependent variable and the endogenous variables.

`estat covariance` displays the covariance matrix of the errors of the dependent variable and the endogenous variables.

`estat correlation` and `estat covariance` are not allowed after the `ivprobit` two-step estimator.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

*Correlation matrix*

```
estat correlation [ , border(bspec) left(#) format(%fmt) ]
```

*Covariance matrix*

```
estat covariance [ , border(bspec) left(#) format(%fmt) ]
```

### Options for estat

Main

`border`(*bspec*) sets border style of the matrix display. The default is `border(all)`.

`left`(#) sets the left indent of the matrix display. The default is `left(2)`.

`format`(%*fmt*) specifies the format for displaying the individual elements of the matrix. The default is `format(%9.0g)`.

## Remarks and examples

Remarks are presented under the following headings:

*Marginal effects*

*Obtaining predicted values*

### Marginal effects

Below, we discuss the interpretation of the predicted probability, `pr`, with the `asf` and `fixedasf` options for the ML estimator using `margins`.

The model is defined by two equations. The first is the equation for the outcome of interest, given by

$$y_{1i}^* = \mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i$$

where we do not observe  $y_{1i}^*$ ; instead, we observe

$$y_{1i} = \begin{cases} 0 & y_{1i}^* < 0 \\ 1 & y_{1i}^* \geq 0 \end{cases}$$

The second is the equation for the endogenous covariates,  $\mathbf{y}_{2i}$ ,

$$\mathbf{y}_{2i} = \mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2 + \mathbf{v}_i$$

This last equation is the difference between a standard probit model and the model fit by `ivprobit`.  $\mathbf{y}_{2i}$  is modeled as an exogenous component,  $\mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2$ , and a component that is correlated with  $u_i$  and causes the endogeneity problem,  $\mathbf{v}_i$ . The ASF predicted probability conditions on an estimate of  $\widehat{\mathbf{v}}_i$ . It is given by

$$\begin{aligned} \Phi(\widehat{m}_i) &= \widehat{P}(y_{1i} | \mathbf{x}_{1i}, \mathbf{x}_{2i}, y_{2i}, \widehat{\mathbf{v}}_i) \\ \widehat{m}_i &= \mathbf{y}_{2i}\widehat{\boldsymbol{\theta}}_1 + \mathbf{x}_{1i}\widehat{\boldsymbol{\theta}}_2 + \widehat{\mathbf{v}}_i\widehat{\boldsymbol{\theta}}_3 \end{aligned}$$

Because the correlation between  $\mathbf{v}_i$  and  $u_i$  is the problem we intended to address, conditioning on  $\mathbf{v}_i$  purges the model of endogeneity. Using the ASF, we can get derivatives and contrast. See [Wooldridge \(2010\)](#) and [Blundell and Powell \(2003\)](#) for an in-depth discussion of ASFs and their interpretation.

The fixed ASF, estimated when the `fixedasf` option is specified, has a different interpretation. Suppose we wanted to analyze  $1(\mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i > 0)$  at two different values of  $\mathbf{y}_2$ , the original  $\mathbf{y}_2$  and  $\mathbf{y}_2 + 1$ .  $1(\cdot)$  is an indicator function that evaluates to 1 if the condition in parentheses is satisfied and 0 otherwise. We want the average difference at these two points for the given values of the other covariates. The values of the covariates are not arrived at via the model; they are fixed by fiat. You can think of them as potential outcomes. The difference of the two values of  $\mathbf{y}_2$  is given by

$$1\{(\mathbf{y}_{2i} + 1)\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i > 0\} - 1(\mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i > 0)$$

If we average over the distribution of  $u$ , we obtain

$$\Phi \{ (y_{2i} + 1) \beta + x_{1i} \gamma \} - \Phi (y_{2i} \beta + x_{1i} \gamma)$$

We do not account for endogeneity because the values of the covariates are given and fixed. If the research question you are pursuing after fitting the model has this interpretation, `fixedasf` gives you an adequate prediction. If, however, you do not want to treat the covariates as fixed, you should account for endogeneity and use `asf` predictions.

## ▷ Example 1

We can obtain marginal effects by using the `margins` command after `ivprobit`. Continuing with [example 1](#) in [\[R\] ivprobit](#), we calculate the difference in the probability of a woman working, `fem_work`, if `other_inc` increases by 10% versus the probability when `other_inc` is unchanged. The effect we get has an ASF interpretation. The probabilities are estimated conditional on the residual from the endogenous variable. In other words, the computed effects condition on the level of endogeneity in the model. See [Wooldridge \(2010\)](#) for a discussion about the interpretation of the estimates and the computation of marginal effects of probit estimators under endogeneity.

```
. use https://www.stata-press.com/data/r18/laborsup
. ivprobit fem_work fem_educ kids (other_inc = male_educ)
  (output omitted)
. margins, at(other_inc = generate(other_inc))
>       at(other_inc = generate(other_inc*1.10))
>       contrast(at(r) nowald) predict(pr)

Contrasts of predictive margins                Number of obs = 500
Model VCE: OIM

Expression: Average structural function probabilities, predict(pr)
1._at: other_inc =          other_inc
2._at: other_inc = other_inc*1.10
```

	Delta-method		
	Contrast	std. err.	[95% conf. interval]
_at (2 vs 1)	-.0762151	.0100472	-.0959073    -.0565229

Here we see that a 10% increase in `other_inc` leads to an average decrease of 0.076 in the probability of `fem_work`. The effect we get has an ASF interpretation. The probabilities are estimated conditional on the residual from the endogenous variable. In other words, the computed effects condition on the level of endogeneity in the model. See [Wooldridge \(2010\)](#) for a discussion about the interpretation of the estimates and the computation of marginal effects of probit estimators under endogeneity.

◀

## Obtaining predicted values

After fitting your model with `ivprobit`, you can obtain the linear prediction and its standard error for both the estimation sample and other samples by using the `predict` command; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#). If you use the maximum likelihood estimator, you can also obtain the predicted probability or the linear prediction with an ASF or fixed ASF interpretation.

`predict`'s `pr` option calculates the probability of a positive outcome, remembering any rules used to identify the model, and calculates missing for excluded observations. `predict`'s `rules` option uses the rules in predicting probabilities, whereas `predict`'s `asif` option ignores both the rules and the exclusion criteria and calculates probabilities for all possible observations by using the estimated parameters from the model. See *Obtaining predicted values* in [R] **probit postestimation** for an example.

## Stored results

`estat correlation` stores the following results in `r()`:

Matrices

`r(corr)` correlation matrix of the errors

`estat covariance` stores the following results in `r()`:

Matrices

`r(cov)` covariance matrix of the errors

## Methods and formulas

The linear prediction is calculated as  $z_i \hat{\delta}$ , where  $\hat{\delta}$  is the estimated value of  $\delta$ , and  $z_i$  and  $\delta$  are defined in (1a) of [R] **ivprobit**. The probability of a positive outcome is evaluated at  $m_i$ ,  $\Phi(m_i)$ , where  $\Phi(\cdot)$  is the standard normal distribution function and  $m_i$  is defined in *Methods and formulas* of [R] **ivprobit**. The ASF uses  $\hat{m}_i$  instead of  $\mathbf{y}_{2i} \hat{\beta} + \mathbf{x}_{1i} \hat{\gamma}$  to evaluate  $\Phi(\cdot)$  and account for endogeneity in the model. The fixed ASF is evaluated at  $\mathbf{y}_{2i} \hat{\beta} + \mathbf{x}_{1i} \hat{\gamma}$ .

# Title

**ivqregress** — Instrumental-variables quantile regression

[Description](#)

[Options](#)

[Acknowledgments](#)

[Quick start](#)

[Remarks and examples](#)

[References](#)

[Menu](#)

[Stored results](#)

[Also see](#)

[Syntax](#)

[Methods and formulas](#)

## Description

`ivqregress` fits a linear instrumental-variables quantile regression (IVQR) model that accounts for endogenous covariates using two estimators: the inverse quantile regression (IQR) estimator proposed in [Chernozhukov and Hansen \(2006\)](#) and the smoothed estimating equations (SEE) estimator outlined in [Kaplan and Sun \(2017\)](#).

## Quick start

Use the IQR estimator to fit the median IVQR model of  $y_1$  on exogenous  $x_1$  and endogenous  $y_2$  with instruments  $z_1$  and  $z_2$

```
ivqregress iqr y1 x1 (y2 = z1 z2)
```

Same as above, but estimate the 0.75 quantile

```
ivqregress iqr y1 x1 (y2 = z1 z2), quantile(0.75)
```

Same as above, but estimate the 0.1, 0.2, ..., 0.9 quantiles

```
ivqregress iqr y1 x1 (y2 = z1 z2), quantile(10(10)90)
```

Use the SEE estimator to estimate the 0.6 quantile regression of  $y_1$  on exogenous  $x_1$  and endogenous  $y_2$  and  $y_3$  with instruments  $z_1$  and  $z_2$

```
ivqregress smooth y1 x1 (y2 y3 = z1 z2), quantile(0.6)
```

Same as above, but estimate the 0.1, 0.2, ..., 0.9 quantiles

```
ivqregress smooth y1 x1 (y2 y3 = z1 z2), quantile(10(10)90)
```

### *IQR options to control optimization*

Use 50 grid points in the IQR estimator to fit the 0.5 and 0.75 IVQR model

```
ivqregress iqr y1 x1 (y2 = z1 z2), ngrid(50) quantile(50 75)
```

Same as above, but construct grid points between 1 and 5 for all the quantiles

```
ivqregress iqr y1 x1 (y2 = z1 z2), ngrid(50) quantile(50 75) bound(1 5)
```

Same as above, but construct grid points using different bounds for different quantiles

```
ivqregress iqr y1 x1 (y2 = z1 z2), ngrid(50) quantile(50 75) ///  
bound(1 5, at(50)) bound(2 6, at(75))
```

### *SEE options to control optimization*

Use 2 as the initial bandwidth in the SEE estimator to fit the 0.5 and 0.75 IVQR model

```
ivqregress smooth y x1 (d1 d2 = z1 z2), quantile(50 75) ///  
initbwidth(2)
```

Same as above, but use different initial bandwidths for different quantiles

```
ivqregress smooth y x1 (d1 d2 = z1 z2), quantile(50 75) ///
    initbwidth(2, at(50)) initbwidth(1, at(75))
```

## Menu

Description

<i>options</i>	Description
Model	
<u>q</u> uantile( <i>numlist</i> )	estimate quantiles specified in <i>numlist</i> ; default is <code>quantile(0.5)</code>
SE/Robust	
<u>v</u> ce( <i>vcetype</i> ) [, <i>vceopts</i> ])	technique used to estimate standard errors; <i>vcetype</i> may be <u>r</u> obust (the default) or <u>b</u> ootstrap
Reporting	
<u>l</u> evel(#)	set confidence level; default is <code>level(95)</code>
<i>display_options</i>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Optimization	
[ <u>n</u> o]log	suppress or display the iteration log
<u>v</u> erbose	display a verbose iteration log
<u>c</u> oef <u>l</u> egend	display legend instead of statistics

<i>IQR_options</i>	Description
Options	
<code>bound(#<sub>min</sub> #<sub>max</sub> [, at(#<sub>q</sub>) ])</code>	specify the lower and upper bounds for the grid in the # <sub>q</sub> th quantile estimation; may be repeated
<code>ngrid(#<sub>g</sub>)</code>	use # <sub>g</sub> grid points; default is <code>ngrid(30)</code>
<i>SEE_options</i>	Description
Options	
<code>initbwidth(#<sub>b</sub> [, at(#<sub>q</sub>) ])</code>	specify initial bandwidth # <sub>b</sub> to smooth the estimating equations for the # <sub>q</sub> th quantile estimation; default is the theoretical optimal bandwidth; may be repeated
<code>iterate(#)</code>	perform maximum of # iterations when solving the estimating equation; default is <code>iterate(100)</code>
<code>nosearchbwidth</code>	do not search for feasible bandwidth if the initial bandwidth is not feasible; default is to search for feasible bandwidth
<code>tolerance(#)</code>	specify the tolerance for the coefficient vector; default is <code>tolerance(1e-9)</code>
<code>ztolerance(#)</code>	specify the tolerance to determine whether the proposed solution for a zero-finding problem is sufficiently close to 0; default is <code>ztolerance(1e-9)</code>
<i>vceopts</i>	Description
<code>kernel(<i>kernel</i>)</code>	use a nonparametric kernel density estimator; default is <code>epanechnikov</code>
<code>bwidth(#   <i>bwrule</i>)</code>	specify the bandwidth to be used by the kernel density estimator; default is <code>silverman</code> , which is Silverman's rule of thumb
<i>kernel</i>	Description
<code>epanechnikov</code>	Epanechnikov kernel function; the default
<code>epan2</code>	alternative Epanechnikov kernel function
<code>biweight</code>	biweight kernel function
<code>cosine</code>	cosine trace kernel function
<code>gaussian</code>	Gaussian kernel function
<code>parzen</code>	Parzen kernel function
<code>rectangle</code>	rectangle kernel function
<code>triangle</code>	triangle kernel function
<i>bwrule</i>	Description
<code>silverman</code>	Silverman's rule of thumb; the default
<code>hsheather</code>	Hall–Sheather's bandwidth
<code>bofinger</code>	Bofinger's bandwidth

*varlist*<sub>1</sub>, *varname*, *varlist*<sub>2</sub>, and *varlist*<sub>iv</sub> may contain factor variables; see [U] 11.4.3 Factor variables.

*bootstrap*, *by*, *collect*, *rolling*, and *statsby* are allowed; see [U] 11.1.10 Prefix commands.

*coeflegend* does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

**quantile**(*numlist*) specifies the quantiles to be estimated and should contain numbers between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default is **quantile**(0.5), which corresponds to the median.

### Options

The following options apply only to the IQR estimator.

**bound**(*#*<sub>min</sub> *#*<sub>max</sub> [ , **at**(*#*<sub>q</sub>) ]) specifies the lower bound (*#*<sub>min</sub>) and the upper bound (*#*<sub>max</sub>) for the grid in the *#*<sub>q</sub>th quantile estimation. By default, the bounds are determined by the two-stage quantile regression, extending the two-stage median regression in Amemiya (1982). This option is repeatable as long as different quantiles *#*<sub>q</sub> are given in each specification.

The specified bound is required to be wider than the *#*<sub>level</sub> confidence interval (CI) that is robust to the weak instruments, which is also known as dual CI. The value of *#*<sub>level</sub> can be specified in the **level**() option; the default is 95% CI.

The grid points are *#*<sub>g</sub> equally spaced points between *#*<sub>min</sub> and *#*<sub>max</sub>, where *#*<sub>g</sub> is specified by the **ngrid**() option.

**ngrid**(*#*<sub>g</sub>) specifies the number of grid points in the IQR estimator. The default is **ngrid**(30); that is, 30 grid points are used.

The following options apply only to the SEE estimator.

**initbwidth**(*#*<sub>b</sub> [ , **at**(*#*<sub>q</sub>) ]) specifies initial bandwidth *#*<sub>b</sub> to smooth the estimating equations for the *#*<sub>q</sub>th quantile estimation. The default is the theoretical optimal bandwidth that minimizes the mean squared errors of the estimating equations; see Kaplan and Sun (2017). This option is repeatable as long as different quantiles *#*<sub>q</sub> are given in each specification.

**iterate**(*#*) specifies the maximum number of iterations to perform when solving the estimating equation; the default is **iterate**(100).

**nosearchbwidth** specifies to not search for a feasible bandwidth if the initial bandwidth is not estimable; the default is to search for a feasible bandwidth.

**tolerance**(*#*) specifies the tolerance used to determine whether successive estimates of the solution have converged. The default is **tolerance**(1e-9).

**ztolerance**(*#*) specifies the tolerance used to determine whether the proposed solution to a zero-finding problem is sufficiently close to 0; the default is **ztolerance**(1e-9).

### SE/Robust

**vce**( [ *vcetype* ] [ , *vceopts* ] ) specifies the type of VCE to compute and the density estimation method to use in computing the VCE.

*vcetype* specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (**robust**) and that use bootstrap methods (**bootstrap**); see [R] *vce\_option*.

*vc\_opts* available with *vcetype* `robust` are the following:

`kernel` (*kernel*) specifies the kernel method to be used by the nonparametric density estimator. The available kernel functions are `epanechnikov`, `epan2`, `biweight`, `cosine`, `gaussian`, `parzen`, `rectangle`, and `triangle`. The default is `epanechnikov`. See [R] [kdensity](#) for the kernel function forms.

`bwidth` (`#` | *bwrule*) specifies the bandwidth to be used by the nonparametric density estimator. If specified as a number, it is used as the bandwidth for the nonparametric density estimator. Otherwise, *bwrule* specifies the method used to compute the bandwidth. Available methods are `silverman` for Silverman’s rule of thumb, `hsheather` for the Hall–Sheather bandwidth, and `bofinger` for the Bofinger bandwidth.

See [R] [kdensity](#) for Silverman’s rule of thumb. See [Koenker \(2005, sec. 4.10\)](#) for a description of the Hall–Sheather and Bofinger bandwidth formulas.

#### Reporting

`level` (`#`); see [R] [Estimation options](#).

*display\_options*: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap` (`#`), `fvwrapon` (*style*), `cformat` (`%fmt`), `pformat` (`%fmt`), `sformat` (`%fmt`), and `nolstretch`; see [R] [Estimation options](#).

#### Optimization

`log` and `nolog` specify whether to display the log showing the progress of the estimation. By default, for the IQR estimator, one dot is shown for each grid point; for the SEE estimator, one line is shown for each bandwidth. The iteration log is displayed by default unless you used `set iterlog off` to suppress it; see `set iterlog` in [R] [set iter](#).

`verbose` displays a verbose log showing the iterations of each computation step. For the IQR estimator, each line is shown for each grid point. For the SEE estimator, iteration logs are shown when solving the estimating equations.

The following option is available with `ivqregress` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

- [Overview](#)
- [When quantile regression matters](#)
- [Examples](#)

## Overview

`ivqregress` fits a linear IVQR model when some covariates are endogenous. The general IVQR model was first proposed by [Chernozhukov and Hansen \(2005\)](#). `ivqregress` is based on the linear IVQR model described in [Chernozhukov and Hansen \(2006, 2008\)](#). For an introduction to the IVQR model, see [Chernozhukov, Hansen, and Wüthrich \(2018\)](#). `ivqregress` implements two estimators: the IQR estimator proposed in [Chernozhukov and Hansen \(2006\)](#) and the SEE estimator outlined in [Kaplan and Sun \(2017\)](#).

In empirical applications, we are usually interested in the effects of some covariate on the outcome variable. The traditional linear regression model is an excellent way to model how the covariate affects the outcome's conditional mean. However, sometimes we would like to study features of the outcome distribution other than the mean to have a complete picture of the effects of covariates. For example, a policymaker may want to learn how participation in a 401(k) would affect the lower-level, median, and upper-level conditional quantiles of net wealth.

Quantile regression in [Koenker and Bassett \(1978\)](#) can help us grasp a better picture than regular linear regression by estimating the effects on different quantiles of the outcome's conditional distribution. For a general discussion, see [\[R\] `qreg`](#). For an illustration of when quantile regression matters, see [When quantile regression matters](#) below.

In practice, some covariates of interest are often endogenous for reasons such as self-selection, omission of some relevant variable, and measurement error. For example, participation in a voluntary savings plan for retirement, such as participation in a 401(k) program, may be endogenous because the people who do and do not participate may have different saving preferences, which will affect net wealth growth.

Endogenous covariates make quantile regression estimates inconsistent, as is the case for the linear regression model. Analogous to the instrumental-variable least-squares estimator, there are IVQR model estimators to consistently estimate the effects at different quantiles. For a discussion of instrumental-variables estimation, see [\[R\] `ivregress`](#).

`ivqregress` fits a quantile regression model that accounts for endogenous covariates using two estimators: the IQR estimator proposed in [Chernozhukov and Hansen \(2006\)](#) and the SEE estimator outlined in [Kaplan and Sun \(2017\)](#). Intuitively, `ivqregress` can be thought of as the `ivregress` version of `qreg`.

Here we outline the Stata commands to fit, visualize, infer, and diagnose the IVQR model. In particular, these Stata commands can be grouped into the following categories.

**Estimation:** `ivqregress iqr` fits the IVQR model by the IQR estimator proposed in [Chernozhukov and Hansen \(2006, 2008\)](#).

`ivqregress smooth` fits the IVQR model by the SEE estimator proposed in [Kaplan and Sun \(2017\)](#).

**Visualization:** `estat coefplot` allows us to visualize how one covariate's effects vary at different quantiles of the outcome.

**Inference:** `estat endogeffects` tests if

1. the endogenous variable does not affect the outcome variable,
2. the effects of the endogenous variable do not vary across estimated quantiles,
3. the effects of the endogenous variable are greater than zero across estimated quantiles, and
4. the variable is exogenous instead of endogenous.

`estat dualci` provides CIs that are robust to weak instruments for the effects of the endogenous variable. It is allowed only after `ivqregress iqr`.

**Diagnosis:** `estat waldplot` helps diagnose the convergence of the IQR estimator (`ivqregress iqr`). In particular, `estat waldplot` allows us to visualize the optimization process during the computation in `ivqregress iqr` and shows if the searching domain contains the true value of the parameter with a predefined probability level.

In addition, some other classical postestimation tools are also available; see [R] [ivqregress postestimation](#).

## When quantile regression matters

Here is an example illustrating the advantages of quantile regressions. Suppose we have a simple model  $E(y|x) = \beta_0 + x\beta_1$ , where  $y$  is the outcome variable and  $x$  is a covariate. For simplicity, we assume  $x$  can only take values in  $\{0, 1, 2, 3, 4, 5, 6\}$ . By definition,  $\beta_1$  fully characterizes the effects of increasing one unit of  $x$  on the conditional mean of outcome  $y$ ; that is,  $\beta_1 = E(y|x = a + 1) - E(y|x = a)$ . Now we consider two scenarios of the data-generating process.

1. The probability density function of the outcome conditional on  $x = a + 1$ ,  $f(y|x = a + 1)$ , is only location shifted relative to  $f(y|x = a)$ . In this case,  $\beta_1$  summarizes the effect of  $x$  not only on the conditional mean but also on each conditional quantile of  $y$ . This case is illustrated in the left panel of figure 1.
2. The probability density function of the outcome conditional on  $x = a + 1$ ,  $f(y|x = a + 1)$ , is both location shifted and rescaled relative to  $f(y|x = a)$ . In this case,  $\beta_1$  summarizes the effect of  $x$  only on the conditional mean but not on conditional quantiles of  $y$ . This case is illustrated in the right panel of figure 1.

Figure 1.

In the left panel, we see that each conditional density is parallel relative to each other, and only the location has been shifted. In this case,  $\beta_1$  captures the shift in both conditional mean and any conditional quantiles of the outcome. As a result, running a linear regression provides as much information on  $\beta_1$  as quantile regression.

In contrast, in the right panel, conditional density for each level of  $x$  has different locations and different shapes. Thus,  $\beta_1$  can only summarize the shifts in conditional mean, which are generally

different from the shifts in conditional quantiles. Quantile regression becomes necessary to learn about the effects of  $x$  on the conditional quantiles of the outcome.

## Examples

### ► Example 1: IVQR with the IQR estimator

Suppose that we want to estimate the effect of 401(k) participation (`p401k`) on different conditional quantiles of net financial assets (`assets`). We use data reported by [Chernozhukov and Hansen \(2004\)](#). These data are from a sample of households in the 1990 Survey of Income and Program Participation (SIPP). For the head of household, we have data on income (`income`), age (`age`), number of people in the family (`familysize`), years of education (`educ`), marital status (`married`), whether participated in an IRA (`ira`), whether received a pension benefit (`pension`), and whether owned a home (`ownhome`).

We suspect 401(k) participation is endogenous because it may depend on unobserved factors such as saving preference that also impact financial assets. Using 401(k) eligibility (`e401k`) as an instrument for 401(k) participation, we use `ivqregress` to estimate how `p401k` affects the entire range of `assets`' conditional distribution. One concern about using `e401k` as an instrument is that choosing to work for a company that offers a 401(k) program is not randomly assigned. [Poterba, Venti, and Wise \(1995\)](#) suggest that after conditioning on income, we can take working for a company that offers a 401(k) plan as exogenous.

The IVQR model we want to fit is

$$\text{assets}_i = \text{p401k}_i \alpha(U) + \text{covariates}'_i \beta(U)$$

where the distribution of  $U$  conditional on the instrument `e401k` and the covariates is assumed to be uniform between 0 and 1. The covariates `income`, `age`, `familysize`, and `educ` are included in the model as continuous variables. The covariates `i.married`, `i.ira`, `i.pension`, and `i.ownhome` are included as categorical (factor) variables. As discussed above, `e401k` is the instrument for `p401k`. The coefficients  $\alpha(U)$  and  $\beta(U)$  are random because they depend on the unobserved random variable  $U$ . In practice,  $U$  can be considered a ranking variable for the asset. When  $U$  is set to a fixed level  $\tau$ , we fit an IVQR model at a specific quantile index  $\tau$ . For example, when  $\tau = 0.5$ , we estimate how 401(k) participation affects the median of net financial assets conditional on other covariates.

The objective of the analysis is to estimate the quantile treatment effects of 401k participation on net financial assets. By definition, the  $\tau$ th conditional quantile of the asset when everyone participates in a 401(k) plan is

$$\text{assets}_{401(k)} = \alpha(\tau) + \text{covariates}'_i \beta(\tau)$$

In contrast, the  $\tau$ th conditional quantile of the asset when everyone does not participate in a 401(k) plan is

$$\text{assets}_{\text{no } 401(k)} = \text{covariates}'_i \beta(\tau)$$

Thus, the coefficient  $\alpha(\tau)$  can fully summarize the quantile treatment effect of `p401k` on `assets`. That is

$$\alpha(\tau) = \text{assets}_{401(k)} - \text{assets}_{\text{no } 401(k)}$$

In this example, we use the IQR estimator (`ivqregress iqr`) to estimate the effect of 401(k) participation on the conditional median of the net financial assets. The dependent variable is `assets`. The endogenous variable `i.p401k` and the instrument `i.e401k` are specified in parentheses; the other covariates follow as a regular variable list. `ivqregress` fits the IV median regression model by default. The estimation result is stored as `est_iqr` for later use.

            1.e401k

. estimates store est_iqr
    
```

The coefficient for p401k is 5,313. It means participation in a 401(k) would increase the median net financial assets by \$5,313, conditional on other covariates, relative to a scenario where no one participates. We store the estimation result as `est_iqr` for later use.

After `ivqregress iqr`, we can use `estat dualci` to obtain the dual CI, which is robust to weak instruments, for the coefficient on the endogenous variable.

```
. estat dualci
Dual confidence interval                                Number of obs = 9,913
```

assets	Coefficient	Robust std. err.	z	P> z	Dual [95% conf. interval]	
p401k Yes	5313.397	573.2818	9.27	0.000	3683.916	7304.986

The dual CI is usually wider than the regular CI, but it provides a more robust inference if the instruments are weak. In this example, we see that the dual 95% CI is [3684, 7305], which is wider than the regular 95% CI [4190, 6437].

◀

## ► Example 2: IVQR with the smooth estimator

In this example, we use `ivqregress` to fit the IVQR model as in [example 1](#) but using the SEE estimator (`ivqregress smooth`). The model specification is the same as in [example 1](#). The estimation result is stored as `est_smooth` for later use.

```
. ivqregress smooth assets (i.p401k = i.e401k) income age familysize
> i.married i.ira i.pension i.ownhome educ
Fitting smoothed IV quantile regression:
Quantile = .5:

1.e401k

. estimates store est\_smooth

The interpretation of the coefficient estimates is the same as in [example 1](#). For example, the coefficient for `p401k` is 5,364. So participation in a 401(k) would increase the median of net financial assets by \$5,364, conditional on other covariates, relative to a scenario where no one participates.

Now we can compare the coefficient on `p401k` between the SEE estimator and the IQR estimator.

```
. estimates table est_iqr est_smooth, keep(i.p401k) se
```

Variable	est_iqr	est_smooth
p401k		
Yes	5313.3974	5364.468
	573.28183	573.37279

Legend: b/se

We see that the point estimates from these two estimators are similar but not the same. It is normal to see different results from the IQR and SEE estimators because these two estimators approximate the original exact estimating equation differently. On one hand, the IQR estimator tries to find the solution by an exhaustive grid search. The estimation result critically depends on the range and finesse of grid points. On the other hand, the SEE estimator uses a kernel method to smooth the original estimating equation. Its result depends on how well the SEE approximates the original, mainly controlled by the bandwidth.

Both the IQR and SEE estimators have their advantages and weaknesses. The IQR estimator is numerically stable, and it allows computing the dual CI, which is robust to weak instruments (use `estat dualci`). However, the IQR becomes computationally intensive when there is more than one endogenous variable. Thus, `ivqregress iqr` allows only one endogenous variable. In contrast, the SEE estimator can handle multiple endogenous variables within a reasonable computation time. However, it does not allow `estat dualci` for inference that is robust to weak instruments. Suppose there is only one endogenous variable in the model. We recommend using both estimators, comparing the results, and using the IQR estimator as a benchmark because it can provide valid inference even if the instrument is weak. If there is more than one endogenous variable, only `ivqregress smooth` is available.

◀

### ▷ Example 3: IVQR at different quantiles

In the first two examples, we estimated the 401(k) participation (`p401k`) treatment effect on the conditional median of net financial assets (`assets`). From a policy designer's point of view, we may be more interested in estimating the treatment effect of `p401k` on other conditional quantiles of `assets`. For example, we can ask questions like 1) how 401(k) participation affects the lower quantile of assets and 2) whether 401(k) participation is unambiguously beneficial for the asset's lower and upper conditional quantiles. In addition, we might also want to know whether the 401(k) participation is endogenous in our model. In this example, we will show how to use `ivqregress` to fit the IVQR model at different quantiles and how to use the postestimation tools to answer the above questions.

First, we use the IQR estimator to fit the model at different quantiles. In particular, we specify the `quantile(10(10)90)` option to fit the IVQR model at the 10th, 20th, ..., 90th quantiles.

```
. ivqregress iqr assets (i.p401k = i.e401k) income age familysize
> i.married i.ira i.pension i.ownhome educ, quantile(10(10)90)
```

```

1.e401k

The results show the estimates for the effect of 401(k) participation on each conditional quantile of the asset. The interpretation of the coefficient is similar to [example 1](#), except we are looking at different conditional quantiles. For example, for quantile q90, the estimate for the coefficient on p401k is 15,983. Thus, 401(k) participation would increase the 90% conditional quantile of net financial assets by \$15,983.

In addition to looking at the numerical estimates from the coefficient table, we can use `estat coefplot` to visualize the trend of p401k’s treatment effect from the lower to the upper quantile. By default, `estat coefplot` shows the first endogenous variable, which is 1.p401k in our example. We specify the `name()` option for later reference of this graph and add a subtitle indicating which estimator we used.

```
. estat coefplot, name(cp_iqr) subtitle(IQR estimator)
```

The dots in the plot show the point estimates of p401k’s treatment effect on different conditional quantiles of `assets`, and the gray bound shows the 95% pointwise CI. We see that there is an upward trend of p401k’s treatment effect. At lower-level quantiles such as the 10th, 20th, . . . , 40th quantiles, the treatment effect is relatively flat. However, we see the treatment effect increases significantly in the upper-level quantiles. The red line shows the two-stage least-squares estimates, which can be used as a benchmark.

`estat coefplot` is a good way to visualize the treatment effect’s trend. If we want to test some hypotheses regarding the trend and the model statistically, we can use `estat endogeffects`. For example, we are interested in testing the following hypotheses:

**No effect:** 401(k) participation does not affect net financial assets for all the estimated quantiles.

**Constant effect:** 401(k) participation’s treatment effect is constant for all the estimated quantiles.

**Dominance:** 401(k) participation is unambiguously positive for all the estimated quantiles; that is, the coefficient values are strictly positive.

**Exogeneity:** 401(k) participation is exogenous.

We will use `estat endogeffects` to show the Kolmogorov–Smirnov statistic and the 95% critical value for each hypothesis. We can reject the null hypothesis if the test statistic is greater than the critical value; otherwise, we cannot reject the null hypothesis. We specify the `rseed()` option to make the results reproducible because the critical values are generated from a bootstrap sample.

```
. estat endogeffects, rseed(12345671)
Tests for endogenous effects          Replications = 100
```

Null hypothesis	KS statistic	95% critical value
No effect	11.271	2.554
Constant effect	5.395	2.446
Dominance	0.000	2.467
Exogeneity	4.145	2.478

Note: If the KS statistic < critical value, there is insufficient evidence to reject the null hypothesis. (KS = Kolmogorov–Smirnov)

In particular, we see that the test statistics are greater than the critical values in testing the hypotheses of no effect, constant effect, and exogeneity. Thus, with a 95% confidence level, we can reject these three hypotheses. In other words, we find that 401(k) participation has some effect, treatment is not constant across different quantiles, and 401(k) participation is endogenous. In contrast, we cannot reject the dominance hypothesis. Thus, we find that 401(k) participation is unambiguously beneficial for all the estimated quantiles of assets.

The test results are consistent with the result of the coefficient plot produced by `estat coefplot`, where we saw that the treatment effects are positive (dominance and no effect hypotheses) and upward trended (constant effect hypothesis).

For comparison, we can also use the SEE estimator to fit the model.

After `ivqregress smooth`, we can also use `estat coefplot` to visualize the treatment effect and `estat endogeffects` to test some hypotheses of particular interest in the context of the IVQR model.

First, we use `estat coefplot` to plot the coefficients and then use `graph combine` so that we can visually compare this plot with the coefficients plot for the IQR estimates.

```
. estat coefplot, name(cp_smooth) subtitle(SEE estimator)
. graph combine cp_iqr cp_smooth, xcommon ycommon altshrink
```

The left and right panels of the figure show the coefficient plots for the IQR and SEE estimates, respectively. We see that both estimators produce similar trends for the coefficients on 1.p401k at different quantiles.

Next, we can use `estat endogeffects` to see if we draw the same conclusion regarding the four hypotheses of interest as we did with the IQR estimator.

```
. estat endogeffects, rseed(12345671)
```

Tests for endogenous effects		Replications = 100

No effect	11.507	2.593
Constant effect	5.351	2.391
Dominance	0.000	2.556
Exogeneity	4.195	2.526

Note: If the KS statistic < critical value, there is insufficient evidence to reject the null hypothesis. (KS = Kolmogorov-Smirnov)

The results align with those produced after `ivqregress iqr`. That is, the treatment effects are positive (dominance and no effect hypotheses), upward trended (constant effect hypothesis), and endogenous (exogeneity hypothesis).

#### ► Example 4: Robustness checks and diagnostics for the IQR estimator

In this example, we will take a closer look at the IQR estimator and show how to use `estat waldplot` to inspect the convergence visually. Nevertheless, let's first briefly discuss the intuition and algorithm behind the IQR estimator.

The IVQR model satisfies the following conditional probability:

$$\Pr(y \leq d\alpha(\tau) + \mathbf{x}'\beta(\tau) | \mathbf{x}, \mathbf{z}) = \tau$$

where  $y$  is the outcome variable,  $d$  is an endogenous variable,  $\mathbf{x}$  is a vector of exogenous covariates, and  $\mathbf{z}$  is a vector of instruments. The coefficients  $\alpha(\tau)$  and  $\beta(\tau)$  are indexed with the quantile level  $\tau$  to indicate that they are for the model of the  $\tau$  conditional quantile of the outcome  $y$ . We cannot fit the above model using the regular quantile regression because the conditional set is on  $\mathbf{x}$  and  $\mathbf{z}$  but the covariates contain  $\mathbf{x}$  and  $d$ . Now suppose we know the value of  $\alpha(\tau)$ . We can then rewrite this conditional probability as

$$\Pr(y - d\alpha(\tau) \leq \mathbf{x}'\beta(\tau) + \mathbf{z}'0 | \mathbf{x}, \mathbf{z}) = \tau$$

By the definition of quantile regression, we can fit this model by running a quantile regression of the transformed outcome variable,  $y - d\alpha(\tau)$ , on the covariates  $\mathbf{x}$  and instruments  $\mathbf{z}$ . Notice that if  $\alpha(\tau)$  is the true value, the coefficient on the instruments, which we denote as  $\gamma(\tau)$ , should be 0. In other words, to solve the original moment conditional for the IVQR model, we need to find a  $\alpha(\tau)$  such that the auxiliary quantile regression of  $y - d\alpha(\tau)$  on  $\mathbf{x}$  and  $\mathbf{z}$  produces 0s for the coefficients on the instrument  $\mathbf{z}$ . In practice, we want  $\gamma(\tau)$  as close to 0 as possible, where the closeness to 0 can be measured by the Wald statistic on  $\gamma(\tau)$ .

Based on the above intuition, here is an outline of the IQR estimator's algorithm.

1. Define a grid of  $A = \{\alpha_1, \dots, \alpha_J\}$  (see [IQR default grid algorithm](#) in *Methods and formulas*).
2. For each  $\alpha_j$  in  $A$ , run an auxiliary quantile regression of  $y - d\alpha_j$  on covariates  $\mathbf{x}$  and instruments  $\mathbf{z}$ .
3. IQR finds  $\alpha_k \in A$  as a solution such that the coefficient on  $\mathbf{z}$  is as close to 0 as possible in the corresponding auxiliary quantile regression, where the Wald statistic measures the closeness to 0.
4. The grid points boundary must be wider than the dual CI, which is robust to weak instruments; otherwise, `ivqregress iqr` will error out. Dual CI means it covers the true value of  $\alpha(\tau)$  with 95% probability (see [Chernozhukov and Hansen \[2008\]](#) and `estat dualci`).

We can use `estat waldplot` to visualize the above procedure. Using the estimation result in [example 1](#), we first restore the result `est_iqr` and then use `estat waldplot` to plot the Wald statistics corresponding to each grid point.

```
. estimates restore est_iqr
(results est_iqr are active now)
. estat waldplot
```

The horizontal axis shows the grid points for  $\alpha$ , and the vertical axis shows the values of the Wald statistics. The dots in the plot show the Wald statistics corresponding to each grid point. The red line is the 95% critical value of the Wald test. Thus, only the Wald statistics below the red line will not reject the hypothesis that  $\gamma_j$  equals 0. Respectively, the 95% dual CI corresponds to the  $\alpha$ 's for which the Wald statistics are below the critical value. See [example 1](#) for the use of `estat dualci` to show the numerical values of the dual CI.

By default, `ivqregress iqr` uses the dual CI to generate the lower and upper bounds for the grid points to make sure that the grid covers the true value of parameter  $\alpha$  with a large probability. Sometimes, we may want to customize the bounds. For example, suppose we want to search grid points between 3,000 and 6,000. We can use the `bound()` option for this purpose.

```
. ivqregress iqr assets (i.p401k = i.e401k) income age familysize
> i.married i.ira i.pension i.ownhome educ, bound(3000 6000)

Initial grid:
Quantile = 0.50: .....10.....20.....30

convergence not achieved
The grid interval should be wider than the 95% dual confidence interval.
Try to set a wider bound using option bound(). Use estat waldplot for
diagnosis.
r(430);
```

We see that `ivqregress iqr` stops with a “convergence not achieved” error message. The reason is that the specified bound is too narrow to cover the true value of the parameter with a 95% probability.

We can now use `estat waldplot` to further visualize the issue.

```
. estat waldplot
```

The graph shows that the upper bound of 6,000 is too small because we need the Wald statistics to intersect with the 95% critical value at the lower and upper bounds.

We can increase the upper bound and see if the IQR estimator converges. For example, below we increase the upper bound to 8,000.

```
. ivqregress iqr assets (i.p401k = i.e401k) income age familysize
> i.married i.ira i.pension i.ownhome educ, bound(3000 8000)

Initial grid
quantile = 0.50: .....10.....20.....30
Adaptive grid
quantile = 0.50: .....10.....20.....30
IV median regression
Estimator: Inverse quantile regression
Number of obs = 9,913
Wald chi2(9) = 1290.41
Prob > chi2 = 0.0000
```

assets	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]

```
Endogenous: 1.p401k
Exogenous: income age familysize 1.married 1.ira 1.pension 1.ownhome educ
1.e401k
```

Now that the IQR estimator converges, we can redraw the Wald plot to confirm that the proposed grid points interval is indeed wider than the dual CI.

```
. estat waldplot
```

◀

## Stored results

`ivqregress iqr` and `ivqregress smooth` store the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(q#)</code>	the quantiles requested
<code>e(n_q)</code>	number of quantiles requested
<code>e(bwidth_q#)</code>	bandwidth used in standard errors for $q_{\#}$ th quantile
<code>e(sm_init_bwidth_q#)</code>	initial bandwidth used in smoothing the indicator function in $q_{\#}$ th quantile estimation ( <i>smooth</i> only)
<code>e(sm_bwidth_q#)</code>	bandwidth used in smoothing the indicator function in $q_{\#}$ th quantile estimation ( <i>smooth</i> only)
<code>e(convcode)</code>	0 if converged; otherwise, return code for why nonconvergence
<code>e(p)</code>	$p$ -value for model test
<code>e(df_m)</code>	model degrees of freedom
<code>e(chi2)</code>	$\chi^2$
<code>e(rank)</code>	rank of $e(V)$

### Macros

<code>e(cmd)</code>	<code>ivqregress</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(inst)</code>	names of instrumental variables
<code>e(bwrule)</code>	method to compute the bandwidth in standard errors
<code>e(kernel)</code>	kernel function
<code>e(title)</code>	title in estimation output
<code>e(vce)</code>	<i>vcetype</i> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(estimator)</code>	<code>iqr</code> or <code>smooth</code>
<code>e(exogr)</code>	exogenous regressors
<code>e(endog)</code>	endogenous regressors
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(predict)</code>	program used to implement <code>predict</code>

e(marginsok)	predictions allowed by margins
e(marginsnotok)	predictions disallowed by margins
Matrices	
e(b)	coefficient vector
e(V)	variance–covariance matrix of the estimators
Functions	
e(sample)	marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices	
r(table)	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

- The model*
- The IQR estimator*
- The IQR algorithm*
- The IQR default grid algorithm*
- The SEE estimator*
- The bandwidth selection algorithm*
- The robust standard errors*

## The model

The general IVQR model was first proposed by [Chernozhukov and Hansen \(2005\)](#). `ivqregress` fits a linear IVQR model described in [Chernozhukov and Hansen \(2006, 2008\)](#). For notational simplicity, we drop the observational subscript  $i$  to refer to a random variable and add the subscript  $i$  to refer to a realization of a random variable.

We can write the linear IVQR model in the form of a “random coefficients” model as

$$y = \mathbf{d}'\boldsymbol{\alpha}(u) + \mathbf{x}'\boldsymbol{\beta}(u)$$

where

- $y$  is a scalar outcome variable,  $\mathbf{d}$  is a vector of endogenous variables,  $\mathbf{x}$  is a vector of exogenous variables, and  $u$  is the unobserved error term;
- $\mathbf{d}$  depends on the exogenous covariates  $\mathbf{x}$ , and the instrumental variables  $\mathbf{z}$  and unobserved error term are correlated with  $u$ ;
- $u$  is a scalar random variable that characterizes the heterogeneity of the outcome and captures all the unobservables in the outcome from item 1 above. Conditional on  $\mathbf{z}$  and  $\mathbf{x}$ ,  $u$  is uniformly distributed between 0 and 1;
- $\boldsymbol{\alpha}(\cdot)$  and  $\boldsymbol{\beta}(\cdot)$  are random coefficient vectors that depend on  $u$ ;
- the function  $\tau \rightarrow \mathbf{d}'\boldsymbol{\alpha}(\tau) + \mathbf{x}'\boldsymbol{\beta}(\tau)$  is strictly increasing in  $\tau$ ; and
- the observable variables are  $\{y_i, \mathbf{x}_i, \mathbf{d}_i, \mathbf{z}_i\}_{i=1}^N$  with a sample of size  $N$ .

Under some regularity conditions (see [Chernozhukov and Hansen \[2005\]](#)), the IVQR model satisfies the conditional probability

$$\Pr\{y \leq \mathbf{d}'\boldsymbol{\alpha}(\tau) + \mathbf{x}'\boldsymbol{\beta}(\tau) | \mathbf{x}, \mathbf{z}\} = \tau \quad (1)$$

By the definition of probability and the law of iterated expectation, (1) implies the following unconditional moment condition:

$$E([\tau - I\{y \leq \mathbf{d}'\boldsymbol{\alpha}(\tau) + \mathbf{x}'\boldsymbol{\beta}(\tau)\}] \Psi) = 0 \quad (2)$$

where  $I(\cdot)$  is the indicator function,  $\Psi = (\widehat{\mathbf{d}}', \mathbf{x}')'$ , and  $\widehat{\mathbf{d}}$  is some function of  $\mathbf{x}$  and  $\mathbf{z}$  and can be treated as instruments for  $\mathbf{d}$ . In practice,  $\widehat{\mathbf{d}}$  is the linear prediction of  $\mathbf{d}$  using  $\mathbf{x}$  and  $\mathbf{z}$ .

Equation (2) can be used as the estimating equation for the IVQR model. However, the objective function based on (2) is nonconvex and nonsmooth because of the indicator function. Thus, it is computationally challenging to fit the IVQR model by directly using (2).

`ivqregress` implements two estimators that approximately solve the original moment condition in (2). In particular, `ivqregress iqr` implements the IQR estimator proposed in [Chernozhukov and Hansen \(2006\)](#), and `ivqregress smooth` implements the SEE estimator outlined in [Kaplan and Sun \(2017\)](#). Here are the main ideas behind these two estimators.

The IQR estimator reduces the original  $p$ -dimensional (where  $p$  is the dimension of  $\mathbf{x}$  and  $\mathbf{d}$ ) nonconvex problem into a low-dimensional nonconvex problem. Then, it solves the problem by doing an exhaustive grid search over a high-quality grid. The grid is high quality in the sense that it covers the true value of the parameter for  $\alpha(\tau)$  with a high probability ([Chernozhukov and Hansen 2008](#)). As a byproduct, the IQR estimator can also provide the CI that is robust to the weak instruments, which is also known as dual CI (see `estat dualci`). However, the IQR estimator becomes computationally intensive if there is more than one endogenous variable. As a result, `ivqregress iqr` allows only one endogenous variable.

The SEE estimator smooths the original moment condition in (2) using a kernel method to approximate the indicator function. Thus, the optimization problem reduces to solving a system of smooth nonlinear equations. One advantage of the SEE estimator compared with the IQR estimator is that it can handle more than one endogenous variable. However, it cannot provide the dual CI, which is robust to weak instruments like the IQR estimator.

While the IQR and SEE estimators are consistent for the IVQR model, their results are generally different. The reason is that the two estimators approximate the original moment condition in different ways. On one hand, the IQR estimator tries to find the solution by an exhaustive grid search. The estimation result critically depends on the range and finesse of grid points. On the other hand, the SEE estimator uses a kernel method to smooth the original estimating equation. Its result depends on how well the SEE estimator approximates the original, mainly controlled by the bandwidth.

In practice, suppose there is only one endogenous variable in the model. We recommend using both estimators, comparing the results, and using the IQR estimator as a benchmark because it can provide valid inference even if the instruments are weak.

## The IQR estimator

Before diving into the details, we discuss the intuition of the IQR estimator. The IVQR model satisfies the conditional probability

$$\Pr\{y \leq d\alpha(\tau) + \mathbf{x}'\boldsymbol{\beta}(\tau) | \mathbf{x}, \mathbf{z}\} = \tau$$

We cannot fit the above model using regular quantile regression because the conditional set is on  $\mathbf{x}$  and  $\mathbf{z}$ , but the covariates contain  $\mathbf{x}$  and  $d$ . Now suppose we know the value of  $\alpha(\tau)$ . We can then rewrite this conditional probability as

$$\Pr\{y - d\alpha(\tau) \leq \mathbf{x}'\beta(\tau) + \mathbf{z}' * 0 | \mathbf{x}, \mathbf{z}\} = \tau$$

By the definition of quantile regression, we can fit this model by running a quantile regression of the transformed outcome variable,  $y - d\alpha(\tau)$ , on the covariates  $\mathbf{x}$  and instruments  $\mathbf{z}$ . Notice that if  $\alpha(\tau)$  is the actual value, the coefficient on the instruments, which we denote as  $\gamma(\tau)$ , should be 0. In other words, to solve the original moment conditional for the IVQR model, we need to find a  $\alpha(\tau)$  such that the auxiliary quantile regression of  $y - d\alpha(\tau)$  on  $\mathbf{x}$  and  $\mathbf{z}$  produces zeros for the coefficients on the instruments  $\mathbf{z}$ . In practice, we want  $\gamma(\tau)$  as close to 0 as possible, where the closeness to 0 can be measured by the Wald statistic on  $\gamma(\tau)$ .

Based on the above intuition, here is an outline of the IQR estimator's algorithm.

## The IQR algorithm

1. Compute  $\hat{\mathbf{d}}$ , which is the linear projection of  $\mathbf{d}$  on  $\mathbf{x}$  and  $\mathbf{z}$ .  $\hat{\mathbf{d}}$  can be treated as instruments for  $\mathbf{d}$ .
2. Define a grid of  $A = \{\alpha_1, \dots, \alpha_J\}$ . For the algorithm of the default grid generation, see [The IQR default grid algorithm](#).
3. For each  $\alpha_j$  in  $A$ , run an auxiliary quantile regression of  $y - d\alpha_j$  on covariates  $\mathbf{x}$  and instruments  $\hat{\mathbf{d}}$ .
4. IQR finds  $\alpha_k \in A$  as a solution such that the coefficient on  $\hat{\mathbf{d}}$  is as close to 0 as possible in the corresponding auxiliary quantile regression, where the Wald statistic measures the closeness to 0.
5. The grid points boundary must be wider than the dual CI, which is robust to weak instruments; otherwise, `ivqregress iqr` will error out. Dual CI means it covers the true value of  $\alpha(\tau)$  with  $\#_{\text{level}}$  probability (see [Chernozhukov and Hansen \[2008\]](#) and `estat dualci`). The `level()` option specifies the confidence level  $\#_{\text{level}}$ ; the default is `level(95)`.

## The IQR default grid algorithm

The default grid algorithm can be divided into two stages: 1) the initial grid generation based on the two-stage quantile regression, which extends the two-stage median regression in [Amemiya \(1982\)](#); and 2) the adaptive grid that depends on the dual CI, which is robust to weak instruments ([Chernozhukov and Hansen 2008](#)).

1. Initial grid based on two-stage quantile regression
  - a. Run a quantile regression of  $y$  on  $\mathbf{x}$  and  $\hat{\mathbf{d}}$ . Denote  $\tilde{\alpha}$  as the point estimate for the coefficient on  $\hat{\mathbf{d}}$  and  $\tilde{s}$  as its standard errors.  $\tilde{s}$  is computed by assuming the error term is normally distributed.
  - b. Compute the lower and upper bounds of the grid. The lower bound is  $\text{lb} = \tilde{\alpha} - 4\tilde{s}$ , and the upper bound is  $\text{ub} = \tilde{\alpha} + 4\tilde{s}$ .
  - c. By default, the grid points are  $\#_g$  equally spaced points between  $\text{lb}$  and  $\text{ub}$ , where the `ngrid()` option specifies the number of grid points  $\#_g$ .

## 2. Adaptive grid based on the dual CI

- a. Given the initial grid, go through the steps 3–5 in *The IQR algorithm*.
- b. Obtain the dual CI based on the initial grid.
- c. Use the dual CI as the bound for the adaptive grid points and generate  $\#_g$  equally spaced points.

**The SEE estimator**

The basic idea of the SEE estimator is to replace the indicator function in (2) with a smooth function. To be precise, we replace the moment condition in (2) with

$$E \left( \left[ \tau - \tilde{I}\{y - \mathbf{d}'\alpha(\tau) - \mathbf{x}'\beta(\tau) \leq 0\} \right] \Psi \right) = 0 \quad (3)$$

where  $\tilde{I}(v/h) = \max[0, \min\{1, (1 - v/h)/2\}]$  and  $h$  is the bandwidth. By default, the bandwidth is computed using the theoretical optimal bandwidth that minimizes the mean squared errors of the estimating equations. See proposition 2 in Kaplan and Sun (2017) for the optimal bandwidth.

Because  $\tilde{I}(\cdot)$  is a smooth function, the SEE estimator reduces to solve a system of smooth nonlinear equations. Let  $F(\theta)$  denote the left-hand side of (3), where  $\theta = \{\alpha(\tau), \beta(\tau)\}$ . Let  $\theta(i)$  denote the proposed solution at iteration  $i$ , and let  $\theta(i-1)$  denote the proposed solution at the previous iteration. The convergence is declared if `mreldif( $\theta(i), \theta(i-1)$ ) < itol` or  $F(\theta)'F(\theta) < ztol$ , where *itol* and *ztol* can be specified by using the `tolerance()` and `ztolerance()` options, respectively. The maximum number of iterations can be specified by using the `iterate()` option.

By default, the SEE estimator searches for the bandwidth as follows.

**The bandwidth selection algorithm**

Denote  $\hat{\theta}_0$  as the initial values for the parameters  $\alpha(\tau)$  and  $\beta(\tau)$ . Denote  $\widehat{\mathbf{h}}_{\text{opt}}(\hat{\theta}_0)$  as the optimal bandwidths based on the initial values  $\hat{\theta}_0$ .  $\widehat{\mathbf{h}}_{\text{opt}}(\hat{\theta}_0)$  is a vector with elements  $(h_1, h_2, h_3)$ , where  $h_1$  is a nonparametrically estimated bandwidth,  $h_2$  assumes Gaussian distribution, and  $h_3$  uses the Silverman rule of thumb. Regardless of the assumption used, each element in  $\widehat{\mathbf{h}}_{\text{opt}}(\hat{\theta}_0)$  requires initial estimates of the error term  $\epsilon = y - \mathbf{d}'\alpha(\tau) - \mathbf{x}'\beta(\tau)$ . Thus, the optimal bandwidth is a function of the initial estimates for  $\alpha(\tau)$  and  $\beta(\tau)$ . For details, see section 5.4 in Kaplan (2022).

1. Let  $\hat{\theta}_0$  be the estimates of a quantile regression of  $y$  on  $\mathbf{d}$  and  $\mathbf{x}$ .
2. Based on  $\hat{\theta}_0$ , compute the optimal bandwidths  $\widehat{\mathbf{h}}_{\text{opt}}(\hat{\theta}_0)$ .
3. Define the initial bandwidth set as  $\mathbf{h}_0 = \{\widehat{\mathbf{h}}_{\text{opt}}(\hat{\theta}_0), h_{\text{init}}\}$ , where  $h_{\text{init}}$  is the bandwidth in the `initbwidth()` option if specified.  $\mathbf{h}_0 = \widehat{\mathbf{h}}_{\text{opt}}(\hat{\theta}_0)$  if `initbwidth()` is not specified.
4. Find the smallest element in  $\mathbf{h}_0$  such that it solves (3). The estimates for  $\alpha(\tau)$  are within the dual CI with  $\#_{\text{level}}$  probability (see Chernozhukov and Hansen [2008]).
  - a. If a valid bandwidth is found, go to step 5.
  - b. Otherwise, do a bisection search of the bandwidth with the upper bound as  $100 \times \min(\mathbf{h}_0)$  and the lower bound as  $\min(\mathbf{h}_0)/100$ .

If a valid bandwidth is found, denote it as  $h^*$ .

- Update  $\widehat{\theta}_0$  as the solution for the SEE estimator based on bandwidth  $h^*$ . Repeat steps 2–4 based on the updated  $\widehat{\theta}_0$ .

By default, steps 1–5 are used to select the bandwidth. If the `nosearchwidth` and `initwidth()` options are both specified, steps 2, 4b, and 5 are omitted. Thus, in this case, `ivqregress smooth` will try to solve (3) with the specified initial bandwidth without searching for the optimal or feasible bandwidths. If only the `nosearchwidth` option is specified, step 4b is omitted.

## The robust standard errors

The robust asymptotic variance–covariance estimator for the IQR and SEE estimators can be estimated as follows (see Chernozhukov and Hansen [2006] and de Castro et al. [2019]). Let  $\theta = \{\alpha(\tau), \beta(\tau)\}$  be the true values of parameters and  $\widehat{\theta} = \{\widehat{\alpha}(\tau), \widehat{\beta}(\tau)\}$  be the IQR or the SEE estimator. For any finite collection of quantile indices  $\tau_j, j \in T$

$$[\sqrt{n}\{\widehat{\theta}(\tau) - \theta(\tau)\}]_{j \in T} \rightarrow N(0, [\mathbf{J}(\tau_k)^{-1} \mathbf{S}(\tau_j, \tau_k) \{\mathbf{J}(\tau_j)^{-1}\}' ]_{k, j \in T})$$

where

$$\begin{aligned} \mathbf{J}(\tau) &= E \{ f_{\epsilon(\tau)}(0|\mathbf{x}, \mathbf{d}, \mathbf{z}) \Psi[\mathbf{d}', \mathbf{x}'] \} \\ \mathbf{S}(\tau_j, \tau_k) &= \{ \min(\tau_j, \tau_k) - \tau_j \tau_k \} E(\Psi \Psi') \end{aligned}$$

and  $f_{\epsilon(\tau)}(0|\mathbf{x}, \mathbf{d}, \mathbf{z})$  is the conditional density of  $\epsilon(\tau)$  evaluated at 0, with  $\epsilon_i(\tau) = y_i - \mathbf{d}'_i \alpha(\tau) - \mathbf{x}'_i \beta(\tau)$ .

The components in the variance can be obtained by their sample counterparts. In particular,  $\mathbf{S}(\cdot)$  can be estimated as

$$\widehat{\mathbf{S}}(\tau_k, \tau_j) = \{ \min(\tau_k, \tau_j) - \tau_k \tau_j \} \frac{1}{N} \sum_{i=1}^N \Psi_i \Psi'_i$$

$\mathbf{J}(\cdot)$  can be estimated as

$$\widehat{\mathbf{J}}(\tau) = \frac{1}{N h_N} \sum_i K \left\{ \frac{-\widehat{\epsilon}_i(\tau)}{h_n} \right\} \Psi_i[\mathbf{d}'_i, \mathbf{x}'_i]$$

where  $\widehat{\epsilon}_i(\tau) = y_i - \mathbf{d}'_i \widehat{\alpha}(\tau) - \mathbf{x}'_i \widehat{\beta}(\tau)$ ,  $K(\cdot)$  is a kernel function, and  $h_n$  is the bandwidth.

`vce(vctype, kernel())` specifies the kernel function form  $K(\cdot)$ . See [R] `kdensity` for the function forms of the eight kernels.

`vce(vctype, bwidht())` specifies which bandwidth to use: `silverman` specifies to use  $h_s$ , `hshether` specifies to use  $h_k$  with  $h_1$  replaced by  $h_{hs}$ , and `bofinger` specifies to use  $h_k$  with  $h_1$  replaced by  $h_{bo}$ .

Silverman’s rule of thumb bandwidth is

$$h_s = 0.9 \min \left\{ \widehat{\sigma}(\epsilon), \frac{M}{1.349} \right\} N^{-\frac{1}{5}}$$

where  $\widehat{\sigma}(\epsilon)$  is the standard deviation of  $\widehat{\epsilon}$  and  $M$  is the interquartile range of  $\widehat{\epsilon}$ .

The bandwidth in Koenker (2005, 81) is

$$h_k = \min \left\{ \widehat{\sigma(\epsilon)}, \frac{M}{1.349} \right\} \{ \Phi^{-1}(\tau + h_1) - \Phi^{-1}(\tau - h_1) \}$$

where  $\Phi^{-1}(\cdot)$  is the inverse cumulative standard normal distribution and  $h_1$  can be one of the bandwidths in Hall and Sheather (1988) ( $h_{hs}$ ) or Bofinger (1975) ( $h_{bo}$ ). In particular,

$$h_{hs} = N^{-1/3} \Phi^{-1} \left( 1 - \frac{\alpha}{2} \right)^{2/3} \left[ \frac{3}{2} \times \frac{\phi \{ \Phi^{-1}(\tau) \}^2}{2\Phi^{-1}(\tau)^2 + 1} \right]^{1/3}$$

$$h_{bo} = N^{-1/5} \left[ \frac{9}{2} \times \frac{\phi \{ \Phi^{-1}(\tau) \}^4}{\{2\Phi^{-1}(\tau)^2 + 1\}^2} \right]^{1/5}$$

where  $\phi(\cdot)$  is the standard normal probability density function.

## Acknowledgments

We thank David M. Kaplan of the Department of Economics at the University of Missouri for the helpful discussions and suggestions.

Stata has an active research community adding features to the area of instrumental-variables quantile regression. We would like to acknowledge their previous and ongoing contributions to this area: `sivqr` by David M. Kaplan; `ivqreg2` by J. A. F. Machado and J. M. C. Santos Silva; `cqiv` by Victor Chernozhukov, Ivan Fernández-Val, Sukjin Han, and Amanda Kowalski; and many more. Type `search instrumental variables quantile regression` to see Stata's official and community-contributed features for instrumental-variables quantile regression.

## Postestimation commands

The following postestimation commands are of special interest after `ivqregress`:

Command	Description
<code>estat coefplot</code>	plot coefficients and their confidence intervals at different quantiles
<code>estat endogeffects</code>	perform tests of endogeneity
* <code>estat dualci</code>	report dual confidence intervals for endogenous variable
* <code>estat waldplot</code>	plot Wald statistics corresponding to each grid point

\* `estat dualci` and `estat waldplot` work only after `ivqregress iqr`.

The following postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>forecast</code>	dynamic forecasts and simulations
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	linear predictions and residuals
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictors and residuals.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic equation([eqno])]
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>xb</code>	linear predictor; the default
<code>residuals</code>	residuals

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`xb`, the default, calculates the linear predictor.

`residuals` calculates the residuals, that is,  $y_j - \mathbf{x}_j\mathbf{b}$ .

`equation`([*eqno*]) specifies the equation to which you are making the calculation.

`equation`() is filled in with one *eqno*. `equation(#1)` would mean that the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(p50)` would refer to the equation named p50 and `equation(p90)` to the equation named p90.

If you do not specify `equation`(), results are the same as if you had specified `equation(#1)`.

## margins

### Description for margins

`margins` estimates margins of response for linear predictors.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [options]
```

<i>statistic</i>	Description
<code>xb</code>	linear predictor; the default
<u><code>residuals</code></u>	not allowed with <code>margins</code>

---

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## estat

### Description for estat

`estat coefplot` plots the estimated coefficients and their confidence intervals (CIs) after `ivqregress`.

`estat endogeffects` tests four hypotheses for the coefficients on the endogenous variables; see [Chernozhukov and Hansen \(2006\)](#). In particular, `estat endogeffects` provides tests for the following null hypotheses:

1. No effect: the endogenous variables do not affect the outcome variable.
2. Constant effect: the effects of the endogenous variables do not vary across estimated quantiles.
3. Dominance: the effects of the endogenous variables are greater than 0 across estimated quantiles.
4. Exogeneity: the variables are exogenous instead of endogenous.

`estat dualci` computes the dual CIs for the coefficients on the endogenous variable (one for each quantile) after `ivqregress iqr`; see [Chernozhukov and Hansen \(2008\)](#). The dual CI is robust to the weak instruments, and it is usually wider than the traditional CI.

`estat waldplot` plots the Wald statistic corresponding to each grid point after `ivqregress iqr`.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

*Plot coefficients and their CIs at different quantiles*

```
estat coefplot [varname] [, coefplot_options]
```

*Perform tests of endogeneity*

```
estat endogeffects [varlist] [, endogeffects_options]
```

*Report dual CIs for endogenous variable*

```
estat dualci [, level(#) display_options]
```

*Plot Wald statistics corresponding to each grid point*

```
estat waldplot [, waldplot_options]
```

*varname* is one of the endogenous regressors or exogenous variables specified when fitting `ivqregress`.

By default, *varname* is the endogenous variable specified with `ivqregress iqr` or the first endogenous variable specified with `ivqregress smooth`.

*varlist* contains one or more of the endogenous variables specified when fitting a model with `ivqregress`; the default is the first endogenous variable.

<i>coefplot_options</i>	Description
<code>nocl</code>	do not plot the CIs
<code>no2sls</code>	do not plot the 2SLS estimates
Plot	
<i><a href="#">connect_options</a></i>	change look of lines or connecting method
<i><a href="#">marker_options</a></i>	change look of markers (color, size, etc.)
CI plot	
<code>ciopts(<i>area_options</i>)</code>	affect rendition of the pointwise CIs
Line options	
<code>lineopts(<i>cline_options</i>)</code>	affect rendition of reference line identifying the 2SLS estimates
Y axis, X axis, Titles, Legend, Overall	
<i><a href="#">twoway_options</a></i>	any options other than <code>by()</code> documented in [G-3] <i><a href="#">twoway_options</a></i>

<i>endogeffects_options</i>	Description
<code>all</code>	test four hypotheses; the default
<code>noeffect</code>	test of no effect
<code>constant</code>	test of constant effect
<code>dominance</code>	test of stochastic dominance
<code>exogeneity</code>	test of exogeneity
<code>level(#)</code>	confidence level of a test; default is <code>level(95)</code>
<code>rseed(#)</code>	set random-number seed to #
<code>reps(#)</code>	perform # bootstrap replications; default is <code>reps(100)</code>

<i>waldplot_options</i>	Description
<code>quantile(#)</code>	plot Wald statistics for the #th quantile estimation
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
Plot	
<i><a href="#">connect_options</a></i>	change look of lines or connecting method
<i><a href="#">marker_options</a></i>	change look of markers (color, size, etc.)
CI plot	
<code>ciopts(<i>area_options</i>)</code>	affect rendition of the dual CI plot
Y axis, X axis, Titles, Legend, Overall	
<i><a href="#">twoway_options</a></i>	any options other than <code>by()</code> documented in [G-3] <i><a href="#">twoway_options</a></i>

## Options for estat

Options for `estat` are presented under the following headings:

*Options for estat coefplot*  
*Options for estat endogeffects*  
*Options for estat dualci*  
*Options for estat waldplot*

### Options for estat coefplot

`noci` removes plots of the pointwise CIs. The default is to plot the CIs.

`no2s1s` removes the plot of the 2SLS estimates. The default is to plot the 2SLS reference line.

#### Plot

`connect_options` specify how points on a graph are to be connected; [G-3] [connect\\_options](#).

`marker_options` affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

#### CI plot

`ciopts(area_options)` affects rendition of the pointwise CIs; see [G-3] [area\\_options](#).

#### Line options

`lineopts(cline_options)` affects rendition of reference line identifying the 2SLS estimates; see [G-3] [cline\\_options](#).

#### Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

### Options for estat endogeffects

`all` provides tests for all the four hypotheses, which is the default. If this option is specified with one of the options `noeffect`, `constant`, `dominance`, or `exogeneity`, then tests for all four hypotheses will be performed.

`noeffect` provides a test for the null hypothesis of no effect, that is, a test that the specified endogenous variables do not affect the outcome variable.

`constant` provides a test for the null hypothesis of constant effect, that is, a test that the effects of the specified endogenous variables do not vary across estimated quantiles.

`dominance` provides a test for the null hypothesis of dominance, that is, a test that the effects of the specified endogenous variables are greater than 0 across estimated quantiles.

`exogeneity` provides a test for the null hypothesis of exogeneity, that is, a test that the specified variables are exogenous instead of endogenous.

`level(#)` specifies the confidence level, as a percentage, for CIs. The default is `level(95)` or as set by `set level`; see [U] [20.8 Specifying the width of confidence intervals](#).

`rseed(#)` sets the random-number seed. Specifying this option makes the results reproducible because the critical values are drawn from a bootstrap sample.

`reps(#)` specifies the number of bootstrap replications to get the critical values of the test. The default is `reps(100)`.

### Options for `estat dualci`

`level(#)` specifies the confidence level, as a percentage, for the dual CIs. The default is `level(95)` or as set by `set level`; see [U] [20.8 Specifying the width of confidence intervals](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Options for `estat waldplot`

`quantile(#)` specifies to plot the Wald statistics for each grid points in the `#`th quantile estimation; the default is the first equation.

`level(#)` specifies the confidence level, as a percentage, for the dual CIs. The default is `level(95)` or as set by `set level`; see [U] [20.8 Specifying the width of confidence intervals](#).

---

#### Plot

*connect\_options* specify how points on a graph are to be connected; [G-3] [connect\\_options](#).

*marker\_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

---

#### CI plot

`ciopts(area_options)` affects rendition of the pointwise dual CI plot; see [G-3] [area\\_options](#).

---

#### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

For examples of using `estat coefplot` and `estat endogeffects`, see [example 3](#) in [R] [ivqregress](#). For an example of using `estat dualci`, see [example 1](#) in [R] [ivqregress](#). For an example of using `estat waldplot`, see [example 4](#) in [R] [ivqregress](#).

### ▷ Example 1

In [example 1](#) in [R] [ivqregress](#), we fit an instrumental-variables quantile regression (IVQR) model to estimate the effects of 401(k) participation on the conditional median of the net financial assets. Suppose that now we want to know the median of the net financial assets when everyone does or does not participate in a 401(k) conditional on other covariates; we can use `margins` to find the answer.

We specify `i.p401k` immediately after `margins` to obtain the median of the assets under 401(k) participation and under no 401(k) participation. The `at()` option specifies the values of other covariates when computing the median. In particular, the continuous variables such as `income`, `age`, `familysize`, and `educ` are fixed at the sample mean, and people are assumed to be married, participate in an IRA, receive pension benefits, and own a home.

```
. use https://www.stata-press.com/data/r18/assets2
(Excerpt from Chernozhukov and Hansen (2004))
. ivqregress iqr assets (i.p401k = i.e401k) income age familysize
> i.married i.ira i.pension i.ownhome educ
(output omitted)
. margins i.p401k, at((mean) income age familysize educ
> married = 1 ira = 1 pension = 1 ownhome = 1)
Adjusted predictions                                Number of obs = 9,913
Model VCE: Robust
Expression: Linear predictor, predict()
At: income      = 37208.4 (mean)
    age         = 41.05891 (mean)
    familysize  = 2.865328 (mean)
    married     = 1
    ira         = 1
    pension     = 1
    ownhome     = 1
    educ        = 13.20629 (mean)
```

	Delta-method					
	Margin	std. err.	z	P> z	[95% conf. interval]	
p401k						
No	23681.37	1007.612	23.50	0.000	21706.49	25656.26
Yes	28994.77	1123.076	25.82	0.000	26793.58	31195.96

The results show that the conditional median of assets when everyone participates in a 401(k) is \$28,995. In contrast, the conditional median of assets when no one participates in a 401(k) is only \$23,681. The difference between these two medians is \$5,313, which is the quantile treatment effect of `p401k` and is the same as the coefficient's value.

◀

## Stored results

`estat endogeffects` stores the following in `r()`:

### Scalars

`r(N_reps)`            number of replications  
`r(level)`            confidence level

### Macros

`r(endog)`            tested endogenous regressors

### Matrices

`r(table)`            matrix containing test statistics and critical values

`estat dualci` stores the following in `r()`:

### Scalars

`r(N)`                number of observations  
`r(level)`            confidence level for the dual CI

### Matrices

`r(table)`            matrix containing test statistics, *p*-values, and confidence errors, test statistics, *p*-values, and confidence intervals

## Methods and formulas

Methods and formulas are presented under the following headings:

*Tests of effects of endogenous variables*  
*Dual CI*

## Tests of effects of endogenous variables

`estat endogeffects` implements the general inference procedure outlined in section 4 of [Chernozhukov and Hansen \(2006\)](#). It tests the following null hypotheses:

1. No effect: the endogenous variables do not affect the outcome variable.
2. Constant effect: the effects of the endogenous variables do not vary across estimated quantiles.
3. Dominance: the effects of the endogenous variables are greater than 0 across estimated quantiles.
4. Exogeneity: the variables are exogenous instead of endogenous.

It is convenient to write each null hypothesis in the following form:

$$\mathbf{R}(\tau)\{\boldsymbol{\theta}(\tau) - \mathbf{r}(\tau)\} = 0 \quad \text{for each } \tau \in T$$

where  $\mathbf{R}(\tau)$  is a  $q \times p$  matrix of rank  $q$  when  $q$  is smaller than the dimension of  $\boldsymbol{\theta}(\tau)$ .  $\boldsymbol{\theta}(\tau)$  is the  $p \times 1$  coefficient vector for the IVQR model in the  $\tau$ th quantile,  $\mathbf{r}(\tau) \in R^p$ , and  $T$  is a set of estimated quantile indexes. This form is different from the classical setting because  $\boldsymbol{\theta}(\cdot)$  and  $\mathbf{r}(\cdot)$  are functions, which need to be estimated in some cases.

Based on the IVQR model estimates  $\widehat{\boldsymbol{\theta}}(\cdot)$ , we focus on the basic inference process

$$\mathbf{v}_n(\cdot) = \mathbf{R}(\cdot)\{\widehat{\boldsymbol{\theta}}(\cdot) - \widehat{\mathbf{r}}(\cdot)\}$$

where  $\widehat{\mathbf{r}}(\cdot)$  is either a vector of constants or a vector of estimates from the classical quantile regression. We use the Kolmogorov–Smirnov statistic  $S_n = f\{\sqrt{n}\mathbf{v}_n(\cdot)\}$ , which is a function of  $\mathbf{v}_n(\cdot)$ .

$$S_n = \sqrt{n} \sup_{\tau \in T} \|\mathbf{v}_n(\tau)\|_{\widehat{\mathbf{\Lambda}}(\tau)}$$

where  $\|\mathbf{v}\|_{\mathbf{A}} = \sqrt{\mathbf{v}'\mathbf{A}\mathbf{v}}$ . For the choice of  $\widehat{\mathbf{\Lambda}}(\tau)$ , see section 4.4 in [Chernozhukov and Hansen \(2006\)](#). In essence,  $\widehat{\mathbf{\Lambda}}(\tau)$  is the empirical variance of the estimating scores implied by the IVQR model.

The null hypothesis is rejected if

$$S_n > c(1 - \alpha)$$

where the critical value  $c(1 - \alpha)$  with confidence level  $1 - \alpha$  can be obtained using the bootstrap resampling procedure described in section 4.3 of [Chernozhukov and Hansen \(2006\)](#).

Now we describe the formal definition of the four hypotheses. For notational simplicity, we assume that there is one endogenous variable but the case of multiple endogenous variables can be extended easily. Let  $\alpha(\tau)$  denote the endogenous coefficient for the  $\tau$ th quantile estimation. In this case,  $\mathbf{R} = (1, 0, \dots, 0)$  for the four hypotheses considered.

1. No effect: the null hypothesis is that the endogenous variable has no impact on the outcome:  $\alpha(\tau) = 0$ . In this case,

$$H_0 : \alpha(\tau) = 0 \quad \text{for all } \tau \in T$$

$$H_1 : \alpha(\tau) \neq 0 \quad \text{for some } \tau \in T$$

and  $\widehat{r}(\cdot) = 0$ .

2. Constant effect: the null hypothesis of a constant effect is that the endogenous variable only affects the location of the outcome but not other moments. That is,  $\alpha(\tau) = c$  for all  $\tau \in T$ , where  $c$  is a constant. In this case,

$$H_0 : \alpha(\tau) = c \quad \text{for all } \tau \in T$$

$$H_1 : \alpha(\tau) \neq c \quad \text{for some } \tau \in T$$

and  $\widehat{r}(\cdot)$  is the estimate of endogenous coefficient for one of the quantile indexes.

3. Dominance: the dominance test tests whether the effects of endogenous variable are unambiguously beneficial. That is,  $\alpha(\tau) > 0$  for all  $\tau \in T$ . For this hypothesis, we use the one-sided Kolmogorov–Smirnov statistic

$$S_n = \sqrt{n} \sup_{\tau \in T} \max(-\alpha(\tau), 0)$$

In this case,

$$H_0 : \alpha(\tau) > 0 \quad \text{for all } \tau \in T$$

$$H_1 : \alpha(\tau) \leq 0 \quad \text{for some } \tau \in T$$

and  $\widehat{r}(\cdot) = 0$ .

4. Exogeneity: if all the covariates are exogenous, we can fit the model by the regular quantile regression and denote  $\eta(\tau)$  as the quantile regression estimator. The difference between  $\theta(\tau)$  and  $\eta(\tau)$  can be used to formulate a Hausman test of exogeneity. In this case, the null and alternative are defined as

$$H_0 : \alpha(\tau) = \mathbf{R}\eta(\tau) \quad \text{for all } \tau \in T$$

$$H_1 : \alpha(\tau) \neq \mathbf{R}\eta(\tau) \quad \text{for some } \tau \in T$$

and  $\widehat{\mathbf{r}}(\tau) = \widehat{\eta}(\tau)$ , where  $\widehat{\eta}(\tau)$  is the regular quantile regression estimate.

## Dual CI

`estat dualci` computes the dual CI proposed in [Chernozhukov and Hansen \(2008\)](#) for the coefficient on the endogenous variable in the IVQR model. The dual CI is robust to the weak instrument, and it is usually wider than the classical CI. `estat dualci` is allowed only after `ivqregress iqr`. If you have not read about the methods for the inverse quantile regression (IQR) estimator, see [The IQR estimator](#) in [Methods and formulas of \[R\] ivqregress](#).

Suppose we know the true value of the coefficient on the endogenous covariates, which we denote as  $\alpha(\tau)$ , and let  $W_n\{\alpha(\tau)\}$  be the Wald statistic for the coefficient on the instruments in the auxiliary quantile regression. Then by proposition 1 in [Chernozhukov and Hansen \(2008\)](#),

$$W_n\{\alpha(\tau)\} \rightarrow_d \chi^2(1)$$

and for the confidence region  $\text{CR}_p\{\alpha(\tau)\} = \{\alpha \in A : W_n(\alpha) < c_p\}$ , where  $P\{\chi^2(1) < c_p\} = p$ , and

$$P[\alpha(\tau) \in \text{CR}_p\{\alpha(\tau)\}] = P[W_n\{\alpha(\tau)\} < c_p] = p$$

Intuitively,  $W_n\{\alpha(\tau)\}$  is the Wald statistic for testing whether the coefficients for the instruments are 0. When  $\alpha$  equals the true value  $\alpha(\tau)$ ,  $W(\cdot)$  is  $\chi^2$  distributed with the degree of freedom of 1. Thus, a valid CI for  $\alpha$  can be constructed by the inversion of the Wald statistic. That is,

$$\text{CR}_p\{\alpha(\tau)\} = \{\alpha \in A : W_n(\alpha) < c_p\}$$

covers the true value of  $\alpha(\tau)$  with probability approaching  $p$ .

In practice, the dual CI is constructed by the lower and upper limits of the grid points such that the corresponding Wald statistic is smaller than the critical value  $c_p$ .

## Description

`ivregress` fits linear models where one or more of the regressors are endogenously determined. `ivregress` supports estimation via two-stage least squares (2SLS), limited-information maximum likelihood (LIML), and generalized method of moments (GMM).

## Quick start

2SLS estimation of a linear regression of  $y_1$  on  $x_1$  and endogenous regressor  $y_2$  that is instrumented by  $z_1$

```
ivregress 2sls y1 x1 (y2 = z1)
```

Same as above, but with two endogenous regressors,  $y_2$  and  $y_3$  instrumented by  $z_1$  and  $z_2$

```
ivregress 2sls y1 x1 (y2 y3 = z1 z2)
```

With robust standard errors

```
ivregress 2sls y1 x1 (y2 y3 = z1 z2), vce(robust)
```

Report small-sample statistics

```
ivregress 2sls y1 x1 (y2 y3 = z1 z2), small
```

Use LIML estimation

```
ivregress liml y1 x1 (y2 y3 = z1 z2)
```

Use GMM estimation

```
ivregress gmm y1 x1 (y2 y3 = z1 z2)
```

Also specify a weighting matrix that allows for correlation within clusters identified by `cvar`

```
ivregress gmm y1 x1 (y2 y3 = z1 z2), wmatrix(cluster cvar)
```

## Menu

Statistics > Endogenous covariates > Linear regression with endogenous covariates

## Syntax

```
ivregress estimator depcvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight]
    [, options]
```

*varlist*<sub>1</sub> is the list of exogenous variables.

*varlist*<sub>2</sub> is the list of endogenous variables.

*varlist*<sub>iv</sub> is the list of exogenous variables used with *varlist*<sub>1</sub> as instruments for *varlist*<sub>2</sub>.

<i>estimator</i>	Description
2sls	two-stage least squares (2SLS)
liml	limited-information maximum likelihood (LIML)
gmm	generalized method of moments (GMM)

<i>options</i>	Description
----------------	-------------

### Model

<u>noconstant</u>	suppress constant term
<u>hascons</u>	has user-supplied constant

### GMM<sup>1</sup>

<u>wmatrix</u> ( <i>wmtype</i> )	<i>wmtype</i> may be <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <i>hac</i> <i>kernel</i> , or <u>unadjusted</u>
<u>center</u>	center moments in weight matrix computation
<u>igmm</u>	use iterative instead of two-step GMM estimator
<u>eps</u> (#) <sup>2</sup>	specify # for parameter convergence criterion; default is <code>eps(1e-6)</code>
<u>weps</u> (#) <sup>2</sup>	specify # for weight matrix convergence criterion; default is <code>weps(1e-6)</code>
<u>optimization_options</u> <sup>2</sup>	control the optimization process; seldom used

### SE/Robust

<u>vce</u> ( <i>vcetype</i> )	<i>vcetype</i> may be <u>unadjusted</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>bootstrap</u> , <u>jackknife</u> , or <i>hac</i> <i>kernel</i>
-------------------------------	--

### Reporting

<u>level</u> (#)	set confidence level; default is <code>level(95)</code>
<u>first</u>	report first-stage regression
<u>small</u>	make degrees-of-freedom adjustments and report small-sample statistics
<u>noheader</u>	display only the coefficient table
<u>depname</u> ( <i>depname</i> )	substitute dependent variable name
<u>eform</u> ( <i>string</i> )	report exponentiated coefficients and use <i>string</i> to label them
<u>display_options</u>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

<code>perfect</code>	do not check for collinearity between endogenous regressors and excluded instruments
<code>coeflegend</code>	display legend instead of statistics

<sup>1</sup>These options may be specified only when `gmm` is specified.

<sup>2</sup>These options may be specified only when `igmm` is specified.

`varlist1`, `varlist2`, and `varlistiv` may contain factor variables; see [U] 11.4.3 Factor variables.

`depvar`, `varlist1`, `varlist2`, and `varlistiv` may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bootstrap`, `by`, `collect`, `fmm`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [FMM] `fmm`: `ivregress`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`aweight`s are not allowed with the `jackknife` prefix; see [R] `jackknife`.

`hascons`, `vce()`, `noheader`, `depname()`, and `weights` are not allowed with the `svy` prefix; see [SVY] `svy`.

`aweight`s, `fweight`s, `iweight`s, and `pweight`s are allowed; see [U] 11.1.6 `weight`.

`perfect` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`noconstant`; see [R] Estimation options.

`hascons` indicates that a user-defined constant or its equivalent is specified among the independent variables.

### GMM

`wmatrix(wmtype)` specifies the type of weighting matrix to be used in conjunction with the GMM estimator.

Specifying `wmatrix(robust)` requests a weighting matrix that is optimal when the error term is heteroskedastic. `wmatrix(robust)` is the default.

Specifying `wmatrix(cluster clustvar)` requests a weighting matrix that accounts for arbitrary correlation among observations within clusters identified by *clustvar*.

Specifying `wmatrix(hac kernel #)` requests a heteroskedasticity- and autocorrelation-consistent (HAC) weighting matrix using the specified kernel (see below) with # lags. The bandwidth of a kernel is equal to # + 1.

Specifying `wmatrix(hac kernel opt [#])` requests an HAC weighting matrix using the specified kernel, and the lag order is selected using Newey and West's (1994) optimal lag-selection algorithm. # is an optional tuning parameter that affects the lag order selected; see the discussion in *Methods and formulas*.

Specifying `wmatrix(hac kernel)` requests an HAC weighting matrix using the specified kernel and  $N - 2$  lags, where  $N$  is the sample size.

There are three kernels available for HAC weighting matrices, and you may request each one by using the name used by statisticians or the name perhaps more familiar to economists:

`bartlett` or `nwest` requests the Bartlett (Newey–West) kernel;

`parzen` or `gallant` requests the Parzen (Gallant 1987) kernel; and

`quadraticspectral` or `andrews` requests the quadratic spectral (Andrews 1991) kernel.

Specifying `wmatrix(unadjusted)` requests a weighting matrix that is suitable when the errors are homoskedastic. The GMM estimator with this weighting matrix is equivalent to the 2SLS estimator. `center` requests that the sample moments be centered (demeaned) when computing GMM weight matrices. By default, centering is not done.

`igmm` requests that the iterative GMM estimator be used instead of the default two-step GMM estimator. Convergence is declared when the relative change in the parameter vector from one iteration to the next is less than `eps()` or the relative change in the weight matrix is less than `weps()`.

`eps(#)` specifies the convergence criterion for successive parameter estimates when the iterative GMM estimator is used. The default is `eps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `eps()` and the relative difference between successive estimates of the weighting matrix is less than `weps()`.

`weps(#)` specifies the convergence criterion for successive estimates of the weighting matrix when the iterative GMM estimator is used. The default is `weps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `eps()` and the relative difference between successive estimates of the weighting matrix is less than `weps()`.

*optimization\_options*: `iterate(#)`, `[no]log`. `iterate()` specifies the maximum number of iterations to perform in conjunction with the iterative GMM estimator. The default is the number set using `set maxiter`, which is 300 by default. `log/nolog` specifies whether to show the iteration log; see `set iterlog` in [R] *set iter*. These options are seldom used.

---

#### SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] *vce\_option*.

`vce(unadjusted)`, the default for `2sls` and `liml`, specifies that an unadjusted (nonrobust) VCE matrix be used. The default for `gmm` is based on the `wmtype` specified in the `wmatrix()` option; see `wmatrix()` above. If `wmatrix()` is specified with `gmm` but `vce()` is not, then `vctype` is set equal to `wmtype`. To override this behavior and obtain an unadjusted (nonrobust) VCE matrix, specify `vce(unadjusted)`.

`ivregress` also allows the following:

`vce(hac kernel [#|opt [#]])` specifies that an HAC covariance matrix be used. The syntax used with `vce(hac kernel ...)` is identical to that used with `wmatrix(hac kernel ...)`; see `wmatrix()` above.

---

#### Reporting

`level(#)`; see [R] *Estimation options*.

`first` requests that the first-stage regression results be displayed.

`small` requests that the degrees-of-freedom adjustment  $N/(N - k)$  be made to the variance-covariance matrix of parameters and that small-sample  $F$  and  $t$  statistics be reported, where  $N$  is the sample size and  $k$  is the number of parameters estimated. By default, no degrees-of-freedom adjustment is made, and Wald and  $z$  statistics are reported. Even with this option, no degrees-of-freedom adjustment is made to the weighting matrix when the GMM estimator is used.

`noheader` suppresses the display of the summary statistics at the top of the output, displaying only the coefficient table.

`depname(depname)` is used only in programs and ado-files that use `ivregress` to fit models other than instrumental-variables regression. `depname()` may be specified only at estimation time. *depname*

is recorded as the identity of the dependent variable, even though the estimates are calculated using `depvar`. This method affects the labeling of the output—not the results calculated—but could affect later calculations made by `predict`, where the residual would be calculated as deviations from `depname` rather than `depvar`. `depname()` is most typically used when `depvar` is a temporary variable (see [P] [macro](#)) used as a proxy for `depname`.

`eform(string)` is used only in programs and ado-files that use `ivregress` to fit models other than instrumental-variables regression. `eform()` specifies that the coefficient table be displayed in “exponentiated form”, as defined in [R] [Maximize](#), and that `string` be used to label the exponentiated coefficients in the table.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

The following options are available with `ivregress` but are not shown in the dialog box:

`perfect` requests that `ivregress` not check for collinearity between the endogenous regressors and excluded instruments, allowing one to specify “perfect” instruments. This option cannot be used with the LIML estimator. This option may be required when using `ivregress` to implement other estimators.

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

`ivregress` performs instrumental-variables regression and weighted instrumental-variables regression. For a general discussion of instrumental variables, see [Baum \(2006\)](#), [Cameron and Trivedi \(2005; 2022, chap. 7\)](#) [Davidson and MacKinnon \(1993\)](#), [Greene \(2018, chap. 8\)](#), and [Wooldridge \(2010, 2020\)](#). See [Hall \(2005\)](#) for a lucid presentation of GMM estimation. [Angrist and Pischke \(2009, chap. 4\)](#) offer a casual yet thorough introduction to instrumental-variables estimators, including their use in estimating treatment effects. Some of the earliest work on simultaneous systems can be found in Cowles Commission monographs—[Koopmans and Marschak \(1950\)](#) and [Koopmans and Hood \(1953\)](#)—with the first developments of 2SLS appearing in [Theil \(1953\)](#) and [Basman \(1957\)](#). However, [Stock and Watson \(2019, 401–402\)](#) present an example of the method of instrumental variables that was first published in 1928 by Philip Wright.

The syntax for `ivregress` assumes that you want to fit one equation from a system of equations or an equation for which you do not want to specify the functional form for the remaining equations of the system. To fit a full system of equations, using either 2SLS equation-by-equation or three-stage least squares, see [R] [reg3](#). An advantage of `ivregress` is that you can fit one equation of a multiple-equation system without specifying the functional form of the remaining equations.

Formally, the model fit by `ivregress` is

$$y_i = \mathbf{y}_i\boldsymbol{\beta}_1 + \mathbf{x}_{1i}\boldsymbol{\beta}_2 + u_i \quad (1)$$

$$\mathbf{y}_i = \mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2 + \mathbf{v}_i \quad (2)$$

Here  $y_i$  is the dependent variable for the  $i$ th observation,  $\mathbf{y}_i$  represents the endogenous regressors (`varlist2` in the syntax diagram),  $\mathbf{x}_{1i}$  represents the included exogenous regressors (`varlist1` in the syntax diagram), and  $\mathbf{x}_{2i}$  represents the excluded exogenous regressors (`varlistiv` in the syntax diagram).  $\mathbf{x}_{1i}$  and  $\mathbf{x}_{2i}$  are collectively called the instruments.  $u_i$  and  $\mathbf{v}_i$  are zero-mean error terms, and the correlations between  $u_i$  and the elements of  $\mathbf{v}_i$  are presumably nonzero.

The rest of the discussion is presented under the following headings:

[2SLS and LIML estimators](#)  
[GMM estimator](#)  
[Video example](#)

## 2SLS and LIML estimators

The most common instrumental-variables estimator is 2SLS.

### ► Example 1: 2SLS estimator

We have state data from the 1980 census on the median dollar value of owner-occupied housing (`hsngval`) and the median monthly gross rent (`rent`). We want to model `rent` as a function of `hsngval` and the percentage of the population living in urban areas (`pcturban`):

$$\text{rent}_i = \beta_0 + \beta_1 \text{hsngval}_i + \beta_2 \text{pcturban}_i + u_i$$

where  $i$  indexes states and  $u_i$  is an error term.

Because random shocks that affect rental rates in a state probably also affect housing values, we treat `hsngval` as endogenous. We believe that the correlation between `hsngval` and  $u$  is not equal to zero. On the other hand, we have no reason to believe that the correlation between `pcturban` and  $u$  is nonzero, so we assume that `pcturban` is exogenous.

Because we are treating `hsngval` as an endogenous regressor, we must have one or more additional variables available that are correlated with `hsngval` but uncorrelated with  $u$ . Moreover, these excluded exogenous variables must not affect `rent` directly, because if they do then they should be included in the regression equation we specified above. In our dataset, we have a variable for family income (`faminc`) and for region of the country (`region`) that we believe are correlated with `hsngval` but not the error term. Together, `pcturban`, `faminc`, and factor variables `2.region`, `3.region`, and `4.region` constitute our set of instruments.

To fit the equation in Stata, we specify the dependent variable and the list of included exogenous variables. In parentheses, we specify the endogenous regressors, an equal sign, and the excluded exogenous variables. Only the additional exogenous variables must be specified to the right of the equal sign; the exogenous variables that appear in the regression equation are automatically included as instruments.

Here we fit our model with the 2SLS estimator:

```
. use https://www.stata-press.com/data/r18/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
Instrumental variables 2SLS regression
```

	Number of obs	=	50	
	Wald chi2(2)	=	90.76	
	Prob > chi2	=	0.0000	
	R-squared	=	0.5989	
	Root MSE	=	22.166	

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
hsngval	.0022398	.0003284	6.82	0.000	.0015961	.0028836
pcturban	.081516	.2987652	0.27	0.785	-.504053	.667085
_cons	120.7065	15.22839	7.93	0.000	90.85942	150.5536

Endogenous: `hsngval`

Exogenous: `pcturban` `faminc` `2.region` `3.region` `4.region`

As we would expect, states with higher housing values have higher rental rates. The proportion of a state's population that is urban does not have a significant effect on rents. ◀

## □ Technical note

In a simultaneous-equations framework, we could write the model we just fit as

$$\begin{aligned} \text{hsngval}_i &= \pi_0 + \pi_1 \text{faminc}_i + \pi_2 \text{2.region}_i + \pi_3 \text{3.region}_i + \pi_4 \text{4.region}_i + v_i \\ \text{rent}_i &= \beta_0 + \beta_1 \text{hsngval}_i + \beta_2 \text{pcturban}_i + u_i \end{aligned}$$

which here happens to be recursive (triangular), because `hsngval` appears in the equation for `rent` but `rent` does not appear in the equation for `hsngval`. In general, however, systems of simultaneous equations are not recursive. Because this system is recursive, we could fit the two equations individually via OLS if we were willing to assume that  $u$  and  $v$  were independent. For a more detailed discussion of triangular systems, see [Kmenta \(1997, 719–720\)](#).

Historically, instrumental-variables estimation and systems of simultaneous equations were taught concurrently, and older textbooks describe instrumental-variables estimation solely in the context of simultaneous equations. However, in recent decades, the treatment of endogeneity and instrumental-variables estimation has taken on a much broader scope, while interest in the specification of complete systems of simultaneous equations has waned. Most recent textbooks, such as [Cameron and Trivedi \(2005\)](#), [Davidson and MacKinnon \(1993\)](#), and [Wooldridge \(2010, 2020\)](#), treat instrumental-variables estimation as an integral part of the modern economists' toolkit and introduce it long before shorter discussions on simultaneous equations. □

In addition to the 2SLS member of the  $\kappa$ -class estimators, `ivregress` implements the LIML estimator. Both theoretical and Monte Carlo exercises indicate that the LIML estimator may yield less bias and confidence intervals with better coverage rates than the 2SLS estimator. See [Poi \(2006\)](#) and [Stock, Wright, and Yogo \(2002\)](#) (and the papers cited therein) for Monte Carlo evidence.

## ▷ Example 2: LIML estimator

Here we refit our model with the LIML estimator:

```
. ivregress liml rent pcturban (hsngval = faminc i.region)
Instrumental variables LIML regression
```

Number of obs	=	50
Wald chi2(2)	=	75.71
Prob > chi2	=	0.0000
R-squared	=	0.4901
Root MSE	=	24.992

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
hsngval	.0026686	.0004173	6.39	0.000	.0018507	.0034865
pcturban	-.1827391	.3571132	-0.51	0.609	-.8826681	.5171899
_cons	117.6087	17.22625	6.83	0.000	83.84587	151.3715

Endogenous: `hsngval`

Exogenous: `pcturban faminc 2.region 3.region 4.region`

These results are qualitatively similar to the [2SLS results](#), although the coefficient on `hsngval` is about 19% higher. ◀

## GMM estimator

Since the celebrated paper of Hansen (1982), the GMM has been a popular method of estimation in economics and finance, and it lends itself well to instrumental-variables estimation. The basic principle is that we have some *moment* or *orthogonality* conditions of the form

$$E(\mathbf{z}_i u_i) = \mathbf{0} \quad (3)$$

From (1), we have  $u_i = y_i - \mathbf{y}_i \beta_1 - \mathbf{x}_{1i} \beta_2$ . What are the elements of the instrument vector  $\mathbf{z}_i$ ? By assumption,  $\mathbf{x}_{1i}$  is uncorrelated with  $u_i$ , as are the excluded exogenous variables  $\mathbf{x}_{2i}$ , and so we use  $\mathbf{z}_i = [\mathbf{x}_{1i} \ \mathbf{x}_{2i}]$ . The moment conditions are simply the mathematical representation of the assumption that the instruments are exogenous—that is, the instruments are orthogonal to (uncorrelated with)  $u_i$ .

If the number of elements in  $\mathbf{z}_i$  is just equal to the number of unknown parameters, then we can apply the analogy principle to (3) and solve

$$\frac{1}{N} \sum_i \mathbf{z}_i u_i = \frac{1}{N} \sum_i \mathbf{z}_i (y_i - \mathbf{y}_i \beta_1 - \mathbf{x}_{1i} \beta_2) = \mathbf{0} \quad (4)$$

This equation is known as the method of moments estimator. Here, where the number of instruments equals the number of parameters, the method of moments estimator coincides with the 2SLS estimator, which also coincides with what has historically been called the indirect least-squares estimator (Judge et al. 1985, 595).

The “generalized” in GMM addresses the case in which the number of instruments (columns of  $\mathbf{z}_i$ ) exceeds the number of parameters to be estimated. Here there is no unique solution to the population moment conditions defined in (3), so we cannot use (4). Instead, we define the objective function

$$Q(\beta_1, \beta_2) = \left( \frac{1}{N} \sum_i \mathbf{z}_i u_i \right)' \mathbf{W} \left( \frac{1}{N} \sum_i \mathbf{z}_i u_i \right) \quad (5)$$

where  $\mathbf{W}$  is a positive-definite matrix with the same number of rows and columns as the number of columns of  $\mathbf{z}_i$ .  $\mathbf{W}$  is known as the weighting matrix, and we specify its structure with the `wmatrix()` option. The GMM estimator of  $(\beta_1, \beta_2)$  minimizes  $Q(\beta_1, \beta_2)$ ; that is, the GMM estimator chooses  $\beta_1$  and  $\beta_2$  to make the moment conditions as close to zero as possible for a given  $\mathbf{W}$ . For a more general GMM estimator, see [R] `gmm`. `gmm` does not restrict you to fitting a single linear equation, though the syntax is more complex.

A well-known result is that if we define the matrix  $\mathbf{S}_0$  to be the covariance of  $\mathbf{z}_i u_i$  and set  $\mathbf{W} = \mathbf{S}_0^{-1}$ , then we obtain the optimal two-step GMM estimator, where by optimal estimator we mean the one that results in the smallest variance given the moment conditions defined in (3).

Suppose that the errors  $u_i$  are heteroskedastic but independent among observations. Then

$$\mathbf{S}_0 = E(\mathbf{z}_i u_i u_i \mathbf{z}_i') = E(u_i^2 \mathbf{z}_i \mathbf{z}_i')$$

and the sample analogue is

$$\hat{\mathbf{S}} = \frac{1}{N} \sum_i \hat{u}_i^2 \mathbf{z}_i \mathbf{z}_i' \quad (6)$$

To implement this estimator, we need estimates of the sample residuals  $\hat{u}_i$ . `ivregress gmm` obtains the residuals by estimating  $\beta_1$  and  $\beta_2$  by 2SLS and then evaluates (6) and sets  $\mathbf{W} = \hat{\mathbf{S}}^{-1}$ . Equation (6) is the same as the center term of the “sandwich” robust covariance matrix available from most Stata estimation commands through the `vce(robust)` option.

### ▷ Example 3: GMM estimator

Here we refit our model of rents by using the GMM estimator, allowing for heteroskedasticity in  $u_i$ :

```
. ivregress gmm rent pcturban (hsngval = faminc i.region), wmatrix(robust)
Instrumental variables GMM regression      Number of obs   =       50
                                           Wald chi2(2)    =     112.09
                                           Prob > chi2     =     0.0000
                                           R-squared       =     0.6616
                                           Root MSE       =     20.358

GMM weight matrix: Robust
```

rent	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
hsngval	.0014643	.0004473	3.27	0.001	.0005877	.002341
pcturban	.7615482	.2895105	2.63	0.009	.1941181	1.328978
_cons	112.1227	10.80234	10.38	0.000	90.95052	133.2949

Endogenous: hsngval

Exogenous: pcturban faminc 2.region 3.region 4.region

Because we requested that a heteroskedasticity-consistent weighting matrix be used during estimation but did not specify the `vce()` option, `ivregress` reported standard errors that are robust to heteroskedasticity. Had we specified `vce(unadjusted)`, we would have obtained standard errors that would be correct only if the weighting matrix  $\mathbf{W}$  does in fact converge to  $\mathbf{S}_0^{-1}$ .

◀

### □ Technical note

Many software packages that implement GMM estimation use the same heteroskedasticity-consistent weighting matrix we used in the [previous example](#) to obtain the optimal two-step estimates but do not use a heteroskedasticity-consistent VCE, even though they may label the standard errors as being “robust”. To replicate results obtained from other packages, you may have to use the `vce(unadjusted)` option. See [Methods and formulas](#) below for a discussion of robust covariance matrix estimation in the GMM framework.

□

By changing our definition of  $\mathbf{S}_0$ , we can obtain GMM estimators suitable for use with other types of data that violate the assumption that the errors are independent and identically distributed. For example, you may have a dataset that consists of multiple observations for each person in a sample. The observations that correspond to the same person are likely to be correlated, and the estimation technique should account for that lack of independence. Say that in your dataset, people are identified by the variable `personid` and you type

```
. ivregress gmm ..., wmatrix(cluster personid)
```

Here `ivregress` estimates  $\mathbf{S}_0$  as

$$\hat{\mathbf{S}} = \frac{1}{N} \sum_{c \in C} \mathbf{q}_c \mathbf{q}_c'$$

where  $C$  denotes the set of clusters and

$$\mathbf{q}_c = \sum_{i \in c_j} \hat{u}_i \mathbf{z}_i$$

where  $c_j$  denotes the  $j$ th cluster. This weighting matrix accounts for the within-person correlation among observations, so the GMM estimator that uses this version of  $\mathbf{S}_0$  will be more efficient than the estimator that ignores this correlation.

#### ▷ Example 4: GMM estimator with clustering

We have data from the National Longitudinal Survey on young women's wages as reported in a series of interviews from 1968 through 1988, and we want to fit a model of wages as a function of each woman's age and age squared, job tenure, birth year, and level of education. We believe that random shocks that affect a woman's wage also affect her job tenure, so we treat tenure as endogenous. As additional instruments, we use her union status, number of weeks worked in the past year, and a dummy indicating whether she lives in a metropolitan area. Because we have several observations for each woman (corresponding to interviews done over several years), we want to control for clustering on each person.

```
. use https://www.stata-press.com/data/r18/nlswork
(National Longitudinal Survey of Young Women, 14-24 years old in 1968)
. ivregress gmm ln_wage age c.age#c.age birth_yr grade
> (tenure = union wks_work msp), wmatrix(cluster idcode)

Endogenous: tenure

Exogenous: age c.age#c.age birth\_yr grade union wks\_work msp

Both job tenure and years of schooling have significant positive effects on wages.

◀

Time-series data are often plagued by serial correlation. In these cases, we can construct a weighting matrix to account for the fact that the error in period  $t$  is probably correlated with the errors in periods  $t - 1$ ,  $t - 2$ , etc. An HAC weighting matrix can be used to account for both serial correlation and potential heteroskedasticity.

To request an HAC weighting matrix, you specify the `wmatrix(hac kernel [#|opt])` option. `kernel` specifies which of three kernels to use: `bartlett`, `parzen`, or `quadraticspectral`. `kernel` determines the amount of weight given to lagged values when computing the HAC matrix, and `#` denotes the maximum number of lags to use. Many texts refer to the bandwidth of the kernel instead of the number of lags; the bandwidth is equal to the number of lags plus one. If neither `opt` nor `#` is specified, then  $N - 2$  lags are used, where  $N$  is the sample size.

If you specify `wmatrix(hac kernel opt)`, then `ivregress` uses Newey and West's (1994) algorithm for automatically selecting the number of lags to use. Although the authors' Monte Carlo simulations do show that the procedure may result in size distortions of hypothesis tests, the procedure is still useful when little other information is available to help choose the number of lags.

For more on GMM estimation, see Baum (2006); Baum, Schaffer, and Stillman (2003, 2007); Cameron and Trivedi (2005); Davidson and MacKinnon (1993); Hayashi (2000); or Wooldridge (2010). See Newey and West (1987) and Wang and Wu (2012) for an introduction to HAC covariance matrix estimation.

## Video example

## Stored results

`ivregress` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(mss)</code>	model sum of squares
<code>e(df_m)</code>	model degrees of freedom
<code>e(rss)</code>	residual sum of squares
<code>e(df_r)</code>	residual degrees of freedom
<code>e(r2)</code>	$R^2$
<code>e(r2_a)</code>	adjusted $R^2$
<code>e(F)</code>	$F$ statistic
<code>e(rmse)</code>	root mean squared error
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(kappa)</code>	$\kappa$ used in LIML estimator
<code>e(J)</code>	value of GMM objective function
<code>e(wlagopt)</code>	lags used in HAC weight matrix (if Newey–West algorithm used)
<code>e(vcelagopt)</code>	lags used in HAC VCE matrix (if Newey–West algorithm used)
<code>e(hac_lag)</code>	HAC lag
<code>e(rank)</code>	rank of $e(V)$
<code>e(iterations)</code>	number of GMM iterations (0 if not applicable)

### Macros

<code>e(cmd)</code>	<code>ivregress</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(endog)</code>	names of endogenous variables
<code>e(exog)</code>	names of exogenous variables
<code>e(constant)</code>	<code>noconstant</code> or <code>hasconstant</code> if specified
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(hac_kernel)</code>	HAC kernel
<code>e(vce)</code>	<code>vcetype</code> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(estimator)</code>	<code>2sls</code> , <code>liml</code> , or <code>gmm</code>
<code>e(exogr)</code>	exogenous regressors
<code>e(wmatrix)</code>	<code>wmtype</code> specified in <code>wmatrix()</code>
<code>e(moments)</code>	<code>centered</code> if <code>center</code> specified
<code>e(small)</code>	<code>small</code> if small-sample statistics
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>

<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(footnote)</code>	program used to implement <code>footnote display</code>
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(marginsnotok)</code>	predictions disallowed by <code>margins</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

## Matrices

<code>e(b)</code>	coefficient vector
<code>e(W)</code>	weight matrix used to compute GMM estimates
<code>e(S)</code>	moment covariance matrix used to compute GMM variance–covariance matrix
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

## Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

## Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals
-----------------------	---

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

*Notation*

*2SLS and LIML estimators*

*GMM estimator*

## Notation

Items printed in lowercase and italicized (for example,  $x$ ) are scalars. Items printed in lowercase and boldfaced (for example,  $\mathbf{x}$ ) are vectors. Items printed in uppercase and boldfaced (for example,  $\mathbf{X}$ ) are matrices.

The model is

$$\mathbf{y} = \mathbf{Y}\boldsymbol{\beta}_1 + \mathbf{X}_1\boldsymbol{\beta}_2 + \mathbf{u} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{Y} = \mathbf{X}_1\boldsymbol{\Pi}_1 + \mathbf{X}_2\boldsymbol{\Pi}_2 + \mathbf{v} = \mathbf{Z}\boldsymbol{\Pi} + \mathbf{V}$$

where  $\mathbf{y}$  is an  $N \times 1$  vector of the left-hand-side variable;  $N$  is the sample size;  $\mathbf{Y}$  is an  $N \times p$  matrix of  $p$  endogenous regressors;  $\mathbf{X}_1$  is an  $N \times k_1$  matrix of  $k_1$  included exogenous regressors;  $\mathbf{X}_2$  is an  $N \times k_2$  matrix of  $k_2$  excluded exogenous variables,  $\mathbf{X} = [\mathbf{Y} \ \mathbf{X}_1]$ ,  $\mathbf{Z} = [\mathbf{X}_1 \ \mathbf{X}_2]$ ;  $\mathbf{u}$  is an  $N \times 1$  vector of errors;  $\mathbf{V}$  is an  $N \times p$  matrix of errors;  $\boldsymbol{\beta} = [\boldsymbol{\beta}_1 \ \boldsymbol{\beta}_2]$  is a  $k = (p + k_1) \times 1$  vector of parameters; and  $\boldsymbol{\Pi}$  is a  $(k_1 + k_2) \times p$  vector of parameters. If a constant term is included in the model, then one column of  $\mathbf{X}_1$  contains all ones.

Let  $\mathbf{v}$  be a column vector of weights specified by the user. If no weights are specified,  $\mathbf{v} = \mathbf{1}$ . Let  $\mathbf{w}$  be a column vector of normalized weights. If no weights are specified or if the user specified `fweights` or `iwweights`,  $\mathbf{w} = \mathbf{v}$ ; otherwise,  $\mathbf{w} = \{\mathbf{v}/(\mathbf{1}'\mathbf{v})\}(\mathbf{1}'\mathbf{1})$ . Let  $\mathbf{D}$  denote the  $N \times N$  matrix with  $\mathbf{w}$  on the main diagonal and zeros elsewhere. If no weights are specified,  $\mathbf{D}$  is the identity matrix.

The weighted number of observations  $n$  is defined as  $\mathbf{1}'\mathbf{w}$ . For `ivregress`, this is truncated to an integer. The *sum of the weights* is  $\mathbf{1}'\mathbf{v}$ . Define  $c = 1$  if there is a constant in the regression and zero otherwise.

The order condition for identification requires that  $k_2 \geq p$ : the number of excluded exogenous variables must be at least as great as the number of endogenous regressors.

In the following formulas, if weights are specified,  $\mathbf{X}'_1\mathbf{X}_1$ ,  $\mathbf{X}'\mathbf{X}$ ,  $\mathbf{X}'\mathbf{y}$ ,  $\mathbf{y}'\mathbf{y}$ ,  $\mathbf{Z}'\mathbf{Z}$ ,  $\mathbf{Z}'\mathbf{X}$ , and  $\mathbf{Z}'\mathbf{y}$  are replaced with  $\mathbf{X}'_1\mathbf{D}\mathbf{X}_1$ ,  $\mathbf{X}'\mathbf{D}\mathbf{X}$ ,  $\mathbf{X}'\mathbf{D}\mathbf{y}$ ,  $\mathbf{y}'\mathbf{D}\mathbf{y}$ ,  $\mathbf{Z}'\mathbf{D}\mathbf{Z}$ ,  $\mathbf{Z}'\mathbf{D}\mathbf{X}$ , and  $\mathbf{Z}'\mathbf{D}\mathbf{y}$ , respectively. We suppress the  $\mathbf{D}$  below to simplify the notation.

## 2SLS and LIML estimators

Define the  $\kappa$ -class estimator of  $\beta$  as

$$\mathbf{b} = \{\mathbf{X}'(\mathbf{I} - \kappa\mathbf{M}_Z)\mathbf{X}\}^{-1}\mathbf{X}'(\mathbf{I} - \kappa\mathbf{M}_Z)\mathbf{y}$$

where  $\mathbf{M}_Z = \mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$ . The 2SLS estimator results from setting  $\kappa = 1$ . The LIML estimator results from selecting  $\kappa$  to be the minimum eigenvalue of  $(\mathbf{Y}'\mathbf{M}_Z\mathbf{Y})^{-1/2}\mathbf{Y}'\mathbf{M}_{\mathbf{X}_1}\mathbf{Y}(\mathbf{Y}'\mathbf{M}_Z\mathbf{Y})^{-1/2}$ , where  $\mathbf{M}_{\mathbf{X}_1} = \mathbf{I} - \mathbf{X}_1(\mathbf{X}'_1\mathbf{X}_1)^{-1}\mathbf{X}'_1$ .

The total sum of squares (TSS) equals  $\mathbf{y}'\mathbf{y}$  if there is no intercept and  $\mathbf{y}'\mathbf{y} - \{(\mathbf{1}'\mathbf{y})^2/n\}$  otherwise. The degrees of freedom is  $n - c$ . The error sum of squares (ESS) is defined as  $\mathbf{y}'\mathbf{y} - 2\mathbf{b}\mathbf{X}'\mathbf{y} + \mathbf{b}'\mathbf{X}'\mathbf{X}\mathbf{b}$ . The model sum of squares (MSS) equals TSS - ESS. The degrees of freedom is  $k - c$ .

The mean squared error,  $s^2$ , is defined as  $\text{ESS}/(n - k)$  if `small` is specified and  $\text{ESS}/n$  otherwise. The root mean squared error is  $s$ , its square root.

If  $c = 1$  and `small` is not specified, a Wald statistic,  $W$ , of the joint significance of the  $k - 1$  parameters of  $\beta$  except the constant term is calculated;  $W \sim \chi^2(k - 1)$ . If  $c = 1$  and `small` is specified, then an  $F$  statistic is calculated as  $F = W/(k - 1)$ ;  $F \sim F(k - 1, n - k)$ .

The  $R^2$  is defined as  $R^2 = 1 - \text{ESS}/\text{TSS}$ .

The adjusted  $R^2$  is  $R^2_a = 1 - (1 - R^2)(n - c)/(n - k)$ .

The unadjusted (default) variance estimate is  $\text{Var}(\mathbf{b}) = s^2\{\mathbf{X}'(\mathbf{I} - \kappa\mathbf{M}_Z)\mathbf{X}\}^{-1}$ .

For a general discussion of robust variance estimates in regression, see [A general notation for the robust variance calculation](#) in [R] `regress`. `ivregress` uses the same definitions for terms discussed in [Robust calculation for regress](#) in its robust variance calculation, except for the following.

The vector of scores is given by

$$\mathbf{u}_j = (y_j - \mathbf{x}_j\mathbf{b})\hat{\mathbf{x}}_j$$

where  $\hat{\mathbf{x}}'_j = \mathbf{P}\mathbf{z}'_j$  and  $\mathbf{P} = (\mathbf{X}'\mathbf{Z})(\mathbf{Z}'\mathbf{Z})^{-1}$ . When the formulas in [R] `regress` are applied,  $q_c$  is given by its regressionlike definition. If `small` is not specified, then  $k = 0$  in the formulas given in [R] `regress`.

`ivregress 2sls` and `ivregress liml` also support estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## GMM estimator

We obtain an initial consistent estimate of  $\beta$  by using the 2SLS estimator; see above. Using this estimate of  $\beta$ , we compute the weighting matrix  $\mathbf{W}$  and calculate the GMM estimator

$$\mathbf{b}_{\text{GMM}} = \{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\}^{-1}\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{y}$$

The variance of  $\mathbf{b}_{\text{GMM}}$  is

$$\text{Var}(\mathbf{b}_{\text{GMM}}) = n\{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\}^{-1}\mathbf{X}'\mathbf{Z}\mathbf{W}\widehat{\mathbf{S}}\mathbf{W}\mathbf{Z}'\mathbf{X}\{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\}^{-1}$$

$\text{Var}(\mathbf{b}_{\text{GMM}})$  is of the sandwich form **DMD**; see [P] **\_robust**. If the user specifies the `small` option, `ivregress` implements a small-sample adjustment by multiplying the VCE by  $N/(N - k)$ .

If `vce(unadjusted)` is specified, then we set  $\widehat{\mathbf{S}} = \mathbf{W}^{-1}$  and the VCE reduces to the “optimal” GMM variance estimator

$$\text{Var}(\beta_{\text{GMM}}) = n\{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\}^{-1}$$

However, if  $\mathbf{W}^{-1}$  is not a good estimator of  $E(\mathbf{z}_i u_i u_i \mathbf{z}_i')$ , then the optimal GMM estimator is inefficient, and inference based on the optimal variance estimator could be misleading.

$\mathbf{W}$  is calculated using the residuals from the initial 2SLS estimates, whereas  $\mathbf{S}$  is estimated using the residuals based on  $\mathbf{b}_{\text{GMM}}$ . The `wmatrix()` option affects the form of  $\mathbf{W}$ , whereas the `vce()` option affects the form of  $\mathbf{S}$ . Except for different residuals being used, the formulas for  $\mathbf{W}^{-1}$  and  $\mathbf{S}$  are identical, so we focus on estimating  $\mathbf{W}^{-1}$ .

If `wmatrix(unadjusted)` is specified, then

$$\mathbf{W}^{-1} = \frac{s^2}{n} \sum_i \mathbf{z}_i \mathbf{z}_i'$$

where  $s^2 = \sum_i u_i^2/n$ . This weight matrix is appropriate if the errors are homoskedastic.

If `wmatrix(robust)` is specified, then

$$\mathbf{W}^{-1} = \frac{1}{n} \sum_i u_i^2 \mathbf{z}_i \mathbf{z}_i'$$

which is appropriate if the errors are heteroskedastic.

If `wmatrix(cluster clustvar)` is specified, then

$$\mathbf{W}^{-1} = \frac{1}{n} \sum_c \mathbf{q}_c \mathbf{q}_c'$$

where  $c$  indexes clusters,

$$\mathbf{q}_c = \sum_{i \in c_j} u_i \mathbf{z}_i$$

and  $c_j$  denotes the  $j$ th cluster.

If `wmatrix(hac kernel [#])` is specified, then

$$\mathbf{W}^{-1} = \frac{1}{n} \sum_i u_i^2 \mathbf{z}_i \mathbf{z}_i' + \frac{1}{n} \sum_{l=1}^{l=n-1} \sum_{i=l+1}^{i=n} K(l, m) u_i u_{i-l} (\mathbf{z}_i \mathbf{z}_{i-l}' + \mathbf{z}_{i-l} \mathbf{z}_i')$$

where  $m = \#$  if  $\#$  is specified and  $m = n - 2$  otherwise. Define  $z = l/(m + 1)$ . If *kernel* is `nwest`, then

$$K(l, m) = \begin{cases} 1 - z & 0 \leq z \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

If *kernel* is `gallant`, then

$$K(l, m) = \begin{cases} 1 - 6z^2 + 6z^3 & 0 \leq z \leq 0.5 \\ 2(1 - z)^3 & 0.5 < z \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

If *kernel* is `quadraticspectral`, then

$$K(l, m) = \begin{cases} 1 & z = 0 \\ 3 \{ \sin(\theta)/\theta - \cos(\theta) \} / \theta^2 & \text{otherwise} \end{cases}$$

where  $\theta = 6\pi z/5$ .

If `wmatrix(hac kernel opt)` is specified, then `ivregress` uses Newey and West's (1994) automatic lag-selection algorithm, which proceeds as follows. Define  $\mathbf{h}$  to be a  $(k_1 + k_2) \times 1$  vector containing ones in all rows except for the row corresponding to the constant term (if present); that row contains a zero. Define

$$\begin{aligned} f_i &= (u_i \mathbf{z}_i) \mathbf{h} \\ \hat{\sigma}_j &= \frac{1}{n} \sum_{i=j+1}^n f_i f_{i-j} \quad j = 0, \dots, m^* \\ \hat{s}^{(q)} &= 2 \sum_{j=1}^{m^*} \hat{\sigma}_j j^q \\ \hat{s}^{(0)} &= \hat{\sigma}_0 + 2 \sum_{j=1}^{m^*} \hat{\sigma}_j \\ \hat{\gamma} &= c_\gamma \left\{ \left( \frac{\hat{s}^{(q)}}{\hat{s}^{(0)}} \right)^2 \right\}^{1/2q+1} \\ m &= \hat{\gamma} n^{1/(2q+1)} \end{aligned}$$

where  $q$ ,  $m^*$ , and  $c_\gamma$  depend on the kernel specified:

Kernel	$q$	$m^*$	$c_\gamma$
Bartlett	1	$\text{int} \{ 20(T/100)^{2/9} \}$	1.1447
Parzen	2	$\text{int} \{ 20(T/100)^{4/25} \}$	2.6614
Quadratic spectral	2	$\text{int} \{ 20(T/100)^{2/25} \}$	1.3221

where  $\text{int}(x)$  denotes the integer obtained by truncating  $x$  toward zero. For the Bartlett and Parzen kernels, the optimal lag is  $\min\{\text{int}(m), m^*\}$ . For the quadratic spectral, the optimal lag is  $\min\{m, m^*\}$ .

If `wmatrix(hac kernel opt #)` is specified, then `ivregress` uses  $\#$  instead of 20 in the definition of  $m^*$  above to select the optimal lag.

If `center` is specified, when computing weighting matrices `ivregress` replaces the term  $u_i \mathbf{z}_i$  in the formulas above with  $u_i \mathbf{z}_i - \bar{u} \bar{\mathbf{z}}$ , where  $\bar{u} \bar{\mathbf{z}} = \sum_i u_i \mathbf{z}_i / N$ .

## Postestimation commands

The following postestimation commands are of special interest after `ivregress`:

Command	Description
<code>estat endogenous</code>	perform tests of endogeneity
<code>estat firststage</code>	report “first-stage” regression statistics
<code>estat overid</code>	perform tests of overidentifying restrictions
* <code>estat sbknown</code>	perform tests for a structural break with a known break date
* <code>estat single</code>	perform tests for a structural break with an unknown break date

These commands are not appropriate with `svy` estimation results.

\* `estat sbknown` and `estat sbsingle` work only after `ivregress 2sls`.

The following postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
† <code>forecast</code>	dynamic forecasts and simulations
† <code>hausman</code>	Hausman’s specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	linear predictions and their SEs, probabilities, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

† `forecast` and `hausman` are not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions, residuals, standard errors, probabilities, and expected values.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
```

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>xb</code>	linear prediction; the default
<code>_residuals</code>	residuals
<code>stdp</code>	standard error of the prediction
<code>stdf</code>	standard error of the forecast
<code>pr(a,b)</code>	$\Pr(a < y_j < b)$ under exogeneity and normal errors
<code>e(a,b)</code>	$E(y_j   a < y_j < b)$ under exogeneity and normal errors
<code>ystar(a,b)</code>	$E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ under exogeneity and normal errors

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where  $a$  and  $b$  may be numbers or variables;  $a$  missing ( $a \geq .$ ) means  $-\infty$ , and  $b$  missing ( $b \geq .$ ) means  $+\infty$ ; see [U] 12.2.1 **Missing values**.

## Options for predict

Main

`xb`, the default, calculates the linear prediction.

`residuals` calculates the residuals, that is,  $y_j - \mathbf{x}_j \mathbf{b}$ . These are based on the estimated equation when the observed values of the endogenous variables are used—not the projections of the instruments onto the endogenous variables.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. This is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see *Methods and formulas* in [R] **regress postestimation**.

**pr**(*a*,*b*) calculates  $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$ , the probability that  $y_j|\mathbf{x}_j$  would be observed in the interval (*a*, *b*) under exogeneity and assuming errors are normally distributed.

*a* and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;

**pr**(20,30) calculates  $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$ ;

**pr**(*lb*,*ub*) calculates  $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$ ; and

**pr**(20,*ub*) calculates  $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ .

*a* missing (*a* ≥ .) means  $-\infty$ ; **pr**(.,30) calculates  $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ ;

**pr**(*lb*,30) calculates  $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$  in observations for which *lb* ≥ .

and calculates  $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$  elsewhere.

*b* missing (*b* ≥ .) means  $+\infty$ ; **pr**(20,.) calculates  $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ ;

**pr**(20,*ub*) calculates  $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$  in observations for which *ub* ≥ .

and calculates  $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$  elsewhere.

**e**(*a*,*b*) calculates  $E(\mathbf{x}_j\mathbf{b} + u_j \mid a < \mathbf{x}_j\mathbf{b} + u_j < b)$ , the expected value of  $y_j|\mathbf{x}_j$  conditional on  $y_j|\mathbf{x}_j$  being in the interval (*a*, *b*), meaning that  $y_j|\mathbf{x}_j$  is truncated. *a* and *b* are specified as they are for **pr**(.). Exogeneity and normally distributed errors are assumed.

**ystar**(*a*,*b*) calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j\mathbf{b} + u_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j\mathbf{b} + u_j \geq b$ , and  $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$  otherwise, meaning that  $y_j^*$  is censored. *a* and *b* are specified as they are for **pr**(.). Exogeneity and normally distributed errors are assumed.

**scores** calculates the scores for the model. A new score variable is created for each endogenous regressor, as well as an equation-level score that applies to all exogenous variables and constant term (if present).

# margins

## Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>xb</code>	linear prediction; the default
<code>pr(<i>a,b</i>)</code>	$\Pr(a < y_j < b)$ under exogeneity and normal errors
<code>e(<i>a,b</i>)</code>	$E(y_j   a < y_j < b)$ under exogeneity and normal errors
<code>ystar(<i>a,b</i>)</code>	$E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ under exogeneity and normal errors
<code>stdp</code>	not allowed with <code>margins</code>
<code>stdf</code>	not allowed with <code>margins</code>
<code>residuals</code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## estat

### Description for estat

`estat endogenous` performs tests to determine whether endogenous regressors in the model are in fact exogenous. After GMM estimation, the  $C$  (difference-in-Sargan) statistic is reported. After 2SLS estimation with an unadjusted VCE, the Durbin (1954) and Wu–Hausman (Wu 1974; Hausman 1978) statistics are reported. After 2SLS estimation with a robust VCE, Wooldridge’s (1995) robust score test and a robust regression-based test are reported. In all cases, if the test statistic is significant, then the variables being tested must be treated as endogenous. `estat endogenous` is not available after LIML estimation.

`estat firststage` reports various statistics that measure the relevance of the excluded exogenous variables. By default, whether the equation has one or more than one endogenous regressor determines what statistics are reported.

`estat overid` performs tests of overidentifying restrictions. If the 2SLS estimator was used, Sargan’s (1958) and Basmann’s (1960)  $\chi^2$  tests are reported, as is Wooldridge’s (1995) robust score test; if the LIML estimator was used, Anderson and Rubin’s (1950)  $\chi^2$  test and Basmann’s  $F$  test are reported; and if the GMM estimator was used, Hansen’s (1982)  $J$  statistic  $\chi^2$  test is reported. A statistically significant test statistic always indicates that the instruments may not be valid.

### Syntax for estat

*Perform tests of endogeneity*

```
estat endogenous [varlist] [, lags(#) forceweights forcenonrobust]
```

*Report “first-stage” regression statistics*

```
estat firststage [, all forcenonrobust]
```

*Perform tests of overidentifying restrictions*

```
estat overid [, lags(#) forceweights forcenonrobust]
```

`collect` is allowed with `estat endogenous`, `estat firststage`, and `estat overid`; see [U] 11.1.10 Prefix commands.

### Options for estat

Options for `estat` are presented under the following headings:

- Options for estat endogenous*
- Options for estat firststage*
- Options for estat overid*

## Options for estat endogenous

**lags(#)** specifies the number of lags to use for prewhitening when computing the heteroskedasticity- and autocorrelation-consistent (HAC) version of the score test of endogeneity. Specifying **lags(0)** requests no prewhitening. This option is valid only when the model was fit via 2SLS and an HAC covariance matrix was requested when the model was fit. The default is **lags(1)**.

**forceweights** requests that the tests of endogeneity be computed even though **aweight**s, **pweight**s, or **iweight**s were used in the previous estimation. By default, these tests are conducted only after unweighted or frequency-weighted estimation. The reported critical values may be inappropriate for weighted data, so the user must determine whether the critical values are appropriate for a given application.

**forcenonrobust** requests that the Durbin and Wu–Hausman tests be performed after 2SLS estimation even though a robust VCE was used at estimation time. This option is available only if the model was fit by 2SLS.

## Options for estat firststage

**all** requests that all first-stage goodness-of-fit statistics be reported regardless of whether the model contains one or more endogenous regressors. By default, if the model contains one endogenous regressor, then the first-stage  $R^2$ , adjusted  $R^2$ , partial  $R^2$ , and  $F$  statistics are reported, whereas if the model contains multiple endogenous regressors, then Shea's partial  $R^2$  and adjusted partial  $R^2$  are reported instead.

**forcenonrobust** requests that the minimum eigenvalue statistic and its critical values be reported even though a robust VCE was used at estimation time. The reported critical values assume that the errors are independent and identically distributed (i.i.d.) normal, so the user must determine whether the critical values are appropriate for a given application.

## Options for estat overid

**lags(#)** specifies the number of lags to use for prewhitening when computing the heteroskedasticity- and autocorrelation-consistent (HAC) version of the score test of overidentifying restrictions. Specifying **lags(0)** requests no prewhitening. This option is valid only when the model was fit via 2SLS and an HAC covariance matrix was requested when the model was fit. The default is **lags(1)**.

**forceweights** requests that the tests of overidentifying restrictions be computed even though **aweight**s, **pweight**s, or **iweight**s were used in the previous estimation. By default, these tests are conducted only after unweighted or frequency-weighted estimation. The reported critical values may be inappropriate for weighted data, so the user must determine whether the critical values are appropriate for a given application.

**forcenonrobust** requests that the Sargan and Basman tests of overidentifying restrictions be performed after 2SLS or LIML estimation even though a robust VCE was used at estimation time. These tests assume that the errors are i.i.d. normal, so the user must determine whether the critical values are appropriate for a given application.

## Remarks and examples

Remarks are presented under the following headings:

```
estat endogenous
estat firststage
estat overid
```

### estat endogenous

A natural question to ask is whether a variable presumed to be endogenous in the previously fit model could instead be treated as exogenous. If the endogenous regressors are in fact exogenous, then the OLS estimator is more efficient; and depending on the strength of the instruments and other factors, the sacrifice in efficiency by using an instrumental-variables estimator can be significant. Thus, unless an instrumental-variables estimator is really needed, OLS should be used instead. `estat endogenous` provides several tests of endogeneity after 2SLS and GMM estimation.

#### ► Example 1

In [example 1](#) of [R] `ivregress`, we fit a model of the average rental rate for housing in a state as a function of the percentage of the population living in urban areas and the average value of houses. We treated `hsngval` as endogenous because unanticipated shocks that affect rental rates probably affect house prices as well. We used family income and region dummies as additional instruments for `hsngval`. Here we test whether we could treat `hsngval` as exogenous.

```
. use https://www.stata-press.com/data/r18/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
(output omitted)
. estat endogenous
Tests of endogeneity
H0: Variables are exogenous
Durbin (score) chi2(1) = 12.8473 (p = 0.0003)
Wu-Hausman F(1,46) = 15.9067 (p = 0.0002)
```

Because we did not specify any variable names after the `estat endogenous` command, Stata by default tested all the endogenous regressors (namely, `hsngval`) in our model. The null hypothesis of the Durbin and Wu–Hausman tests is that the variable under consideration can be treated as exogenous. Here both test statistics are highly significant, so we reject the null of exogeneity; we must continue to treat `hsngval` as endogenous.

◀

The difference between the Durbin and Wu–Hausman tests of endogeneity is that the former uses an estimate of the error term’s variance based on the model assuming the variables being tested are exogenous, while the latter uses an estimate of the error variance based on the model assuming the variables being tested are endogenous. Under the null hypothesis that the variables being tested are exogenous, both estimates of the error variance are consistent. What we label the Wu–Hausman statistic is Wu’s (1974) “ $T_2$ ” statistic, which Hausman (1978) showed can be calculated very easily via linear regression. Baum, Schaffer, and Stillman (2003, 2007) provide a lucid discussion of these tests.

When you fit a model with multiple endogenous regressors, you can test the exogeneity of a subset of the regressors while continuing to treat the others as endogenous. For example, say you have three endogenous regressors, `y1`, `y2`, and `y3`, and you fit your model by typing

```
. ivregress depvar ... (y1 y2 y3 = ...)
```

Suppose you are confident that  $y_1$  must be treated as endogenous, but you are undecided about  $y_2$  and  $y_3$ . To test whether  $y_2$  and  $y_3$  can be treated as exogenous, you would type

```
. estat endogenous y2 y3
```

The Durbin and Wu–Hausman tests assume that the error term is i.i.d. Therefore, if you requested a robust VCE at estimation time, `estat endogenous` will instead report Wooldridge’s (1995) score test and a regression-based test of exogeneity. Both these tests can tolerate heteroskedastic and autocorrelated errors, while only the regression-based test is amenable to clustering.

## ► Example 2

We refit our housing model, requesting robust standard errors, and then test the exogeneity of `hsngval`:

```
. use https://www.stata-press.com/data/r18/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region), vce(robust)
(output omitted)
. estat endogenous
Tests of endogeneity
H0: Variables are exogenous
Robust score chi2(1)          = 2.10428 (p = 0.1469)
Robust regression F(1,46)    = 4.31101 (p = 0.0435)
```

Wooldridge’s score test does not reject the null hypothesis that `hsngval` is exogenous at conventional significance levels ( $p = 0.1469$ ). However, the regression-based test does reject the null hypothesis at the 5% significance level ( $p = 0.0435$ ). Typically, these two tests yield the same conclusion; the fact that our dataset has only 50 observations could be contributing to the discrepancy. Here we would be inclined to continue to treat `hsngval` as endogenous. Even if `hsngval` is exogenous, the 2SLS estimates are still consistent. On the other hand, if `hsngval` is in fact endogenous, the OLS estimates would not be consistent. Moreover, as we will see in our discussion of the `estat overid` command, our additional instruments may be invalid. To test whether an endogenous variable can be treated as exogenous, we must have a valid set of instruments to use to fit the model in the first place!

◄

Unlike the Durbin and Wu–Hausman tests, Wooldridge’s score and the regression-based tests do not allow you to test a subset of the endogenous regressors in the model; you can test only whether all the endogenous regressors are in fact exogenous.

After GMM estimation, `estat endogenous` calculates what Hayashi (2000, 220) calls the  $C$  statistic, also known as the difference-in-Sargan statistic. The  $C$  statistic can be made robust to heteroskedasticity, autocorrelation, and clustering; and the version reported by `estat endogenous` is determined by the weight matrix requested via the `wmatrix()` option used when fitting the model with `ivregress`. Additionally, the test can be used to determine the exogeneity of a subset of the endogenous regressors, regardless of the type of weight matrix used.

If you fit your model using the LIML estimator, you can use the `hausman` command to carry out a traditional Hausman (1978) test between the OLS and LIML estimates.

## estat firststage

For an excluded exogenous variable to be a valid instrument, it must be sufficiently correlated with the included endogenous regressors but uncorrelated with the error term. In recent decades, researchers have paid considerable attention to the issue of instruments that are only weakly correlated with the endogenous regressors. In such cases, the usual 2SLS, GMM, and LIML estimators are biased toward the OLS estimator, and inference based on the standard errors reported by, for example, `ivregress` can be severely misleading. For more information on the theory behind instrumental-variables estimation with weak instruments, see Nelson and Startz (1990); Staiger and Stock (1997); Hahn and Hausman (2003); the survey article by Stock, Wright, and Yogo (2002); and Angrist and Pischke (2009, chap. 4).

When the instruments are only weakly correlated with the endogenous regressors, some Monte Carlo evidence suggests that the LIML estimator performs better than the 2SLS and GMM estimators; see, for example, Poi (2006) and Stock, Wright, and Yogo (2002) (and the papers cited therein). On the other hand, the LIML estimator often results in confidence intervals that are somewhat larger than those from the 2SLS estimator.

Moreover, using more instruments is not a solution, because the biases of instrumental-variables estimators increase with the number of instruments. See Hahn and Hausman (2003).

`estat firststage` produces several statistics for judging the explanatory power of the instruments and is most easily explained with examples.

### ► Example 3

Again building on the model fit in [example 1](#) of [\[R\] ivregress](#), we now explore the degree of correlation between the additional instruments `faminc`, `2.region`, `3.region`, and `4.region` and the endogenous regressor `hsngval`:

```
. use https://www.stata-press.com/data/r18/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
(output omitted)
. estat firststage
```

First-stage regression summary statistics

Variable	R-sq.	Adjusted R-sq.	Partial R-sq.	F(4,44)	Prob > F
hsngval	0.6908	0.6557	0.5473	13.2978	0.0000

Minimum eigenvalue statistic = 13.2978

Critical Values	# of endogenous regressors:	1
H0: Instruments are weak	# of excluded instruments:	4

2SLS relative bias	5%	10%	20%	30%
	16.85	10.27	6.71	5.34
2SLS size of nominal 5% Wald test	10%	15%	20%	25%
	24.58	13.96	10.26	8.31
LIML size of nominal 5% Wald test	5.44	3.87	3.30	2.98

To understand these results, recall that the first-stage regression is

$$\text{hsngval}_i = \pi_0 + \pi_1 \text{pcturban}_i + \pi_2 \text{faminc} + \pi_3 \text{2.region} + \pi_4 \text{3.region} + \pi_5 \text{4.region} + v_i$$

where  $v_i$  is an error term. The column marked “R-sq.” is the simple  $R^2$  from fitting the first-stage regression by OLS, and the column marked “Adjusted R-sq.” is the adjusted  $R^2$  from that regression. Higher values purportedly indicate stronger instruments, and instrumental-variables estimators exhibit less bias when the instruments are strongly correlated with the endogenous variable.

Looking at just the  $R^2$  and adjusted  $R^2$  can be misleading, however. If `hshgval` were strongly correlated with the included exogenous variable `pcturban` but only weakly correlated with the additional instruments, then these statistics could be large even though a weak-instrument problem is present.

The partial  $R^2$  statistic measures the correlation between `hshgval` and the additional instruments after *partialing out* the effect of `pcturban`. Unlike the  $R^2$  and adjusted  $R^2$  statistics, the partial  $R^2$  statistic will not be inflated because of strong correlation between `hshgval` and `pcturban`. Bound, Jaeger, and Baker (1995) and others have promoted using this statistic.

The column marked “F(4, 44)” is an  $F$  statistic for the joint significance of  $\pi_2$ ,  $\pi_3$ ,  $\pi_4$ , and  $\pi_5$ , the coefficients on the additional instruments. Its  $p$ -value is listed in the column marked “Prob > F”. If the  $F$  statistic is not significant, then the additional instruments have no significant explanatory power for `hshgval` after controlling for the effect of `pcturban`. However, Hall, Rudebusch, and Wilcox (1996) used Monte Carlo simulation to show that simply having an  $F$  statistic that is significant at the typical 5% or 10% level is not sufficient. Stock, Wright, and Yogo (2002) suggest that the  $F$  statistic should exceed 10 for inference based on the 2SLS estimator to be reliable when there is one endogenous regressor.

`estat firststage` also presents the Cragg and Donald (1993) minimum eigenvalue statistic as a further test of weak instruments. Stock and Yogo (2005) discuss two characterizations of weak instruments: first, weak instruments cause instrumental-variables estimators to be biased; second, hypothesis tests of parameters estimated by instrumental-variables estimators may suffer from severe size distortions. The test statistic in our example is 13.30, which is identical to the  $F$  statistic just discussed because our model contains one endogenous regressor.

The null hypothesis of each of Stock and Yogo’s tests is that the set of instruments is weak. To perform these tests, we must first choose either the largest relative bias of the 2SLS estimator we are willing to tolerate or the largest rejection rate of a nominal 5% Wald test we are willing to tolerate. If the test statistic exceeds the critical value, we can conclude that our instruments are not weak.

The row marked “2SLS relative bias” contains critical values for the test that the instruments are weak based on the bias of the 2SLS estimator *relative to* the bias of the OLS estimator. For example, from past experience we might know that the OLS estimate of a parameter  $\beta$  may be 50% too high. Saying that we are willing to tolerate a 10% relative bias means that we are willing to tolerate a bias of the 2SLS estimator no greater than 5% (that is, 10% of 50%). In our rental rate model, if we are willing to tolerate a 10% relative bias, then we can conclude that our instruments are not weak because the test statistic of 13.30 exceeds the critical value of 10.27. However, if we were willing to tolerate only a relative bias of 5%, we would conclude that our instruments are weak because  $13.30 < 16.85$ .

The rows marked “2SLS Size of nominal 5% Wald test” and “LIML Size of nominal 5% Wald test” contain critical values pertaining to Stock and Yogo’s (2005) second characterization of weak instruments. This characterization defines a set of instruments to be weak if a Wald test at the 5% level can have an actual rejection rate of no more than 10%, 15%, 20%, or 25%. Using the current example, suppose that we are willing to accept a rejection rate of at most 10%. Because  $13.30 < 24.58$ , we cannot reject the null hypothesis of weak instruments. On the other hand, if we use the LIML estimator instead, then we can reject the null hypothesis because  $13.30 > 5.44$ .

## □ Technical note

Stock and Yogo (2005) tabulated critical values for 2SLS relative biases of 5%, 10%, 20%, and 30% for models with 1, 2, or 3 endogenous regressors and between 3 and 30 excluded exogenous variables (instruments). They also provide critical values for worst-case rejection rates of 5%, 10%, 20%, and 25% for nominal 5% Wald tests of the endogenous regressors with 1 or 2 endogenous regressors and between 1 and 30 instruments. If the model previously fit by `ivregress` has more instruments or endogenous regressors than these limits, the critical values are not shown. Stock and Yogo did not consider GMM estimators. □

When the model being fit contains more than one endogenous regressor, the  $R^2$  and  $F$  statistics described above can overstate the relevance of the excluded instruments. Suppose that there are two endogenous regressors,  $Y_1$  and  $Y_2$ , and that there are two additional instruments,  $z_1$  and  $z_2$ . Say that  $z_1$  is highly correlated with both  $Y_1$  and  $Y_2$  but  $z_2$  is not correlated with either  $Y_1$  or  $Y_2$ . Then, the first-stage regression of  $Y_1$  on  $z_1$  and  $z_2$  (along with the included exogenous variables) will produce large  $R^2$  and  $F$  statistics, as will the regression of  $Y_2$  on  $z_1$ ,  $z_2$ , and the included exogenous variables. Nevertheless, the lack of correlation between  $z_2$  and  $Y_1$  and  $Y_2$  is problematic. Here, although the order condition indicates that the model is just identified (the number of excluded instruments equals the number of endogenous regressors), the irrelevance of  $z_2$  implies that the model is in fact not identified. Even if the model is overidentified, including irrelevant instruments can adversely affect the properties of instrumental-variables estimators, because their biases increase as the number of instruments increases.

## ▷ Example 4

`estat firststage` presents different statistics when the model contains multiple endogenous regressors. For illustration, we refit our model of rental rates, assuming that both `hshngval` and `faminc` are endogenously determined. We use `i.region` along with `popden`, a measure of population density, as additional instruments.

```
. ivregress 2sls rent pcturban (hsngval faminc = i.region popden)
(output omitted)
. estat firststage
Shea's partial R-squared
```

Variable	Shea's partial R-sq.	Shea's adj. partial R-sq.
hsngval	0.3477	0.2735
faminc	0.1893	0.0972

```
Minimum eigenvalue statistic = 2.51666
```

```
Critical Values # of endogenous regressors: 2
H0: Instruments are weak # of excluded instruments: 4
```

2SLS relative bias	5%	10%	20%	30%
	11.04	7.56	5.57	4.73
2SLS size of nominal 5% Wald test	10%	15%	20%	25%
	16.87	9.93	7.54	6.28
LIML size of nominal 5% Wald test	4.72	3.39	2.99	2.79

Consider the endogenous regressor `hsngval`. Part of its variation is attributable to its correlation with the other regressors `pcturban` and `faminc`. The other component of `hsngval`'s variation is peculiar to it and orthogonal to the variation in the other regressors. Similarly, we can think of the instruments as predicting the variation in `hsngval` in two ways, one stemming from the fact that the predicted values of `hsngval` are correlated with the predicted values of the other regressors and one from the variation in the predicted values of `hsngval` that is orthogonal to the variation in the predicted values of the other regressors.

What really matters for instrumental-variables estimation is whether the component of `hsngval` that is orthogonal to the other regressors can be explained by the component of the predicted value of `hsngval` that is orthogonal to the predicted values of the other regressors in the model. Shea's (1997) partial  $R^2$  statistic measures this correlation. Because the bias of instrumental-variables estimators increases as more instruments are used, Shea's adjusted partial  $R^2$  statistic is often used instead, as it makes a degrees-of-freedom adjustment for the number of instruments, analogous to the adjusted  $R^2$  measure used in OLS regression. Although what constitutes a "low" value for Shea's partial  $R^2$  depends on the specifics of the model being fit and the data used, these results, taken in isolation, do not strike us as being a particular cause for concern.

However, with this specification the minimum eigenvalue statistic is low. We cannot reject the null hypothesis of weak instruments for either of the characterizations we have discussed.

◀

By default, `estat firststage` determines which statistics to present based on the number of endogenous regressors in the model previously fit. However, you can specify the `all` option to obtain all the statistics.

## □ Technical note

If the previous estimation was conducted using `aweight`s, `pweight`s, or `iweight`s, then the first-stage regression summary statistics are computed using those weights. However, in these cases the minimum eigenvalue statistic and its critical values are not available.

If the previous estimation included a robust VCE, then the first-stage  $F$  statistic is based on a robust VCE as well; for example, if you fit your model with an HAC VCE using the Bartlett kernel and four lags, then the  $F$  statistic reported is based on regression results using an HAC VCE using the Bartlett kernel and four lags. By default, the minimum eigenvalue statistic and its critical values are not displayed. You can use the `forcenonrobust` option to obtain them in these cases; the minimum eigenvalue statistic is computed using the weights, though the critical values reported may not be appropriate. □

## estat overid

In addition to the requirement that instrumental variables be correlated with the endogenous regressors, the instruments must also be uncorrelated with the structural error term. If the model is overidentified, meaning that the number of additional instruments exceeds the number of endogenous regressors, then we can test whether the instruments are uncorrelated with the error term. If the model is just identified, then we cannot perform a test of overidentifying restrictions.

The estimator you used to fit the model determines which tests of overidentifying restrictions `estat overid` reports. If you used the 2SLS estimator without a robust VCE, `estat overid` reports Sargan's (1958) and Basman's (1960)  $\chi^2$  tests. If you used the 2SLS estimator and requested a robust VCE, Wooldridge's robust score test of overidentifying restrictions is performed instead; without a robust VCE, Wooldridge's test statistic is identical to Sargan's test statistic. If you used the LIML estimator, `estat overid` reports the Anderson–Rubin (1950) likelihood-ratio test and Basman's (1960)  $F$  test. `estat overid` reports Hansen's (1982)  $J$  statistic if you used the GMM estimator. Davidson and MacKinnon (1993, 235–236) give a particularly clear explanation of the intuition behind tests of overidentifying restrictions. Also see Judge et al. (1985, 614–616) for a summary of tests of overidentifying restrictions for the 2SLS and LIML estimators.

Tests of overidentifying restrictions actually test two different things simultaneously. One, as we have discussed, is whether the instruments are uncorrelated with the error term. The other is that the equation is misspecified and that one or more of the excluded exogenous variables should in fact be included in the structural equation. Thus, a significant test statistic could represent either an invalid instrument or an incorrectly specified structural equation.

## ► Example 5

Here we refit the model that treated just `hsngval` as endogenous using 2SLS, and then we perform tests of overidentifying restrictions:

```
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
(output omitted)
. estat overid

Tests of overidentifying restrictions:
Sargan (score) chi2(3) = 11.2877 (p = 0.0103)
Basman chi2(3)      = 12.8294 (p = 0.0050)
```

Both test statistics are significant at the 5% test level, which means that either one or more of our instruments are invalid or that our structural model is misspecified.

One possibility is that the error term in our structural model is heteroskedastic. Both Sargan's and Basman's tests assume that the errors are i.i.d.; if the errors are not i.i.d., then these tests are not valid. Here we refit the model by requesting heteroskedasticity-robust standard errors, and then we use `estat overid` to obtain Wooldridge's score test of overidentifying restrictions, which is robust to heteroskedasticity.

```
. ivregress 2sls rent pcturban (hsngval = faminc i.region), vce(robust)
(output omitted)
. estat overid
Test of overidentifying restrictions:
Score chi2(3)          =   6.8364   (p = 0.0773)
```

Here we no longer reject the null hypothesis that our instruments are valid at the 5% significance level, though we do reject the null at the 10% level. You can verify that the robust standard error on the coefficient for `hsngval` is more than twice as large as its nonrobust counterpart and that the robust standard error for `pcturban` is nearly 50% larger. ◀

## □ Technical note

The test statistic for the test of overidentifying restrictions performed after GMM estimation is simply the sample size times the value of the objective function  $Q(\beta_1, \beta_2)$  defined in (5) of [R] **ivregress**, evaluated at the GMM parameter estimates. If the weighting matrix  $\mathbf{W}$  is optimal, meaning that  $\mathbf{W} = \text{Var}(z_i u_i)$ , then  $Q(\beta_1, \beta_2) \overset{A}{\sim} \chi^2(q)$ , where  $q$  is the number of overidentifying restrictions. However, if the estimated  $\mathbf{W}$  is not optimal, then the test statistic will not have an asymptotic  $\chi^2$  distribution.

Like the Sargan and Basman tests of overidentifying restrictions for the 2SLS estimator, the Anderson–Rubin and Basman tests after LIML estimation are predicated on the errors’ being i.i.d. If the previous LIML results were reported with robust standard errors, then `estat overid` by default issues an error message and refuses to report the Anderson–Rubin and Basman test statistics. You can use the `forcenonrobust` option to override this behavior. You can also use `forcenonrobust` to obtain the Sargan and Basman test statistics after 2SLS estimation with robust standard errors. □

By default, `estat overid` issues an error message if the previous estimation was conducted using `aweight`s, `pweight`s, or `iweight`s. You can use the `forceweights` option to override this behavior, though the test statistics may no longer have the expected  $\chi^2$  distributions.

## Stored results

After 2SLS estimation, `estat endogenous` stores the following in `r()`:

### Scalars

<code>r(durbin)</code>	Durbin $\chi^2$ statistic
<code>r(p_durbin)</code>	$p$ -value for Durbin $\chi^2$ statistic
<code>r(wu)</code>	Wu–Hausman $F$ statistic
<code>r(p_wu)</code>	$p$ -value for Wu–Hausman $F$ statistic
<code>r(df)</code>	degrees of freedom
<code>r(wudf_r)</code>	denominator degrees of freedom for Wu–Hausman $F$
<code>r(r_score)</code>	robust score statistic
<code>r(p_r_score)</code>	$p$ -value for robust score statistic
<code>r(hac_score)</code>	HAC score statistic
<code>r(p_hac_score)</code>	$p$ -value for HAC score statistic
<code>r(lags)</code>	lags used in prewhitening
<code>r(regF)</code>	regression-based $F$ statistic
<code>r(p_regF)</code>	$p$ -value for regression-based $F$ statistic
<code>r(regFdf_n)</code>	regression-based $F$ numerator degrees of freedom
<code>r(regFdf_r)</code>	regression-based $F$ denominator degrees of freedom

After GMM estimation, `estat endogenous` stores the following in `r()`:

Scalars

<code>r(C)</code>	$C$ $\chi^2$ statistic
<code>r(p_C)</code>	$p$ -value for $C$ $\chi^2$ statistic
<code>r(df)</code>	degrees of freedom

`estat firststage` stores the following in `r()`:

Scalars

<code>r(mineig)</code>	minimum eigenvalue statistic
------------------------	------------------------------

Matrices

<code>r(mineigcv)</code>	critical values for minimum eigenvalue statistic
<code>r(multiresults)</code>	Shea's partial $R^2$ statistics
<code>r(singleresults)</code>	first-stage $R^2$ and $F$ statistics

After 2SLS estimation, `estat overid` stores the following in `r()`:

Scalars

<code>r(lags)</code>	lags used in prewhitening
<code>r(df)</code>	$\chi^2$ degrees of freedom
<code>r(score)</code>	score $\chi^2$ statistic
<code>r(p_score)</code>	$p$ -value for score $\chi^2$ statistic
<code>r(basmann)</code>	Basmann $\chi^2$ statistic
<code>r(p_basmann)</code>	$p$ -value for Basmann $\chi^2$ statistic
<code>r(sargan)</code>	Sargan $\chi^2$ statistic
<code>r(p_sargan)</code>	$p$ -value for Sargan $\chi^2$ statistic

After LIML estimation, `estat overid` stores the following in `r()`:

Scalars

<code>r(ar)</code>	Anderson–Rubin $\chi^2$ statistic
<code>r(p_ar)</code>	$p$ -value for Anderson–Rubin $\chi^2$ statistic
<code>r(ar_df)</code>	$\chi^2$ degrees of freedom
<code>r(basmann)</code>	Basmann $F$ statistic
<code>r(p_basmann)</code>	$p$ -value for Basmann $F$ statistic
<code>r(basmann_df_n)</code>	$F$ numerator degrees of freedom
<code>r(basmann_df_d)</code>	$F$ denominator degrees of freedom

After GMM estimation, `estat overid` stores the following in `r()`:

Scalars

<code>r(HansenJ)</code>	Hansen's $J$ $\chi^2$ statistic
<code>r(p_HansenJ)</code>	$p$ -value for Hansen's $J$ $\chi^2$ statistic
<code>r(J_df)</code>	$\chi^2$ degrees of freedom

## Methods and formulas

Methods and formulas are presented under the following headings:

*Notation*  
*estat endogenous*  
*estat firststage*  
*estat overid*

## Notation

Recall from [R] **ivregress** that the model is

$$\mathbf{y} = \mathbf{Y}\boldsymbol{\beta}_1 + \mathbf{X}_1\boldsymbol{\beta}_2 + \mathbf{u} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{Y} = \mathbf{X}_1\boldsymbol{\Pi}_1 + \mathbf{X}_2\boldsymbol{\Pi}_2 + \mathbf{V} = \mathbf{Z}\boldsymbol{\Pi} + \mathbf{V}$$

where  $\mathbf{y}$  is an  $N \times 1$  vector of the left-hand-side variable,  $N$  is the sample size,  $\mathbf{Y}$  is an  $N \times p$  matrix of  $p$  endogenous regressors,  $\mathbf{X}_1$  is an  $N \times k_1$  matrix of  $k_1$  included exogenous regressors,  $\mathbf{X}_2$  is an  $N \times k_2$  matrix of  $k_2$  excluded exogenous variables,  $\mathbf{X} = [\mathbf{Y} \ \mathbf{X}_1]$ ,  $\mathbf{Z} = [\mathbf{X}_1 \ \mathbf{X}_2]$ ,  $\mathbf{u}$  is an  $N \times 1$  vector of errors,  $\mathbf{V}$  is an  $N \times p$  matrix of errors,  $\boldsymbol{\beta} = [\boldsymbol{\beta}_1 \ \boldsymbol{\beta}_2]$  is a  $k = (p + k_1) \times 1$  vector of parameters, and  $\boldsymbol{\Pi}$  is a  $(k_1 + k_2) \times p$  vector of parameters. If a constant term is included in the model, then one column of  $\mathbf{X}_1$  contains all ones.

## estat endogenous

Partition  $\mathbf{Y}$  as  $\mathbf{Y} = [\mathbf{Y}_1 \ \mathbf{Y}_2]$ , where  $\mathbf{Y}_1$  represents the  $p_1$  endogenous regressors whose endogeneity is being tested and  $\mathbf{Y}_2$  represents the  $p_2$  endogenous regressors whose endogeneity is not being tested. If the endogeneity of all endogenous regressors is being tested,  $\mathbf{Y} = \mathbf{Y}_1$  and  $p_2 = 0$ . After GMM estimation, **estat endogenous** refits the model treating  $\mathbf{Y}_1$  as exogenous using the same type of weight matrix as requested at estimation time with the `wmatrix()` option; denote the Sargan statistic from this model by  $J_e$  and the estimated weight matrix by  $\mathbf{W}_e$ . Let  $\mathbf{S}_e = \mathbf{W}_e^{-1}$ . **estat endogenous** removes from  $\mathbf{S}_e$  the rows and columns corresponding to the variables represented by  $\mathbf{Y}_1$ ; denote the inverse of the resulting matrix by  $\mathbf{W}'_e$ . Next, **estat endogenous** fits the model treating both  $\mathbf{Y}_1$  and  $\mathbf{Y}_2$  as endogenous, using the weight matrix  $\mathbf{W}'_e$ ; denote the Sargan statistic from this model by  $J_c$ . Then,  $C = (J_e - J_c) \sim \chi^2(p_1)$ . If one simply used the  $J$  statistic from the original model fit by **ivregress** in place of  $J_e$ , then in finite samples  $J_e - J$  might be negative. The procedure used by **estat endogenous** is guaranteed to yield  $C \geq 0$ ; see Hayashi (2000, 220).

Let  $\hat{\mathbf{u}}_c$  denote the residuals from the model treating both  $\mathbf{Y}_1$  and  $\mathbf{Y}_2$  as endogenous, and let  $\hat{\mathbf{u}}_e$  denote the residuals from the model treating only  $\mathbf{Y}_2$  as endogenous. Then, Durbin's (1954) statistic is

$$D = \frac{\hat{\mathbf{u}}'_e \mathbf{P}_{Z\mathbf{Y}_1} \hat{\mathbf{u}}_e - \hat{\mathbf{u}}'_c \mathbf{P}_Z \hat{\mathbf{u}}_c}{\hat{\mathbf{u}}'_e \hat{\mathbf{u}}_e / N}$$

where  $\mathbf{P}_Z = \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$  and  $\mathbf{P}_{Z\mathbf{Y}_1} = [\mathbf{Z} \ \mathbf{Y}_1](\mathbf{Z} \ \mathbf{Y}_1)'(\mathbf{Z} \ \mathbf{Y}_1)^{-1}[\mathbf{Z} \ \mathbf{Y}_1]'$ .  $D \sim \chi^2(p_1)$ . The Wu–Hausman (Wu 1974; Hausman 1978) statistic is

$$WH = \frac{(\hat{\mathbf{u}}'_e \mathbf{P}_{Z\mathbf{Y}_1} \hat{\mathbf{u}}_e - \hat{\mathbf{u}}'_c \mathbf{P}_Z \hat{\mathbf{u}}_c) / p_1}{\{\hat{\mathbf{u}}'_e \hat{\mathbf{u}}_e - (\hat{\mathbf{u}}'_e \mathbf{P}_{Z\mathbf{Y}_1} \hat{\mathbf{u}}_e - \hat{\mathbf{u}}'_c \mathbf{P}_Z \hat{\mathbf{u}}_c)\} / (N - k_1 - p - p_1)}$$

$WH \sim F(p_1, N - k_1 - p - p_1)$ . Baum, Schaffer, and Stillman (2003, 2007) discuss these tests in more detail.

Next, we describe Wooldridge's (1995) score test. The nonrobust version of Wooldridge's test is identical to Durbin's test. Suppose a robust covariance matrix was used at estimation time. Let  $\hat{\mathbf{e}}$  denote the sample residuals obtained by fitting the model via OLS, treating  $\mathbf{Y}$  as exogenous. We then regress each variable represented in  $\mathbf{Y}$  on  $\mathbf{Z}$ ; call the residuals for the  $j$ th regression  $\hat{\mathbf{r}}_j$ ,  $j = 1, \dots, p$ . Define  $\hat{k}_{ij} = \hat{e}_i \hat{r}_{ij}$ ,  $i = 1, \dots, N$ . We then run the regression

$$\mathbf{1} = \theta_1 \hat{\mathbf{k}}_1 + \dots + \theta_p \hat{\mathbf{k}}_p + \epsilon$$

where  $\mathbf{1}$  is an  $N \times 1$  vector of ones and  $\epsilon$  is a regression error term.  $N - \text{RSS} \sim \chi^2(p)$ , where RSS is the residual sum of squares from the regression just described. If instead an HAC VCE was used at estimation time, then before running the final regression we prewhiten the  $\widehat{\mathbf{k}}_j$  series by using a VAR( $q$ ) model, where  $q$  is the number of lags specified with the `lags()` option.

The regression-based test proceeds as follows. Following Hausman (1978, 1259), we regress  $\mathbf{Y}$  on  $\mathbf{Z}$  and obtain the residuals  $\widehat{\mathbf{V}}$ . Next, we fit the augmented regression

$$\mathbf{y} = \mathbf{Y}\beta_1 + \mathbf{X}_1\beta_2 + \widehat{\mathbf{V}}\gamma + \epsilon$$

by OLS regression, where  $\epsilon$  is a regression error term. A test of the exogeneity of  $\mathbf{Y}$  is equivalent to a test of  $\gamma = \mathbf{0}$ . As Cameron and Trivedi (2005, 276) suggest, this test can be made robust to heteroskedasticity, autocorrelation, or clustering by using the appropriate robust VCE when testing  $\gamma = \mathbf{0}$ . When a nonrobust VCE is used, this test is equivalent to the Wu–Hausman test described earlier. One cannot simply fit this augmented regression via 2SLS to test the endogeneity of a subset of the endogenous regressors; Davidson and MacKinnon (1993, 229–231) discuss a test of  $\gamma = \mathbf{0}$  for the homoskedastic version of the augmented regression fit by 2SLS, but an appropriate robust test is not apparent.

## estat firststage

When the structural equation includes one endogenous regressor, `estat firststage` fits the regression

$$\mathbf{Y} = \mathbf{X}_1\pi_1 + \mathbf{X}_2\pi_2 + \mathbf{v}$$

via OLS. The  $R^2$  and adjusted  $R^2$  from that regression are reported in the output, as well as the  $F$  statistic from the Wald test of  $H_0: \pi_2 = \mathbf{0}$ . To obtain the partial  $R^2$  statistic, `estat firststage` fits the regression

$$\mathbf{M}_{\mathbf{X}_1}\mathbf{y} = \mathbf{M}_{\mathbf{X}_1}\mathbf{X}_2\xi + \epsilon$$

by OLS, where  $\epsilon$  is a regression error term,  $\xi$  is a  $k_2 \times 1$  parameter vector, and  $\mathbf{M}_{\mathbf{X}_1} = \mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-1}\mathbf{X}_1'$ ; that is, the partial  $R^2$  is the  $R^2$  between  $\mathbf{y}$  and  $\mathbf{X}_2$  after eliminating the effects of  $\mathbf{X}_1$ . If the model contains multiple endogenous regressors and the `all` option is specified, these statistics are calculated for each endogenous regressor in turn.

To calculate Shea's partial  $R^2$ , let  $\mathbf{y}_1$  denote the endogenous regressor whose statistic is being calculated and  $\mathbf{Y}_0$  denote the other endogenous regressors. Define  $\widetilde{\mathbf{y}}_1$  as the residuals obtained from regressing  $\mathbf{y}_1$  on  $\mathbf{Y}_0$  and  $\mathbf{X}_1$ . Let  $\widehat{\mathbf{y}}_1$  denote the fitted values obtained from regressing  $\mathbf{y}_1$  on  $\mathbf{X}_1$  and  $\mathbf{X}_2$ ; that is,  $\widehat{\mathbf{y}}_1$  are the fitted values from the first-stage regression for  $\mathbf{y}_1$ , and define the columns of  $\widehat{\mathbf{Y}}_0$  analogously. Finally, let  $\widetilde{\widehat{\mathbf{y}}}_1$  denote the residuals from regressing  $\widehat{\mathbf{y}}_1$  on  $\widehat{\mathbf{Y}}_0$  and  $\mathbf{X}_1$ . Shea's partial  $R^2$  is the simple  $R^2$  from the regression of  $\widetilde{\widehat{\mathbf{y}}}_1$  on  $\widehat{\mathbf{y}}_1$ ; denote this as  $R_S^2$ . Shea's adjusted partial  $R^2$  is equal to  $1 - (1 - R_S^2)(N - 1)/(N - k_Z + 1)$  if a constant term is included and  $1 - (1 - R_S^2)(N - 1)/(N - k_Z)$  if there is no constant term included in the model, where  $k_Z = k_1 + k_2$ . For one endogenous regressor, one instrument, no exogenous regressors, and a constant term,  $R_S^2$  equals the adjusted  $R_S^2$ .

The Stock and Yogo minimum eigenvalue statistic, first proposed by Cragg and Donald (1993) as a test for underidentification, is the minimum eigenvalue of the matrix

$$\mathbf{G} = \frac{1}{k_Z} \widehat{\Sigma}_{\mathbf{V}\mathbf{V}}^{-1/2} \mathbf{Y}'\mathbf{M}'_{\mathbf{X}_1} \mathbf{X}_2(\mathbf{X}_2'\mathbf{M}_{\mathbf{X}_1}\mathbf{X}_2)^{-1}\mathbf{X}_2'\mathbf{M}_{\mathbf{X}_1} \mathbf{Y}\widehat{\Sigma}_{\mathbf{V}\mathbf{V}}^{-1/2}$$

where

$$\widehat{\Sigma}_{\mathbf{V}\mathbf{V}} = \frac{1}{N - k_Z} \mathbf{Y}' \mathbf{M}_Z \mathbf{Y}$$

$\mathbf{M}_Z = \mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$ , and  $\mathbf{Z} = [\mathbf{X}_1 \ \mathbf{X}_2]$ . Critical values are obtained from the tables in [Stock and Yogo \(2005\)](#).

## estat overid

The [Sargan \(1958\)](#) and [Basmann \(1960\)](#)  $\chi^2$  statistics are calculated by running the auxiliary regression

$$\widehat{\mathbf{u}} = \mathbf{Z}\boldsymbol{\delta} + \mathbf{e}$$

where  $\widehat{\mathbf{u}}$  are the sample residuals from the model and  $\mathbf{e}$  is an error term. Then, Sargan's statistic is

$$S = N \left( 1 - \frac{\widehat{\mathbf{e}}'\widehat{\mathbf{e}}}{\widehat{\mathbf{u}}'\widehat{\mathbf{u}}} \right)$$

where  $\widehat{\mathbf{e}}$  are the residuals from that auxiliary regression. Basmann's statistic is calculated as

$$B = S \frac{N - k_Z}{N - S}$$

Both  $S$  and  $B$  are distributed  $\chi^2(m)$ , where  $m$ , the number of overidentifying restrictions, is equal to  $k_Z - k$ , where  $k$  is the number of endogenous regressors.

Wooldridge's (1995) score test of overidentifying restrictions is identical to Sargan's (1958) statistic under the assumption of i.i.d. and therefore is not recomputed unless a robust VCE was used at estimation time. If a heteroskedasticity-robust VCE was used, Wooldridge's test proceeds as follows. Let  $\widehat{\mathbf{Y}}$  denote the  $N \times k$  matrix of fitted values obtained by regressing the endogenous regressors on  $\mathbf{X}_1$  and  $\mathbf{X}_2$ . Let  $\mathbf{Q}$  denote an  $N \times m$  matrix of excluded exogenous variables; the test statistic to be calculated is invariant to whichever  $m$  of the  $k_2$  excluded exogenous variables is chosen. Define the  $i$ th element of  $\widehat{\mathbf{k}}_j$ ,  $i = 1, \dots, N$ ,  $j = 1, \dots, m$ , as

$$k_{ij} = \widehat{q}_{ij} \widehat{u}_i$$

where  $\widehat{q}_{ij}$  is the  $i$ th element of  $\widehat{\mathbf{q}}_j$ , the residuals from regressing the  $j$ th column of  $\mathbf{Q}$  on  $\widehat{\mathbf{Y}}$  and  $\mathbf{X}_1$ . Finally, fit the regression

$$\mathbf{1} = \theta_1 \widehat{\mathbf{k}}_1 + \dots + \theta_m \widehat{\mathbf{k}}_m + \boldsymbol{\epsilon}$$

where  $\mathbf{1}$  is an  $N \times 1$  vector of ones and  $\boldsymbol{\epsilon}$  is a regression error term, and calculate the residual sum of squares, RSS. Then, the test statistic is  $W = N - \text{RSS}$ .  $W \sim \chi^2(m)$ . If an HAC VCE was used at estimation, then the  $\widehat{\mathbf{k}}_j$  are prewhitened using a VAR( $p$ ) model, where  $p$  is specified using the `lags()` option.

The Anderson–Rubin (1950), AR, test of overidentifying restrictions for use after the LIML estimator is calculated as  $\text{AR} = N(\kappa - 1)$ , where  $\kappa$  is the minimal eigenvalue of a certain matrix defined in [Methods and formulas](#) of [\[R\] ivregress](#).  $\text{AR} \sim \chi^2(m)$ . (Some texts define this statistic as  $N \ln(\kappa)$  because  $\ln(x) \approx (x - 1)$  for  $x$  near 1.) Basmann's  $F$  statistic for use after the LIML estimator is calculated as  $B_F = (\kappa - 1)(N - k_Z)/m$ .  $B_F \sim F(m, N - k_Z)$ .

Hansen's  $J$  statistic is simply the sample size times the value of the GMM objective function defined in (5) of [\[R\] ivregress](#), evaluated at the estimated parameter values. Under the null hypothesis that the overidentifying restrictions are valid,  $J \sim \chi^2(m)$ .

John Denis Sargan (1924–1996) was born in Yorkshire, UK. He pioneered the theory of instrumental-variables (IV) estimation in an article published in 1958. In the article, he also developed overidentification tests, developed significance tests, and discussed possible instruments for applied work. A year later, he wrote an article extending the theory to models containing autoregressive errors. This extension was one of his many contributions to time-series econometric analysis. For example, in 1964 he published a paper in which he developed misspecification tests for dynamic equations, along with an IV estimator for models with nonlinear parameters, and a model with a long-run equilibrium. His paper laid the foundation for other econometric methods, such as cointegration analysis, and established what would be known as the London School of Economics (LSE) approach to econometric modeling. He spent twenty years at this institution, supervising the doctoral work of many econometricians who themselves made important contributions to econometrics. In addition to Sargan's many lasting contributions to econometrics, he also left a lasting impression on his students and colleagues through his generosity.

## Description

`ivtobit` fits tobit models where one or more of the covariates are endogenously determined. By default, `ivtobit` uses maximum likelihood estimation, but Newey's (1987) minimum  $\chi^2$  (two-step) estimator can be requested. Both estimators assume that the endogenous covariates are continuous and so are not appropriate for use with discrete endogenous covariates.

## Quick start

Tobit regression of `y1` on `x` and endogenous regressor `y2` that is instrumented by `z` where `y1` is left-censored at its observed minimum

```
ivtobit y1 x (y2 = z), ll
```

Same as above, but specify that `y1` is left-censored at 0 and right-censored at 20

```
ivtobit y1 x (y2 = z), ll(0) ul(20)
```

Use Newey's two-step estimator

```
ivtobit y1 x (y2 = z), ll(0) ul(20) twostep
```

Same as above, and show first-stage regression results

```
ivtobit y1 x (y2 = z), ll(0) ul(20) twostep first
```

## Menu

Statistics > Endogenous covariates > Tobit model with endogenous covariates

## Syntax

Maximum likelihood estimator

```
ivtobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight],
      ll[(#)] ul[(#)] [mle_options]
```

Two-step estimator

```
ivtobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight], twostep
      ll[(#)] ul[(#)] [tse_options]
```

*varlist*<sub>1</sub> is the list of exogenous variables.

*varlist*<sub>2</sub> is the list of endogenous variables.

*varlist*<sub>iv</sub> is the list of exogenous variables used with *varlist*<sub>1</sub> as instruments for *varlist*<sub>2</sub>.

<i>mle_options</i>	Description
Model	
* <i>ll</i> [(#)]	left-censoring limit
* <i>ul</i> [(#)]	right-censoring limit
<i>mle</i>	use conditional maximum-likelihood estimator; the default
<i>constraints</i> ( <i>constraints</i> )	apply specified linear constraints
SE/Robust	
<i>vce</i> ( <i>vcetype</i> )	<i>vcetype</i> may be <i>oim</i> , <i>robust</i> , <i>cluster</i> <i>clustvar</i> , <i>opg</i> , <i>bootstrap</i> , or <i>jackknife</i>
Reporting	
<i>level</i> (#)	set confidence level; default is <i>level</i> (95)
<i>first</i>	report first-stage regression
<i>nocnsreport</i>	do not display constraints
<i>display_options</i>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<i>maximize_options</i>	control the maximization process
<i>coeflegend</i>	display legend instead of statistics

\*You must specify at least one of *ll*[(#)] and *ul*[(#)].

<i>tse_options</i>	Description
Model	
* <b>twostep</b>	use Newey's two-step estimator; the default is <code>mle</code>
* <b>ll</b> [(#)]	left-censoring limit
* <b>ul</b> [(#)]	right-censoring limit
SE	
<b>vce</b> ( <i>vcetype</i> )	<i>vcetype</i> may be <code>twostep</code> , <code>bootstrap</code> , or <code>jackknife</code>
Reporting	
<b>level</b> (#)	set confidence level; default is <code>level(95)</code>
<b>first</b>	report first-stage regression
<i>display_options</i>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>coeflegend</b>	display legend instead of statistics

\*`twostep` is required. You must specify at least one of `ll[(#)]` and `ul[(#)]`.

*varlist<sub>1</sub>* and *varlist<sub>v</sub>* may contain factor variables; see [U] 11.4.3 Factor variables.

*depar*, *varlist<sub>1</sub>*, *varlist<sub>2</sub>*, and *varlist<sub>v</sub>* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bootstrap`, `by`, `collect`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. `fp` is allowed with the maximum likelihood estimator.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()`, `first`, `twostep`, and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iweights`, and `pweights` are allowed with the maximum likelihood estimator. `fweights` are allowed with Newey's two-step estimator. See [U] 11.1.6 weight.

`coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options for ML estimator

### Model

`ll[(#)]` and `ul[(#)]` indicate the lower and upper limits for censoring, respectively. You may specify one or both. Observations with *depar* ≤ `ll()` are left-censored; observations with *depar* ≥ `ul()` are right-censored; and remaining observations are not censored. You do not have to specify the censoring values at all. It is enough to type `ll`, `ul`, or both. When you do not specify a censoring value, `ivtobit` assumes that the lower limit is the minimum observed in the data (if `ll` is specified) and that the upper limit is the maximum (if `ul` is specified).

`mle` requests that the conditional maximum-likelihood estimator be used. This is the default.

`constraints`(*constraints*); see [R] Estimation options.

### SE/Robust

`vce`(*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster` *clustvar*), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] *vce\_option*.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the tobit equation. The default is not to show these parameter estimates.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#).

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following option is available with `ivtobit` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Options for two-step estimator

## Model

`twostep` is required and requests that Newey's (1987) efficient two-step estimator be used to obtain the coefficient estimates.

`ll[ (#) ]` and `ul[ (#) ]` indicate the lower and upper limits for censoring, respectively. You may specify one or both. Observations with  $deprvar \leq ll()$  are left-censored; observations with  $deprvar \geq ul()$  are right-censored; and remaining observations are not censored. You do not have to specify the censoring values at all. It is enough to type `ll`, `ul`, or both. When you do not specify a censoring value, `ivtobit` assumes that the lower limit is the minimum observed in the data (if `ll` is specified) and that the upper limit is the maximum (if `ul` is specified).

## SE

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`twostep`) and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the tobit equation. The default is not to show these parameter estimates.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

The following option is available with `ivtobit` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

`ivtobit` fits models with censored dependent variables and endogenous covariates. You can use it to fit a tobit model when you suspect that one or more of the covariates is correlated with the error term. `ivtobit` is to tobit what `ivregress` is to linear regression analysis; see [R] [ivregress](#) for more information.

Formally, the model is

$$\begin{aligned}y_{1i}^* &= \mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i \\ \mathbf{y}_{2i} &= \mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2 + \mathbf{v}_i\end{aligned}$$

where  $i = 1, \dots, N$ ;  $\mathbf{y}_{2i}$  is a  $1 \times p$  vector of endogenous variables;  $\mathbf{x}_{1i}$  is a  $1 \times k_1$  vector of exogenous variables;  $\mathbf{x}_{2i}$  is a  $1 \times k_2$  vector of additional instruments; and the equation for  $\mathbf{y}_{2i}$  is written in reduced form. By assumption,  $(u_i, \mathbf{v}_i) \sim N(\mathbf{0}, \boldsymbol{\Sigma})$ .  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$  are vectors of structural parameters, and  $\boldsymbol{\Pi}_1$  and  $\boldsymbol{\Pi}_2$  are matrices of reduced-form parameters. We do not observe  $y_{1i}^*$ ; instead, we observe

$$y_{1i} = \begin{cases} a & y_{1i}^* < a \\ y_{1i}^* & a \leq y_{1i}^* \leq b \\ b & y_{1i}^* > b \end{cases}$$

The order condition for identification of the structural parameters is that  $k_2 \geq p$ . Presumably,  $\boldsymbol{\Sigma}$  is not block diagonal between  $u_i$  and  $\mathbf{v}_i$ ; otherwise,  $\mathbf{y}_{2i}$  would not be endogenous.

### □ Technical note

This model is derived under the assumption that  $(u_i, \mathbf{v}_i)$  is independent and identically distributed multivariate normal for all  $i$ . The `vce(cluster clustvar)` option can be used to control for a lack of independence. As with the standard tobit model without endogeneity, if  $u_i$  is heteroskedastic, point estimates will be inconsistent. □

### ▷ Example 1: Estimation and parameter interpretation

We model the number of hours per week that high school boys spend using social media (`hsocial`). The data collection process caused the observations on the number of hours spent to be censored at 12 hours. A tobit-type model is therefore reasonable for our data.

We model each boy's number of hours spent using social media as a function of whether he has a smartphone (`sphone`), whether he has a computer at home (`computer`), the year in high school in which he is enrolled (`year`), and the hours per week he spends studying (`hstudy`).

We believe that there are unobservable variables that simultaneously affect `hstudy` and `hsocial`, which is to say that `hstudy` is endogenous. Because `hstudy` is endogenous, we must model it as well. Our model for the endogenous `hstudy` always includes the exogenous covariates used to model the outcome `hsocial`. We must also include at least one covariate in the model for the endogenous `hstudy` that was not included in the model for the outcome `hsocial`.

We use `ivtobit` with the default maximum-likelihood estimator to model the endogenous variable `hstudy` as a function of the highest educational degree attained by their parents (`pedu`), the time spent watching television (`tvhours`), and the exogenous covariates used to model `hsocial`.

```

```

The coefficients in the table tell us how much the linear prediction for the outcome changes when there is a change in a covariate.

Below the table, we see a Wald test for whether the correlation between the residuals from the main equation (predicting `hstudy`) and the residuals from the auxiliary equation (predicting `hsocial`) is 0. The correlation itself is 0.47 and shown in the table as `corr(e.hstudy,e.hsocal)`. If the test statistic is not significant, there is not sufficient information in the sample to reject the null hypothesis of no endogeneity. In our example, we reject the null hypothesis that supports our choice of a tobit model that accounts for endogeneity.

## □ Technical note

In the tobit model with endogenous covariates, we assume that  $(u_i, \mathbf{v}_i)$  is multivariate normal with covariance matrix

$$\text{Var}(u_i, \mathbf{v}_i) = \Sigma = \begin{bmatrix} \sigma_u^2 & \Sigma'_{21} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}$$

Using the properties of the multivariate normal distribution,  $\text{Var}(u_i | \mathbf{v}_i) \equiv \sigma_{u|v}^2 = \sigma_u^2 - \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21}$ . Calculating the marginal effects on the conditional expected values of the observed and latent dependent variables and on the probability of censoring requires an estimate of  $\sigma_{u|v}^2$ . Unlike the default maximum-likelihood estimator, the two-step estimator identifies only  $\sigma_{u|v}^2$ , not  $\sigma_u^2$ , so only the linear prediction and its standard error are available after you have used the `twostep` option.

□

## Stored results

`ivtobit`, `mle` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(N_unc)</code>	number of uncensored observations

## Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals
-----------------------	---

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

`ivtobit`, `twostep` stores the following in `e()`:

## Scalars

<code>e(N)</code>	number of observations
<code>e(N_unc)</code>	number of uncensored observations
<code>e(N_lc)</code>	number of left-censored observations
<code>e(N_rc)</code>	number of right-censored observations
<code>e(llopt)</code>	contents of <code>ll()</code>
<code>e(ulopt)</code>	contents of <code>ul()</code>
<code>e(df_m)</code>	model degrees of freedom
<code>e(df_exog)</code>	degrees of freedom for $\chi^2$ test of exogeneity
<code>e(p)</code>	model Wald $p$ -value
<code>e(p_exog)</code>	exogeneity test Wald $p$ -value
<code>e(chi2)</code>	model Wald $\chi^2$
<code>e(chi2_exog)</code>	Wald $\chi^2$ test of exogeneity
<code>e(rank)</code>	rank of <code>e(V)</code>

## Macros

<code>e(cmd)</code>	<code>ivtobit</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(endog)</code>	names of endogenous variables
<code>e(exog)</code>	names of exogenous variables
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(chi2type)</code>	Wald; type of model $\chi^2$ test
<code>e(vce)</code>	<code>vcetype</code> specified in <code>vce()</code>
<code>e(method)</code>	<code>twostep</code>
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(predict)</code>	program used to implement <code>predict</code>

e(footnote)	program used to implement the footnote display
e(marginsok)	predictions allowed by margins
e(marginsprop)	signals to the margins command
e(asbalanced)	factor variables fvset as asbalanced
e(asobserved)	factor variables fvset as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample
-----------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals
-----------------------	--

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Methods and formulas

The estimation procedure used by `ivtobit` is similar to that used by `ivprobit`. For compactness, we write the model as

$$y_{1i}^* = z_i \delta + u_i \tag{1a}$$

$$y_{2i} = x_i \Pi + v_i \tag{1b}$$

where  $z_i = (y_{2i}, x_{1i})$ ,  $x_i = (x_{1i}, x_{2i})$ ,  $\delta = (\beta', \gamma')'$ , and  $\Pi = (\Pi'_1, \Pi'_2)'$ . We do not observe  $y_{1i}^*$ ; instead, we observe

$$y_{1i} = \begin{cases} a & y_{1i}^* < a \\ y_{1i}^* & a \leq y_{1i}^* \leq b \\ b & y_{1i}^* > b \end{cases}$$

$(u_i, v_i)$  is distributed multivariate normal with mean zero and covariance matrix

$$\Sigma = \begin{bmatrix} \sigma_u^2 & \Sigma'_{21} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}$$

Using the properties of the multivariate normal distribution, we can write  $u_i = v'_i \alpha + \epsilon_i$ , where  $\alpha = \Sigma_{22}^{-1} \Sigma_{21}$ ;  $\epsilon_i \sim N(0; \sigma_{u|v}^2)$ , where  $\sigma_{u|v}^2 = \sigma_u^2 - \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21}$ ; and  $\epsilon_i$  is independent of  $v_i$ ,  $z_i$ , and  $x_i$ .

The likelihood function is straightforward to derive because we can write the joint density  $f(y_{1i}, y_{2i} | x_i)$  as  $f(y_{1i} | y_{2i}, x_i) f(y_{2i} | x_i)$ . We have that

$$\ln f(y_{2i} | x_i) = -\frac{1}{2} (p \ln 2\pi + \ln |\Sigma_{22}| + v'_i \Sigma_{22}^{-1} v_i)$$

and

$$\ln f(y_{1i} | \mathbf{y}_{2i}, \mathbf{x}_i) = \begin{cases} \ln \left\{ 1 - \Phi \left( \frac{m_i - a}{\sigma_{u|v}} \right) \right\} & y_{1i} = a \\ -\frac{1}{2} \left\{ \ln 2\pi + \ln \sigma_{u|v}^2 + \frac{(y_{1i} - m_i)^2}{\sigma_{u|v}^2} \right\} & a < y_{1i} < b \\ \ln \Phi \left( \frac{m_i - b}{\sigma_{u|v}} \right) & y_{1i} = b \end{cases}$$

where

$$m_i = \mathbf{z}_i \boldsymbol{\delta} + (\mathbf{y}_{2i} - \mathbf{x}_i \boldsymbol{\Pi}) \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21}$$

and  $\Phi(\cdot)$  is the normal distribution function so that the log likelihood for observation  $i$  is

$$\ln L_i = w_i \{ \ln f(y_{1i} | \mathbf{y}_{2i}, \mathbf{x}_i) + \ln f(\mathbf{y}_{2i} | \mathbf{x}_i) \}$$

where  $w_i$  is the weight for observation  $i$  or one if no weights were specified. Instead of estimating  $\sigma_{u|v}$  and  $\sigma_v$  directly, we estimate  $\ln \sigma_{u|v}$  and  $\ln \sigma_v$ .

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

The maximum likelihood version of `ivtobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

The two-step estimates are obtained using Newey's (1987) minimum  $\chi^2$  estimator. For more details on the minimum  $\chi^2$  estimator, see [R] [ivprobit](#).

## Acknowledgments

The two-step estimator is based on the `tobitiv` command written by Jonah Gelbach of the University of California at Berkeley Law School and the `ivtobit` command written by Joe Harkness of the University of Connecticut.

## Postestimation commands

The following postestimation commands are of special interest after `ivtobit`:

Command	Description
<code>estat correlation</code>	report the correlation matrix of the errors of the dependent variable and the endogenous variables
<code>estat covariance</code>	report the covariance matrix of the errors of the dependent variable and the endogenous variables

These commands are not appropriate after the two-step estimator or with `svy` estimation results.

The following standard postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
* <code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
*† <code>forecast</code>	dynamic forecasts and simulations
† <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
† <code>lrtest</code>	likelihood-ratio test; not available with two-step estimator
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	linear predictions and their SEs, probabilities, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
* <code>suest</code>	seemingly unrelated estimation

<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`estat ic`, `forecast`, and `suest` are not appropriate after `ivtobit`, `twostep`.

†`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as structural functions, linear predictions, standard errors, probabilities, and expected values.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

After ML

```
predict [type] newvar [if] [in] [, statistic asfmethod]
```

```
predict [type] { stub* | newvarlist } [if] [in] , scores
```

After twostep

```
predict [type] newvar [if] [in] [, twostep_statistic]
```

<i>statistic</i>	Description
------------------	-------------

Main	
<code>xb</code>	linear prediction excluding endogeneity; the default
<code>mean</code>	linear prediction accounting for endogeneity
<code>stdp</code>	standard error of the linear prediction
<code>stdf</code>	standard error of the forecast
<code>pr(a,b)</code>	$\Pr(a < y_j < b)$ accounting for endogeneity
<code>e(a,b)</code>	$E(y_j   a < y_j < b)$ accounting for endogeneity
<code>ystar(a,b)</code>	$E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ accounting for endogeneity

`stdf` is not allowed with `svy` estimation results.

where  $a$  and  $b$  may be numbers or variables;  $a$  missing ( $a \geq .$ ) means  $-\infty$ , and  $b$  missing ( $b \geq .$ ) means  $+\infty$ ; see [U] 12.2.1 Missing values.

<i>asfmethod</i>	Description
------------------	-------------

Main	
<code>asf</code>	average structural function; the default
<code>fixedasf</code>	fixed average structural function

*twostep\_statistic* Description

Main

<b>xb</b>	linear prediction; the default
<b>stdp</b>	standard error of the linear prediction

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

**xb**, the default, calculates the linear prediction.

**mean** calculates the linear prediction. Results depend on how the endogeneity complication is handled, which is determined by the **asf** or **fixedasf** option. **mean** is not available with the two-step estimator.

**stdp** calculates the standard error of the linear prediction. It can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

**stdf** calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by **stdf** are always larger than those produced by **stdp**; see [Methods and formulas](#) in [R] **regress postestimation**.

**pr(a,b)** calculates  $\Pr(a < y_j < b | \mathbf{z}_j)$ , the probability that  $y_j | \mathbf{z}_j$  would be observed in the interval  $(a, b)$ .

$a$  and  $b$  may be specified as numbers or variable names;  $lb$  and  $ub$  are variable names;

**pr(20,30)** calculates  $\Pr(20 < y_j < 30 | \mathbf{z}_j)$ ;

**pr(lb,ub)** calculates  $\Pr(lb < y_j < ub | \mathbf{z}_j)$ ; and

**pr(20,ub)** calculates  $\Pr(20 < y_j < ub | \mathbf{z}_j)$ .

$a$  missing ( $a \geq .$ ) means  $-\infty$ ; **pr(.,30)** calculates  $\Pr(-\infty < y_j < 30 | \mathbf{z}_j)$ ;

**pr(lb,30)** calculates  $\Pr(-\infty < y_j < 30 | \mathbf{z}_j)$  in observations for which  $lb \geq .$  and calculates  $\Pr(lb < y_j < 30 | \mathbf{z}_j)$  elsewhere.

$b$  missing ( $b \geq .$ ) means  $+\infty$ ; **pr(20,.)** calculates  $\Pr(+\infty > y_j > 20 | \mathbf{z}_j)$ ;

**pr(20,ub)** calculates  $\Pr(+\infty > y_j > 20 | \mathbf{z}_j)$  in observations for which  $ub \geq .$  and calculates  $\Pr(20 < y_j < ub | \mathbf{z}_j)$  elsewhere.

Results depend on how the endogeneity complication is handled, which is determined by the **asf** or **fixedasf** option.

**pr(a,b)** is not available with the two-step estimator.

**e(a,b)** calculates  $E(y_j \mid a < y_j < b)$ , the expected value of  $y_j | \mathbf{z}_j$  conditional on  $y_j | \mathbf{z}_j$  being in the interval  $(a, b)$ , meaning that  $y_j | \mathbf{z}_j$  is truncated.  $a$  and  $b$  are specified as they are for **pr()**. Results depend on how the endogeneity complication is handled, which is determined by the **asf** or **fixedasf** option. **e(a,b)** is not available with the two-step estimator.

**ystar(a,b)** calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{z}_i \delta + u_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{z}_i \delta + u_j \geq b$ , and  $y_j^* = \mathbf{z}_i \delta + u_j$  otherwise, meaning that  $y_j^*$  is censored.  $a$  and  $b$  are specified as they are for **pr()**. Results depend on how the endogeneity complication is handled, which is determined by the **asf** or **fixedasf** option. **ystar(a,b)** is not available with the two-step estimator.

`asf` and `fixedasf` determine how the average structural function (ASF) of the specified statistic is computed. These options are not allowed with `xb`, `stdp`, or `stdf`.

`asf` is the default for the ML estimator when the `mean`, `pr(a,b)`, `e(a,b)`, or `ystar(a,b)` statistic is specified. `asf` computes the ASF of the specified statistic. It is the statistic conditional on the errors of the endogenous variable equations. Put another way, it is the statistic accounting for the correlation of the endogenous covariates with the errors of the main equation. Derivatives and contrasts based on `asf` have a structural interpretation. See `margins` for computing derivatives and contrasts.

`fixedasf` calculates a fixed ASF. It is the specified statistic using only the coefficients and variables of the outcome equation. `fixedasf` does not condition on the errors of the endogenous variable equations. Contrasts between two fixed counterfactuals averaged over the whole sample have a potential-outcome interpretation. Intuitively, it is as if the values of the covariates were fixed at a value exogenously by fiat. See `margins` for computing derivatives and contrasts.

To be clear, derivatives and contrasts between two fixed counterfactuals using the default `asf` option also have a potential-outcome interpretation. And, unlike `fixedasf`, they retain that interpretation when computed over subpopulations for both linear and nonlinear models.

`scores`, not available with `twostep`, calculates equation-level score variables.

For models with one endogenous regressor, five new variables are created.

The first new variable will contain  $\partial \ln L / \partial (z_i \delta)$ .

The second new variable will contain  $\partial \ln L / \partial (x_i \mathbf{\Pi})$ .

The third new variable will contain  $\partial \ln L / \partial \alpha$ .

The fourth new variable will contain  $\partial \ln L / \partial \ln \sigma_{u|v}$ .

The fifth new variable will contain  $\partial \ln L / \partial \ln \sigma_v$ .

For models with  $p$  endogenous regressors,  $p + \{(p + 1)(p + 2)\} / 2 + 1$  new variables are created.

The first new variable will contain  $\partial \ln L / \partial (z_i \delta)$ .

The second through  $(p + 1)$ th new score variables will contain  $\partial \ln L / \partial (x_i \mathbf{\Pi}_k)$ ,  $k = 1, \dots, p$ , where  $\mathbf{\Pi}_k$  is the  $k$ th column of  $\mathbf{\Pi}$ .

The remaining score variables will contain the partial derivatives of  $\ln L$  with respect to the  $(p + 1)(p + 2) / 2$  ancillary parameters.

# margins

## Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

### After ML

<i>statistic</i>	Description

### After twostep

<i>statistic</i>	Description
Main	
<code>xb</code>	linear prediction; the default
<code>stdp</code>	not allowed with <code>margins</code>

---

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

# estat

## Description for estat

`estat correlation` displays the correlation matrix of the errors of the dependent variable and the endogenous variables.

`estat covariance` displays the covariance matrix of the errors of the dependent variable and the endogenous variables.

`estat correlation` and `estat covariance` are not allowed after the `ivprobit` two-step estimator.

## Menu for estat

Statistics > Postestimation

## Syntax for estat

*Correlation matrix*

```
estat correlation [ , border(bspec) left(#) format(%fmt) ]
```

*Covariance matrix*

```
estat covariance [ , border(bspec) left(#) format(%fmt) ]
```

## Options for estat

Main

`border`(*bspec*) sets border style of the matrix display. The default is `border(all)`.

`left`(#) sets the left indent of the matrix display. The default is `left(2)`.

`format`(%*fmt*) specifies the format for displaying the individual elements of the matrix. The default is `format(%9.0g)`.

## Remarks and examples

Remarks are presented under the following headings:

*Marginal effects*

*Obtaining predicted values*

### Marginal effects

Below, we discuss the interpretation of predictions with the `asf` and `fixedasf` options for the ML estimator using `margins`.

The model is defined by two equations. The first is the equation for the outcome of interest, given by

$$y_{1i}^* = \mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i$$

where we do not observe  $y_{1i}^*$ ; instead, we observe

$$y_{1i} = \begin{cases} a & y_{1i}^* < a \\ y_{1i}^* & a \leq y_{1i}^* \leq b \\ b & y_{1i}^* > b \end{cases}$$

The second is the equation for the endogenous covariates,  $\mathbf{y}_{2i}$ ,

$$\mathbf{y}_{2i} = \mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2 + \mathbf{v}_i$$

This last equation is the difference between a standard tobit model and the model fit by `ivtobit`.  $\mathbf{y}_{2i}$  is modeled by an exogenous component,  $\mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2$ , and a component that is correlated with  $u_i$  and causes the endogeneity problem,  $\mathbf{v}_i$ . The ASF linear prediction conditions on an estimate of  $\widehat{\mathbf{v}}_i$ . It is given by

$$\begin{aligned} \widehat{m}_i &= \widehat{E}(y_{1i} | \mathbf{x}_{1i}, \mathbf{x}_{2i}, y_{2i}, \widehat{\mathbf{v}}_i) \\ \widehat{m}_i &= \mathbf{y}_{2i}\widehat{\boldsymbol{\theta}}_1 + \mathbf{x}_{1i}\widehat{\boldsymbol{\theta}}_2 + \widehat{\mathbf{v}}_i\widehat{\boldsymbol{\theta}}_3 \end{aligned}$$

Because the correlation between  $\mathbf{v}_i$  and  $u_i$  is the problem we intended to address, conditioning on  $\mathbf{v}_i$  purges the model of endogeneity. Using the ASF, we can get derivatives and contrast. See [Wooldridge \(2010\)](#) and [Blundell and Powell \(2003\)](#) for an in-depth discussion of ASFs and their interpretation.

The fixed ASF, estimated when the `fixedasf` option is specified, has a different interpretation. Suppose we wanted to analyze  $\mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i$  at two different values of  $\mathbf{y}_2$ , the original  $\mathbf{y}_2$  and  $\mathbf{y}_2 + 1$ . We want the average difference at these two points for the given values of the other covariates. The values of the covariates are not arrived at via the model; they are fixed by fiat. You can think of them as potential outcomes. The difference of the two values of  $\mathbf{y}_2$  is given by

$$\{(\mathbf{y}_{2i} + 1)\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i\} - (\mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i)$$

If we average over the distribution of  $u$ , we obtain

$$E\{(y_{2i} + 1)\beta + x_{1i}\gamma\} - E(y_{2i}\beta + x_{1i}\gamma)$$

We do not account for endogeneity because the values of the covariates are given and fixed. If the research question you are pursuing after fitting the model has this interpretation, `fixedasf` gives you an adequate prediction. If, however, you do not want to treat the covariates as fixed, you should account for endogeneity and use `asf` predictions.

## ► Example 1: Obtaining marginal effects

We can obtain average marginal effects by using the `margins` command after `ivtobit`. For the social-media model of [example 1](#) in [\[R\] ivtobit](#), suppose that we wanted to know the average marginal effects on the probability of spending more than 12 hours using social media. Average marginal effects are equivalent to estimating how a change in a covariate affects every individual in our sample and taking the average of these effects. The effect of each covariate is estimated with all other covariates kept at their observed values.

```
. use https://www.stata-press.com/data/r18/smedia
(Fictional data on hours spent on social media)
. ivtobit hsocial i.sphone i.computer i.year (hstudy = tvhours i.pedu), ul(12)
(output omitted)
. margins, dydx(*) predict(p(12, .))
Average marginal effects          Number of obs = 1,324
Model VCE: OIM
Expression: Pr(hsocial>12), predict(p(12, .))
dy/dx wrt:  hstudy 1.sphone 1.computer 2.year 3.year 4.year
```

	Delta-method				
	dy/dx	std. err.	z	P> z	[95% conf. interval]
hstudy	-.1508219	.0044544	-33.86	0.000	-.1595523 -.1420914
1.sphone	.3943071	.0085181	46.29	0.000	.3776119 .4110022
1.computer	.3993489	.0082484	48.42	0.000	.3831824 .4155154
year					
2	.0663908	.0120746	5.50	0.000	.042725 .0900567
3	.1334667	.012488	10.69	0.000	.1089908 .1579426
4	.2343393	.0123729	18.94	0.000	.2100888 .2585897

Note: dy/dx for factor levels is the discrete change from the base level.

Having a smartphone increases the probability of spending more than 12 hours on social media by 0.39, on average. Any additional study time decreases the probability of spending more than 12 hours using social media by 0.15, on average. The other average marginal effects are interpreted similarly. All effects above have a structural interpretation because we are conditioning on the level of endogeneity. See [Wooldridge \(2010\)](#) and [Blundell and Powell \(2003\)](#) for an in-depth discussion of ASFs and their interpretation.

## Obtaining predicted values

After fitting your model with `ivtobit`, you can obtain the linear prediction and its standard error for both the estimation sample and other samples by using the `predict` command. If you used the ML estimator, you can also obtain the linear prediction, the conditional expected values of the observed and latent dependent variables, and the probability of observing the dependent variable in a specified interval—each of these can be computed with an ASF or a fixed ASF interpretation. In addition, with the ML estimator, you can obtain the standard error of the forecast. See [U] 20 **Estimation and postestimation commands** and [R] **predict**.

## Stored results

`estat correlation` stores the following results in `r()`:

Matrices

`r(corr)` correlation matrix of the errors

`estat covariance` stores the following results in `r()`:

Matrices

`r(cov)` covariance matrix of the errors

## Methods and formulas

The linear prediction is calculated as  $z_i \hat{\delta}$ , where  $\hat{\delta}$  is the estimated value of  $\delta$ , and  $z_i$  and  $\delta$  are defined in (1a) of [R] **ivtobit**. Expected values and probabilities are calculated using the same formulas as those used by the standard tobit model. However, when we use the default `asf` option with `mean`, `pr(a,b)`, `e(a,b)`, or `ystar(a,b)`, instead of evaluating the standard normal cumulative density and probability density at the linear prediction, we evaluate expected values and probabilities at  $\hat{m}_i$ , where  $\hat{m}_i$  is defined in *Methods and formulas* of [R] **ivtobit**. Using  $\hat{m}_i$  instead of  $z_i \hat{\delta}$  in the formulas produces the ASF, which accounts for endogeneity. The fixed ASF, obtained with the `fixedasf` option, evaluates the statistic at  $z_i \hat{\delta}$ .

## Description

`jackknife` performs jackknife estimation of the specified statistics (or expressions) for a Stata command or a user-written program. Statistics are jackknifed by estimating the command once for each observation or cluster in the dataset, leaving the associated observation or cluster out of the calculations. `jackknife` is designed for use with nonestimation commands, functions of coefficients, or user-written programs. To jackknife coefficients, we recommend using the `vce(jackknife)` option when allowed by the estimation command.

## Quick start

Jackknife estimate of the standard deviation of `v1` returned by `summarize` in `r(sd)`

```
jackknife sd=r(sd), rclass: summarize v1
```

Jackknife estimate of the statistic `r(mystat)` returned by `rclass` program `myprog1` that returns the sample size in `r(N)`

```
jackknife stat=r(mystat), rclass: myprog1 v1
```

Same as above, and save the results from each replication in `mydata.dta`

```
jackknife stat=r(mystat), rclass saving(mydata): myprog1 v1
```

Jackknife estimate of a difference in coefficients estimated by `regress`

```
jackknife diff=(_b[x2]-_b[x1]): regress y x1 x2 x3
```

Jackknife estimate of the statistic `e(mystat)` returned by `eclass` program `myprog2` that returns the sample size in `e(N)`

```
jackknife stat=e(mystat), eclass: myprog2 y x1 x2 x3
```

Jackknife estimates of coefficients stored in `e(b)` by `myprog2`

```
jackknife _b, eclass: myprog2 y x1 x2 x3
```

Add variables containing the pseudovalues of the coefficients to the dataset

```
jackknife _b, eclass keep: myprog2 y x1 x2 x3
```

## Menu

Statistics > Resampling > Jackknife estimation

## Syntax

```
jackknife exp_list [ , options eform_option ] : command
```

<i>options</i>	Description
Main	
<code>eclass</code>	number of observations used is stored in <code>e(N)</code>
<code>rclass</code>	number of observations used is stored in <code>r(N)</code>
<code>n(<i>exp</i>)</code>	specify <i>exp</i> that evaluates to the number of observations used
Options	
<code>cluster(<i>varlist</i>)</code>	variables identifying sample clusters
<code>idcluster(<i>newvar</i>)</code>	create new cluster ID variable
<code>saving(<i>filename</i>, ...)</code>	save results to <i>filename</i> ; save statistics in double precision; save results to <i>filename</i> every # replications
<code>keep</code>	keep pseudovalues
<code>mse</code>	use MSE formula for variance estimation
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>notable</code>	suppress table of results
<code>noheader</code>	suppress table header
<code>nolegend</code>	suppress table legend
<code>verbose</code>	display the full table legend
<code>nodots</code>	suppress replication dots
<code>dots(#)</code>	display dots every # replications
<code>noisily</code>	display any output from <i>command</i>
<code>trace</code>	trace <i>command</i>
<code>title(<i>text</i>)</code>	use <i>text</i> as title for jackknife results
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<code>eform_option</code>	display coefficient table in exponentiated form
Advanced	
<code>nodrop</code>	do not drop observations
<code>reject(<i>exp</i>)</code>	identify invalid results
<code>coeflegend</code>	display legend instead of statistics

*command* is any command that follows standard Stata syntax. All weight types supported by *command* are allowed except `aweight`s; see [U] 11.1.6 [weight](#).

`collect` and `svy` are allowed; see [U] 11.1.10 [Prefix commands](#).

`coeflegend` does not appear in the dialog box.

See [U] 20 [Estimation and postestimation commands](#) for more capabilities of estimation commands.

```

exp_list contains    (name: elist)
                    elist
                    eexp
elist contains      newvar = (exp)
                    (exp)
eexp is             specname
                    [eqno]specname
specname is        _b
                    _b[]
                    _se
                    _se[]
eqno is            ##
                    name

```

*exp* is a standard Stata expression; see [U] 13 Functions and expressions.

Distinguish between [], which are to be typed, and [], which indicate optional arguments.

## Options

Main

`eclass`, `rclass`, and `n(exp)` specify where *command* stores the number of observations on which it based the calculated results. We strongly advise you to specify one of these options.

`eclass` specifies that *command* store the number of observations in  $e(N)$ .

`rclass` specifies that *command* store the number of observations in  $r(N)$ .

`n(exp)` specifies an expression that evaluates to the number of observations used. Specifying `n(r(N))` is equivalent to specifying the `rclass` option. Specifying `n(e(N))` is equivalent to specifying the `eclass` option. If *command* stores the number of observations in  $r(N1)$ , specify `n(r(N1))`.

If you specify no options, `jackknife` will assume `eclass` or `rclass`, depending on which of  $e(N)$  and  $r(N)$  is not missing (in that order). If both  $e(N)$  and  $r(N)$  are missing, `jackknife` assumes that all observations in the dataset contribute to the calculated result. If that assumption is incorrect, the reported standard errors will be incorrect. For instance, say that you specify

```
. jackknife coef=_b[x2]: myreg y x1 x2 x3
```

where `myreg` uses  $e(n)$  instead of  $e(N)$  to identify the number of observations used in calculations. Further assume that observation 42 in the dataset has `x3` equal to missing. The 42nd observation plays no role in obtaining the estimates, but `jackknife` has no way of knowing that and will use the wrong  $N$ . If, on the other hand, you specify

```
. jackknife coef=_b[x2], n(e(n)): myreg y x1 x2 x3
```

`jackknife` will notice that observation 42 plays no role. The `n(e(n))` option is specified because `myreg` is an estimation command but it stores the number of observations used in  $e(n)$  (instead of the standard  $e(N)$ ). When `jackknife` runs the regression omitting the 42nd observation, `jackknife` will observe that  $e(n)$  has the same value as when `jackknife` previously ran the regression using all the observations. Thus `jackknife` will know that `myreg` did not use the observation.

## Options

`cluster(varlist)` specifies the variables identifying sample clusters. If `cluster()` is specified, one cluster is left out of each call to `command`, instead of 1 observation.

`idcluster(newvar)` creates a new variable containing a unique integer identifier for each resampled cluster, starting at 1 and leading up to the number of clusters. This option may be specified only when the `cluster()` option is specified. `idcluster()` helps identify the cluster to which a pseudo-value belongs.

`saving(filename [, suboptions ])` creates a Stata data file (.dta file) consisting of (for each statistic in *exp\_list*) a variable containing the replicates.

`double` specifies that the results for each replication be saved as doubles, meaning 8-byte reals. By default, they are saved as floats, meaning 4-byte reals. This option may be used without the `saving()` option to compute the variance estimates by using double precision.

`every(#)` specifies that results be written to disk every #th replication. `every()` should be specified only in conjunction with `saving()` when `command` takes a long time for each replication. This option will allow recovery of partial results should some other software crash your computer. See [P] [postfile](#).

`replace` specifies that *filename* be overwritten if it exists. This option does not appear in the dialog box.

`keep` specifies that new variables be added to the dataset containing the pseudo-values of the requested statistics. For instance, if you typed

```
. jackknife coef=_b[x2], eclass keep: regress y x1 x2 x3
```

new variable `coef` would be added to the dataset containing the pseudo-values for `_b[x2]`. Let  $b$  be the value of `_b[x2]` when all observations are used to fit the model, and let  $b(j)$  be the value when the  $j$ th observation is omitted. The pseudo-values are defined as

$$\text{pseudo-value}_j = N \{b - b(j)\} + b(j)$$

where  $N$  is the number of observations used to produce  $b$ .

When the `cluster()` option is specified, each cluster is given at most one nonmissing pseudo-value. The `keep` option implies the `nodrop` option.

`mse` specifies that `jackknife` compute the variance by using deviations of the replicates from the observed value of the statistics based on the entire dataset. By default, `jackknife` computes the variance by using deviations of the pseudo-values from their mean.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`notable` suppresses the display of the table of results.

`noheader` suppresses the display of the table header. This option implies `nolegend`.

`nolegend` suppresses the display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

`verbose` specifies that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

`nodots` and `dots(#)` specify whether to display replication dots. By default, one dot character is displayed for each successful replication. An “x” is displayed if `command` returns an error or if

any value in *exp\_list* is missing. You can also control whether dots are displayed using `set dots`; see [R] [set](#).

`nodots` suppresses display of the replication dots.

`dots(#)` displays dots every # replications. `dots(0)` is a synonym for `nodots`.

`noisily` specifies that any output from *command* be displayed. This option implies the `nodots` option.

`trace` causes a trace of the execution of *command* to be displayed. This option implies the `noisily` option.

`title(text)` specifies a title to be displayed above the table of jackknife results; the default title is `Jackknife results` or what is produced in `e(title)` by an estimation command.

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

*eform\_option* causes the coefficient table to be displayed in exponentiated form; see [R] [eform\\_option](#). *command* determines which *eform\_option* is allowed (`eform(string)` and `eform` are always allowed).

*command* determines which of the following are allowed (`eform(string)` and `eform` are always allowed):

<i>eform_option</i>	Description
<code>eform(<i>string</i>)</code>	use <i>string</i> for the column title
<code>eform</code>	exponentiated coefficient, <i>string</i> is <code>exp(b)</code>
<code>hr</code>	hazard ratio, <i>string</i> is <code>Haz. ratio</code>
<code>shr</code>	subhazard ratio, <i>string</i> is <code>SHR</code>
<code>irr</code>	incidence-rate ratio, <i>string</i> is <code>IRR</code>
<code>or</code>	odds ratio, <i>string</i> is <code>Odds ratio</code>
<code>rrr</code>	relative-risk ratio, <i>string</i> is <code>RRR</code>

#### Advanced

`nodrop` prevents observations outside `e(sample)` and the `if` and `in` qualifiers from being dropped before the data are resampled.

`reject(exp)` identifies an expression that indicates when results should be rejected. When *exp* is true, the resulting values are reset to missing values.

The following option is available with `jackknife` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

- [Introduction](#)
- [Using jackknife](#)
- [Jackknifed standard deviation](#)
- [Collecting multiple statistics](#)
- [Collecting coefficients](#)

## Introduction

Although the jackknife—developed in the late 1940s and early 1950s—is of largely historical interest today, it is still useful in searching for overly influential observations. This feature is often forgotten. In any case, the jackknife is

- an alternative, first-order unbiased estimator for a statistic;
- a data-dependent way to calculate the standard error of the statistic and to obtain significance levels and confidence intervals; and
- a way of producing measures called pseudovalues for each observation, reflecting the observation’s influence on the overall statistic.

The idea behind the simplest form of the jackknife—the one implemented here—is to repeatedly calculate the statistic in question, each time omitting just one of the dataset’s observations. Assume that our statistic of interest is the sample mean. Let  $y_j$  be the  $j$ th observation of our data on some measurement  $y$ , where  $j = 1, \dots, N$  and  $N$  is the sample size. If  $\bar{y}$  is the sample mean of  $y$  using the entire dataset and  $\bar{y}_{(j)}$  is the mean when the  $j$ th observation is omitted, then

$$\bar{y} = \frac{(N - 1)\bar{y}_{(j)} + y_j}{N}$$

Solving for  $y_j$ , we obtain

$$y_j = N\bar{y} - (N - 1)\bar{y}_{(j)}$$

These are the pseudovalues that `jackknife` calculates. To move this discussion beyond the sample mean, let  $\hat{\theta}$  be the value of our statistic (not necessarily the sample mean) using the entire dataset, and let  $\hat{\theta}_{(j)}$  be the computed value of our statistic with the  $j$ th observation omitted. The pseudovalue for the  $j$ th observation is

$$\hat{\theta}_j^* = N\hat{\theta} - (N - 1)\hat{\theta}_{(j)}$$

The mean of the pseudovalues is the alternative, first-order unbiased estimator mentioned above, and the standard error of the mean of the pseudovalues is an estimator for the standard error of  $\hat{\theta}$  (Tukey 1958).

The jackknife estimate of variance has been largely replaced by the bootstrap estimate (see [R] [bootstrap](#)), which is widely viewed as more efficient and robust. The use of jackknife pseudovalues to detect outliers is too often forgotten and is something the bootstrap does not provide. See Mosteller and Tukey (1977, 133–163) and Mooney and Duval (1993, 22–27) for more information.

## Using jackknife

Typing

```
. jackknife exp_list: command
```

executes *command* once for each observation in the dataset, leaving the associated observation out of the calculations that make up *exp\_list*.

*command* defines the statistical command to be executed. Most Stata commands and user-written programs can be used with `jackknife`, as long as they follow standard Stata syntax and allow the `if` qualifier; see [U] [11 Language syntax](#). The `by` prefix may not be part of *command*.

*exp\_list* specifies the statistics to be collected from the execution of *command*. If *command* changes the contents in `e(b)`, *exp\_list* is optional and defaults to `_b`.

When the `cluster()` option is given, clusters are omitted instead of observations, and  $N$  is the number of clusters instead of the sample size.

### ▷ Example 1

As our first example, we will show that the jackknife standard error of the sample mean is equivalent to the standard error of the sample mean computed using the classical formula in the `ci means` command. We use the `double` option to compute the standard errors with the same precision as the `ci means` command.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. jackknife r(mean), double: summarize mpg
(running summarize on estimation sample)
Jackknife replications (74): .....10.....20.....30.....40.....
> ...50.....60.....70.... done
Jackknife results
                                                    Number of obs = 74
                                                    Replications = 74

Command: summarize mpg
      _jk_1: r(mean)
         n(): r(N)
```

	Coefficient	Jackknife std. err.	t	P> t	[95% conf. interval]	
_jk_1	21.2973	.6725511	31.67	0.000	19.9569	22.63769

```
. ci means mpg
Variable | Obs   Mean   Std. err.   [95% conf. interval]
-----+-----
      mpg |    74  21.2973  .6725511   19.9569   22.63769
```

◀

## Jackknifed standard deviation

### ▷ Example 2

Mosteller and Tukey (1977, 139–140) request a 95% confidence interval for the standard deviation of the 11 values:

0.1, 0.1, 0.1, 0.4, 0.5, 1.0, 1.1, 1.3, 1.9, 1.9, 4.7

Stata's `summarize` command calculates the mean and standard deviation and stores them as `r(mean)` and `r(sd)`. To obtain the jackknifed standard deviation of the 11 values and save the pseudovalues as a new variable, `sd`, we would type

```

. clear
. input x
      x
1. 0.1
2. 0.1
3. 0.1
4. 0.4
5. 0.5
6. 1.0
7. 1.1
8. 1.3
9. 1.9
10. 1.9
11. 4.7
12. end

. jackknife sd=r(sd), rclass keep: summarize x
(running summarize on estimation sample)
Jackknife replications (11): .....10. done
Jackknife results
                                         Number of obs = 11
                                         Replications = 11

Command: summarize x
sd: r(sd)
n(): r(N)

```

	Coefficient	Jackknife std. err.	t	P> t	[95% conf. interval]
sd	1.343469	.624405	2.15	0.057	-.047792 2.73473

Interpreting the output, the standard deviation reported by `summarize mpg` is 1.34. The jackknife standard error is 0.62. The 95% confidence interval for the standard deviation is  $-0.048$  to  $2.73$ .

By specifying `keep`, `jackknife` creates in our dataset a new variable, `sd`, for the pseudovalues.

```
. list, sep(4)
```

	x	sd
1.	.1	1.139977
2.	.1	1.139977
3.	.1	1.139977
4.	.4	.8893147
5.	.5	.824267
6.	1	.632489
7.	1.1	.6203189
8.	1.3	.6218889
9.	1.9	.835419
10.	1.9	.835419
11.	4.7	7.703949

The jackknife estimate is the average of the `sd` variable, so `sd` contains the individual values of our statistic. We can see that the last observation is substantially larger than the others. The last observation is certainly an outlier, but whether that reflects the considerable information it contains or indicates that it should be excluded from analysis depends on the context of the problem. Mosteller and Tukey created the data by sampling from an exponential distribution, so the observation is informative. ◀

## ▷ Example 3

Let's repeat the example above using the automobile dataset, obtaining the standard error of the standard deviation of mpg.

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. jackknife sd=r(sd), rclass keep: summarize mpg
(running summarize on estimation sample)
Jackknife replications (74): .....10.....20.....30.....40.....
> ...50.....60.....70.... done

Jackknife results                                     Number of obs = 74
                                                    Replications = 74

Command: summarize mpg
      sd: r(sd)
      n(): r(N)
```

	Coefficient	Jackknife std. err.	t	P> t	[95% conf. interval]	
sd	5.785503	.6072509	9.53	0.000	4.575254	6.995753

Let's look at sd more carefully:

```
. summarize sd, detail
                pseudovalues: r(sd)

-----+-----
Percentiles      Smallest
 1%      2.870471      2.870471
 5%      2.870471      2.870471
10%      2.906255      2.870471      Obs              74
25%      3.328489      2.870471      Sum of wgt.      74
50%      3.948335
                    Largest      Mean              5.817374
75%      6.844418      17.34316      Std. dev.        5.22377
90%      9.597018      19.7617      Variance         27.28777
95%      17.34316      19.7617      Skewness         4.07202
99%      38.60905      38.60905      Kurtosis         23.37823

. list make mpg sd if sd > 30
```

	make	mpg	sd
71.	VW Diesel	41	38.60905

Here the VW Diesel is the only diesel car in our dataset.

## Collecting multiple statistics

### ▷ Example 4

jackknife is not limited to collecting just one statistic. For instance, we can use `summarize`, `detail` and then obtain the jackknife estimate of the standard deviation and skewness. `summarize`, `detail` stores the standard deviation in `r(sd)` and the skewness in `r(skewness)`, so we might type

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. jackknife sd=r(sd) skew=r(skewness), rclass: summarize mpg, detail
(running summarize on estimation sample)
Jackknife replications (74): .....10.....20.....30.....40.....
> ...50.....60.....70.... done

Jackknife results
```

Number of obs = 74  
Replications = 74

```
Command: summarize mpg, detail
sd: r(sd)
skew: r(skewness)
n(): r(N)
```

	Coefficient	Jackknife std. err.	t	P> t	[95% conf. interval]	
sd	5.785503	.6072509	9.53	0.000	4.575254	6.995753
skew	.9487176	.3367242	2.82	0.006	.2776272	1.619808

◀

## Collecting coefficients

### ▷ Example 5

jackknife can also collect coefficients from estimation commands. For instance, using `auto.dta`, we might wish to obtain the jackknife standard errors of the coefficients from a regression in which we model the mileage of a car by its weight and trunk space. To do this, we could refer to the coefficients as `_b[weight]`, `_b[trunk]`, `_se[weight]`, and `_se[trunk]` in the `exp_list`, or we could simply use the extended expressions `_b`. In fact, `jackknife` assumes `_b` by default when used with estimation commands.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. jackknife: regress mpg weight trunk
(running regress on estimation sample)
Jackknife replications (74): .....10.....20.....30.....40.....
> ...50.....60.....70.... done
```

```
Linear regression                                Number of obs =    74
                                                Replications =    74
                                                F(2, 73)         =   78.10
                                                Prob > F         =  0.0000
                                                R-squared       =  0.6543
                                                Adj R-squared   =  0.6446
                                                Root MSE       =  3.4492
```

mpg	Coefficient	Jackknife std. err.	t	P> t	[95% conf. interval]	
weight	-.0056527	.0010216	-5.53	0.000	-.0076887	-.0036167
trunk	-.096229	.1486236	-0.65	0.519	-.3924354	.1999773
_cons	39.68913	1.873324	21.19	0.000	35.9556	43.42266

If you are going to use `jackknife` to estimate standard errors of model coefficients, we recommend using the `vce(jackknife)` option when it is allowed with the estimation command; see [R] [vce\\_option](#).

```
. regress mpg weight trunk, vce(jackknife, nodots)
Linear regression                                Number of obs =    74
                                                Replications =    74
                                                F(2, 73)         =   78.10
                                                Prob > F         =  0.0000
                                                R-squared       =  0.6543
                                                Adj R-squared   =  0.6446
                                                Root MSE       =  3.4492
```

mpg	Coefficient	Jackknife std. err.	t	P> t	[95% conf. interval]	
weight	-.0056527	.0010216	-5.53	0.000	-.0076887	-.0036167
trunk	-.096229	.1486236	-0.65	0.519	-.3924354	.1999773
_cons	39.68913	1.873324	21.19	0.000	35.9556	43.42266

## □ Technical note

When the `jackknife` prefix is used with a user-defined program and when the expression list is `_b`, `jackknife` calls

```
set coeftabresults off
```

before entering the replication loop to prevent Stata from performing unnecessary calculations. This means that, provided option `noisily` is not specified, estimation commands will not build or post the coefficient table matrix `r(table)`.

If your program calls an estimation command and needs `r(table)` to exist to perform properly, then your program will need to call

```
set coeftabresults on
```

before calling other estimation commands.

□

**John Wilder Tukey** (1915–2000) was born in Massachusetts. He studied chemistry at Brown and mathematics at Princeton and afterward worked at both Princeton and Bell Labs, as well as being involved in a great many government projects, consultancies, and committees. He made outstanding contributions to several areas of statistics, including time series, multiple comparisons, robust statistics, and exploratory data analysis. Tukey was extraordinarily energetic and inventive, not least in his use of terminology: he is credited with inventing the terms `bit` and `software`, in addition to `ANOVA`, `boxplot`, `data analysis`, `hat matrix`, `jackknife`, `stem-and-leaf plot`, `trimming`, and `winsorizing`, among many others. Tukey's direct and indirect impacts mark him as one of the greatest statisticians of all time.

## Stored results

`jackknife` stores the following in `e()`:

### Scalars

<code>e(N)</code>	sample size
<code>e(N_reps)</code>	number of complete replications
<code>e(N_misreps)</code>	number of incomplete replications
<code>e(N_clust)</code>	number of clusters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_extra)</code>	number of extra equations
<code>e(k_exp)</code>	number of expressions
<code>e(k_eeexp)</code>	number of extended expressions ( <code>_b</code> or <code>_se</code> )
<code>e(df_r)</code>	degrees of freedom

### Macros

<code>e(cmdname)</code>	command name from <i>command</i>
<code>e(cmd)</code>	same as <code>e(cmdname)</code> or <code>jackknife</code>
<code>e(command)</code>	<i>command</i>
<code>e(cmdline)</code>	command as typed
<code>e(prefix)</code>	<code>jackknife</code>
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(cluster)</code>	cluster variables
<code>e(pseudo)</code>	new variables containing pseudovalues
<code>e(nfunction)</code>	<code>e(N)</code> , <code>r(N)</code> , <code>n()</code> option, or empty
<code>e(exp#)</code>	expression for the #th statistic

e(mse)	from mse option
e(vce)	jackknife
e(vctype)	title used to label Std. err.
e(properties)	b v

## Matrices

e(b)	observed statistics
e(b_jk)	jackknife estimates
e(V)	jackknife variance-covariance matrix
e(V_modelbased)	model-based variance

In addition to the above, the following is stored in `r()`:

## Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals
-----------------------	---

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

When `exp_list` is `_b`, `jackknife` will also carry forward most of the results already in `e()` from *command*.

## Methods and formulas

Let  $\hat{\theta}$  be the observed value of the statistic, that is, the value of the statistic calculated using the original dataset. Let  $\hat{\theta}_{(j)}$  be the value of the statistic computed by leaving out the  $j$ th observation (or cluster); thus  $j = 1, 2, \dots, N$  identifies an individual observation (or cluster), and  $N$  is the total number of observations (or clusters). The  $j$ th pseudovalue is given by

$$\hat{\theta}_j^* = \hat{\theta}_{(j)} + N\{\hat{\theta} - \hat{\theta}_{(j)}\}$$

When the `mse` option is specified, the standard error is estimated as

$$\hat{s}e = \left\{ \frac{N-1}{N} \sum_{j=1}^N (\hat{\theta}_{(j)} - \hat{\theta})^2 \right\}^{1/2}$$

and the jackknife estimate is

$$\bar{\theta}_{(.)} = \frac{1}{N} \sum_{j=1}^N \hat{\theta}_{(j)}$$

Otherwise, the standard error is estimated as

$$\hat{s}e = \left\{ \frac{1}{N(N-1)} \sum_{j=1}^N (\hat{\theta}_j^* - \bar{\theta}^*)^2 \right\}^{1/2} \quad \bar{\theta}^* = \frac{1}{N} \sum_{j=1}^N \hat{\theta}_j^*$$

where  $\bar{\theta}^*$  is the jackknife estimate. The variance-covariance matrix is similarly computed.

## Postestimation commands

The following postestimation commands are available after `jackknife`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	predictions, residuals, influence statistics, and other diagnostic measures
<code>predictnl</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

The postestimation command is allowed only if it may be used after *command*.

## predict

The syntax of `predict` (and whether `predict` is even allowed) following `jackknife` depends on the *command* used with `jackknife`.

## margins

The syntax of `margins` (and whether `margins` is even allowed) following `jackknife` depends on the *command* used with `jackknife`.

# Title

## kappa — Interrater agreement

[Description](#)  
[Options](#)  
[References](#)

[Quick start](#)  
[Remarks and examples](#)

[Menu](#)  
[Stored results](#)

[Syntax](#)  
[Methods and formulas](#)

## Description

`kap` and `kappa` calculate the kappa-statistic measure of interrater agreement. `kap` calculates the statistic for two unique raters or at least two nonunique raters. `kappa` calculates only the statistic for nonunique raters, but it handles the case where data have been recorded as rating frequencies. `kapwgt` defines weights used by `kap` in measuring the importance of disagreements.

## Quick start

Calculate interrater agreement for values `rater1` and `rater2`

```
kap rater1 rater2
```

Add table of assessments

```
kap rater1 rater2, tab
```

Same as above, and apply frequency weights defined by `wvar`

```
kap rater1 rater2 [fweight=wvar], tab
```

Agreement for values from three nonunique raters stored in `rater1`, `rater2`, and `rater3`

```
kap rater1 rater2 rater3
```

Add values from an additional three raters stored in `rater4`, `rater5`, and `rater6`

```
kap rater1-rater6
```

Use weights  $1 - |i - j| / (k - 1)$  to weight disagreements between rater 1 and rater 2

```
kap rater1 rater2, wgt(w)
```

Number of times each subject classified in categories stored in `poor`, `fair`, and `good`

```
kappa poor fair good
```

## Menu

### kap: two unique raters

Statistics > Epidemiology and related > Other > Interrater agreement, two unique raters

### kapwgt

Statistics > Epidemiology and related > Other > Define weights for the above (kap)

### kap: nonunique raters

Statistics > Epidemiology and related > Other > Interrater agreement, nonunique raters

### kappa

Statistics > Epidemiology and related > Other > Interrater agreement, nonunique raters with frequencies

## Syntax

*Interrater agreement, two unique raters*

```
kap varname1 varname2 [if] [in] [weight] [, options]
```

*Weights for weighting disagreements*

```
kapwgt wgtid [1 \ # 1 [\ # # 1 ... ]]
```

*Interrater agreement, nonunique raters, variables record ratings for each rater*

```
kap varname1 varname2 varname3 [...] [if] [in] [weight]
```

*Interrater agreement, nonunique raters, variables record frequency of ratings*

```
kappa varlist [if] [in]
```

<i>options</i>	Description
----------------	-------------

---

<b>tab</b>	display table of assessments
<b>wgt</b> ( <i>wgtid</i> )	specify how to weight disagreements; see <a href="#">Options</a> for alternatives
<b>absolute</b>	treat rating categories as absolute

---

*collect* is allowed with *kap* and *kappa*; see [\[U\] 11.1.10 Prefix commands](#).

*fweights* are allowed; see [\[U\] 11.1.6 weight](#).

## Options

Main

`tab` displays a tabulation of the assessments by the two raters.

`wgt(wgtid)` specifies that `wgtid` be used to weight disagreements. You can define your own weights by using `kapwgt`; `wgt()` then specifies the name of the user-defined matrix. For instance, you might define

```
. kapwgt mine 1 \ .8 1 \ 0 .8 1 \ 0 0 .8 1
```

and then

```
. kap rata ratb, wgt(mine)
```

Also, two prerecorded weights are available.

`wgt(w)` specifies weights  $1 - |i - j| / (k - 1)$ , where  $i$  and  $j$  index the rows and columns of the ratings by the two raters and  $k$  is the maximum number of possible ratings.

`wgt(w2)` specifies weights  $1 - \{(i - j) / (k - 1)\}^2$ .

`absolute` is relevant only if `wgt()` is also specified. The `absolute` option modifies how  $i$ ,  $j$ , and  $k$  are defined and how corresponding entries are found in a user-defined weighting matrix. When `absolute` is not specified,  $i$  and  $j$  refer to the row and column index, not to the ratings themselves. Say that the ratings are recorded as  $\{0, 1, 1.5, 2\}$ . There are four ratings;  $k = 4$ , and  $i$  and  $j$  are still 1, 2, 3, and 4 in the formulas above. Index 3, for instance, corresponds to rating = 1.5. This system is convenient but can, with some data, lead to difficulties.

When `absolute` is specified, all ratings must be integers, and they must be coded from the set  $\{1, 2, 3, \dots\}$ . Not all values need be used; integer values that do not occur are simply assumed to be unobserved.

## Remarks and examples

Remarks are presented under the following headings:

*Two raters*

*More than two raters*

The kappa-statistic measure of agreement is scaled to be 0 when the amount of agreement is what would be expected to be observed by chance and 1 when there is perfect agreement. For intermediate values, [Landis and Koch \(1977a, 165\)](#) suggest the following interpretations:

below 0.0	Poor
0.00–0.20	Slight
0.21–0.40	Fair
0.41–0.60	Moderate
0.61–0.80	Substantial
0.81–1.00	Almost perfect

**Two raters**▷ **Example 1**

Consider the classification by two radiologists of 85 xeromammograms as normal, benign disease, suspicion of cancer, or cancer (a subset of the data from Boyd et al. [1982] and discussed in the context of kappa in Altman [1991, 403–405]).

```
. use https://www.stata-press.com/data/r18/rate2
(Altman p. 403)
. tabulate rada radb
```

Radiologist A's assessment	Radiologist B's assessment				Total
	Normal	Benign	Suspect	Cancer	
Normal	21	12	0	0	33
Benign	4	17	1	0	22
Suspect	3	9	15	2	29
Cancer	0	0	0	1	1
Total	28	38	16	3	85

Our dataset contains two variables: `rada`, radiologist A's assessment, and `radb`, radiologist B's assessment. Each observation is a patient.

We can obtain the kappa measure of interrater agreement by typing

```
. kap rada radb
```

Agreement	Expected agreement	Kappa	Std. err.	Z	Prob>Z
63.53%	30.82%	0.4728	0.0694	6.81	0.0000

If each radiologist had made his determination randomly (but with probabilities equal to the overall proportions), we would expect the two radiologists to agree on 30.8% of the patients. In fact, they agreed on 63.5% of the patients, or 47.3% of the way between random agreement and perfect agreement. The amount of agreement indicates that we can reject the hypothesis that they are making their determinations randomly.

### ▷ Example 2: Weighted kappa, prerecorded weight w

There is a difference between two radiologists disagreeing about whether a xeromammogram indicates cancer or the suspicion of cancer and disagreeing about whether it indicates cancer or is normal. The weighted kappa attempts to deal with this. `kap` provides two “prerecorded” weights, `w` and `w2`:

```
. kap rada radb, wgt(w)
Ratings weighted by:
  1.0000  0.6667  0.3333  0.0000
  0.6667  1.0000  0.6667  0.3333
  0.3333  0.6667  1.0000  0.6667
  0.0000  0.3333  0.6667  1.0000
```

Agreement	Expected agreement	Kappa	Std. err.	Z	Prob>Z
86.67%	69.11%	0.5684	0.0788	7.22	0.0000

The `w` weights are given by  $1 - |i - j|/(k - 1)$ , where  $i$  and  $j$  index the rows of columns of the ratings by the two raters and  $k$  is the maximum number of possible ratings. The weighting matrix is printed above the table. Here the rows and columns of the  $4 \times 4$  matrix correspond to the ratings normal, benign, suspicious, and cancerous.

A weight of 1 indicates that an observation should count as perfect agreement. The matrix has 1s down the diagonals—when both radiologists make the same assessment, they are in agreement. A weight of, say, 0.6667 means that they are in two-thirds agreement. In our matrix, they get that score if they are “one apart”—one radiologist assesses cancer and the other is merely suspicious, or one is suspicious and the other says benign, and so on. An entry of 0.3333 means that they are in one-third agreement, or, if you prefer, two-thirds disagreement. That is the score attached when they are “two apart”. Finally, they are in complete disagreement when the weight is zero, which happens only when they are three apart—one says cancer and the other says normal. ◀

### ▷ Example 3: Weighted kappa, prerecorded weight w2

The other prerecorded weight is `w2`, where the weights are given by  $1 - \{(i - j)/(k - 1)\}^2$ :

```
. kap rada radb, wgt(w2)
Ratings weighted by:
  1.0000  0.8889  0.5556  0.0000
  0.8889  1.0000  0.8889  0.5556
  0.5556  0.8889  1.0000  0.8889
  0.0000  0.5556  0.8889  1.0000
```

Agreement	Expected agreement	Kappa	Std. err.	Z	Prob>Z
94.77%	84.09%	0.6714	0.1079	6.22	0.0000

The `w2` weight makes the categories even more alike and is probably inappropriate here. ◀

### ► Example 4: Weighted kappa, user-defined weights

In addition to using prerecorded weights, we can define our own weights with the `kapwgt` command. For instance, we might feel that suspicious and cancerous are reasonably similar, that benign and normal are reasonably similar, but that the suspicious/cancerous group is nothing like the benign/normal group:

```
. kapwgt xm 1 \ .8 1 \ 0 0 1 \ 0 0 .8 1
. kapwgt xm
1.0000
0.8000 1.0000
0.0000 0.0000 1.0000
0.0000 0.0000 0.8000 1.0000
```

We name the weights `xm`, and after the weight name, we enter the lower triangle of the weighting matrix, using `\` to separate rows. We have four outcomes, so we continued entering numbers until we had defined the fourth row of the weighting matrix. If we type `kapwgt` followed by a name and nothing else, it shows us the weights recorded under that name. Satisfied that we have entered them correctly, we now use the weights to recalculate kappa:

```
. kap rada radb, wgt(xm)
Ratings weighted by:
  1.0000  0.8000  0.0000  0.0000
  0.8000  1.0000  0.0000  0.0000
  0.0000  0.0000  1.0000  0.8000
  0.0000  0.0000  0.8000  1.0000
```

Agreement	Expected agreement	Kappa	Std. err.	Z	Prob>Z
80.47%	52.67%	0.5874	0.0865	6.79	0.0000

◀

### □ Technical note

In addition to using weights for weighting the differences in categories, you can specify Stata's traditional weights for weighting the data. In the examples above, we have 85 observations in our dataset—one for each patient. If we only knew the table of outcomes—that there were 21 patients rated normal by both radiologists, etc.—it would be easier to enter the table into Stata and work from it. The easiest way to enter the data is with `tabi`; see [R] [tabulate twoway](#).

```
. tabi 21 12 0 0 \ 4 17 1 0 \ 3 9 15 2 \ 0 0 0 1, replace
```

row	col				Total
	1	2	3	4	
1	21	12	0	0	33
2	4	17	1	0	22
3	3	9	15	2	29
4	0	0	0	1	1
Total	28	38	16	3	85

Pearson chi2(9) = 77.8111 Pr = 0.000

`tabi` reported the Pearson  $\chi^2$  for this table, but we do not care about it. The important thing is that, with the `replace` option, `tabi` left the table in memory:

```
. list in 1/5
```

	row	col	pop
1.	1	1	21
2.	1	2	12
3.	1	3	0
4.	1	4	0
5.	2	1	4

The variable `row` is radiologist A's assessment, `col` is radiologist B's assessment, and `pop` is the number so assessed by both. Thus,

```
. kap row col [fweight=pop]
```

Agreement	Expected agreement	Kappa	Std. err.	Z	Prob>Z
63.53%	30.82%	0.4728	0.0694	6.81	0.0000

If we are going to keep these data, the names `row` and `col` are not indicative of what the data reflect. We could try (see [U] 12.6 Dataset, variable, and value labels)

```
. rename row rada
. rename col radb
. label var rada "Radiologist A's assessment"
. label var radb "Radiologist B's assessment"
. label define assess 1 normal 2 benign 3 suspect 4 cancer
. label values rada assess
. label values radb assess
. label data "Altman, page 403"
```

`kap`'s `tab` option, which can be used with or without weighted data, shows the table of assessments:

```
. kap rada radb [fweight=pop], tab
```

Radiologist A's assessment	Radiologist B's assessment				Total
	normal	benign	suspect	cancer	
normal	21	12	0	0	33
benign	4	17	1	0	22
suspect	3	9	15	2	29
cancer	0	0	0	1	1
Total	28	38	16	3	85

Agreement	Expected agreement	Kappa	Std. err.	Z	Prob>Z
63.53%	30.82%	0.4728	0.0694	6.81	0.0000

□

## □ Technical note

You have data on individual patients. There are two raters, and the possible ratings are 1, 2, 3, and 4, but neither rater ever used rating 3:

```
. use https://www.stata-press.com/data/r18/rate2no3, clear
. tabulate ratera raterb
```

Rater A	Rater B			Total
	1	2	4	
1	6	4	3	13
2	5	3	3	11
4	1	1	26	28
Total	12	8	32	52

Here `kap` would determine that the ratings are from the set  $\{1, 2, 4\}$  because those were the only values observed. `kap` would expect a user-defined weighting matrix to be  $3 \times 3$ , and if it were not, `kap` would issue an error message. In the formula-based weights, the calculation would be based on  $i, j = 1, 2, 3$  corresponding to the three observed ratings  $\{1, 2, 4\}$ .

Specifying the `absolute` option would clarify that the ratings are 1, 2, 3, and 4; it just so happens that rating 3 was never assigned. If a user-defined weighting matrix were also specified, `kap` would expect it to be  $4 \times 4$  or larger (larger because we can think of the ratings being 1, 2, 3, 4, 5, ... and it just so happens that ratings 5, 6, ... were never observed, just as rating 3 was not observed). In the formula-based weights, the calculation would be based on  $i, j = 1, 2, 4$ .

```
. kap ratera raterb, wgt(w)
```

Ratings weighted by:

```
1.0000 0.5000 0.0000
0.5000 1.0000 0.5000
0.0000 0.5000 1.0000
```

Agreement	Expected agreement	Kappa	Std. err.	Z	Prob>Z
79.81%	57.17%	0.5285	0.1169	4.52	0.0000

```
. kap ratera raterb, wgt(w) absolute
```

Ratings weighted by:

```
1.0000 0.6667 0.0000
0.6667 1.0000 0.3333
0.0000 0.3333 1.0000
```

Agreement	Expected agreement	Kappa	Std. err.	Z	Prob>Z
81.41%	55.08%	0.5862	0.1209	4.85	0.0000

If all conceivable ratings are observed in the data, specifying `absolute` makes no difference. For instance, if rater A assigns ratings  $\{1, 2, 4\}$  and rater B assigns  $\{1, 2, 3, 4\}$ , the complete set of assigned ratings is  $\{1, 2, 3, 4\}$ , the same that `absolute` would specify. Without `absolute`, it makes no difference whether the ratings are coded  $\{1, 2, 3, 4\}$ ,  $\{0, 1, 2, 3\}$ ,  $\{1, 7, 9, 100\}$ ,  $\{0, 1, 1.5, 2.0\}$ , or otherwise.

□

## More than two raters

For more than two raters, the mathematics are such that the two raters are not considered unique. For instance, if there are three raters, there is no assumption that the three raters who rate the first subject are the same as the three raters who rate the second. Although we call this the “more than two raters” case, it can be used with two raters when the raters’ identities vary.

The nonunique rater case can be usefully broken down into three subcases: 1) there are two possible ratings, which we will call positive and negative; 2) there are more than two possible ratings, but the number of raters per subject is the same for all subjects; and 3) there are more than two possible ratings, and the number of raters per subject varies. `kappa` handles all these cases. To emphasize that there is no assumption of constant identity of raters across subjects, the variables specified contain counts of the number of raters rating the subject into a particular category.

Jacob Cohen (1923–1998) was born in New York City. After studying psychology at City College of New York and New York University, he worked as a medical psychologist until 1959 when he became a full professor in the Department of Psychology at New York University. He made many contributions to research methods, including the kappa measure. He persistently emphasized the value of multiple regression and the importance of power and of measuring effects rather than testing significance.

### ► Example 5: Two ratings

Fleiss, Levin, and Paik (2003, 612) offer the following hypothetical ratings by different sets of raters on 25 subjects:

Subject	No. of raters	No. of pos. ratings	Subject	No. of raters	No. of pos. ratings
1	2	2	14	4	3
2	2	0	15	2	0
3	3	2	16	2	2
4	4	3	17	3	1
5	3	3	18	2	1
6	4	1	19	4	1
7	3	0	20	5	4
8	5	0	21	3	2
9	2	0	22	4	0
10	4	4	23	3	0
11	5	5	24	3	3
12	3	3	25	2	2
13	4	4			

We have entered these data into Stata, and the variables are called `subject`, `raters`, and `pos`. `kappa`, however, requires that we specify variables containing the number of positive ratings and negative ratings, that is, `pos` and `raters-pos`:

```
. use https://www.stata-press.com/data/r18/p612
. generate neg = raters-pos
. kappa pos neg
Two-outcomes, multiple raters:
```

Kappa	Z	Prob>Z
0.5415	5.28	0.0000

We would have obtained the same results if we had typed `kappa neg pos`.

◀

### ▶ Example 6: More than two ratings, constant number of raters, kappa

Each of 10 subjects is rated into one of three categories by five raters (Fleiss, Levin, and Paik 2003, 615):

```
. use https://www.stata-press.com/data/r18/p615, clear
. list
```

	subject	cat1	cat2	cat3
1.	1	1	4	0
2.	2	2	0	3
3.	3	0	0	5
4.	4	4	0	1
5.	5	3	0	2
6.	6	1	4	0
7.	7	5	0	0
8.	8	0	4	1
9.	9	1	0	4
10.	10	3	0	2

We obtain the kappa statistic:

```
. kappa cat1-cat3
```

Outcome	Kappa	Z	Prob>Z
Category 1	0.2917	2.92	0.0018
Category 2	0.6711	6.71	0.0000
Category 3	0.3490	3.49	0.0002
combined	0.4179	5.83	0.0000

The first part of the output shows the results of calculating kappa for each of the categories separately against an amalgam of the remaining categories. For instance, the `cat1` line is the two-rating kappa, where positive is `cat1` and negative is `cat2` or `cat3`. The test statistic, however, is calculated differently (see *Methods and formulas*). The combined kappa is the appropriately weighted average of the individual kappas. There is considerably less agreement about the rating of subjects into the first category than there is for the second.

◀

▷ Example 7: More than two ratings, constant number of raters, kap

Now, suppose that we have the same data as in the previous example but that the data are organized differently:

```
. use https://www.stata-press.com/data/r18/p615b
. list
```

	subject	rater1	rater2	rater3	rater4	rater5
1.	1	1	2	2	2	2
2.	2	1	1	3	3	3
3.	3	3	3	3	3	3
4.	4	1	1	1	1	3
5.	5	1	1	1	3	3
6.	6	1	2	2	2	2
7.	7	1	1	1	1	1
8.	8	2	2	2	2	3
9.	9	1	3	3	3	3
10.	10	1	1	1	3	3

Here we would use `kap` rather than `kappa` because the variables record ratings for each rater.

```
. kap rater1 rater2 rater3 rater4 rater5
```

There are 5 raters per subject:

Outcome	Kappa	Z	Prob>Z
1	0.2917	2.92	0.0018
2	0.6711	6.71	0.0000
3	0.3490	3.49	0.0002
combined	0.4179	5.83	0.0000

It does not matter which rater is which when there are more than two raters.

◀

▷ Example 8: More than two ratings, varying number of raters, kappa

In this unfortunate case, `kappa` can be calculated, but there is no test statistic for testing against  $\kappa > 0$ . We do nothing differently—`kappa` calculates the total number of raters for each subject, and, if it is not a constant, `kappa` suppresses the calculation of test statistics.

```
. use https://www.stata-press.com/data/r18/rvary
. list
```

	subject	cat1	cat2	cat3
1.	1	1	3	0
2.	2	2	0	3
3.	3	0	0	5
4.	4	4	0	1
5.	5	3	0	2
6.	6	1	4	0
7.	7	5	0	0
8.	8	0	4	1
9.	9	1	0	2
10.	10	3	0	2

```
. kappa cat1-cat3
```

Outcome	Kappa	Z	Prob>Z
Category 1	0.2685	.	.
Category 2	0.6457	.	.
Category 3	0.2938	.	.
combined	0.3816	.	.

Note: Number of ratings per subject vary; cannot calculate test statistics.

◀

### ► Example 9: More than two ratings, varying number of raters, kap

This case is similar to the [previous example](#), but the data are organized differently:

```
. use https://www.stata-press.com/data/r18/rvary2
. list
```

	subject	rater1	rater2	rater3	rater4	rater5
1.	1	1	2	2	.	2
2.	2	1	1	3	3	3
3.	3	3	3	3	3	3
4.	4	1	1	1	1	3
5.	5	1	1	1	3	3
6.	6	1	2	2	2	2
7.	7	1	1	1	1	1
8.	8	2	2	2	2	3
9.	9	1	3	.	.	3
10.	10	1	1	1	3	3

Here we specify kap instead of kappa because the variables record ratings for each rater.

```
. kap rater1-rater5
```

There are between 3 and 5 (median = 5.00) raters per subject:

Outcome	Kappa	Z	Prob>Z
1	0.2685	.	.
2	0.6457	.	.
3	0.2938	.	.
combined	0.3816	.	.

Note: Number of ratings per subject vary; cannot calculate test statistics.

◀

## Stored results

kap and kappa store the following in `r()`:

Scalars

<code>r(N)</code>	number of subjects (kap only)	<code>r(kappa)</code>	kappa
<code>r(prop_o)</code>	observed proportion of agreement (kap only)	<code>r(z)</code>	z statistic
<code>r(prop_e)</code>	expected proportion of agreement (kap only)	<code>r(se)</code>	standard error for kappa statistic

## Methods and formulas

The kappa statistic was first proposed by [Cohen \(1960\)](#). The generalization for weights reflecting the relative seriousness of each possible disagreement is due to [Cohen \(1968\)](#). The analysis-of-variance approach for  $k = 2$  and  $m \geq 2$  is due to [Landis and Koch \(1977b\)](#). See [Altman \(1991, 403–409\)](#) or [Dunn \(2000, chap. 2\)](#) for an introductory treatment and [Fleiss, Levin, and Paik \(2003, chap. 18\)](#) for a more detailed treatment. All formulas below are as presented in [Fleiss, Levin, and Paik \(2003\)](#). Let  $m$  be the number of raters, and let  $k$  be the number of rating outcomes.

Methods and formulas are presented under the following headings:

*kap*:  $m = 2$   
*kappa*:  $m > 2, k = 2$   
*kappa*:  $m > 2, k > 2$

### kap: m = 2

Define  $w_{ij}$  ( $i = 1, \dots, k$  and  $j = 1, \dots, k$ ) as the weights for agreement and disagreement (`wgt()`), or, if the data are not weighted, define  $w_{ii} = 1$  and  $w_{ij} = 0$  for  $i \neq j$ . If `wgt(w)` is specified,  $w_{ij} = 1 - |i - j|/(k - 1)$ . If `wgt(w2)` is specified,  $w_{ij} = 1 - \{(i - j)/(k - 1)\}^2$ .

The observed proportion of agreement is

$$p_o = \sum_{i=1}^k \sum_{j=1}^k w_{ij} p_{ij}$$

where  $p_{ij}$  is the fraction of ratings  $i$  by the first rater and  $j$  by the second. The expected proportion of agreement is

$$p_e = \sum_{i=1}^k \sum_{j=1}^k w_{ij} p_{i \cdot} p_{\cdot j}$$

where  $p_{i \cdot} = \sum_j p_{ij}$  and  $p_{\cdot j} = \sum_i p_{ij}$ .

Kappa is given by  $\hat{\kappa} = (p_o - p_e)/(1 - p_e)$ .

The standard error of  $\hat{\kappa}$  for testing against 0 is

$$\hat{s}_0 = \frac{1}{(1 - p_e)\sqrt{n}} \left( \left[ \sum_i \sum_j p_{i \cdot} p_{\cdot j} \{w_{ij} - (\bar{w}_{i \cdot} + \bar{w}_{\cdot j})\}^2 \right] - p_e^2 \right)^{1/2}$$

where  $n$  is the number of subjects being rated,  $\bar{w}_{i \cdot} = \sum_j p_{\cdot j} w_{ij}$ , and  $\bar{w}_{\cdot j} = \sum_i p_{i \cdot} w_{ij}$ . The test statistic  $Z = \hat{\kappa}/\hat{s}_0$  is assumed to be distributed  $N(0, 1)$ .

### kappa: m > 2, k = 2

Each subject  $i$ ,  $i = 1, \dots, n$ , is found by  $x_i$  of  $m_i$  raters to be positive (the choice as to what is labeled positive is arbitrary).

The overall proportion of positive ratings is  $\bar{p} = \sum_i x_i / (n\bar{m})$ , where  $\bar{m} = \sum_i m_i / n$ . The between-subjects mean square is (approximately)

$$B = \frac{1}{n} \sum_i \frac{(x_i - m_i \bar{p})^2}{m_i}$$

and the within-subject mean square is

$$W = \frac{1}{n(\bar{m} - 1)} \sum_i \frac{x_i(m_i - x_i)}{m_i}$$

Kappa is then defined as

$$\hat{\kappa} = \frac{B - W}{B + (\bar{m} - 1)W}$$

The standard error for testing against 0 (Fleiss and Cuzick 1979) is approximately equal to and is calculated as

$$\hat{s}_0 = \frac{1}{(\bar{m} - 1)\sqrt{n\bar{m}_H}} \left\{ 2(\bar{m}_H - 1) + \frac{(\bar{m} - \bar{m}_H)(1 - 4\bar{p}\bar{q})}{\bar{m}\bar{p}\bar{q}} \right\}^{1/2}$$

where  $\bar{m}_H$  is the harmonic mean of  $m_i$  and  $\bar{q} = 1 - \bar{p}$ .

The test statistic  $Z = \hat{\kappa}/\hat{s}_0$  is assumed to be distributed  $N(0, 1)$ .

**kappa:  $m > 2$ ,  $k > 2$** 

Let  $x_{ij}$  be the number of ratings on subject  $i$ ,  $i = 1, \dots, n$ , into category  $j$ ,  $j = 1, \dots, k$ . Define  $\bar{p}_j$  as the overall proportion of ratings in category  $j$ ,  $\bar{q}_j = 1 - \bar{p}_j$ , and let  $\hat{\kappa}_j$  be the kappa statistic given above for  $k = 2$  when category  $j$  is compared with the amalgam of all other categories. Kappa is

$$\bar{\kappa} = \frac{\sum_j \bar{p}_j \bar{q}_j \hat{\kappa}_j}{\sum_j \bar{p}_j \bar{q}_j}$$

(Landis and Koch 1977b). In the case where the number of raters per subject,  $\sum_j x_{ij}$ , is a constant  $m$  for all  $i$ , Fleiss, Nee, and Landis (1979) derived the following formulas for the approximate standard errors. The standard error for testing  $\hat{\kappa}_j$  against 0 is

$$\hat{s}_j = \left\{ \frac{2}{nm(m-1)} \right\}^{1/2}$$

and the standard error for testing  $\bar{\kappa}$  is

$$\bar{s} = \frac{\sqrt{2}}{\sum_j \bar{p}_j \bar{q}_j \sqrt{nm(m-1)}} \left\{ \left( \sum_j \bar{p}_j \bar{q}_j \right)^2 - \sum_j \bar{p}_j \bar{q}_j (\bar{q}_j - \bar{p}_j) \right\}^{1/2}$$

## Description

`kdensity` produces kernel density estimates and graphs the result.

## Quick start

Graph of the kernel density estimate for `v1`

```
kdensity v1
```

Add a normal curve

```
kdensity v1, normal
```

With a kernel bandwidth of 2

```
kdensity v1, bwidth(2)
```

Gaussian kernel function for `v1`

```
kdensity v1, kernel(gaussian)
```

Kernel density estimate for `v1` and `v2` in the same graph area

```
twoway kdensity v1 || kdensity v2
```

Separate graphs of kernel density estimate of `v1` for each level of `catvar`

```
twoway kdensity v1, by(catvar)
```

Kernel density estimates of `v1` for `catvar = 0` and `1` in the same graph area

```
twoway kdensity v1 if catvar==0 || kdensity v1 if catvar==1
```

## Menu

Statistics > Nonparametric analysis > Kernel density estimation

## Syntax

```
kdensity varname [if] [in] [weight] [, options]
```

<i>options</i>	Description
Main	
<u>kernel</u> ( <i>kernel</i> )	specify kernel function; default is <code>kernel(epanechnikov)</code>
<u>bwidth</u> (#)	half-width of kernel
<u>generate</u> ( <i>newvar<sub>x</sub></i> <i>newvar<sub>d</sub></i> )	store the estimation points in <i>newvar<sub>x</sub></i> and the density estimate in <i>newvar<sub>d</sub></i>
<u>n</u> (#)	estimate density using # points; default is <code>min(N, 50)</code>
<u>at</u> ( <i>var<sub>x</sub></i> )	estimate density using the values specified by <i>var<sub>x</sub></i>
<u>nograph</u>	suppress graph
Kernel plot	
<u>cline_options</u>	affect rendition of the plotted kernel density estimate
Density plots	
<u>normal</u>	add normal density to the graph
<u>normopts</u> ( <i>cline_options</i> )	affect rendition of normal density
<u>student</u> (#)	add Student's <i>t</i> density with # degrees of freedom to the graph
<u>stopts</u> ( <i>cline_options</i> )	affect rendition of the Student's <i>t</i> density
Add plots	
<u>addplot</u> ( <i>plot</i> )	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
<u>twoway_options</u>	any options other than <code>by()</code> documented in [G-3] <a href="#">twoway_options</a>

<i>kernel</i>	Description
<u>epanechnikov</u>	Epanechnikov kernel function; the default
<u>epan2</u>	alternative Epanechnikov kernel function
<u>biweight</u>	biweight kernel function
<u>cosine</u>	cosine trace kernel function
<u>gaussian</u>	Gaussian kernel function
<u>parzen</u>	Parzen kernel function
<u>rectangle</u>	rectangle kernel function
<u>triangle</u>	triangle kernel function

`collect` is allowed; see [U] 11.1.10 [Prefix commands](#).

`fweights`, `awweights`, and `iweights` are allowed; see [U] 11.1.6 [weight](#).

## Options

Main

`kernel` (*kernel*) specifies the kernel function for use in calculating the kernel density estimate. The default kernel is the Epanechnikov kernel (`epanechnikov`).

`bwidth(#)` specifies the half-width of the kernel, the width of the density window around each point.

If `bwidth()` is not specified, the “optimal” width is calculated and used. The optimal width is the width that would minimize the mean integrated squared error if the data were Gaussian and a Gaussian kernel were used, so it is not optimal in any global sense. In fact, for multimodal and highly skewed densities, this width is usually too wide and oversmooths the density (Silverman 1986).

`generate(newvarx newvard)` stores the results of the estimation. `newvarx` will contain the points at which the density is estimated. `newvard` will contain the density estimate.

`n(#)` specifies the number of points at which the density estimate is to be evaluated. The default is  $\min(N, 50)$ , where  $N$  is the number of observations in memory.

`at(varx)` specifies a variable that contains the values at which the density should be estimated. This option allows you to more easily obtain density estimates for different variables or different subsamples of a variable and then overlay the estimated densities for comparison.

`nograph` suppresses the graph. This option is often used with the `generate()` option.

#### Kernel plot

`cline_options` affect the rendition of the plotted kernel density estimate. See [G-3] [cline\\_options](#).

#### Density plots

`normal` requests that a normal density be overlaid on the density estimate for comparison.

`normopts(cline_options)` specifies details about the rendition of the normal curve, such as the color and style of line used. See [G-3] [cline\\_options](#).

`student(#)` specifies that a Student’s  $t$  density with  $\#$  degrees of freedom be overlaid on the density estimate for comparison.

`stopts(cline_options)` affects the rendition of the Student’s  $t$  density. See [G-3] [cline\\_options](#).

#### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

#### Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

Kernel density estimators approximate the density  $f(x)$  from observations on  $x$ . Histograms do this, too, and the histogram itself is a kind of kernel density estimate. The data are divided into nonoverlapping intervals, and counts are made of the number of data points within each interval. Histograms are bar graphs that depict these frequency counts—the bar is centered at the midpoint of each interval—and its height reflects the average number of data points in the interval.

In more general kernel density estimates, the range is still divided into intervals, and estimates of the density at the center of intervals are produced. One difference is that the intervals are allowed to overlap. We can think of sliding the interval—called a window—along the range of the data and collecting the center-point density estimates. The second difference is that, rather than merely counting the number of observations in a window, a kernel density estimator assigns a weight between

0 and 1—based on the distance from the center of the window—and sums the weighted values. The function that determines these weights is called the kernel.

Kernel density estimates have the advantages of being smooth and of being independent of the choice of origin (corresponding to the location of the bins in a histogram).

See [Salgado-Ugarte, Shimizu, and Taniuchi \(1993\)](#) and [Fox \(1990\)](#) for discussions of kernel density estimators that stress their use as exploratory data-analysis tools.

[Cox \(2007\)](#) gives a lucid introductory tutorial on kernel density estimation with several Stata produced examples. He provides tips and tricks for working with skewed or bounded distributions and applying the same techniques to estimate the intensity function of a point process.

### ► Example 1: Histogram and kernel density estimate

[Goeden \(1978\)](#) reports data consisting of 316 length observations of coral trout. We wish to investigate the underlying density of the lengths. To begin on familiar ground, we might draw a histogram. In [\[R\] histogram](#), we suggest setting the bins to  $\min(\sqrt{n}, 10 \cdot \log_{10} n)$ , which for  $n = 316$  is roughly 18:

```
. use https://www.stata-press.com/data/r18/trocolen
. histogram length, bins(18)
(bin=18, start=226, width=19.77778)
```

The kernel density estimate, on the other hand, is smooth.

```
. kdensity length
```

Kernel density estimators are, however, sensitive to an assumption, just as are histograms. In histograms, we specify a number of bins. For kernel density estimators, we specify a width. In the graph above, we used the default width. `kdensity` is smarter than `twoway histogram` in that its default width is not a fixed constant. Even so, the default width is not necessarily best.

`kdensity` stores the width in the returned scalar `bwidth`, so typing `display r(bwidth)` reveals it. Doing this, we discover that the width is approximately 20.

Widths are similar to the inverse of the number of bins in a histogram in that smaller widths provide more detail. The units of the width are the units of  $x$ , the variable being analyzed. The width is specified as a half-width, meaning that the kernel density estimator with half-width 20 corresponds to sliding a window of size 40 across the data.

We can specify half-widths for ourselves by using the `bwidth()` option. Smaller widths do not smooth the density as much:

```
. kdensity length, bwidth(10)
```

```
. kdensity length, bwidth(15)
```

### ▷ Example 2: Different kernels can produce different results

When widths are held constant, different kernels can produce surprisingly different results. This is really an attribute of the kernel and width combination; for a given width, some kernels are more sensitive than others at identifying peaks in the density estimate.

We can see this when using a dataset with lots of peaks. In the automobile dataset, we characterize the density of weight, the weight of the vehicles. Below, we compare the Epanechnikov and Parzen kernels.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. kdensity weight, kernel(epanechnikov) nograph generate(x epan)
. kdensity weight, kernel(parzen) nograph generate(x2 parzen)
. label var epan "Epanechnikov density estimate"
. label var parzen "Parzen density estimate"
. line epan parzen x, sort ytitle("Density") legend(pos(6))
```

We did not specify a width, so we obtained the default width. That width is not a function of the selected kernel, but of the data. See [Methods and formulas](#) for the calculation of the optimal width. ↩

### ▷ Example 3: Density with overlaid normal density

In examining the density estimates, we may wish to overlay a normal density or a Student's  $t$  density for comparison. Using automobile weights, we can get an idea of the distance from normality by using the `normal` option.

```
. kdensity weight, kernel(epanechnikov) normal
```

### ▷ Example 4: Compare two densities

We also may want to compare two or more densities. In this example, we will compare the density estimates of the weights for the foreign and domestic cars.

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. kdensity weight, nograph generate(x fx)
. kdensity weight if foreign==0, nograph generate(fx0) at(x)
. kdensity weight if foreign==1, nograph generate(fx1) at(x)
. label var fx0 "Domestic cars"
. label var fx1 "Foreign cars"
```

```
. line fx0 fx1 x, sort ytitle(Density)
```

◀

### □ Technical note

Although all the examples we included had densities of less than 1, the density may exceed 1.

The probability density  $f(x)$  of a continuous variable,  $x$ , has the units and dimensions of the reciprocal of  $x$ . If  $x$  is measured in meters,  $f(x)$  has units 1/meter. Thus, the density is not measured on a probability scale, so it is possible for  $f(x)$  to exceed 1.

To see this, think of a uniform density on the interval 0 to 1. The area under the density curve is 1: this is the product of the density, which is constant at 1, and the range, which is 1. If the variable is then transformed by doubling, the area under the curve remains 1 and is the product of the density, constant at 0.5, and the range, which is 2. Conversely, if the variable is transformed by halving, the area under the curve also remains at 1 and is the product of the density, constant at 2, and the range, which is 0.5. (Strictly, the range is measured in certain units, and the density is measured in the reciprocal of those units, so the units cancel on multiplication.)

□

## Stored results

**kdensity** stores the following in `r()`:

### Scalars

<code>r(bwidth)</code>	kernel bandwidth
<code>r(n)</code>	number of points at which the estimate was evaluated
<code>r(scale)</code>	density bin width

### Macros

<code>r(kernel)</code>	name of kernel
------------------------	----------------

## Methods and formulas

A kernel density estimate is formed by summing the weighted values calculated with the kernel function  $K$ , as in

$$\hat{f}_K = \frac{1}{qh} \sum_{i=1}^n w_i K\left(\frac{x - X_i}{h}\right)$$

where  $q = \sum_i w_i$  if weights are frequency weights (`fweight`) or analytic weights (`aweight`), and  $q = 1$  if weights are importance weights (`iweights`). Analytic weights are rescaled so that  $\sum_i w_i = n$  (see [U] 11 Language syntax). If weights are not used, then  $w_i = 1$ , for  $i = 1, \dots, n$ . `kdensity` includes seven different kernel functions. The Epanechnikov is the default function if no other kernel is specified and is the most efficient in minimizing the mean integrated squared error.

Kernel	Formula	
Biweight	$K[z] = \begin{cases} \frac{15}{16}(1 - z^2)^2 \\ 0 \end{cases}$	if $ z  < 1$ otherwise
Cosine	$K[z] = \begin{cases} 1 + \cos(2\pi z) \\ 0 \end{cases}$	if $ z  < 1/2$ otherwise
Epanechnikov	$K[z] = \begin{cases} \frac{3}{4}(1 - \frac{1}{5}z^2)/\sqrt{5} \\ 0 \end{cases}$	if $ z  < \sqrt{5}$ otherwise
Epan2	$K[z] = \begin{cases} \frac{3}{4}(1 - z^2) \\ 0 \end{cases}$	if $ z  < 1$ otherwise
Gaussian	$K[z] = \frac{1}{\sqrt{2\pi}} e^{-z^2/2}$	
Parzen	$K[z] = \begin{cases} \frac{4}{3} - 8z^2 + 8 z ^3 \\ 8(1 -  z )^3/3 \\ 0 \end{cases}$	if $ z  \leq 1/2$ if $1/2 <  z  \leq 1$ otherwise
Rectangular	$K[z] = \begin{cases} 1/2 \\ 0 \end{cases}$	if $ z  < 1$ otherwise
Triangular	$K[z] = \begin{cases} 1 -  z  \\ 0 \end{cases}$	if $ z  < 1$ otherwise

From the definitions given in the table, we can see that the choice of  $h$  will drive how many values are included in estimating the density at each point. This value is called the *window width* or *bandwidth*. If the window width is not specified, it is determined as

$$m = \min\left(\sqrt{\text{variance}_x}, \frac{\text{interquartile range}_x}{1.349}\right)$$

$$h = \frac{0.9m}{n^{1/5}}$$

where  $x$  is the variable for which we wish to estimate the kernel and  $n$  is the number of observations.

Most researchers agree that the choice of kernel is not as important as the choice of bandwidth. There is a great deal of literature on choosing bandwidths under various conditions; see, for example, Parzen (1962) or Tapia and Thompson (1978). Also see Newton (1988) for a comparison with sample spectral density estimation in time-series applications.

## Acknowledgments

We gratefully acknowledge the previous work by Isaías H. Salgado-Ugarte of the Universidad Nacional Autónoma de México, Makoto Shimizu of the University of Tokyo, and Toru Taniuchi formerly of the University of Tokyo; see [Salgado-Ugarte, Shimizu, and Taniuchi \(1993\)](#). Their article provides a good overview of the subject of univariate kernel density estimation and presents arguments for its use in exploratory data analysis.

# Title

**ksmirnov** — Kolmogorov–Smirnov equality-of-distributions test

[Description](#)

[Syntax](#)

[Stored results](#)

[Also see](#)

[Quick start](#)

[Options for two-sample test](#)

[Methods and formulas](#)

[Menu](#)

[Remarks and examples](#)

[References](#)

## Description

`ksmirnov` performs one- and two-sample Kolmogorov–Smirnov tests of the equality of distributions. A one-sample test compares the distribution of the tested variable with the specified distribution. A two-sample test tests the equality of the distributions of two samples.

When testing for normality, please see [\[R\] sktest](#) and [\[R\] swilk](#).

## Quick start

One-sample test comparing the distribution of `v1` with a Student's  $t$  distribution with 5 degrees of freedom

```
ksmirnov v1 = t(5,v1)
```

Two-sample test comparing distributions of `v2` in two groups defined by `catvar`

```
ksmirnov v2, by(catvar)
```

Same as above, but calculate an exact  $p$ -value

```
ksmirnov v2, by(catvar) exact
```

## Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Kolmogorov–Smirnov test

## Syntax

One-sample Kolmogorov–Smirnov test

```
ksmirnov varname = exp [if] [in]
```

Two-sample Kolmogorov–Smirnov test

```
ksmirnov varname [if] [in] , by(groupvar) [exact]
```

In the first syntax, *varname* is the variable whose distribution is being tested, and *exp* must evaluate to the corresponding (theoretical) cumulative. In the second syntax, *groupvar* must take on two distinct values. The distribution of *varname* for the first value of *groupvar* is compared with that of the second value.

`collect` is allowed; see [U] 11.1.10 Prefix commands.

## Options for two-sample test

Main

`by(groupvar)` is required. It specifies a binary variable that identifies the two groups.

`exact` specifies that the exact *p*-value be computed.

## Remarks and examples

### ► Example 1: Two-sample test

Say that we have data on *x* that resulted from two different experiments, labeled as `group==1` and `group==2`. Our data contain

```
. use https://www.stata-press.com/data/r18/ksxmpl
. list
```

	group	x
1.	2	2
2.	1	0
3.	2	3
4.	1	4
5.	1	5
6.	2	8
7.	2	10

We wish to use the two-sample Kolmogorov–Smirnov test to determine if there are any differences in the distribution of *x* for these two groups:

```
. ksmirnov x, by(group)
```

Two-sample Kolmogorov–Smirnov test for equality of distribution functions

Smaller group	D	p-value
1	0.5000	0.424
2	-0.1667	0.909
Combined K-S	0.5000	0.785

The first line tests the hypothesis that  $x$  for group 1 contains *smaller* values than for group 2. The largest difference between the distribution functions is 0.5. The approximate asymptotic  $p$ -value for this is 0.424, which is not significant.

The second line tests the hypothesis that  $x$  for group 1 contains *larger* values than for group 2. The largest difference between the distribution functions in this direction is 0.1667. The approximate asymptotic  $p$ -value for this small difference is 0.909.

Finally, the approximate asymptotic  $p$ -value for the combined test is 0.785. The approximate  $p$ -values `ksmirnov` calculates are based on the five-term approximation of the asymptotic distributions derived by [Smirnov \(1933\)](#). These approximations are not good for small samples ( $n < 50$ ). They are too conservative.

An exact  $p$ -value can be calculated using the `exact` option:

```
. ksmirnov x, by(group) exact
Two-sample Kolmogorov-Smirnov test for equality of distribution functions
```

Smaller group	D	p-value	Exact
1	0.5000	0.424	
2	-0.1667	0.909	
Combined K-S	0.5000	0.785	0.657

◀

## ► Example 2: One-sample test

Let's now test whether  $x$  in the example above is distributed normally. Kolmogorov–Smirnov is not a particularly powerful test in testing for normality, and we do not endorse such use of it; see [\[R\] sktest](#) and [\[R\] swilk](#) for better tests.

In any case, we will test against a normal distribution with the same mean and standard deviation:

```
. summarize x
```

Variable	Obs	Mean	Std. dev.	Min	Max
x	7	4.571429	3.457222	0	10

```
. ksmirnov x = normal((x-4.571429)/3.457222)
One-sample Kolmogorov-Smirnov test against theoretical distribution
normal((x-4.571429)/3.457222)
```

Smaller group	D	p-value
x	0.1650	0.683
Cumulative	-0.1250	0.803
Combined K-S	0.1650	0.991

Because Stata has no way of knowing that we based this calculation on the calculated mean and standard deviation of  $x$ , the  $p$ -values will be slightly conservative in addition to being approximations. Nevertheless, they clearly indicate that the data cannot be distinguished from normally distributed data.

◀

## Stored results

`ksmirnov` stores the following in `r()`:

### Scalars

<code>r(D_1)</code>	<i>D</i> from line 1
<code>r(p_1)</code>	<i>p</i> -value from line 1
<code>r(D_2)</code>	<i>D</i> from line 2
<code>r(p_2)</code>	<i>p</i> -value from line 2
<code>r(D)</code>	combined <i>D</i>
<code>r(p)</code>	combined <i>p</i> -value
<code>r(p_exact)</code>	exact combined <i>p</i> -value

### Macros

<code>r(group1)</code>	name of group from line 1
<code>r(group2)</code>	name of group from line 2

## Methods and formulas

In general, the Kolmogorov–Smirnov test (Kolmogorov 1933; Smirnov 1933; also see Conover [1999], 428–465) is not very powerful against differences in the tails of distributions. In return for this, it is fairly powerful for alternative hypotheses that involve lumpiness or clustering in the data.

The directional hypotheses are evaluated with the statistics

$$D^+ = \max_x \{F(x) - G(x)\}$$

$$D^- = \min_x \{F(x) - G(x)\}$$

where  $F(x)$  and  $G(x)$  are the empirical distribution functions for the sample being compared. The combined statistic is

$$D = \max(|D^+|, |D^-|)$$

The *p*-value for this statistic may be obtained by evaluating the asymptotic limiting distribution. Let  $m$  be the sample size for the first sample, and let  $n$  be the sample size for the second sample. Smirnov (1933) shows that

$$\lim_{m,n \rightarrow \infty} \Pr\left\{\sqrt{mn/(m+n)}D_{m,n} \leq z\right\} = 1 - 2 \sum_{i=1}^{\infty} (-1)^{i-1} \exp(-2i^2 z^2)$$

The first five terms form the approximation  $P_a$  used by Stata. The exact *p*-value is calculated by a counting algorithm; see Gibbons and Chakraborti (2011, 236–238).

Andrei Nikolayevich Kolmogorov (1903–1987), of Russia, was one of the great mathematicians of the twentieth century, making outstanding contributions in many different branches, including set theory, measure theory, probability and statistics, approximation theory, functional analysis, classical dynamics, and theory of turbulence. He was a faculty member at Moscow State University for more than 60 years.

Nikolai Vasilyevich Smirnov (1900–1966) was a Russian statistician whose work included contributions in nonparametric statistics, order statistics, and goodness of fit. After army service and the study of philosophy and philology, he turned to mathematics and eventually rose to be head of mathematical statistics at the Steklov Mathematical Institute in Moscow.

# Title

**kwallis** — Kruskal–Wallis equality-of-populations rank test

<a href="#">Description</a>	<a href="#">Quick start</a>	<a href="#">Menu</a>	<a href="#">Syntax</a>
<a href="#">Option</a>	<a href="#">Remarks and examples</a>	<a href="#">Stored results</a>	<a href="#">Methods and formulas</a>
<a href="#">References</a>	<a href="#">Also see</a>		

## Description

`kwallis` performs a Kruskal–Wallis test of the hypothesis that several samples are from the same population. This test is a multisample generalization of the two-sample Wilcoxon (Mann–Whitney) rank-sum test.

## Quick start

Test the equality of distribution of `v1` across all levels of categorical variable `cvar`

```
kwallis v1, by(cvar)
```

Same as above, but perform the test only for observations with `v2 = 1`

```
kwallis v1 if v2==1, by(cvar)
```

## Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Kruskal–Wallis rank test

## Syntax

```
kwallis varname [if] [in], by(groupvar)
```

`collect` is allowed; see [U] [11.1.10 Prefix commands](#).

## Option

`by(groupvar)` is required. It specifies a variable that identifies the groups.

## Remarks and examples

### ▷ Example 1

We have data on the 50 states. The data contain the median age of the population, `medage`, and the region of the country, `region`, for each state. We wish to test for the equality of the median age distribution across all four regions simultaneously:

```
. use https://www.stata-press.com/data/r18/census
(1980 Census data by state)
. kwallis medage, by(region)
Kruskal-Wallis equality-of-populations rank test
```

region	Obs	Rank sum
NE	9	376.50
N Cntrl	12	294.00
South	16	398.00
West	13	206.50

```
chi2(3) = 17.041
Prob = 0.0007
chi2(3) with ties = 17.062
Prob = 0.0007
```

From the output, we see that we can reject the hypothesis that the populations are the same at any level below 0.07%. ◀

## Stored results

kwallis stores the following in `r()`:

Scalars

```
r(df)          degrees of freedom
r(chi2)         $\chi^2$ 
r(chi2_adj)     $\chi^2$  adjusted for ties
```

## Methods and formulas

The Kruskal–Wallis test (Kruskal and Wallis 1952, 1953; also see Altman [1991, 213–215]; Conover [1999, 288–297]; and Riffenburgh [2012, sec. 11.6]) is a multiple-sample generalization of the two-sample Wilcoxon (also called Mann–Whitney) rank-sum test (Wilcoxon 1945; Mann and Whitney 1947). Samples of sizes  $n_j$ ,  $j = 1, \dots, m$ , are combined and ranked in ascending order of magnitude. Tied values are assigned the average ranks. Let  $n$  denote the overall sample size, and let  $R_j = \sum_{i=1}^{n_j} R(X_{ji})$  denote the sum of the ranks for the  $j$ th sample. The Kruskal–Wallis one-way analysis-of-variance test,  $H$ , is defined as

$$H = \frac{1}{S^2} \left\{ \sum_{j=1}^m \frac{R_j^2}{n_j} - \frac{n(n+1)^2}{4} \right\}$$

where

$$S^2 = \frac{1}{n-1} \left\{ \sum_{\text{all ranks}} R(X_{ji})^2 - \frac{n(n+1)^2}{4} \right\}$$

If there are no ties, this equation simplifies to

$$H = \frac{12}{n(n+1)} \sum_{j=1}^m \frac{R_j^2}{n_j} - 3(n+1)$$

The sampling distribution of  $H$  is approximately  $\chi^2$  with  $m - 1$  degrees of freedom.

William Henry Kruskal (1919–2005) was born in New York City. He studied mathematics and statistics at Antioch College, Harvard, and Columbia, and joined the University of Chicago in 1951. He made many outstanding contributions to linear models, nonparametric statistics, government statistics, and the history and methodology of statistics.

Wilson Allen Wallis (1912–1998) was born in Philadelphia. He studied psychology and economics at the Universities of Minnesota and Chicago and at Columbia. He taught at Yale, Stanford, and Chicago, before moving as president (later chancellor) to the University of Rochester in 1962. He also served in several Republican administrations. Wallis served as editor of the *Journal of the American Statistical Association*, coauthored a popular introduction to statistics, and contributed to nonparametric statistics.

[References](#)

## Description

`ladder` searches a subset of the ladder of powers (Tukey 1977) for a transform that converts *varname* into a normally distributed variable.

`gladder` and `qladder` each display a graph matrix. `gladder` displays nine histograms of transforms of *varname* according to the ladder of powers. `qladder` displays the quantiles of transforms of *varname* according to the ladder of powers against the quantiles of a normal distribution.

## Quick start

Table showing Tukey's ladder of powers transformations for *v*

```
ladder v
```

Same as above, but with separate tables for each level of the categorical variable *catvar*

```
by catvar: ladder v
```

Display transformations graphically using histograms

```
gladder v
```

Same as above, but using quantile plots

```
qladder v
```

## Menu

### **ladder**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder of powers

### **gladder**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder-of-powers histograms

### **qladder**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder-of-powers quantile-normal plots

## Syntax

*Ladder of powers*

```
ladder varname [if] [in] [ , generate(newvar) noadjust ]
```

*Ladder-of-powers histograms*

```
gladder varname [if] [in] [ , histogram_options combine_options ]
```

*Ladder-of-powers quantile–normal plots*

```
qladder varname [if] [in] [ , qnorm_options combine_options ]
```

by and collect are allowed with ladder; see [U] **11.1.10 Prefix commands**.

## Options for ladder

Main

`generate(newvar)` saves the transformed values corresponding to the minimum  $\chi^2$  value from the table. We do not recommend using `generate()` because it is literal in interpreting the minimum, thus ignoring nearly equal but perhaps more interpretable transforms.

`noadjust` is the `noadjust` option to `sktest`; see [R] **sktest**.

## Options for gladder

*histogram\_options* affect the rendition of the histograms across all relevant transformations; see [R] **histogram**. Here the `normal` option is assumed, so you must supply the `nonnormal` option to suppress the overlaid normal density. Also, `gladder` does not allow the `width(#)` option of `histogram`.

*combine\_options* are any of the options documented in [G-2] **graph combine**. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

## Options for qladder

*qnorm\_options* affect the rendition of the quantile–normal plots across all relevant transformations. See [R] **Diagnostic plots**.

*combine\_options* are any of the options documented in [G-2] **graph combine**. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

## Remarks and examples

### ▷ Example 1: ladder

We have data on the mileage rating of 74 automobiles and wish to find a transform that makes the variable normally distributed:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. ladder mpg
```

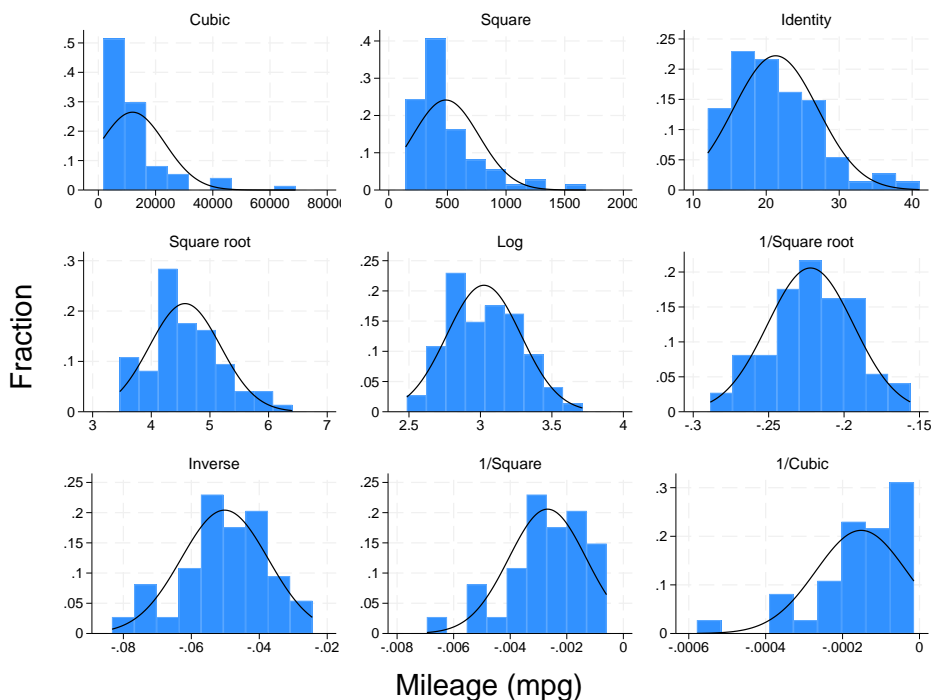

Transformation	Formula	chi2(2)	Prob > chi2
Cubic	$\text{mpg}^3$	43.59	0.000
Square	$\text{mpg}^2$	27.03	0.000
Identity	$\text{mpg}$	10.95	0.004
Square root	$\sqrt{\text{mpg}}$	4.94	0.084
Log	$\log(\text{mpg})$	0.87	0.647
1/(Square root)	$1/\sqrt{\text{mpg}}$	0.20	0.905
Inverse	$1/\text{mpg}$	2.36	0.307
1/Square	$1/(\text{mpg}^2)$	11.99	0.002
1/Cubic	$1/(\text{mpg}^3)$	24.30	0.000

If we had typed `ladder mpg, gen(mpgx)`, the variable `mpgx` containing  $1/\sqrt{\text{mpg}}$  would have been automatically generated for us. This is the perfect example of why you should not, in general, specify the `generate()` option. We also cannot reject the hypothesis that the inverse of `mpg` is normally distributed and that  $1/\text{mpg}$ —gallons per mile—has a better interpretation. It is a measure of energy consumption.

## ► Example 2: gladder

gladder explores the same transforms as ladder but presents results graphically:

```
. gladder mpg, fraction
```

Histograms by transformation

◀

## □ Technical note

gladder is useful pedagogically, but be careful when using it for research work, especially with many observations. For instance, consider the following data on the average July temperature in degrees Fahrenheit for 954 U.S. cities:

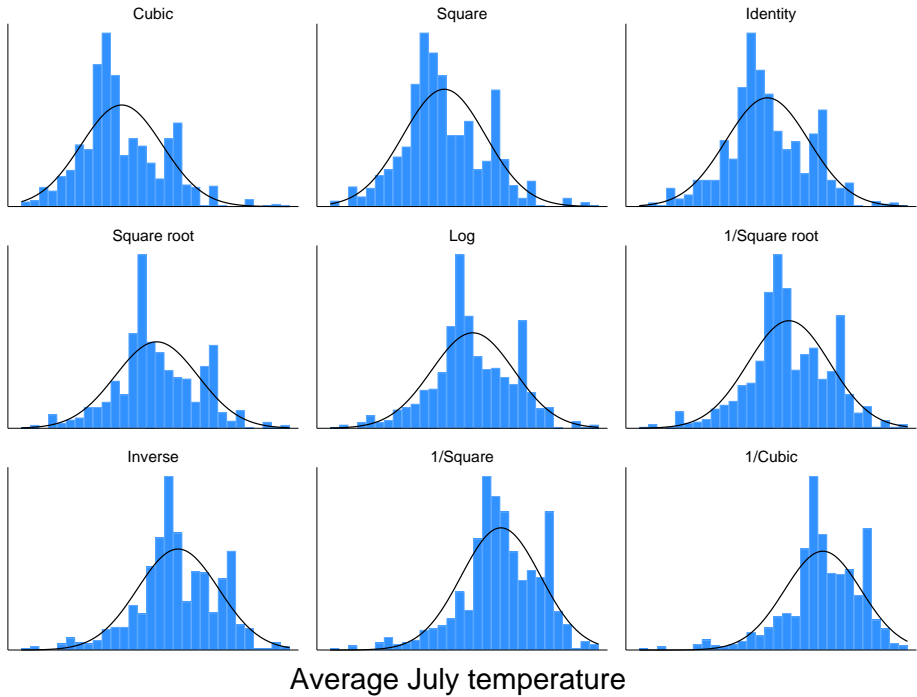

```
. use https://www.stata-press.com/data/r18/citytemp
(City temperature data)
```

```
. ladder tempjuly
```

Transformation	Formula	chi2(2)	Prob > chi2
Cubic	tempjuly <sup>3</sup>	47.49	0.000
Square	tempjuly <sup>2</sup>	19.70	0.000
Identity	tempjuly	3.83	0.147
Square root	sqrt(tempjuly)	1.83	0.400
Log	log(tempjuly)	5.40	0.067
1/(Square root)	1/sqrt(tempjuly)	13.72	0.001
Inverse	1/tempjuly	26.36	0.000
1/Square	1/(tempjuly <sup>2</sup> )	64.44	0.000
1/Cubic	1/(tempjuly <sup>3</sup> )	116.16	0.000

From the table, we see that there is certainly a difference in normality between the square and square-root transform. If, however, you can see the difference between the transforms in the diagram below, you have better eyes than we do:

```
. gladder tempjuly, l1title("") ylabel(none) xlabel(none)
```

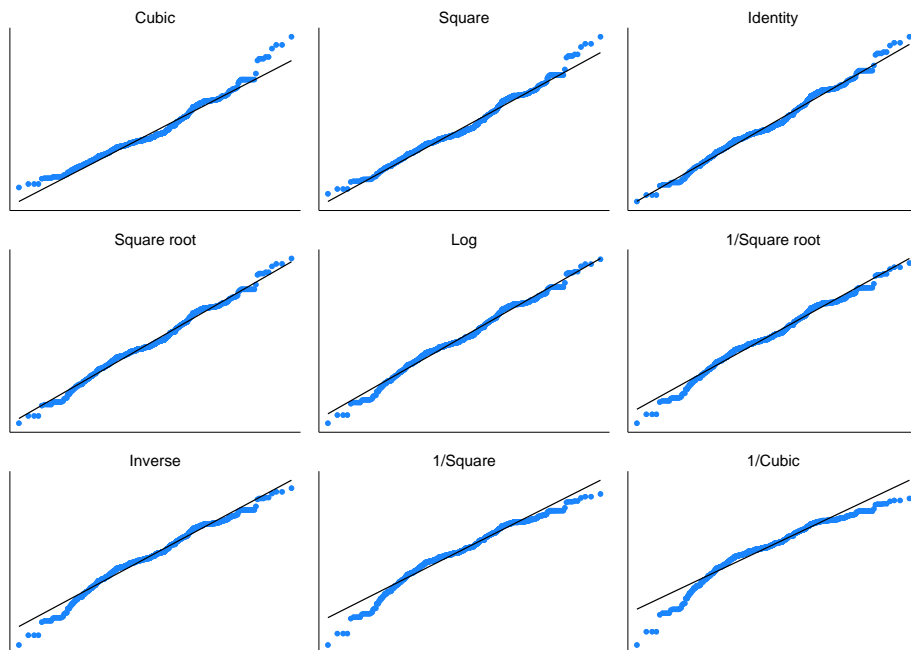

Histograms by transformation

### ► Example 3: qladder

A better graph for seeing normality is the quantile–normal graph, which can be produced by `qladder`.

```
. qladder tempjuly, ylabel(none) xlabel(none)
```

Average July temperature

Quantile-normal plots by transformation

This graph shows that for the square transform, the upper tail—and only the upper tail—diverges from what would be expected. This divergence is detected by `sktest` (see [R] [sktest](#)) as a problem with skewness, as we would learn from using `sktest` to examine `tempjuly` squared and square rooted.

## Stored results

`ladder` stores the following in `r()`:

Scalars

<code>r(N)</code>	number of observations
<code>r(invcube)</code>	$\chi^2$ for inverse-cubic transformation
<code>r(P_invcube)</code>	$p$ -value for normality test after inverse-cubic transformation
<code>r(invsq)</code>	$\chi^2$ for inverse-square transformation
<code>r(P_invsq)</code>	$p$ -value for normality test after inverse-square transformation
<code>r(inv)</code>	$\chi^2$ for inverse transformation
<code>r(P_inv)</code>	$p$ -value for normality test after inverse transformation
<code>r(invsqrt)</code>	$\chi^2$ for inverse-root transformation
<code>r(P_invsqrt)</code>	$p$ -value for normality test after inverse-root transformation
<code>r(log)</code>	$\chi^2$ for log transformation
<code>r(P_log)</code>	$p$ -value for normality test after log transformation
<code>r(sqrt)</code>	$\chi^2$ for square-root transformation
<code>r(P_sqrt)</code>	$p$ -value for normality test after square-root transformation
<code>r(ident)</code>	$\chi^2$ for untransformed data
<code>r(P_ident)</code>	$p$ -value for normality test of untransformed data
<code>r(square)</code>	$\chi^2$ for square transformation
<code>r(P_square)</code>	$p$ -value for normality test after square transformation
<code>r(cube)</code>	$\chi^2$ for cubic transformation
<code>r(P_cube)</code>	$p$ -value for normality test after cubic transformation

## Methods and formulas

For `ladder`, results are as reported by `sktest`; see [R] [sktest](#). If `generate()` is specified, the transform with the minimum  $\chi^2$  value is chosen.

`gladder` sets the number of bins to  $\min(\sqrt{n}, 10 \log_{10} n)$ , rounded to the closest integer, where  $n$  is the number of unique values of `varname`. See [R] [histogram](#) for a discussion of the optimal number of bins.

Also see [Findley \(1990\)](#) for a ladder-of-powers variable transformation program that produces one-way graphs with overlaid box plots, in addition to histograms with overlaid normals. [Buchner and Findley \(1990\)](#) discuss ladder-of-powers transformations as one aspect of preliminary data analysis. Also see [Hamilton \(1992, 18–23\)](#) and [Hamilton \(2013, 129–132\)](#).

## Acknowledgment

`qladder` was written by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands.

# Title

**level** — Set default confidence level

[Description](#)

[Syntax](#)

[Option](#)

[Remarks and examples](#)

[Also see](#)

## Description

`set level` specifies the default confidence level for confidence intervals for all commands that report confidence intervals. The initial value is 95, meaning 95% confidence intervals.

## Syntax

```
set level # [ , permanently ]
```

# is any number between 10.00 and 99.99 and may be specified with at most two digits after the decimal point.

## Option

`permanently` specifies that, in addition to making the change right now, the `level` setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

To change the level of confidence intervals reported by a particular command, you need not reset the default confidence level. All commands that report confidence intervals have a `level(#)` option. When you do not specify the option, the confidence intervals are calculated for the default level set by `set level`, or for 95% if you have not reset `set level`.

### ▷ Example 1

We use the `ci means` command to obtain the confidence interval for the mean of `mpg`:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. ci means mpg
```

Variable	Obs	Mean	Std. err.	[95% conf. interval]	
mpg	74	21.2973	.6725511	19.9569	22.63769

To obtain 90% confidence intervals, we would type

```
. ci means mpg, level(90)
```

Variable	Obs	Mean	Std. err.	[90% conf. interval]	
mpg	74	21.2973	.6725511	20.17683	22.41776

or

```
. set level 90  
. ci means mpg
```

Variable	Obs	Mean	Std. err.	[90% conf. interval]	
mpg	74	21.2973	.6725511	20.17683	22.41776

If we opt for the second alternative, the next time that we fit a model (say, with `regress`), 90% confidence intervals will be reported. If we wanted 95% confidence intervals, we could specify `level(95)` on the estimation command, or we could reset the default by typing `set level 95`.

The current setting of `level()` is stored as the c-class value `c(level)`; see [P] [creturn](#).

- (1) For Stata/MP, the maximum number of observations is 1,099,511,627,775, and for Stata/SE, the maximum number is 2,147,483,619. In practice, both editions are limited by memory.
- (2) The maximum length of the contents of a macro are fixed in Stata/BE and settable in Stata/SE and Stata/MP. The currently set maximum length is recorded in `c(macrolen)`; type `display c(macrolen)`. The maximum length can be changed with `set maxvar`. If you set `maxvar` to a larger value, the maximum length increases; if you set `maxvar` to a smaller value, the maximum length decreases. The relationship between them is  $maximum\_length = 129 \times maxvar + 200$ .
- (3) In Mata, matrices are limited only by the amount of memory on your computer.

## Determining which edition of Stata you are running

Type

```
. about
```

The response will be Stata/MP, Stata/SE, or Stata/BE. Other information is also shown, including your serial number. See [R] [about](#).

# Title

**lincom** — Linear combinations of parameters

[Description](#)  
[Options](#)  
[Also see](#)

[Quick start](#)  
[Remarks and examples](#)

[Menu](#)  
[Stored results](#)

[Syntax](#)  
[References](#)

## Description

`lincom` computes point estimates, standard errors,  $t$  or  $z$  statistics,  $p$ -values, and confidence intervals for linear combinations of coefficients after any estimation command, including survey estimation. Results can optionally be displayed as odds ratios, hazard ratios, incidence-rate ratios, or relative-risk ratios.

## Quick start

Point estimate and confidence interval for sum of coefficients of `x1` and `x2`

```
lincom x1 + x2
```

Same as above, but report results as a relative-risk ratio

```
lincom x1 + x2, rrr
```

Same as above, but use coefficients from second equation of a multiequation model

```
lincom [2]x1 + [2]x2, rrr
```

Difference between coefficients of first and third level of categorical variable `a`

```
lincom 1.a - 3.a
```

Sum of coefficients of `x1` and `x2` after a model adjusted for complex survey design

```
lincom x1 + x2
```

## Menu

Statistics > Postestimation

## Syntax

```
lincom exp [ , options ]
```

<i>options</i>	Description
<code>eform</code>	generic label; <code>exp(b)</code>
<code>or</code>	odds ratio
<code>hr</code>	hazard ratio
<code>shr</code>	subhazard ratio
<code>irr</code>	incidence-rate ratio
<code>rrr</code>	relative-risk ratio
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>display_options</code>	control column formats
<code>df(#)</code>	use <i>t</i> distribution with # degrees of freedom for computing <i>p</i> -values and confidence intervals

*exp* is any linear combination of coefficients that is a valid syntax for `test`; see [R] `test`. *exp* must not contain an equal sign.

`collect` is allowed; see [U] 11.1.10 [Prefix commands](#).

`df(#)` does not appear in the dialog box.

## Options

`eform`, `or`, `hr`, `shr`, `irr`, and `rrr` all report coefficient estimates as  $\exp(\hat{\beta})$  rather than  $\hat{\beta}$ . Standard errors and confidence intervals are similarly transformed. `or` is the default after `logistic`. The only difference in these options is how the output is labeled.

Option	Label	Explanation	Example commands
<code>eform</code>	<code>exp(b)</code>	Generic label	<code>cloglog</code>
<code>or</code>	<code>Odds ratio</code>	Odds ratio	<code>logistic</code> , <code>logit</code>
<code>hr</code>	<code>Haz. ratio</code>	Hazard ratio	<code>stcox</code> , <code>streg</code>
<code>shr</code>	<code>SHR</code>	Subhazard ratio	<code>stcrreg</code>
<code>irr</code>	<code>IRR</code>	Incidence-rate ratio	<code>poisson</code>
<code>rrr</code>	<code>RRR</code>	Relative-risk ratio	<code>mlogit</code>

*exp* may not contain any additive constants when you use the `eform`, `or`, `hr`, `irr`, or `rrr` option.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 [Specifying the width of confidence intervals](#).

`display_options`: `cformat(%fmt)`, `pformat(%fmt)`, and `sformat(%fmt)`; see [R] [Estimation options](#).

The following option is available with `lincom` but is not shown in the dialog box:

`df(#)` specifies that the *t* distribution with # degrees of freedom be used for computing *p*-values and confidence intervals. The default is to use `e(df_r)` degrees of freedom or the standard normal distribution if `e(df_r)` is missing.

## Remarks and examples

Remarks are presented under the following headings:

*Using lincom*  
*Odds ratios and incidence-rate ratios*  
*Multiple-equation models*

### Using lincom

After fitting a model and obtaining estimates for coefficients  $\beta_1, \beta_2, \dots, \beta_k$ , you may want to view estimates for linear combinations of the  $\beta_i$ , such as  $\beta_1 - \beta_2$ . `lincom` can display estimates for any linear combination of the form  $c_0 + c_1\beta_1 + c_2\beta_2 + \dots + c_k\beta_k$ .

`lincom` works after any estimation command for which `test` works. Any valid expression for `test` syntax 1 (see [R] `test`) is a valid expression for `lincom`.

`lincom` is useful for viewing odds ratios, hazard ratios, etc., for one group (that is, one set of covariates) relative to another group (that is, another set of covariates). See the examples below.

### ► Example 1

We perform a linear regression:

```
. use https://www.stata-press.com/data/r18/regress
. regress y x1 x2 x3
```

Source	SS	df	MS	Number of obs	=	148
Model	3259.3561	3	1086.45203	F(3, 144)	=	96.12
Residual	1627.56282	144	11.3025196	Prob > F	=	0.0000
				R-squared	=	0.6670
				Adj R-squared	=	0.6600
Total	4886.91892	147	33.2443464	Root MSE	=	3.3619

y	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
x1	1.457113	1.07461	1.36	0.177	-.666934	3.581161
x2	2.221682	.8610358	2.58	0.011	.5197797	3.923583
x3	-.006139	.0005543	-11.08	0.000	-.0072345	-.0050435
_cons	36.10135	4.382693	8.24	0.000	27.43863	44.76407

To see the difference of the coefficients of `x2` and `x1`, we type

```
. lincom x2 - x1
( 1) - x1 + x2 = 0
```

y	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
(1)	.7645682	.9950282	0.77	0.444	-1.20218	2.731316

The expression can be any linear combination.

```
. lincom 3*x1 + 500*x3
( 1) 3*x1 + 500*x3 = 0
```

y	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
(1)	1.301825	3.396624	0.38	0.702	-5.411858	8.015507

Nonlinear expressions are not allowed.

```
. lincom x2/x1
not possible with test
r(131);
```

For information about estimating nonlinear expressions, see [R] [nlcom](#).

◀

## □ Technical note

`lincom` uses the same shorthands for coefficients as does `test` (see [R] [test](#)). When you type `x1`, for instance, `lincom` knows that you mean the coefficient of `x1`. The formal syntax for referencing this coefficient is actually `_b[x1]`, or alternatively, `_coef[x1]`. So, more formally, in the last example we could have typed

```
. lincom 3*_b[x1] + 500*_b[x3]
(output omitted)
```

□

## Odds ratios and incidence-rate ratios

After logistic regression, the `or` option can be specified with `lincom` to display odds ratios for any effect. Incidence-rate ratios after commands such as `poisson` can be similarly obtained by specifying the `irr` option.

## ▷ Example 2

Consider the low birthweight dataset from [Hosmer, Lemeshow, and Sturdivant \(2013, 24\)](#). We fit a logistic regression model of low birthweight (variable `low`) on the following variables:

Variable	Description	Coding
<code>age</code>	age in years	
<code>race</code>	race	1 if white, 2 if black, 3 if other
<code>smoke</code>	smoking status	1 if smoker, 0 if nonsmoker
<code>ht</code>	history of hypertension	1 if yes, 0 if no
<code>ui</code>	uterine irritability	1 if yes, 0 if no
<code>lwd</code>	maternal weight before pregnancy	1 if weight < 110 lb., 0 otherwise
<code>ptd</code>	history of premature labor	1 if yes, 0 if no
<code>c.age##lwd</code>	age main effects, lwd main effects, and their interaction	
<code>smoke##lwd</code>	smoke main effects, lwd main effects, and their interaction	

We first fit a model without the interaction terms by using logit.

```
. use https://www.stata-press.com/data/r18/lbw3
(Hosmer & Lemeshow data)
. logit low age lwd i.race smoke ptd ht ui
Iteration 0:  Log likelihood =  -117.336
Iteration 1:  Log likelihood =  -99.3982
Iteration 2:  Log likelihood = -98.780418
Iteration 3:  Log likelihood = -98.777998
Iteration 4:  Log likelihood = -98.777998
Logistic regression
Log likelihood = -98.777998
Number of obs = 189
LR chi2(8) = 37.12
Prob > chi2 = 0.0000
Pseudo R2 = 0.1582
```

low	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
age	-.0464796	.0373888	-1.24	0.214	-.1197603	.0268011
lwd	.8420615	.4055338	2.08	0.038	.0472299	1.636893
race						
Black	1.073456	.5150753	2.08	0.037	.0639273	2.082985
Other	.815367	.4452979	1.83	0.067	-.0574008	1.688135
smoke	.8071996	.404446	2.00	0.046	.0145001	1.599899
ptd	1.281678	.4621157	2.77	0.006	.3759478	2.187408
ht	1.435227	.6482699	2.21	0.027	.1646414	2.705813
ui	.6576256	.4666192	1.41	0.159	-.2569313	1.572182
_cons	-1.216781	.9556797	-1.27	0.203	-3.089878	.656317

To get the odds ratio for black smokers relative to white nonsmokers (the reference group), we type

```
. lincom 2.race + smoke, or
( 1) [low]2.race + [low]smoke = 0
```

low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
(1)	6.557805	4.744692	2.60	0.009	1.588176	27.07811

`lincom` computed  $\exp(\beta_{2.race} + \beta_{smoke}) = 6.56$ . To see the odds ratio for white smokers relative to black nonsmokers, we type

```
. lincom smoke - 2.race, or
( 1) - [low]2.race + [low]smoke = 0
```

low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
(1)	.7662425	.4430176	-0.46	0.645	.2467334	2.379603

Now let's add the interaction terms to the model (Hosmer and Lemeshow 1989, table 4.10). This time, we will use logistic rather than logit. By default, logistic displays odds ratios.

```
. logistic low i.race ht ui ptd c.age##lwd smoke##lwd
Logistic regression                                Number of obs =   189
                                                    LR chi2(10)    =  42.66
                                                    Prob > chi2    =  0.0000
Log likelihood = -96.00616                          Pseudo R2     =  0.1818
```

	low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
<b>race</b>							
Black		2.95383	1.532789	2.09	0.037	1.068277	8.167465
Other		2.137589	.9919138	1.64	0.102	.8608708	5.307752
<b>ht</b>							
ht		3.893141	2.575201	2.05	0.040	1.064768	14.2346
<b>ui</b>							
ui		2.071284	.9931388	1.52	0.129	.8092926	5.301192
<b>ptd</b>							
ptd		3.426633	1.615282	2.61	0.009	1.360252	8.632089
<b>age</b>							
age		.9194513	.041896	-1.84	0.065	.8408967	1.005344
<b>1.lwd</b>							
1.lwd		.1772934	.3312384	-0.93	0.354	.0045539	6.902367
<b>lwd#c.age</b>							
1		1.15883	.09602	1.78	0.075	.9851215	1.36317
<b>smoke</b>							
Smoker		3.168096	1.452378	2.52	0.012	1.289956	7.78076
<b>smoke#lwd</b>							
Smoker#1		.2447849	.2003996	-1.72	0.086	.0491956	1.217988
<b>_cons</b>							
_cons		.599443	.6519163	-0.47	0.638	.0711271	5.051971

Note: **\_cons** estimates baseline odds.

Hosmer and Lemeshow (1989, table 4.13) consider the effects of smoking (smoke = 1) and low maternal weight before pregnancy (lwd = 1). The effect of smoking among non-low-weight mothers (lwd = 0) is given by the odds ratio 3.17 for smoke in the logistic output. The effect of smoking among low-weight mothers is given by

```
. lincom 1.smoke + 1.smoke#1.lwd
( 1) [low]1.smoke + [low]1.smoke#1.lwd = 0
```

	low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
(1)		.7755022	.574951	-0.34	0.732	.1813465	3.316323

We did not have to specify the or option. After logistic, lincom assumes or by default.

The effect of low weight (lwd = 1) is more complicated because we fit an age × lwd interaction. We must specify the age of mothers for the effect. The effect among 30-year-old nonsmokers is given by

```
. lincom 1.lwd + 30*1.lwd#c.age
( 1) [low]1.lwd + 30*[low]1.lwd#c.age = 0
```

	low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
(1)		14.7669	13.5669	2.93	0.003	2.439264	89.39633

`lincom` computed  $\exp(\beta_{1\text{ld}} + 30\beta_{\text{age}1\text{ld}}) = 14.8$ . It may seem odd that we entered it as `1.1wd + 30*1.1wd#c.age`, but remember that these terms are just `lincom`'s (and `test`'s) shorthands for `_b[1.1wd]` and `_b[1.1wd#c.age]`. We could have typed

```
. lincom _b[1.1wd] + 30*_b[1.1wd#c.age]
(1) [low]1.1wd + 30*[low]1.1wd#c.age = 0
```

low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
(1)	14.7669	13.5669	2.93	0.003	2.439264	89.39633

## Multiple-equation models

`lincom` also works with multiple-equation models. The only difference is how you refer to the coefficients. Recall that for multiple-equation models, coefficients are referenced using the syntax

`[eqno]varname`

where *eqno* is the equation number or equation name and *varname* is the corresponding variable name for the coefficient; see [U] 13.5 Accessing coefficients and standard errors and [R] test for details.

### ▶ Example 3

Let's consider [example 4](#) from [R] `mlogit` (Tarlov et al. 1989; Wells et al. 1989).

```
. use https://www.stata-press.com/data/r18/sysdsn1
(Health insurance data)
. mlogit insure age male nonwhite i.site, nolog
Multinomial logistic regression
Log likelihood = -534.36165
Number of obs = 615
LR chi2(10) = 42.99
Prob > chi2 = 0.0000
Pseudo R2 = 0.0387
```

insure	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
Indemnity	(base outcome)					
Prepaid						
age	-.011745	.0061946	-1.90	0.058	-.0238862	.0003962
male	.5616934	.2027465	2.77	0.006	.1643175	.9590693
nonwhite	.9747768	.2363213	4.12	0.000	.5115955	1.437958
site						
2	.1130359	.2101903	0.54	0.591	-.2989296	.5250013
3	-.5879879	.2279351	-2.58	0.010	-1.034733	-.1412433
_cons	.2697127	.3284422	0.82	0.412	-.3740222	.9134476
Uninsure						
age	-.0077961	.0114418	-0.68	0.496	-.0302217	.0146294
male	.4518496	.3674867	1.23	0.219	-.268411	1.17211
nonwhite	.2170589	.4256361	0.51	0.610	-.6171725	1.05129
site						
2	-1.211563	.4705127	-2.57	0.010	-2.133751	-.2893747
3	-.2078123	.3662926	-0.57	0.570	-.9257327	.510108
_cons	-1.286943	.5923219	-2.17	0.030	-2.447872	-.1260134

To see the estimate of the sum of the coefficient of `male` and the coefficient of `nonwhite` for the `Prepaid` outcome, we type

```
. lincom [Prepaid]male + [Prepaid]nonwhite
(1) [Prepaid]male + [Prepaid]nonwhite = 0
```

insure	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
(1)	1.53647	.3272489	4.70	0.000	.8950741	2.177866

To view the estimate as a ratio of relative risks (see [R] `mlogit` for the definition and interpretation), we specify the `rrr` option.

```
. lincom [Prepaid]male + [Prepaid]nonwhite, rrr
(1) [Prepaid]male + [Prepaid]nonwhite = 0
```

insure	RRR	Std. err.	z	P> z	[95% conf. interval]	
(1)	4.648154	1.521103	4.70	0.000	2.447517	8.827451

4

## Stored results

`lincom` stores the following in `r()`:

Scalars

```
r(estimate) point estimate
r(se)        estimate of standard error
r(df)        degrees of freedom
r(t) or r(z) t or z statistic
r(p)         p-value
r(lb)        lower bound of confidence interval
r(ub)        upper bound of confidence interval
r(level)     confidence level
```

# Title

**linktest** — Specification link test for single-equation models

<a href="#">Description</a>	<a href="#">Quick start</a>	<a href="#">Menu</a>	<a href="#">Syntax</a>
<a href="#">Option</a>	<a href="#">Remarks and examples</a>	<a href="#">Stored results</a>	<a href="#">Methods and formulas</a>
<a href="#">References</a>	<a href="#">Also see</a>		

## Description

`linktest` performs a link test for model specification.

## Quick start

Specification link test after a single-equation estimation command without options

```
linktest
```

After `tobit` estimated with right-censoring limit at 24

```
linktest, ul(24)
```

After `stcox` estimated with Efron method for tied failures

```
linktest, efron
```

Perform test on full dataset when estimation used a subset of observations

```
linktest if e(sample) < .
```

## Menu

Statistics > Postestimation

## Syntax

```
linktest [if] [in] [, cmd_options]
```

When `if` and `in` are not specified, the link test is performed on the same sample as the previous estimation. `collect` is allowed; see [U] [11.1.10 Prefix commands](#).

## Option

Main

---

*cmd\_options* must be the same options specified with the underlying estimation command, except the *display\_options* may differ.

## Remarks and examples

The form of the link test implemented here is based on an idea of [Tukey \(1949\)](#), which was further described by [Pregibon \(1980\)](#), elaborating on work in his unpublished thesis ([Pregibon 1979](#)). See *Methods and formulas* below for more details.

### ▷ Example 1

We want to explain the mileage ratings of cars in our automobile dataset by using the weight, engine displacement, and whether the car is manufactured outside the United States:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
```

```
. regress mpg weight displ foreign
```

Source	SS	df	MS	Number of obs	=	74
Model	1619.71935	3	539.906448	F(3, 70)	=	45.88
Residual	823.740114	70	11.7677159	Prob > F	=	0.0000
				R-squared	=	0.6629
				Adj R-squared	=	0.6484
Total	2443.45946	73	33.4720474	Root MSE	=	3.4304

mpg	Coefficient	Std. err.	t	P> t	[95% conf. interval]
weight	-.0067745	.0011665	-5.81	0.000	-.0091011 -.0044479
displacement	.0019286	.0100701	0.19	0.849	-.0181556 .0220129
foreign	-1.600631	1.113648	-1.44	0.155	-3.821732 .6204699
_cons	41.84795	2.350704	17.80	0.000	37.15962 46.53628

On the basis of the  $R^2$ , we are reasonably pleased with this model.

If our model really is specified correctly, then if we were to regress mpg on the prediction and the prediction squared, the prediction squared would have no explanatory power. This is what `linktest` does:

```
. linktest
```

Source	SS	df	MS	Number of obs	=	74
Model	1670.71514	2	835.357572	F(2, 71)	=	76.75
Residual	772.744316	71	10.8837228	Prob > F	=	0.0000
				R-squared	=	0.6837
				Adj R-squared	=	0.6748
Total	2443.45946	73	33.4720474	Root MSE	=	3.299

mpg	Coefficient	Std. err.	t	P> t	[95% conf. interval]
_hat	-.4127198	.6577736	-0.63	0.532	-1.724283 .8988434
_hatsq	.0338198	.015624	2.16	0.034	.0026664 .0649732
_cons	14.00705	6.713276	2.09	0.041	.6211539 27.39294

We find that the prediction squared does have explanatory power, so our specification is not as good as we thought.

Although `linktest` is formally a test of the specification of the dependent variable, it is often interpreted as a test that, conditional on the specification, the independent variables are specified incorrectly. We will follow that interpretation and now include weight squared in our model:

```
. regress mpg weight c.weight#c.weight displ foreign
```

Source	SS	df	MS	Number of obs	=	74
Model	1699.02634	4	424.756584	F(4, 69)	=	39.37
Residual	744.433124	69	10.7888859	Prob > F	=	0.0000
				R-squared	=	0.6953
				Adj R-squared	=	0.6777
Total	2443.45946	73	33.4720474	Root MSE	=	3.2846

mpg	Coefficient	Std. err.	t	P> t	[95% conf. interval]
weight	-.0173257	.0040488	-4.28	0.000	-.0254028 - .0092486
c.weight# c.weight	1.87e-06	6.89e-07	2.71	0.008	4.93e-07 3.24e-06
displacement	-.0101625	.0106236	-0.96	0.342	-.031356 .011031
foreign	-2.560016	1.123506	-2.28	0.026	-4.801349 -.3186832
_cons	58.23575	6.449882	9.03	0.000	45.36859 71.10291

Now, we perform the link test on our new model:

```
. linktest
```

Source	SS	df	MS	Number of obs	=	74
Model	1699.39489	2	849.697445	F(2, 71)	=	81.08
Residual	744.06457	71	10.4797827	Prob > F	=	0.0000
				R-squared	=	0.6955
				Adj R-squared	=	0.6869
Total	2443.45946	73	33.4720474	Root MSE	=	3.2372

mpg	Coefficient	Std. err.	t	P> t	[95% conf. interval]
_hat	1.141987	.7612218	1.50	0.138	-.3758456 2.659821
_hatsq	-.0031916	.0170194	-0.19	0.852	-.0371272 .0307441
_cons	-1.50305	8.196444	-0.18	0.855	-17.84629 14.84019

We now pass the link test.

## ▷ Example 2

Above, we followed a standard misinterpretation of the link test—when we discovered a problem, we focused on the explanatory variables of our model. We might consider varying exactly what the link test tests. The link test told us that our dependent variable was misspecified. For those with an engineering background, mpg is indeed a strange measure. It would make more sense to model energy consumption—gallons per mile—in terms of weight and displacement:

```
. gen gpm = 1/mpg
. regress gpm weight displ foreign
```

Source	SS	df	MS	Number of obs	=	74
Model	.009157962	3	.003052654	F(3, 70)	=	76.33
Residual	.002799666	70	.000039995	Prob > F	=	0.0000
				R-squared	=	0.7659
				Adj R-squared	=	0.7558
Total	.011957628	73	.000163803	Root MSE	=	.00632

gpm	Coefficient	Std. err.	t	P> t	[95% conf. interval]
weight	.0000144	2.15e-06	6.72	0.000	.0000102 .0000187
displacement	.0000186	.0000186	1.00	0.319	-.0000184 .0000557
foreign	.0066981	.0020531	3.26	0.002	.0026034 .0107928
_cons	.0008917	.0043337	0.21	0.838	-.0077515 .009535

This model looks every bit as reasonable as our original model:

```
. linktest
```

Source	SS	df	MS	Number of obs	=	74
Model	.009175219	2	.004587609	F(2, 71)	=	117.06
Residual	.002782409	71	.000039189	Prob > F	=	0.0000
				R-squared	=	0.7673
				Adj R-squared	=	0.7608
Total	.011957628	73	.000163803	Root MSE	=	.00626

gpm	Coefficient	Std. err.	t	P> t	[95% conf. interval]
_hat	.6608413	.515275	1.28	0.204	-.3665877 1.68827
_hatsq	3.275857	4.936655	0.66	0.509	-6.567553 13.11927
_cons	.008365	.0130468	0.64	0.523	-.0176496 .0343795

Specifying the model in terms of gallons per mile also solves the specification problem and results in a more parsimonious specification.

### ▷ Example 3

The link test can be used with any single-equation estimation procedure, not solely regression. Let's turn our problem around and attempt to explain whether a car is manufactured outside the United States by its mileage rating and weight. To save paper, we will specify `logit`'s `nolog` option, which suppresses the iteration log:

```
. logit foreign mpg weight, nolog
Logistic regression                               Number of obs =    74
                                                LR chi2(2)      =   35.72
                                                Prob > chi2     =  0.0000
Log likelihood = -27.175156                    Pseudo R2      =  0.3966
```

foreign	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
mpg	-.1685869	.0919175	-1.83	0.067	-.3487418	.011568
weight	-.0039067	.0010116	-3.86	0.000	-.0058894	-.001924
_cons	13.70837	4.518709	3.03	0.002	4.851859	22.56487

When we run `linktest` after `logit`, the result is another logit specification:

```
. linktest, nolog
Logistic regression                               Number of obs =    74
                                                LR chi2(2)      =   36.83
                                                Prob > chi2     =  0.0000
Log likelihood = -26.615714                    Pseudo R2      =  0.4090
```

foreign	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
_hat	.8438531	.2738759	3.08	0.002	.3070661	1.38064
_hatsq	-.1559115	.1568642	-0.99	0.320	-.4633596	.1515366
_cons	.2630557	.4299598	0.61	0.541	-.57965	1.105761

The link test reveals no problems with our specification.

If there had been a problem, we would have been virtually forced to accept the misinterpretation of the link test—we would have reconsidered our specification of the independent variables. When using `logit`, we have no control over the specification of the dependent variable other than to change likelihood functions.

We admit to having seen a dataset once for which the link test rejected the logit specification. We did change the likelihood function, refitting the model using `probit`, and satisfied the link test. `Probit` has thinner tails than `logit`. In general, however, you will not be so lucky.

◀

### □ Technical note

You should specify the same options with `linktest` that you do with the estimation command, although you do not have to follow this advice as literally as we did in the preceding example. `logit`'s `nolog` option merely suppresses a part of the output, not what is estimated. We specified `nolog` both times to save space.

If you are testing a tobit model, you must specify the censoring points just as you do with the `tobit` command.

If you are not sure which options are important, duplicate exactly what you specified on the estimation command.

If you do not specify *if exp* or *in range* with `linktest`, Stata will by default perform the link test on the same sample as the previous estimation. Suppose that you omitted some data when performing your estimation but want to calculate the link test on all the data, which you might do if you believe the model is appropriate for all the data. You would type `linktest if e(sample) < .` to do this.

## Stored results

`linktest` stores the following in `r()`:

Scalars

<code>r(t)</code>	<i>t</i> statistic on <code>_hatsq</code>
<code>r(df)</code>	degrees of freedom

`linktest` is *not* an estimation command in the sense that it leaves previous estimation results unchanged. For instance, after running a regression and performing the link test, typing `regress` without arguments after the link test still replays the original regression.

For integrating an estimation command with `linktest`, `linktest` assumes that the name of the estimation command is stored in `e(cmd)` and that the name of the dependent variable is stored in `e(depvar)`. After estimation, it assumes that the number of degrees of freedom for the *t* test is given by `e(df_m)` if the macro is defined.

If the estimation command reports *z* statistics instead of *t* statistics, `linktest` will also report *z* statistics. The *z* statistic, however, is still returned in `r(t)`, and `r(df)` is set to a missing value.

## Methods and formulas

The link test is based on the idea that if a regression or regression-like equation is properly specified, you should be able to find no additional independent variables that are significant except by chance. One kind of specification error is called a link error. In regression, this means that the dependent variable needs a transformation or “link” function to properly relate to the independent variables. The idea of a link test is to add an independent variable to the equation that is especially likely to be significant if there is a link error.

Let

$$\mathbf{y} = f(\mathbf{X}\boldsymbol{\beta})$$

be the model and  $\widehat{\boldsymbol{\beta}}$  be the parameter estimates. `linktest` calculates

$$\_hat = \mathbf{X}\widehat{\boldsymbol{\beta}}$$

and

$$\_hatsq = \_hat^2$$

The model is then refit with these two variables, and the test is based on the significance of `_hatsq`. This is the form suggested by Pregibon (1979) based on an idea of Tukey (1949). Pregibon (1980) suggests a slightly different method that has come to be known as “Pregibon’s goodness-of-link test”. We prefer the older version because it is universally applicable, straightforward, and a good second-order approximation. It can be applied to any single-equation estimation technique, whereas Pregibon’s more recent tests are estimation-technique specific.

## Description

`lnskew0` creates  $newvar = \ln(\pm exp - k)$ , choosing  $k$  and the sign of  $exp$  so that the skewness of  $newvar$  is zero.

`bcskew0` creates  $newvar = (exp^\lambda - 1)/\lambda$ , the Box–Cox power transformation (Box and Cox 1964), choosing  $\lambda$  so that the skewness of  $newvar$  is zero.  $exp$  must be strictly positive.

## Quick start

Generate `newv1`, the zero-skewness log transform of continuous variable `v1`

```
lnskew0 newv1 = v1
```

Same as above, but transform ratio of `v1` to `v2`

```
lnskew0 newv1 = v1/v2
```

Zero-skewness Box–Cox transform, `newv2`, of `v2`

```
bcskew0 newv2 = v2
```

Same as above, and change the value for convergence to 0.0001 from the default 0.001

```
bcskew0 newv2 = v2, zero(.0001)
```

```

Zero-skewness Box–Cox transform

```
bcskew0 newvar = exp [if] [in] [, options]
```

*options*

Description

Main

<code>delta(#)</code>	increment for derivative of skewness function; default is <code>delta(0.02)</code> for <code>lnskew0</code> and <code>delta(0.01)</code> for <code>bcskew0</code>
<code>zero(#)</code>	value for determining convergence; default is <code>zero(0.001)</code>
<code>level(#)</code>	compute the confidence interval at confidence level #; by default, no confidence interval is calculated

collect is allowed with `lnskew0` and `bcskew0`; see [U] 11.1.10 Prefix commands.

## Options

Main

`delta(#)` specifies the increment used for calculating the derivative of the skewness function with respect to  $k$  (`lnskew0`) or  $\lambda$  (`bcskew0`). The default values are 0.02 for `lnskew0` and 0.01 for `bcskew0`.

`zero(#)` specifies a value for skewness to determine convergence that is small enough to be considered zero and is, by default, 0.001.

`level(#)` specifies the confidence level for the confidence interval for  $k$  (`lnskew0`) or  $\lambda$  (`bcskew0`). The confidence interval is calculated only if `level()` is specified. # is specified as an integer; 95 means 95% confidence intervals. The `level()` option is honored only if the number of observations exceeds 7.

## Remarks and examples

### ► Example 1: Inskew0

Using our automobile dataset (see [U] 1.2.2 Example datasets), we want to generate a new variable equal to  $\ln(\text{mpg} - k)$  to be approximately normally distributed. `mpg` records the miles per gallon for each of our cars. One feature of the normal distribution is that it has skewness 0.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
```

```
. lnskew0 lnmpg = mpg
```

Transform	k	[95% conf. interval]	Skewness
ln(mpg-k)	5.383659	(not calculated)	-7.05e-06

This created the new variable `lnmpg = ln(mpg - 5.384)`:

```
. describe lnmpg
```

Variable name	Storage type	Display format	Value label	Variable label
lnmpg	float	%9.0g		ln(mpg-5.383659)

Because we did not specify the `level()` option, no confidence interval was calculated. At the outset, we could have typed

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. lnskew0 lnmpg = mpg, level(95)
```

Transform	k	[95% conf. interval]		Skewness
ln(mpg-k)	5.383659	-17.12339	9.892416	-7.05e-06

The confidence interval is calculated under the assumption that  $\ln(\text{mpg} - k)$  really does have a normal distribution. It would be perfectly reasonable to use `lnskew0`, even if we did not believe that the transformed variable would have a normal distribution—if we literally wanted the zero-skewness transform—although, then the confidence interval would be an approximation of unknown quality to the true confidence interval. If we now wanted to test the believability of the confidence interval, we could also test our new variable `lnmpg` by using `swilk` (see [R] [swilk](#)) with the `lnnormal` option. ◀

## □ Technical note

`lnskew0` and `bcskew0` report the resulting skewness of the variable merely to reassure you of the accuracy of its results. In our example above, `lnskew0` found  $k$  such that the resulting skewness was  $-7 \times 10^{-6}$ , a number close enough to zero for all practical purposes. If we wanted to make it even smaller, we could specify the `zero()` option. Typing `lnskew0 new=mpg, zero(1e-8)` changes the estimated  $k$  to 5.383552 from 5.383659 and reduces the calculated skewness to  $-2 \times 10^{-11}$ .

When you request a confidence interval, `lnskew0` may report the lower confidence interval as `.'`, which should be taken as indicating the lower confidence limit  $k_L = -\infty$ . (This cannot happen with `bcskew0`.)

As an example, consider a sample of size  $n$  on  $x$  and assume that the skewness of  $x$  is positive, but not significantly so, at the desired significance level—say, 5%. Then, no matter how large and negative you make  $k_L$ , there is no value extreme enough to make the skewness of  $\ln(x - k_L)$  equal the corresponding percentile (97.5 for a 95% confidence interval) of the distribution of skewness in a normal distribution of the same sample size. You cannot do this because the distribution of  $\ln(x - k_L)$  tends to that of  $x$ —apart from location and scale shift—as  $x \rightarrow \infty$ . This “problem” never applies to the upper confidence limit,  $k_U$ , because the skewness of  $\ln(x - k_U)$  tends to  $-\infty$  as  $k$  tends upward to the minimum value of  $x$ . □

## ▷ Example 2: `bcskew0`

In [example 1](#), using `lnskew0` with a variable such as `mpg` is probably undesirable. `mpg` has a natural zero, and we are shifting that zero arbitrarily. On the other hand, use of `lnskew0` with a variable such as temperature measured in Fahrenheit or Celsius would be more appropriate because the zero is indeed arbitrary.

For a variable like mpg, it makes more sense to use the Box–Cox power transform (Box and Cox 1964):

$$y^{(\lambda)} = \frac{y^\lambda - 1}{\lambda}$$

$\lambda$  is free to take on any value, but  $y^{(1)} = y - 1$ ,  $y^{(0)} = \ln(y)$ , and  $y^{(-1)} = 1 - 1/y$ .

`bcskew0` works like `lnskew0`:

```
. bcskew0 bcmpg = mpg, level(95)
```

Transform	L	[95% conf. interval]		Skewness
(mpg^L-1)/L	-0.3673283	-1.212752	.4339645	.0001898

The 95% confidence interval includes  $\lambda = -1$  ( $\lambda$  is labeled L in the output), which has a rather more pleasing interpretation—gallons per mile—than  $(\text{mpg}^{-0.3673} - 1)/(-0.3673)$ . The confidence interval, however, is calculated assuming that the power transformed variable is normally distributed. It makes perfect sense to use `bcskew0`, even when you do not believe that the transformed variable will be normally distributed, but then the confidence interval is an approximation of unknown quality. If you believe that the transformed data are normally distributed, you can alternatively use `boxcox` to estimate  $\lambda$ ; see [R] [boxcox](#).

◀

## Stored results

`lnskew0` and `bcskew0` store the following in `r()`:

Scalars

<code>r(gamma)</code>	$k$ ( <code>lnskew0</code> )
<code>r(lambda)</code>	$\lambda$ ( <code>bcskew0</code> )
<code>r(lb)</code>	lower bound of confidence interval
<code>r(ub)</code>	upper bound of confidence interval
<code>r(skewness)</code>	resulting skewness of transformed variable

## Methods and formulas

Skewness is as calculated by `summarize`; see [R] [summarize](#). Newton's method with numeric, uncentered derivatives is used to estimate  $k$  (`lnskew0`) and  $\lambda$  (`bcskew0`). For `lnskew0`, the initial value is chosen so that the minimum of  $x - k$  is 1, and thus  $\ln(x - k)$  is 0. `bcskew0` starts with  $\lambda = 1$ .

## Acknowledgment

`lnskew0` and `bcskew0` were written by Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*.

[Reference](#)

## Description

`log` and its subcommands tell Stata to open a log file and create a record of what you type and any output that appears in the Results window, to suspend or resume logging, to check logging status, and to close the log file. The default format is Stata Markup and Control Language (SMCL) but can be plain text. You can have up to five SMCL and five text logs open at a time. `cmdlog` and its subcommands are similar to `log` but create a command log recording only what you type and can be only plain text. That is, `cmdlog` is designed only for interactive use. You can have only one command log open at a time.

`set logtype`, `set logmsg`, and `set linesize` are commands to control system parameters that relate to logs.

## Quick start

Begin recording your Stata session in `mylog.smcl`

```
log using mylog
```

Same as above, but use a text format that can be read by a word processor

```
log using mylog, text
```

Save a subset of output to `mylog2.smcl` while `mylog.smcl` is still open

```
log using mylog2, name(mylog2)
```

Close `mylog2.smcl` and keep `mylog.smcl` open

```
log close mylog2
```

Create a do-file from commands typed interactively

```
cmdlog using mydo.do
```

## Menu

File > Log

## Syntax

*Report status of log file*

```
log
```

```
log query [ logname | _all ]
```

*Open log file*

```
log using filename [ , append replace [ ttext | smc1 ] name(logname) [ nomsg | msg ] ]
```

*Close log*

```
log close [ logname | _all ]
```

*Temporarily suspend logging or resume logging*

```
log { off | on } [ logname ]
```

*Report status of command log file*

```
cmdlog
```

*Open command log file*

```

```

*Close command log, temporarily suspend logging, or resume logging*

```
cmdlog { close | on | off }
```

*Set default format for logs*

```
set logtype { ttext | smc1 } [ , permanently ]
```

*Set default for display of log messages*

```
set logmsg { on | off }
```

*Specify screen width*

```
set linesize #
```

In addition to using the `log` command, you may access the capabilities of `log` by selecting **File > Log** from the menu and choosing one of the options in the list.

`collect` is allowed with `log query`, `log`, and `cmdlog`; see [\[U\] 11.1.10 Prefix commands](#).

## Options for use with both log and cmdlog

`append` specifies that results be appended to an existing file. If the file does not already exist, a new file is created.

`replace` specifies that *filename*, if it already exists, be overwritten. When you do not specify either `replace` or `append`, the file is assumed to be new. If the specified file already exists, an error message is issued and logging is not started.

## Options for use with log

`text` and `smcl` specify the format in which the log is to be recorded. The default is complicated to describe but is what you would expect:

If you specify the file as *filename*.`smcl`, the default is to write the log in SMCL format (regardless of the value of `set logtype`).

If you specify the file as *filename*.`log`, the default is to write the log in text format (regardless of the value of `set logtype`).

If you type *filename* without an extension and specify neither the `smcl` option nor the `text` option, the default is to write the file according to the value of `set logtype`. If you have not `set logtype`, then the default is SMCL. Also, the *filename* you specified will be fixed to read *filename*.`smcl` if a SMCL log is being created or *filename*.`log` if a text log is being created.

If you specify either the `text` or `smcl` option, then what you specify determines how the log is written. If *filename* was specified without an extension, the appropriate extension is added for you.

If you open multiple log files, you may choose a different format for each file.

`name(logname)` specifies an optional name you may use to refer to the log while it is open. You can start multiple log files, give each a different *logname*, and then close, temporarily suspend, or resume them each individually. The default *logname* is `<unnamed>`.

`nomsg` and `msg` specify whether to display or suppress the default message at the top and bottom of the log file.

`nomsg` suppresses the default message displayed at the top and bottom of the log file. This message consists of the log name (if specified in `name()`, otherwise `unnamed`), log path, log type, and date opened or closed.

`msg` displays the default message at the top and bottom of the log file. This option is for use when `set logmsg` is turned off.

## Option for use with set logtype

`permanently` specifies that, in addition to making the change right now, the `logtype` setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

A full log is a file containing what you type and Stata's output that is shown in the Results window. To begin logging your session, you type `log using filename`. If *filename* contains embedded spaces, remember to enclose it in double quotation marks.

When the default log format is SMCL, `log` will add the extension `.smcl` if *filename* is specified without one. If *text* is specified or the default log type is changed to `text`, `log` adds the extension `.log`.

We recommend using SMCL because it preserves fonts and colors. SMCL logs can be viewed and printed from the Viewer window, as can any text file; see [\[R\] view](#). Users of console Stata can use `translate` to produce printable versions of log files. `translate` also converts SMCL logs to text or other formats, such as PostScript or PDF; see [\[R\] translate](#).

When you open a full log, the default is to show the name of the file and a time and date stamp:

```
. log using myfile
```

---

```
name: <unnamed>
log: C:\data\proj1\myfile.smcl
log type: smcl
opened on: 12 Jan 2023, 12:28:23
```

The above information will appear in the log. If you do not want this information to appear, precede the command by `quietly`:

```
. quietly log using myfile
```

`quietly` will not suppress any error messages or anything else you need to know.

Similarly, when you close a full log, the default is to show the full information,

```
. log close
```

---

```
name: <unnamed>
log: C:\data\proj1\myfile.smcl
log type: smcl
closed on: 12 Jan 2023, 12:32:41
```

and that information will also appear in the log. If you want to suppress that, type `quietly log close`. Alternatively, specifying `nomsg` with `log using` will suppress these messages.

If you do not specify `name(logname)`, Stata will use the name `<unnamed>`, as shown above. However, you can start multiple log files by specifying the `name()` option with each new `log using` command. To control a specific log, type, for example, `log close logname`; to close all log files at one time, type `log close _all`.

Stata also lets you log only your commands using `cmdlog`. Command logs are always text files, which makes them easy to convert to do-files. The default extension is `.txt` instead of `.do` to keep you from accidentally overwriting your important do-files. However, `cmdlog` will allow you to specify `.do` as the extension of *filename*.

You can have only one command log open at a time. However, you can have full logs open while logging your commands. Moreover, the text file you create for your command log does not count against the limit of five text logs.

`set logtype` specifies the default format in which full logs are to be recorded. Initially, full logs are recorded in SMCL format.

`set logmsg` specifies whether the default message is displayed at the top and bottom of the log file. The default is `on`. Specifying `set logmsg off` suppresses the default message from both `log using` and `log close` just as if the `nomsg` option were used with `log using`.

`set linesize` specifies the maximum width, in characters, of Stata output. Most commands in Stata do not respect `linesize`, because it is not important for most commands. Most users never

need to `set linesize`, because it will automatically be reset if you resize your Results window. This is also why there is no `permanently` option allowed with `set linesize`. `set linesize` is for use with commands such as `list` and `display` and is typically used by programmers who wish the output of those commands to be wider or narrower than the current width of the Results window.

## Stored results

`log` and `cmdlog` store the following in `r()`:

Macros

<code>r(name)</code>	<i>logname</i>
<code>r(filename)</code>	name of file
<code>r(status)</code>	on or off
<code>r(type)</code>	smcl or text

`log query _all` stores the following in `r()`:

Scalars

<code>r(numlogs)</code>	number of open log files
-------------------------	--------------------------

For each open log file, `log query _all` also stores

<code>r(name#)</code>	<i>logname</i>
<code>r(filename#)</code>	name of file
<code>r(status#)</code>	on or off
<code>r(type#)</code>	smcl or text

where `#` varies between 1 and the value of `r(numlogs)`. Be aware that `#` will not necessarily represent the order in which the log files were first opened, nor will it necessarily remain constant for a given log file upon multiple calls to `log query`.

# Title

**logistic** — Logistic regression, reporting odds ratios

[Description](#)  
[Options](#)  
[References](#)

[Quick start](#)  
[Remarks and examples](#)  
[Also see](#)

[Menu](#)  
[Stored results](#)

[Syntax](#)  
[Methods and formulas](#)

## Description

`logistic` fits a logistic regression model of *depvar* on *indepvars*, where *depvar* is a 0/1 variable (or, more precisely, a 0/non-0 variable). Without arguments, `logistic` redisplay the last `logistic` estimates. `logistic` displays estimates as odds ratios; to view coefficients, type `logit` after running `logistic`. To obtain odds ratios for any covariate pattern relative to another, see [\[R\] lincom](#).

## Quick start

Report odds ratios from logistic regression of *y* on *x1* and *x2*

```
logistic y x1 x2
```

Add indicators for values of categorical variable *a*

```
logistic y x1 x2 i.a
```

Same as above, and apply frequency weights defined by *wvar*

```
logistic y x1 x2 i.a [fweight=wvar]
```

Show base level of *a*

```
logistic y x1 x2 i.a, baselevels
```

## Menu

Statistics > Binary outcomes > Logistic regression

## Syntax

```
logistic depvar indepvars [if] [in] [weight] [, options]
```

<i>options</i>	Description
Model	
<code>noconstant</code>	suppress constant term
<code>offset(<i>varname</i>)</code>	include <i>varname</i> in model with coefficient constrained to 1
<code>asis</code>	retain perfect predictor variables
<code>constraints(<i>constraints</i>)</code>	apply specified linear constraints
SE/Robust	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>opg</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>bootstrap</code> , or <code>jackknife</code>
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>coef</code>	report estimated coefficients
<code>nocnsreport</code>	do not display constraints
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<code>maximize_options</code>	control the maximization process; seldom used
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*depvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bootstrap`, `by`, `collect`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] **bayes: logistic**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

Model

`noconstant`, `offset(varname)`, `constraints(constraints)`; see [R] **Estimation options**.

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] **probit**.

## SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`coef` causes `logistic` to report the estimated coefficients rather than the odds ratios (exponentiated coefficients). `coef` may be specified when the model is fit or may be used later to redisplay results. `coef` affects only how results are displayed and not how they are estimated.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `logistic` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[logistic and logit](#)  
[Robust estimate of variance](#)  
[Video examples](#)

## logistic and logit

`logistic` provides an alternative and preferred way to fit maximum-likelihood logit models, the other choice being `logit` ([R] [logit](#)).

First, let's dispose of some confusing terminology. We use the words `logit` and `logistic` to mean the same thing: maximum likelihood estimation. To some, one or the other of these words connotes transforming the dependent variable and using weighted least squares to fit the model, but that is not how we use either word here. Thus, the `logit` and `logistic` commands produce the same results.

The `logistic` command is generally preferred to the `logit` command because `logistic` presents the estimates in terms of odds ratios rather than coefficients. To some people, this may seem disadvantageous, but you can type `logit` without arguments after `logistic` to see the underlying coefficients. You should be cautious when interpreting the odds ratio of the constant term. Usually, this odds ratio represents the baseline odds of the model when all predictor variables are set to zero. However, you must verify that a zero value for all predictor variables in the model actually makes sense before continuing with this interpretation.

Nevertheless, [R] `logit` is still worth reading because `logistic` shares the same features as `logit`, including omitting variables due to collinearity or one-way causation.

For an introduction to logistic regression, see [Lemeshow and Hosmer \(2005\)](#), [Pagano and Gauvreau \(2022, 455–478\)](#), or [Pampel \(2021\)](#); for a complete but nonmathematical treatment, see [Kleinbaum and Klein \(2010\)](#); and for a thorough discussion, see [Hosmer, Lemeshow, and Sturdivant \(2013\)](#). See [Gould \(2000\)](#) for a discussion of the interpretation of logistic regression. See [Dupont \(2009\)](#) or [Hilbe \(2009\)](#) for a discussion of logistic regression with examples using Stata. For a discussion using Stata with an emphasis on model specification, see [Vittinghoff et al. \(2012\)](#).

Stata has a variety of commands for performing estimation when the dependent variable is dichotomous or polytomous. See [Long and Freese \(2014\)](#) for a book devoted to fitting these models with Stata. See `help estimation commands` for a complete list of all of Stata’s estimation commands.

## ▷ Example 1

Consider the following dataset from a study of risk factors associated with low birthweight described in [Hosmer, Lemeshow, and Sturdivant \(2013, 24\)](#).

```
. use https://www.stata-press.com/data/r18/lbw
(Hosmer & Lemeshow data)
```

```
. describe
```

```
Contains data from https://www.stata-press.com/data/r18/lbw.dta
Observations:      189      Hosmer & Lemeshow data
Variables:         11      15 Jan 2022 05:01
```

Variable name	Storage type	Display format	Value label	Variable label
<code>id</code>	<code>int</code>	<code>%8.0g</code>		Identification code
<code>low</code>	<code>byte</code>	<code>%8.0g</code>		Birthweight<2500g
<code>age</code>	<code>byte</code>	<code>%8.0g</code>		Age of mother
<code>lwt</code>	<code>int</code>	<code>%8.0g</code>		Weight at last menstrual period
<code>race</code>	<code>byte</code>	<code>%8.0g</code>	<code>race</code>	Race
<code>smoke</code>	<code>byte</code>	<code>%9.0g</code>	<code>smoke</code>	Smoked during pregnancy
<code>ptl</code>	<code>byte</code>	<code>%8.0g</code>		Premature labor history (count)
<code>ht</code>	<code>byte</code>	<code>%8.0g</code>		Has history of hypertension
<code>ui</code>	<code>byte</code>	<code>%8.0g</code>		Presence, uterine irritability
<code>ftv</code>	<code>byte</code>	<code>%8.0g</code>		Number of visits to physician during 1st trimester
<code>bwt</code>	<code>int</code>	<code>%8.0g</code>		Birthweight (grams)

Sorted by:

We want to investigate the causes of low birthweight. Here `race` is a categorical variable indicating whether a person is white (`race = 1`), black (`race = 2`), or some other race (`race = 3`). We want indicator (dummy) variables for `race` included in the regression, so we will use factor variables.

```
. logistic low age lwt i.race smoke ptl ht ui
```

```
Logistic regression
```

```
Number of obs = 189
```

```
LR chi2(8) = 33.22
```

```
Prob > chi2 = 0.0001
```

```
Pseudo R2 = 0.1416
```

```
Log likelihood = -100.724
```

low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
age	.9732636	.0354759	-0.74	0.457	.9061578	1.045339
lwt	.9849634	.0068217	-2.19	0.029	.9716834	.9984249
race						
Black	3.534767	1.860737	2.40	0.016	1.259736	9.918406
Other	2.368079	1.039949	1.96	0.050	1.001356	5.600207
smoke	2.517698	1.00916	2.30	0.021	1.147676	5.523162
ptl	1.719161	.5952579	1.56	0.118	.8721455	3.388787
ht	6.249602	4.322408	2.65	0.008	1.611152	24.24199
ui	2.1351	.9808153	1.65	0.099	.8677528	5.2534
_cons	1.586014	1.910496	0.38	0.702	.1496092	16.8134

Note: **\_cons** estimates baseline odds.

The odds ratios are for a one-unit change in the variable. If we wanted the odds ratio for **age** to be in terms of 4-year intervals, we would type

```
. generate age4 = age/4
```

```
. logistic low age4 lwt i.race smoke ptl ht ui
```

(output omitted)

After **logistic**, we can type **logit** to see the model in terms of coefficients and standard errors:

```
. logit
```

```
Logistic regression
```

```
Number of obs = 189
```

```
LR chi2(8) = 33.22
```

```
Prob > chi2 = 0.0001
```

```
Pseudo R2 = 0.1416
```

```
Log likelihood = -100.724
```

low	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
age4	-.1084012	.1458017	-0.74	0.457	-.3941673	.1773649
lwt	-.0151508	.0069259	-2.19	0.029	-.0287253	-.0015763
race						
Black	1.262647	.5264101	2.40	0.016	.2309024	2.294392
Other	.8620792	.4391532	1.96	0.050	.0013548	1.722804
smoke	.9233448	.4008266	2.30	0.021	.137739	1.708951
ptl	.5418366	.346249	1.56	0.118	-.136799	1.220472
ht	1.832518	.6916292	2.65	0.008	.4769494	3.188086
ui	.7585135	.4593768	1.65	0.099	-.1418484	1.658875
_cons	.4612239	1.20459	0.38	0.702	-1.899729	2.822176

If we wanted to see the logistic output again, we would type **logistic** without arguments.

## ▷ Example 2

We can specify the confidence interval for the odds ratios with the `level()` option, and we can do this either at estimation time or when replaying the model. For instance, to see our first model in [example 1](#) with narrower, 90% confidence intervals, we might type

```
. logistic, level(90)
Logistic regression                               Number of obs =   189
                                                LR chi2(8)      =   33.22
                                                Prob > chi2     = 0.0001
Log likelihood = -100.724                       Pseudo R2      = 0.1416
```

low	Odds ratio	Std. err.	z	P> z	[90% conf. interval]	
age4	.8972675	.1308231	-0.74	0.457	.7059409	1.140448
lwt	.9849634	.0068217	-2.19	0.029	.9738063	.9962483
race						
Black	3.534767	1.860737	2.40	0.016	1.487028	8.402379
Other	2.368079	1.039949	1.96	0.050	1.149971	4.876471
smoke	2.517698	1.00916	2.30	0.021	1.302185	4.867819
ptl	1.719161	.5952579	1.56	0.118	.9726876	3.038505
ht	6.249602	4.322408	2.65	0.008	2.003487	19.49478
ui	2.1351	.9808153	1.65	0.099	1.00291	4.545424
_cons	1.586014	1.910496	0.38	0.702	.2186791	11.50288

Note: **\_cons** estimates baseline odds.

◀

**Robust estimate of variance**

If you specify `vce(robust)`, Stata reports the robust estimate of variance described in [\[U\] 20.22 Obtaining robust variance estimates](#). Here is the model previously fit with the robust estimate of variance:

```
. logistic low age lwt i.race smoke ptl ht ui, vce(robust)
Logistic regression                               Number of obs =   189
                                                Wald chi2(8)     = 29.02
                                                Prob > chi2     = 0.0003
Log pseudolikelihood = -100.724                 Pseudo R2      = 0.1416
```

low	Odds ratio	Robust std. err.	z	P> z	[95% conf. interval]	
age	.9732636	.0329376	-0.80	0.423	.9108015	1.040009
lwt	.9849634	.0070209	-2.13	0.034	.9712984	.9988206
race						
Black	3.534767	1.793616	2.49	0.013	1.307504	9.556051
Other	2.368079	1.026563	1.99	0.047	1.012512	5.538501
smoke	2.517698	.9736417	2.39	0.017	1.179852	5.372537
ptl	1.719161	.7072902	1.32	0.188	.7675715	3.850476
ht	6.249602	4.102026	2.79	0.005	1.726445	22.6231
ui	2.1351	1.042775	1.55	0.120	.8197749	5.560858
_cons	1.586014	1.939482	0.38	0.706	.144345	17.42658

Note: **\_cons** estimates baseline odds.

Also, you can specify `vce(cluster clustvar)` and then, within cluster, relax the assumption of independence. To illustrate this, we have made some fictional additions to the low-birthweight data.

Say that these data are not a random sample of mothers but instead are a random sample of mothers from a random sample of hospitals. In fact, that may be true—we do not know the history of these data.

Hospitals specialize, and it would not be too incorrect to say that some hospitals specialize in more difficult cases. We are going to show two extremes. In one, all hospitals are alike, but we are going to estimate under the possibility that they might differ. In the other, hospitals are strikingly different. In both cases, we assume that patients are drawn from 20 hospitals.

In both examples, we will fit the same model, and we will type the same command to fit it. Below are the same data we have been using but with a new variable, `hospid`, that identifies from which of the 20 hospitals each patient was drawn (and which we have made up):

```
. use https://www.stata-press.com/data/r18/hospid1, clear
. logistic low age lwt i.race smoke ptl ht ui, vce(cluster hospid)
Logistic regression                                Number of obs =   189
                                                    Wald chi2(8)    =  49.67
                                                    Prob > chi2    =  0.0000
Log pseudolikelihood = -100.724                    Pseudo R2      =  0.1416
                                                    (Std. err. adjusted for 20 clusters in hospid)
```

low	Odds ratio	Robust std. err.	z	P> z	[95% conf. interval]	
age	.9732636	.0397476	-0.66	0.507	.898396	1.05437
lwt	.9849634	.0057101	-2.61	0.009	.9738352	.9962187
race						
Black	3.534767	2.013285	2.22	0.027	1.157563	10.79386
Other	2.368079	.8451325	2.42	0.016	1.176562	4.766257
smoke	2.517698	.8284259	2.81	0.005	1.321062	4.79826
ptl	1.719161	.6676221	1.40	0.163	.8030814	3.680219
ht	6.249602	4.066275	2.82	0.005	1.74591	22.37086
ui	2.1351	1.093144	1.48	0.138	.7827337	5.824014
_cons	1.586014	1.661913	0.44	0.660	.2034094	12.36639

Note: `_cons` estimates baseline odds.

The standard errors are similar to the standard errors we have previously obtained, whether we used the robust or conventional estimators. In this example, we invented the hospital IDs randomly.

Here are the results of the estimation with the same data but with a different set of hospital IDs:

```
. use https://www.stata-press.com/data/r18/hospid2
. logistic low age lwt i.race smoke ptl ht ui, vce(cluster hospid)
Logistic regression
Number of obs = 189
Wald chi2(8) = 7.19
Prob > chi2 = 0.5167
Pseudo R2 = 0.1416
Log pseudolikelihood = -100.724
(Std. err. adjusted for 20 clusters in hospid)
```

low	Odds ratio	Robust std. err.	z	P> z	[95% conf. interval]	
age	.9732636	.0293064	-0.90	0.368	.9174862	1.032432
lwt	.9849634	.0106123	-1.41	0.160	.9643817	1.005984
race						
Black	3.534767	3.120338	1.43	0.153	.6265521	19.9418
Other	2.368079	1.297738	1.57	0.116	.8089594	6.932114
smoke	2.517698	1.570287	1.48	0.139	.7414969	8.548655
ptl	1.719161	.6799153	1.37	0.171	.7919045	3.732161
ht	6.249602	7.165454	1.60	0.110	.660558	59.12808
ui	2.1351	1.411977	1.15	0.251	.5841231	7.804266
_cons	1.586014	1.946253	0.38	0.707	.1431423	17.573

Note: **\_cons** estimates baseline odds.

Note the strikingly larger standard errors. What happened? In these data, women most likely to have low-birthweight babies are sent to certain hospitals, and the decision on likeliness is based not just on age, smoking history, etc., but on other things that doctors can see but that are not recorded in our data. Thus, merely because a woman is at one of the centers identifies her to be more likely to have a low-birthweight baby.

## Video examples

[Logistic regression, part 1: Binary predictors](#)

[Logistic regression, part 2: Continuous predictors](#)

[Logistic regression, part 3: Factor variables](#)

## Stored results

`logistic` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(N_cds)</code>	number of completely determined successes
<code>e(N_cdf)</code>	number of completely determined failures
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(r2_p)</code>	pseudo- $R^2$
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(p)</code>	$p$ -value for model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>logistic</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset)</code>	linear offset variable
<code>e(chi2type)</code>	Wald or LR; type of model $\chi^2$ test
<code>e(vce)</code>	<i>vce</i> type specified in <code>vce()</code>
<code>e(vctype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(marginsnotok)</code>	predictions disallowed by <code>margins</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(mns)</code>	vector of means of the independent variables
<code>e(rules)</code>	information about perfect predictors
<code>e(V)</code>	variance-covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices	
<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

Define  $\mathbf{x}_j$  as the (row) vector of independent variables, augmented by 1, and  $\mathbf{b}$  as the corresponding estimated parameter (column) vector. The logistic regression model is fit by `logit`; see [R] [logit](#) for details of estimation.

The odds ratio corresponding to the  $i$ th coefficient is  $\psi_i = \exp(b_i)$ . The standard error of the odds ratio is  $s_i^\psi = \psi_i s_i$ , where  $s_i$  is the standard error of  $b_i$  estimated by `logit`.

Define  $I_j = \mathbf{x}_j \mathbf{b}$  as the predicted index of the  $j$ th observation. The predicted probability of a positive outcome is

$$p_j = \frac{\exp(I_j)}{1 + \exp(I_j)}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`logistic` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are of special interest after `logistic`:

Command	Description
<code>estat classification</code>	report various summary statistics, including the classification table
<code>estat gof</code>	Pearson or Hosmer–Lemeshow goodness-of-fit test
<code>lroc</code>	compute area under ROC curve and graph the curve
<code>lsens</code>	graph sensitivity and specificity versus probability cutoff

These commands are not appropriate with `svy` estimation results.

The following standard postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>linktest</code>	link test for model specification
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	probabilities, influence statistics, residuals, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions

<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, standard errors, influence statistics, deviance residuals, leverages, sequential numbers, Pearson residuals, and the equation-level score.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset rules asif]
```

<i>statistic</i>	Description
------------------	-------------

Main	
<code>pr</code>	probability of a positive outcome; the default
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the prediction
* <code>dbeta</code>	<a href="#">Pregibon (1981)</a> $\Delta \hat{\beta}$ influence statistic
* <code>ddeviance</code>	deviance residual
* <code>dx2</code>	<a href="#">Hosmer, Lemeshow, and Sturdivant (2013)</a> $\Delta \chi^2$ influence statistic
* <code>ddeviance</code>	<a href="#">Hosmer, Lemeshow, and Sturdivant (2013)</a> $\Delta D$ influence statistic
* <code>hat</code>	<a href="#">Pregibon (1981)</a> leverage
* <code>number</code>	sequential number of the covariate pattern
* <code>residuals</code>	Pearson residuals; adjusted for number sharing covariate pattern
* <code>rstandard</code>	standardized Pearson residuals; adjusted for number sharing covariate pattern
<code>score</code>	first derivative of the log likelihood with respect to $x_j\beta$

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

`pr`, `xb`, `stdp`, and `score` are the only options allowed with `svy` estimation results.

## Options for predict

## Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`dbeta` calculates the Pregibon (1981)  $\Delta\hat{\beta}$  influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation along with all others that share the same covariate pattern. In Hosmer, Lemeshow, and Sturdivant (2013, 154–155) jargon, this statistic is *M*-asymptotic; that is, it is adjusted for the number of observations that share the same covariate pattern.

`deviance` calculates the deviance residual.

`dx2` calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191)  $\Delta\chi^2$  influence statistic, reflecting the decrease in the Pearson  $\chi^2$  that is due to deletion of the observation and all others that share the same covariate pattern.

`ddeviance` calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191)  $\Delta D$  influence statistic, which is the change in the deviance residual that is due to deletion of the observation and all others that share the same covariate pattern.

`hat` calculates the Pregibon (1981) leverage or the diagonal elements of the hat matrix adjusted for the number of observations that share the same covariate pattern.

`number` numbers the covariate patterns—observations with the same covariate pattern have the same `number`. Observations not used in estimation have `number` set to missing. The first covariate pattern is numbered 1, the second 2, and so on.

`residuals` calculates the Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 155) and adjusted for the number of observations that share the same covariate pattern.

`rstandard` calculates the standardized Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 191) and adjusted for the number of observations that share the same covariate pattern.

`score` calculates the equation-level score,  $\partial \ln L / \partial (\mathbf{x}_j \boldsymbol{\beta})$ .

## Options

`nooffset` is relevant only if you specified `offset(varname)` for `logistic`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j$ .

`rules` requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations. See [example 1](#) in [\[R\] logit postestimation](#).

`asif` requests that Stata ignore the rules and the exclusion criteria and calculate predictions for all observations possible by using the estimated parameter from the model. See [example 1](#) in [\[R\] logit postestimation](#).

# margins

## Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>pr</code>	probability of a positive outcome; the default
<code>xb</code>	linear prediction
<code>stdp</code>	not allowed with <code>margins</code>
<code>dbeta</code>	not allowed with <code>margins</code>
<code>ddeviance</code>	not allowed with <code>margins</code>
<code>dx2</code>	not allowed with <code>margins</code>
<code>ddeviance</code>	not allowed with <code>margins</code>
<code>hat</code>	not allowed with <code>margins</code>
<code>number</code>	not allowed with <code>margins</code>
<code>residuals</code>	not allowed with <code>margins</code>
<code>rstandard</code>	not allowed with <code>margins</code>
<code>score</code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

`predict` is used after `logistic` to obtain predicted probabilities, residuals, and influence statistics for the estimation sample. The suggested diagnostic graphs below are from [Hosmer, Lemeshow, and Sturdivant \(2013\)](#), where they are more elaborately explained. Also see [Collett \(2003, 129–168\)](#) for a thorough discussion of model checking.

Remarks are presented under the following headings:

*predict without options*  
*predict with the xb and stdp options*  
*predict with the residuals option*  
*predict with the number option*  
*predict with the deviance option*  
*predict with the rstandard option*  
*predict with the hat option*  
*predict with the dx2 option*  
*predict with the ddeviance option*  
*predict with the dbeta option*

## predict without options

Typing `predict newvar` after estimation calculates the predicted probability of a positive outcome.

In [example 1](#) of [\[R\] logistic](#), we ran the model `logistic low age lwt i.race smoke ptl ht ui`. We obtain the predicted probabilities of a positive outcome by typing

```
. use https://www.stata-press.com/data/r18/lbw
(Hosmer & Lemeshow data)
. logistic low age lwt i.race smoke ptl ht ui
(output omitted)
. predict p
(option pr assumed; Pr(low))
. summarize p low
```

Variable	Obs	Mean	Std. dev.	Min	Max
p	189	.3121693	.1913915	.0272559	.8391283
low	189	.3121693	.4646093	0	1

## predict with the xb and stdp options

`predict` with the `xb` option calculates the linear combination  $x_j\mathbf{b}$ , where  $x_j$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector. This is sometimes known as the index function because the cumulative distribution function indexed at this value is the probability of a positive outcome.

With the `stdp` option, `predict` calculates the standard error of the prediction, which is *not* adjusted for replicated covariate patterns in the data. The influence statistics described below are adjusted for replicated covariate patterns in the data.

## predict with the residuals option

`predict` can calculate more than predicted probabilities. The Pearson residual is defined as the square root of the contribution of the covariate pattern to the Pearson  $\chi^2$  goodness-of-fit statistic, signed according to whether the observed number of positive responses within the covariate pattern is less than or greater than expected. For instance,

```
. predict r, residuals
. summarize r, detail
```

Pearson residual					
	Percentiles	Smallest			
1%	-1.750923	-2.283885			
5%	-1.129907	-1.750923			
10%	-.9581174	-1.636279	Obs		189
25%	-.6545911	-1.636279	Sum of wgt.		189
50%	-.3806923		Mean	-.0242299	
		Largest	Std. dev.	.9970949	
75%	.8162894	2.23879			
90%	1.510355	2.317558	Variance	.9941981	
95%	1.747948	3.002206	Skewness	.8618271	
99%	3.002206	3.126763	Kurtosis	3.038448	

We notice the prevalence of a few large positive residuals:

```
. sort r
. list id r low p age race in -5/1
```

	id	r	low	p	age	race
185.	33	2.224501	1	.1681123	19	White
186.	57	2.23879	1	.166329	15	White
187.	16	2.317558	1	.1569594	27	Other
188.	77	3.002206	1	.0998678	26	White
189.	36	3.126763	1	.0927932	24	White

## predict with the number option

Covariate patterns play an important role in logistic regression. Two observations are said to share the same covariate pattern if the independent variables for the two observations are identical. Although we might think of having individual observations, the statistical information in the sample can be summarized by the covariate patterns, the number of observations with that covariate pattern, and the number of positive outcomes within the pattern. Depending on the model, the number of covariate patterns can approach or be equal to the number of observations, or it can be considerably less.

Stata calculates all the residual and diagnostic statistics in terms of covariate patterns, not observations. That is, all observations with the same covariate pattern are given the same residual and diagnostic statistics. [Hosmer, Lemeshow, and Sturdivant \(2013, 154–155\)](#) argue that such “*M*-asymptotic” statistics are more useful than “*N*-asymptotic” statistics.

To understand the difference, think of an observed positive outcome with predicted probability of 0.8. Taking the observation in isolation, the residual must be positive—we expected 0.8 positive responses and observed 1. This may indeed be the correct residual, but not necessarily. Under the *M*-asymptotic definition, we ask how many successes we observed across all observations with this covariate pattern. If that number were, say, six, and there were a total of 10 observations with this covariate pattern, then the residual is negative for the covariate pattern—we expected eight positive outcomes but observed six. `predict` makes this kind of calculation and then attaches the same residual to all observations in the covariate pattern.

Occasionally, you might want to find all observations sharing a covariate pattern. `number` allows you to do this:

```
. predict pattern, number
. summarize pattern
```

Variable	Obs	Mean	Std. dev.	Min	Max
pattern	189	89.2328	53.16573	1	182

We previously fit the model `logistic low age lwt i.race smoke ptl ht ui` over 189 observations. There are 182 covariate patterns in our data.

## predict with the deviance option

The deviance residual is defined as the square root of the contribution to the likelihood-ratio test statistic of a saturated model versus the fitted model. It has slightly different properties from the Pearson residual (see [Hosmer, Lemeshow, and Sturdivant \[2013, 155–157\]](#)):

```
. predict d, deviance
. summarize d, detail
```

deviance residual					
Percentiles		Smallest			
1%	-1.843472	-1.911621			
5%	-1.33477	-1.843472			
10%	-1.148316	-1.843472	Obs	189	
25%	-.8445325	-1.674869	Sum of wgt.	189	
50%	-.5202702		Mean	-.1228811	
		Largest	Std. dev.	1.049237	
75%	.9129041	1.894089			
90%	1.541558	1.924457	Variance	1.100898	
95%	1.673338	2.146583	Skewness	.6598857	
99%	2.146583	2.180542	Kurtosis	2.036938	

## predict with the rstandard option

Pearson residuals do not have a standard deviation equal to 1. `rstandard` generates Pearson residuals normalized to have an *expected* standard deviation equal to 1.

```
. predict rs, rstandard
. summarize r rs
```

Variable	Obs	Mean	Std. dev.	Min	Max
r	189	-.0242299	.9970949	-2.283885	3.126763
rs	189	-.0279135	1.026406	-2.4478	3.149081

```
. correlate r rs
(obs=189)
```

	r	rs
r	1.0000	
rs	0.9998	1.0000

Remember that we previously created `r` containing the (unstandardized) Pearson residuals. In these data, whether we use standardized or unstandardized residuals does not matter much.

## predict with the hat option

`hat` calculates the leverage of a covariate pattern—a scaled measure of distance in terms of the independent variables. Large values indicate covariate patterns far from the average covariate pattern that can have a large effect on the fitted model even if the corresponding residual is small. Consider the following graph:

```
. predict h, hat
. scatter h r, xline(0) ytitle("Leverage")
```

The points to the left of the vertical line are observed negative outcomes; here our data contain almost as many covariate patterns as observations, so most covariate patterns are unique. In such unique patterns, we observe either 0 or 1 success and expect  $p$ , thus forcing the sign of the residual. If we had fewer covariate patterns—if we did not have continuous variables in our model—there would be no such interpretation, and we would not have drawn the vertical line at 0.

Points on the left and right edges of the graph represent large residuals—covariate patterns that are not fit well by our model. Points at the top of our graph represent high leverage patterns. When analyzing the influence of observations on the model, we are most interested in patterns with high leverage and small residuals—patterns that might otherwise escape our attention.

## predict with the dx2 option

There are many ways to measure influence, and `hat` is one example. `dx2` measures the decrease in the Pearson  $\chi^2$  goodness-of-fit statistic that would be caused by deleting an observation (and others sharing the covariate pattern):

```
. predict dx2, dx2
. scatter dx2 p
```

Paraphrasing [Hosmer, Lemeshow, and Sturdivant \(2013, 195–197\)](#), the points going from the top left to the bottom right correspond to covariate patterns with the number of positive outcomes equal to the number in the group; the points on the other curve correspond to 0 positive outcomes. In our data, most of the covariate patterns are unique, so the points tend to lie along one or the other curves; the points that are off the curves correspond to the few repeated covariate patterns in our data in which all the outcomes are not the same.

We examine this graph for large values of `dx2`—there are two at the top left.

## predict with the ddeviance option

Another measure of influence is the change in the deviance residuals due to deletion of a covariate pattern:

```
. predict dd, ddeviance
```

As with `dx2`, we typically graph `ddeviance` against the probability of a positive outcome. We direct you to [Hosmer, Lemeshow, and Sturdivant \(2013, 195\)](#) for an example and for the interpretation of this graph.

**predict with the dbeta option**

One of the more direct measures of influence of interest to model fitters is the [Pregibon \(1981\)](#) dbeta measure, a measure of the change in the coefficient vector that would be caused by deleting an observation (and all others sharing the covariate pattern):

```
. predict db, dbeta
. scatter db p
```

One observation has a large effect on the estimated coefficients. We can easily find this point:

```
. sort db
. list in 1
```

189.

id	low	age	lwt	race	smoke	pt1	ht	ui	ftv	bwt
188	0	25	95	White	Smoker	3	0	1	0	3637
p		r		pattern		d		rs		h
.8391283		-2.283885		117		-1.911621		-2.4478		.1294439
dx2				dd			db			
5.991726				4.197658			.8909163			

Hosmer, Lemeshow, and Sturdivant (2013, 196) suggest a graph that combines two of the influence measures:

```
. scatter dx2 p [aw=db], title("Symbol size proportional to dBeta") mfcolor(none)
```

We can easily spot the most influential points by the *dbeta* and *dx2* measures.

## Methods and formulas

Let  $j$  index observations. Define  $M_j$  for each observation as the total number of observations sharing  $j$ 's covariate pattern. Define  $Y_j$  as the total number of positive responses among observations sharing  $j$ 's covariate pattern.

The Pearson residual for the  $j$ th observation is defined as

$$r_j = \frac{Y_j - M_j p_j}{\sqrt{M_j p_j (1 - p_j)}}$$

For  $M_j > 1$ , the deviance residual  $d_j$  is defined as

$$d_j = \pm \left( 2 \left[ Y_j \ln \left( \frac{Y_j}{M_j p_j} \right) + (M_j - Y_j) \ln \left\{ \frac{M_j - Y_j}{M_j (1 - p_j)} \right\} \right] \right)^{1/2}$$

where the sign is the same as the sign of  $(Y_j - M_j p_j)$ . In the limiting cases, the deviance residual is given by

$$d_j = \begin{cases} -\sqrt{2M_j |\ln(1 - p_j)|} & \text{if } Y_j = 0 \\ \sqrt{2M_j |\ln p_j|} & \text{if } Y_j = M_j \end{cases}$$

The *unadjusted* diagonal elements of the hat matrix  $h_{Uj}$  are given by  $h_{Uj} = (\mathbf{XVX}')_{jj}$ , where  $V$  is the estimated covariance matrix of parameters. The adjusted diagonal elements  $h_j$  created by **hat** are then  $h_j = M_j p_j (1 - p_j) h_{Uj}$ .

The standardized Pearson residual  $r_{Sj}$  is  $r_j / \sqrt{1 - h_j}$ .

The Pregibon (1981)  $\Delta\widehat{\beta}_j$  influence statistic is

$$\Delta\widehat{\beta}_j = \frac{r_j^2 h_j}{(1 - h_j)^2}$$

The corresponding change in the Pearson  $\chi^2$  is  $r_{Sj}^2$ . The corresponding change in the deviance residual is  $\Delta D_j = d_j^2 / (1 - h_j)$ .

## Description

`logit` fits a logit model for a binary response by maximum likelihood; it models the probability of a positive outcome given a set of regressors. *deprvar* equal to nonzero and nonmissing (typically *deprvar* equal to one) indicates a positive outcome, whereas *deprvar* equal to zero indicates a negative outcome.

Also see [\[R\] `logistic`](#); `logistic` displays estimates as odds ratios. Many users prefer the `logistic` command to `logit`. Results are the same regardless of which you use—both are the maximum-likelihood estimator. Several auxiliary commands that can be run after `logit`, `probit`, or `logistic` estimation are described in [\[R\] `logistic postestimation`](#).

## Quick start

Logit model of *y* on *x1* and *x2*

```
logit y x1 x2
```

Add indicators for categorical variable *a*

```
logit y x1 x2 i.a
```

With cluster-robust standard errors for clustering by levels of *cvar*

```
logit y x1 x2 i.a, vce(cluster cvar)
```

Save separate coefficient estimates for each level of *cvar* to `myresults.dta`

```
statsby _b, by(cvar) saving(myresults): logit y x1 x2 i.a
```

Adjust for complex survey design using `svyset` data

```
svy: logit y x1 x2 i.a
```

## Menu

Statistics > Binary outcomes > Logistic regression

## Syntax

```
logit devar [indepvars] [if] [in] [weight] [, options]
```

<i>options</i>	Description
<b>Model</b>	
<code>noconstant</code>	suppress constant term
<code>offset(<i>varname</i>)</code>	include <i>varname</i> in model with coefficient constrained to 1
<code>asis</code>	retain perfect predictor variables
<code>constraints(<i>constraints</i>)</code>	apply specified linear constraints
<b>SE/Robust</b>	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>opg</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>bootstrap</code> , or <code>jackknife</code>
<b>Reporting</b>	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>or</code>	report odds ratios
<code>nocnsreport</code>	do not display constraints
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>Maximization</b>	
<code>maximize_options</code>	control the maximization process; seldom used
<code>nocoef</code>	do not display coefficient table; seldom used
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*devar* and *indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] `bayes: logit` and [FMM] `fmm: logit`.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] `mi estimate`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()`, `nocoef`, and `weights` are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`nocoef`, `collinear`, and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

Model

`noconstant`, `offset(varname)`, `constraints(constraints)`; see [R] **Estimation options**.

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] `probit`.

## SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`or` reports the estimated coefficients transformed to odds ratios, that is,  $e^b$  rather than  $b$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `or` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `logit` but are not shown in the dialog box:

`nocoef` specifies that the coefficient table not be displayed. This option is sometimes used by program writers but is of no use interactively.

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[Basic usage](#)  
[Model identification](#)

### Basic usage

`logit` fits maximum likelihood models with dichotomous dependent (left-hand-side) variables coded as 0/1 (or, more precisely, coded as 0 and not-0).

For grouped data or data in binomial form, a probit model can be fit using `glm` with the `family(binomial)` and `link(logit)` options.

### ▷ Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a logit model explaining whether a car is foreign on the basis of its weight and mileage. Here is an overview of our data:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. keep make mpg weight foreign
. describe
Contains data from https://www.stata-press.com/data/r18/auto.dta
Observations:      74                1978 automobile data
Variables:         4                 13 Apr 2022 17:45
                                   (_dta has notes)
```

Variable name	Storage type	Display format	Value label	Variable label
make	str18	%-18s		Make and model
mpg	int	%8.0g		Mileage (mpg)
weight	int	%8.0gc		Weight (lbs.)
foreign	byte	%8.0g	origin	Car origin

Sorted by: foreign

Note: Dataset has changed since last saved.

```
. inspect foreign
```

```
foreign: Car origin
```

		Number of observations		
		Total	Integers	Nonintegers
#	Negative	-	-	-
#	Zero	52	52	-
#	Positive	22	22	-
#				
# #	Total	74	74	-
# #	Missing	-		
0		74		
1				

(2 unique values)

foreign is labeled and all values are documented in the label.

The variable `foreign` takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$\Pr(\text{foreign} = 1) = F(\beta_0 + \beta_1 \text{weight} + \beta_2 \text{mpg})$$

where  $F(z) = e^z / (1 + e^z)$  is the cumulative logistic distribution.

To fit this model, we type

```
. logit foreign weight mpg
Iteration 0:  Log likelihood = -45.03321
Iteration 1:  Log likelihood = -29.238536
Iteration 2:  Log likelihood = -27.244139
Iteration 3:  Log likelihood = -27.175277
Iteration 4:  Log likelihood = -27.175156
Iteration 5:  Log likelihood = -27.175156

Logistic regression                               Number of obs =      74
                                                    LR chi2(2)          = 35.72
                                                    Prob > chi2         = 0.0000
                                                    Pseudo R2          = 0.3966

Log likelihood = -27.175156
```

foreign	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
weight	-.0039067	.0010116	-3.86	0.000	-.0058894	-.001924
mpg	-.1685869	.0919175	-1.83	0.067	-.3487418	.011568
_cons	13.70837	4.518709	3.03	0.002	4.851859	22.56487

We find that heavier cars are less likely to be foreign and that cars yielding better gas mileage are also less likely to be foreign, at least holding the weight of the car constant. ◀

## □ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

If you prefer a more formal mathematical statement, when you type `logit y x`, Stata fits the model

$$\Pr(y_j \neq 0 \mid \mathbf{x}_j) = \frac{\exp(\mathbf{x}_j\boldsymbol{\beta})}{1 + \exp(\mathbf{x}_j\boldsymbol{\beta})}$$

□

## Model identification

The `logit` command has one more feature, and it is probably the most useful. `logit` automatically checks the model for identification and, if it is underidentified, drops whatever variables and observations are necessary for estimation to proceed. (`logistic`, `probit`, and `ivprobit` do this as well.)

## ▷ Example 2

Have you ever fit a logit model where one or more of your independent variables perfectly predicted one or the other outcome?

For instance, consider the following data:

Outcome $y$	Independent variable $x$
0	1
0	1
0	0
1	0

Say that we wish to predict the outcome on the basis of the independent variable. The outcome is always zero whenever the independent variable is one. In our data,  $\Pr(y = 0 \mid x = 1) = 1$ , which means that the logit coefficient on  $x$  must be minus infinity with a corresponding infinite standard error. At this point, you may suspect that we have a problem.

Unfortunately, not all such problems are so easily detected, especially if you have a lot of independent variables in your model. If you have ever had such difficulties, you have experienced one of the more unpleasant aspects of computer optimization. The computer has no idea that it is trying to solve for an infinite coefficient as it begins its iterative process. All it knows is that at each step, making the coefficient a little bigger, or a little smaller, works wonders. It continues on its merry way until either 1) the whole thing comes crashing to the ground when a numerical overflow error occurs or 2) it reaches some predetermined cutoff that stops the process. In the meantime, you have been waiting. The estimates that you finally receive, if you receive any at all, may be nothing more than numerical roundoff.

Stata watches for these sorts of problems, alerts us, fixes them, and properly fits the model.

Let's return to our automobile data. Among the variables we have in the data is one called `repair`, which takes on three values. A value of 1 indicates that the car has a poor repair record, 2 indicates an average record, and 3 indicates a better-than-average record. Here is a tabulation of our data:

```
. use https://www.stata-press.com/data/r18/repair, clear
(1978 automobile data)
. tabulate foreign repair
```

Car origin	Repair			Total
	1	2	3	
Domestic	10	27	9	46
Foreign	0	3	9	12
Total	10	30	18	58

All the cars with poor repair records (`repair = 1`) are domestic. If we were to attempt to predict `foreign` on the basis of the repair records, the predicted probability for the `repair = 1` category would have to be zero. This in turn means that the logit coefficient must be minus infinity, and that would set most computer programs buzzing.

Let's try Stata on this problem.

```
. logit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly;
      1.repair omitted and 10 obs not used.

Iteration 0:  Log likelihood = -26.992087
Iteration 1:  Log likelihood = -22.483187
Iteration 2:  Log likelihood = -22.230498
Iteration 3:  Log likelihood = -22.229139
Iteration 4:  Log likelihood = -22.229138

Logistic regression
Log likelihood = -22.229138
Number of obs = 48
LR chi2(1) = 9.53
Prob > chi2 = 0.0020
Pseudo R2 = 0.1765
```

foreign	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
repair						
1	0 (empty)					
2	-2.197225	.7698003	-2.85	0.004	-3.706005	-.6884436
_cons	7.94e-17	.4714045	0.00	1.000	-.9239359	.9239359

Remember that all the cars with poor repair records (`repair = 1`) are domestic, so the model cannot be fit, or at least it cannot be fit if we restrict ourselves to finite coefficients. Stata noted that fact “note: 1.repair !=0 predicts failure perfectly”. This is Stata’s mathematically precise way of saying what we said in English. When `repair` is 1, the car is domestic.

Stata then went on to say “1.repair omitted and 10 obs not used”. This is Stata eliminating the problem. First `1.repair` had to be removed from the model because it would have an infinite coefficient. Then, the 10 observations that led to the problem had to be eliminated, as well, so as not to bias the remaining coefficients in the model. The 10 observations that are not used are the 10 domestic cars that have poor repair records.

Stata then fit what was left of the model, using the remaining observations. Because no observations remained for cars with poor repair records, Stata reports “(empty)” in the row for `repair = 1`.

◀

## □ Technical note

Stata is pretty smart about catching problems like this. It will catch “one-way causation by a dummy variable”, as we demonstrated above.

Stata also watches for “two-way causation”, that is, a variable that perfectly determines the outcome, both successes and failures. Here Stata says, “so-and-so predicts outcome perfectly” and stops. Statistics dictates that no model can be fit.

Stata also checks your data for collinear variables; it will say, “so-and-so omitted because of collinearity”. No observations need to be eliminated in this case, and model fitting will proceed without the offending variable.

It will also catch a subtle problem that can arise with continuous data. For instance, if we were estimating the chances of surviving the first year after an operation, and if we included in our model `age`, and if all the persons over 65 died within the year, Stata would say, “`age > 65` predicts failure perfectly”. It would then inform us about the fix-up it takes and fit what can be fit of our model.

logit (and logistic, probit, and ivprobit) will also occasionally display messages such as

Note: 4 failures and 0 successes completely determined.

There are two causes for a message like this. The first—and most unlikely—case occurs when a continuous variable (or a combination of a continuous variable with other continuous or dummy variables) is simply a great predictor of the dependent variable. Consider Stata's `auto.dta` dataset with 6 observations removed.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. drop if foreign==0 & gear_ratio > 3.1
(6 observations deleted)
. logit foreign mpg weight gear_ratio, nolog
Logistic regression
Log likelihood = -6.4874814
```

Number of obs =	68
LR chi2(3) =	72.64
Prob > chi2 =	0.0000
Pseudo R2 =	0.8484

	foreign	Coefficient	Std. err.	z	P> z	[95% conf. interval]
	mpg	-.4944907	.2655508	-1.86	0.063	-1.014961 .0259792
	weight	-.0060919	.003101	-1.96	0.049	-.0121698 -.000014
	gear_ratio	15.70509	8.166234	1.92	0.054	-.300436 31.71061
	_cons	-21.39527	25.41486	-0.84	0.400	-71.20747 28.41694

Note: 4 failures and 0 successes completely determined.

There are no missing standard errors in the output. If you receive the “completely determined” message and have one or more missing standard errors in your output, see the second case discussed below.

Note `gear_ratio`'s large coefficient. `logit` thought that the 4 observations with the smallest predicted probabilities were essentially predicted perfectly.

```
. predict p
(option pr assumed; Pr(foreign))
. sort p
. list p in 1/4
```

	P
1.	1.34e-10
2.	6.26e-09
3.	7.84e-09
4.	1.49e-08

If this happens to you, you do not have to do anything. Computationally, the model is sound. The second case discussed below requires careful examination.

The second case occurs when the independent terms are all dummy variables or continuous ones with repeated values (for example, age). Here one or more of the estimated coefficients will have missing standard errors. For example, consider this dataset consisting of 6 observations.

```
. use https://www.stata-press.com/data/r18/logitxmpl, clear
. list, separator(0)
```

	y	x1	x2
1.	0	0	0
2.	0	0	0
3.	0	1	0
4.	1	1	0
5.	0	0	1
6.	1	0	1

```
. logit y x1 x2
```

```
Iteration 0: Log likelihood = -3.819085
Iteration 1: Log likelihood = -2.9527336
Iteration 2: Log likelihood = -2.8110282
Iteration 3: Log likelihood = -2.7811973
Iteration 4: Log likelihood = -2.7746107
Iteration 5: Log likelihood = -2.7730128
(output omitted)
Iteration 296: Log likelihood = -2.7725887 (not concave)
Iteration 297: Log likelihood = -2.7725887 (not concave)
Iteration 298: Log likelihood = -2.7725887 (not concave)
Iteration 299: Log likelihood = -2.7725887 (not concave)
Iteration 300: Log likelihood = -2.7725887 (not concave)
convergence not achieved
```

```
Logistic regression
```

```
Number of obs =      6
LR chi2(1)      =    2.09
Prob > chi2     = 0.1480
Pseudo R2      = 0.2740
```

```
Log likelihood = -2.7725887
```

	y	Coefficient	Std. err.	z	P> z	[95% conf. interval]
	x1	18.3704	2	9.19	0.000	14.45047 22.29033
	x2	18.3704	.	.	.	.
	_cons	-18.3704	1.414214	-12.99	0.000	-21.14221 -15.5986

```
Note: 2 failures and 0 successes completely determined.
```

```
convergence not achieved
r(430);
```

Three things are happening here. First, `logit` iterates almost forever and then declares nonconvergence. Second, `logit` can fit the outcome ( $y = 0$ ) for the covariate pattern  $x_1 = 0$  and  $x_2 = 0$  (that is, the first two observations) perfectly. This observation is the “2 failures and 0 successes completely determined”. Third, if this observation is excluded, then  $x_1$ ,  $x_2$ , and the constant are collinear.

This is the cause of the nonconvergence, the message “completely determined”, and the missing standard errors. It happens when you have a covariate pattern (or patterns) with only one outcome and there is collinearity when the observations corresponding to this covariate pattern are excluded.

If this happens to you, confirm the causes. First, identify the covariate pattern with only one outcome. (For your data, replace  $x_1$  and  $x_2$  with the independent variables of your model.)

```
. egen pattern = group(x1 x2)
. quietly logit y x1 x2, iterate(100)
. predict p
(option pr assumed; Pr(y))
. summarize p
```

Variable	Obs	Mean	Std. dev.	Min	Max
p	6	.3333333	.2581989	1.05e-08	.5

If successes were completely determined, that means that there are predicted probabilities that are almost 1. If failures were completely determined, that means that there are predicted probabilities that are almost 0. The latter is the case here, so we locate the corresponding value of `pattern`:

```
. tabulate pattern if p < 1e-7
```

group(x1 x2)	Freq.	Percent	Cum.
1	2	100.00	100.00
Total	2	100.00	

Once we omit this covariate pattern from the estimation sample, `logit` can deal with the collinearity:

```
. logit y x1 x2 if pattern != 1, nolog
note: x2 omitted because of collinearity.
```

Logistic regression

Number of obs =	4
LR chi2(1) =	0.00
Prob > chi2 =	1.0000
Pseudo R2 =	0.0000

Log likelihood = -2.7725887

y	Coefficient	Std. err.	z	P> z	[95% conf. interval]
x1	0	2	0.00	1.000	-3.919928 3.919928
x2	0 (omitted)				
_cons	0	1.414214	0.00	1.000	-2.771808 2.771808

We omit the collinear variable. Then we must decide whether to include or omit the observations with `pattern = 1`. We could include them,

```
. logit y x1, nolog
```

Logistic regression

Number of obs =	6
LR chi2(1) =	0.37
Prob > chi2 =	0.5447
Pseudo R2 =	0.0480

Log likelihood = -3.6356349

y	Coefficient	Std. err.	z	P> z	[95% conf. interval]
x1	1.098612	1.825742	0.60	0.547	-2.479776 4.677001
_cons	-1.098612	1.154701	-0.95	0.341	-3.361784 1.164559

or exclude them,

```
. logit y x1 if pattern != 1, nolog
Logistic regression                                Number of obs =      4
                                                    LR chi2(1)          =    0.00
                                                    Prob > chi2         =  1.0000
Log likelihood = -2.7725887                          Pseudo R2          =  0.0000
```

y	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
x1	0	2	0.00	1.000	-3.919928	3.919928
_cons	0	1.414214	0.00	1.000	-2.771808	2.771808

If the covariate pattern that predicts outcome perfectly is meaningful, you may want to exclude these observations from the model. Here you would report that covariate pattern such and such predicted outcome perfectly and that the best model for the rest of the data is . . . . But, more likely, the perfect prediction was simply the result of having too many predictors in the model. Then you would omit the extraneous variables from further consideration and report the best model for all the data. □

## Stored results

logit stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(N_cds)</code>	number of completely determined successes
<code>e(N_cdf)</code>	number of completely determined failures
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(r2_p)</code>	pseudo- $R^2$
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(p)</code>	$p$ -value for model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	logit
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset)</code>	linear offset variable
<code>e(chi2type)</code>	Wald or LR; type of model $\chi^2$ test
<code>e(vce)</code>	<i>vctype</i> specified in <code>vce()</code>
<code>e(vctype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program

<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(marginsnotok)</code>	predictions disallowed by <code>margins</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

## Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(mns)</code>	vector of means of the independent variables
<code>e(rules)</code>	information about perfect predictors
<code>e(V)</code>	variance-covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

## Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

## Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals
-----------------------	---

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

Cramer (2003, chap. 9) surveys the prehistory and history of the logit model. The word “logit” was coined by Berkson (1944) and is analogous to the word “probit”. For an introduction to probit and logit, see, for example, Aldrich and Nelson (1984), Cameron and Trivedi (2022), Jones (2007), Long (1997), Long and Freese (2014), Pampel (2021), or Powers and Xie (2008).

The likelihood function for logit is

$$\ln L = \sum_{j \in S} w_j \ln F(\mathbf{x}_j \mathbf{b}) + \sum_{j \notin S} w_j \ln \{1 - F(\mathbf{x}_j \mathbf{b})\}$$

where  $S$  is the set of all observations  $j$ , such that  $y_j \neq 0$ ,  $F(z) = e^z / (1 + e^z)$ , and  $w_j$  denotes the optional weights.  $\ln L$  is maximized as described in [R] **Maximize**.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*. The scores are calculated as  $\mathbf{u}_j = \{1 - F(\mathbf{x}_j \mathbf{b})\} \mathbf{x}_j$  for the positive outcomes and  $-F(\mathbf{x}_j \mathbf{b}) \mathbf{x}_j$  for the negative outcomes.

`logit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

Joseph Berkson (1899–1982) was born in New York City and studied at the College of the City of New York, Columbia, and Johns Hopkins, earning both an MD and a doctorate in statistics. He then worked at Johns Hopkins before moving to the Mayo Clinic in 1931 as a biostatistician. Among many other contributions, his most influential one drew upon a long-sustained interest in the logistic function, especially his 1944 paper on bioassay, in which he introduced the term “logit”. Berkson was a frequent participant in controversy—sometimes humorous, sometimes bitter—on subjects such as the evidence for links between smoking and various diseases and the relative merits of probit and logit methods and of different calculation methods.

## Postestimation commands

The following postestimation commands are of special interest after `logit`:

Command	Description
<code>estat classification</code>	report various summary statistics, including the classification table
<code>estat gof</code>	Pearson or Hosmer–Lemeshow goodness-of-fit test
<code>lroc</code>	compute area under ROC curve and graph the curve
<code>lsens</code>	graph sensitivity and specificity versus probability cutoff
<code>lassogof</code>	calculate goodness-of-fit predictions

These commands are not appropriate with `svy` estimation results.

The following standard postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike’s, consistent Akaike’s, corrected Akaike’s, and Schwarz’s Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman’s specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>linktest</code>	link test for model specification
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	probabilities, influence statistics, residuals, etc.

<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, standard errors, influence statistics, deviance residuals, leverages, sequential numbers, Pearson residuals, and the equation-level score.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset rules asif]
```

<i>statistic</i>	Description
Main	
<code>pr</code>	probability of a positive outcome; the default
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the prediction
* <code>dbeta</code>	<a href="#">Pregibon (1981)</a> $\Delta \hat{\beta}$ influence statistic
* <code>deviance</code>	deviance residual
* <code>dx2</code>	<a href="#">Hosmer, Lemeshow, and Sturdivant (2013)</a> $\Delta \chi^2$ influence statistic
* <code>ddeviance</code>	<a href="#">Hosmer, Lemeshow, and Sturdivant (2013)</a> $\Delta D$ influence statistic
* <code>hat</code>	<a href="#">Pregibon (1981)</a> leverage
* <code>number</code>	sequential number of the covariate pattern
* <code>residuals</code>	Pearson residuals; adjusted for number sharing covariate pattern
* <code>rstandard</code>	standardized Pearson residuals; adjusted for number sharing covariate pattern
<code>score</code>	first derivative of the log likelihood with respect to $x_j \beta$

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

`pr`, `xb`, `stdp`, and `score` are the only options allowed with `svy` estimation results.

## Options for predict

## Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`dbeta` calculates the Pregibon (1981)  $\Delta\hat{\beta}$  influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation along with all others that share the same covariate pattern. In Hosmer, Lemeshow, and Sturdivant (2013, 154–155) jargon, this statistic is  $M$ -asymptotic; that is, it is adjusted for the number of observations that share the same covariate pattern.

`deviance` calculates the deviance residual.

`dx2` calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191)  $\Delta\chi^2$  influence statistic, reflecting the decrease in the Pearson  $\chi^2$  that is due to deletion of the observation and all others that share the same covariate pattern.

`ddeviance` calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191)  $\Delta D$  influence statistic, which is the change in the deviance residual that is due to deletion of the observation and all others that share the same covariate pattern.

`hat` calculates the Pregibon (1981) leverage or the diagonal elements of the hat matrix adjusted for the number of observations that share the same covariate pattern.

`number` numbers the covariate patterns—observations with the same covariate pattern have the same `number`. Observations not used in estimation have `number` set to missing. The first covariate pattern is numbered 1, the second 2, and so on.

`residuals` calculates the Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 155) and adjusted for the number of observations that share the same covariate pattern.

`rstandard` calculates the standardized Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 191) and adjusted for the number of observations that share the same covariate pattern.

`score` calculates the equation-level score,  $\partial \ln L / \partial (\mathbf{x}_j \beta)$ .

## Options

`nooffset` is relevant only if you specified `offset(varname)` for `logit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j$ .

`rules` requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations.

`asif` requests that Stata ignore the rules and exclusion criteria and calculate predictions for all observations possible by using the estimated parameter from the model.

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>pr</code>	probability of a positive outcome; the default
<code>xb</code>	linear prediction
<code>stdp</code>	not allowed with <code>margins</code>
<code>dbeta</code>	not allowed with <code>margins</code>
<code>deviance</code>	not allowed with <code>margins</code>
<code>dx2</code>	not allowed with <code>margins</code>
<code>ddeviance</code>	not allowed with <code>margins</code>
<code>hat</code>	not allowed with <code>margins</code>
<code>number</code>	not allowed with <code>margins</code>
<code>residuals</code>	not allowed with <code>margins</code>
<code>rstandard</code>	not allowed with <code>margins</code>
<code>score</code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [\[R\] margins](#).

### Remarks and examples

Once you have fit a logit model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#). Here we will make only a few more comments.

`predict` without arguments calculates the predicted probability of a positive outcome, that is,  $\Pr(y_j = 1) = F(\mathbf{x}_j \mathbf{b})$ . With the `xb` option, `predict` calculates the linear combination  $\mathbf{x}_j \mathbf{b}$ , where  $\mathbf{x}_j$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector. This is sometimes known as the index function because the cumulative distribution function indexed at this value is the probability of a positive outcome.

In both cases, Stata remembers any rules used to identify the model and calculates missing for excluded observations, unless `rules` or `asif` is specified. For information about the other statistics available after `predict`, see [\[R\] logistic postestimation](#).

## ▷ Example 1: Predicted probabilities

In [example 2](#) of [\[R\] logit](#), we fit the logit model `logit foreign b3.repair`. To obtain predicted probabilities, type

```
. use https://www.stata-press.com/data/r18/repair
(1978 automobile data)
. logit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly
      1.repair omitted and 10 obs not used

(output omitted)
. predict p
(option pr assumed; Pr(foreign))
(10 missing values generated)
. summarize foreign p
```

Variable	Obs	Mean	Std. dev.	Min	Max
foreign	58	.2068966	.4086186	0	1
p	48	.25	.1956984	.1	.5

Stata remembers any rules used to identify the model and sets predictions to missing for any excluded observations. `logit` omitted the variable `1.repair` from our model and excluded 10 observations. Thus when we typed `predict p`, those same 10 observations were again excluded, and their predictions were set to missing.

`predict`'s `rules` option uses the rules in the prediction. During estimation, we were told “`1.repair != 0` predicts failure perfectly”, so the rule is that when `1.repair` is not zero, we should predict 0 probability of success or a positive outcome:

```
. predict p2, rules
(option pr assumed; Pr(foreign))
. summarize foreign p p2
```

Variable	Obs	Mean	Std. dev.	Min	Max
foreign	58	.2068966	.4086186	0	1
p	48	.25	.1956984	.1	.5
p2	58	.2068966	.2016268	0	.5

`predict`'s `asif` option ignores the rules and exclusion criteria and calculates predictions for all observations possible by using the estimated parameters from the model:

```
. predict p3, asif
(option pr assumed; Pr(foreign))
. summarize foreign p p2 p3
```

Variable	Obs	Mean	Std. dev.	Min	Max
foreign	58	.2068966	.4086186	0	1
p	48	.25	.1956984	.1	.5
p2	58	.2068966	.2016268	0	.5
p3	58	.2931035	.2016268	.1	.5

Which is right? What `predict` does by default is the most conservative approach. If many observations had been excluded because of a simple rule, we could be reasonably certain that the `rules` prediction is correct. The `asif` prediction is correct only if the exclusion is a fluke, and we would be willing to exclude the variable from the analysis anyway. Then, however, we would refit the model to include the excluded observations.

## ► Example 2: Predictive margins

We can use the command `margins, contrast` after `logit` to make comparisons on the probability scale. Let's fit a model predicting low birthweight from characteristics of the mother:

```
. use https://www.stata-press.com/data/r18/lbw, clear
(Hosmer & Lemeshow data)

. logit low age i.race i.smoke ptl i.ht i.ui

Iteration 0:  Log likelihood =  -117.336
Iteration 1:  Log likelihood = -103.81846
Iteration 2:  Log likelihood = -103.40486
Iteration 3:  Log likelihood = -103.40384
Iteration 4:  Log likelihood = -103.40384

Logistic regression                                Number of obs =   189
LR chi2(7)    = 27.86
Prob > chi2   = 0.0002
Pseudo R2    = 0.1187

Log likelihood = -103.40384
```

	low	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
age		-.0403293	.0357127	-1.13	0.259	-.1103249	.0296663
race							
Black		1.009436	.5025122	2.01	0.045	.0245302	1.994342
Other		1.001908	.4248342	2.36	0.018	.1692485	1.834568
smoke							
Smoker		.9631876	.3904357	2.47	0.014	.1979477	1.728427
ptl		.6288678	.3399067	1.85	0.064	-.0373371	1.295073
1.ht		1.358142	.6289555	2.16	0.031	.125412	2.590872
1.ui		.8001832	.4572306	1.75	0.080	-.0959724	1.696339
_cons		-1.184127	.9187461	-1.29	0.197	-2.984837	.6165818

The coefficients are log odds-ratios: conditional on the other predictors, smoking during pregnancy is associated with an increase of 0.96 in the log odds of low birthweight. The model is linear in the log odds-scale, so the estimate of 0.96 has the same interpretation, whatever the values of the other predictors might be. We could convert 0.96 to an odds ratio by replaying the results with `logit, or`.

But what if we want to talk about the probability of low birthweight, and not the odds? Then we will need the command `margins, contrast`. We will use the `r.` contrast operator to compare each level of `smoke` with a reference level. (`smoke` has only two levels, so there will be only one comparison: a comparison of smokers with nonsmokers.)

```
. margins r.smoke, contrast
```

```
Contrasts of predictive margins
```

```
Number of obs = 189
```

```
Model VCE: OIM
```

```
Expression: Pr(low), predict()
```

	df	chi2	P>chi2
smoke	1	6.32	0.0119

	Delta-method		
	Contrast	std. err.	[95% conf. interval]
smoke (Smoker vs Nonsmoker)	.1832779	.0728814	.0404329 .3261229

We see that maternal smoking is associated with an 18.3% increase in the probability of low birthweight. (We received a contrast in the probability scale because predicted probabilities are the default when `margins` is used after `logit`.)

The contrast of 18.3% is a difference of margins that are computed by averaging over the predictions for observations in the estimation sample. If the values of the other predictors were different, the contrast for `smoke` would be different, too. Let's estimate the contrast for 25-year-old mothers:

```
. margins r.smoke, contrast at(age=25)
```

```
Contrasts of predictive margins
```

```
Number of obs = 189
```

```
Model VCE: OIM
```

```
Expression: Pr(low), predict()
```

```
At: age = 25
```

	df	chi2	P>chi2
smoke	1	6.19	0.0129

	Delta-method		
	Contrast	std. err.	[95% conf. interval]
smoke (Smoker vs Nonsmoker)	.1808089	.0726777	.0383632 .3232547

Specifying a maternal age of 25 changed the contrast to 18.1%. Our contrast of probabilities changed because the `logit` model is nonlinear in the probability scale. A contrast of log odds would not have changed.

# Title

**loneway** — Large one-way ANOVA, random effects, and reliability

[Description](#)

[Quick start](#)

[Menu](#)

[Syntax](#)

[Options](#)

[Remarks and examples](#)

[Stored results](#)

[Methods and formulas](#)

[Acknowledgment](#)

[References](#)

[Also see](#)

## Description

`loneway` fits one-way analysis-of-variance (ANOVA) models. `loneway` relaxes the restriction imposed by `oneway` that factors must have fewer than 376 levels. The command additionally reports the intraclass correlation, its standard error, and confidence interval; the estimated reliability of the group-averaged mean; the standard deviation of the group effect; and the standard deviation of the within-group effect.

## Quick start

One-way ANOVA model of  $y$  for factor  $a$

```
loneway y a
```

Report an exact 95% confidence interval for the intraclass correlation

```
loneway y a, exact
```

Same as above, but report a 90% confidence interval

```
loneway y a, exact level(90)
```

## Menu

Statistics > Linear models and related > ANOVA/MANOVA > Large one-way ANOVA

## Syntax

```
loneway response_var group_var [if] [in] [weight] [, options]
```

options	Description
<b>mean</b>	expected value of $F$ distribution; default is 1
<b>median</b>	median of $F$ distribution; default is 1
<b>exact</b>	exact confidence intervals (groups must be equal with no weights)
<b>level(#)</b>	set confidence level; default is level(95)

Main

<b>mean</b>	expected value of $F$ distribution; default is 1
<b>median</b>	median of $F$ distribution; default is 1
<b>exact</b>	exact confidence intervals (groups must be equal with no weights)
<b>level(#)</b>	set confidence level; default is level(95)

by and collect are allowed; see [U] 11.1.10 **Prefix commands**.

aweights are allowed; see [U] 11.1.6 **weight**.

## Options

Main

**mean** specifies that the expected value of the  $F_{k-1, N-k}$  distribution be used as the reference point  $F_m$  in the estimation of  $\rho$  instead of the default value of 1.

**median** specifies that the median of the  $F_{k-1, N-k}$  distribution be used as the reference point  $F_m$  in the estimation of  $\rho$  instead of the default value of 1.

**exact** requests that exact confidence intervals be computed, as opposed to the default asymptotic confidence intervals. This option is allowed only if the groups are equal in size and weights are not used.

**level(#)** specifies the confidence level, as a percentage, for confidence intervals of the coefficients. The default is level(95) or as set by set level; see [U] 20.8 **Specifying the width of confidence intervals**.

## Remarks and examples

loneway and oneway both fit ANOVA models, but loneway presents different ancillary statistics from oneway:

Feature	oneway	loneway
Fit one-way model	x	x
on 375 or fewer levels	x	x
on more than 375 levels		x
Bartlett's test for equal variance	x	
Multiple-comparison tests	x	
Intraclass correlation and SE		x
Intraclass correlation confidence interval		x
Est. reliability of group-averaged mean		x
Est. SD of group effect		x
Est. SD within group		x

Remarks are presented under the following headings:

*The one-way ANOVA model*

$R^2$

*The random-effects ANOVA model*

*Intraclass correlation*

*Estimated reliability of the group-averaged score*

## The one-way ANOVA model

### ▷ Example 1

loneway's output looks like that of oneway, except that loneway presents more information at the end. Using our automobile dataset, we have created a (numeric) variable called `manufacturer_grp` identifying the manufacturer of each car, and within each manufacturer we have retained a maximum of four models, selecting those with the lowest mpg. We can compute the intraclass correlation of mpg for all manufacturers with at least four models as follows:

```
. use https://www.stata-press.com/data/r18/auto7
(1978 automobile data)

. loneway mpg manufacturer_grp if nummake == 4
```

One-way analysis of variance for mpg: Mileage (mpg)

Source	SS	df	MS	F	Prob > F
Between manufactur~p	621.88889	8	77.736111	3.70	0.0049
Within manufactur~p	567.75	27	21.027778		
Total	1189.6389	35	33.989683		

Intraclass correlation	Asy. S.E.	[95% conf. interval]	
0.40270	0.18770	0.03481	0.77060
Estimated SD of manufactur~p effect			3.765247
Estimated SD within manufactur~p			4.585605
Est. reliability of a manufactur~p mean			0.72950
(evaluated at n=4.00)			

◀

In addition to the standard one-way ANOVA output, loneway produces the  $R^2$ , the estimated standard deviation of the group effect, the estimated standard deviation within group, the intragroup correlation, the estimated reliability of the group-averaged mean, and, for unweighted data, the asymptotic standard error and confidence interval for the intragroup correlation.

### $R^2$

The  $R^2$  is, of course, simply the underlying  $R^2$  for a regression of `response_var` on the levels of `group_var`, or mpg on the various manufacturers here.

## The random-effects ANOVA model

loneway assumes that we observe a variable,  $y_{ij}$ , measured for  $n_i$  elements within  $k$  groups or classes such that

$$y_{ij} = \mu + \alpha_i + \epsilon_{ij}, \quad i = 1, 2, \dots, k, \quad j = 1, 2, \dots, n_i$$

and  $\alpha_i$  and  $\epsilon_{ij}$  are independent zero-mean random variables with variance  $\sigma_\alpha^2$  and  $\sigma_\epsilon^2$ , respectively. This is the random-effects ANOVA model, also known as the components-of-variance model, in which it is typically assumed that the  $y_{ij}$  are normally distributed.

The interpretation with respect to our example is that the observed value of our response variable, `mpg`, is created in two steps. First, the  $i$ th manufacturer is chosen, and a value,  $\alpha_i$ , is determined—the typical `mpg` for that manufacturer less the overall `mpg`  $\mu$ . Then a deviation,  $\epsilon_{ij}$ , is chosen for the  $j$ th model within this manufacturer. This is how much that particular automobile differs from the typical `mpg` value for models from this manufacturer.

For our sample of 36 car models, the estimated standard deviations are  $\sigma_\alpha = 3.8$  and  $\sigma_\epsilon = 4.6$ . Thus, a little more than half of the variation in `mpg` between cars is attributable to the car model, with the rest attributable to differences between manufacturers. These standard deviations differ from those that would be produced by a (standard) fixed-effects regression in that the regression would require the sum within each manufacturer of the  $\epsilon_{ij}$ ,  $\epsilon_i$ , for the  $i$ th manufacturer, to be zero, whereas these estimates merely impose the constraint that the sum is *expected* to be zero.

## Intraclass correlation

There are various estimators of the intraclass correlation, such as the pairwise estimator, which is defined as the Pearson product-moment correlation computed over all possible pairs of observations that can be constructed within groups. For a discussion of various estimators, see [Donner \(1986\)](#). `loneway` computes what is termed the analysis of variance, or ANOVA, estimator. This intraclass correlation is the theoretical upper bound on the variation in `response_var` that is explainable by `group_var`, of which  $R^2$  is an overestimate because of the serendipity of fitting. This correlation is comparable to an  $R^2$ —you do not have to square it.

In our example, the intra-manu correlation, the correlation of `mpg` within manufacturer, is 0.40. Because `aweights` were not used and the default correlation was computed (that is, the `mean` and `median` options were not specified), `loneway` also provided the asymptotic confidence interval and standard error of the intraclass correlation estimate.

## Estimated reliability of the group-averaged score

The estimated reliability of the group-averaged score or mean has an interpretation similar to that of the intragroup correlation; it is a comparable number if we average `response_var` by `group_var`, or `mpg` by `manu` in our example. It is the theoretical upper bound of a regression of manufacturer-averaged `mpg` on characteristics of manufacturers. Why would we want to collapse our 36-observation dataset into a 9-observation dataset of manufacturer averages? Because the 36 observations might be a mirage. When General Motors builds cars, do they sometimes put a Pontiac label and sometimes a Chevrolet label on them, so that it appears in our data as if we have two cars when we really have only one, replicated? If that were the case, and if it were the case for many other manufacturers, then we would be forced to admit that we do not have data on 36 cars; we instead have data on nine manufacturer-averaged characteristics.

## Stored results

`loneway` stores the following in `r()`:

Scalars

<code>r(N)</code>	number of observations	<code>r(rho_t)</code>	estimated reliability
<code>r(rho)</code>	intraclass correlation	<code>r(se)</code>	asymp. SE of intraclass correlation
<code>r(lb)</code>	lower bound of 95% CI for rho	<code>r(sd_w)</code>	estimated SD within group
<code>r(ub)</code>	upper bound of 95% CI for rho	<code>r(sd_b)</code>	estimated SD of group effect

## Methods and formulas

The mean squares in the loneway's ANOVA table are computed as

$$MS_{\alpha} = \sum_i w_i \cdot (\bar{y}_i - \bar{y}_{..})^2 / (k - 1)$$

and

$$MS_{\epsilon} = \sum_i \sum_j w_{ij} (y_{ij} - \bar{y}_i)^2 / (N - k)$$

in which

$$w_i = \sum_j w_{ij} \quad w_{..} = \sum_i w_i \quad \bar{y}_i = \sum_j w_{ij} y_{ij} / w_i \quad \text{and} \quad \bar{y}_{..} = \sum_i w_i \bar{y}_i / w_{..}$$

The corresponding expected values of these mean squares are

$$E(MS_{\alpha}) = \sigma_{\epsilon}^2 + g\sigma_{\alpha}^2 \quad \text{and} \quad E(MS_{\epsilon}) = \sigma_{\epsilon}^2$$

in which

$$g = \frac{w_{..} - \sum_i w_i^2 / w_{..}}{k - 1}$$

In the unweighted case, we get

$$g = \frac{N - \sum_i n_i^2 / N}{k - 1}$$

As expected,  $g = m$  for the case of no weights and equal group sizes in the data, that is,  $n_i = m$  for all  $i$ . Replacing the expected values with the observed values and solving yields the ANOVA estimates of  $\sigma_{\alpha}^2$  and  $\sigma_{\epsilon}^2$ . Substituting these into the definition of the intraclass correlation

$$\rho = \frac{\sigma_{\alpha}^2}{\sigma_{\alpha}^2 + \sigma_{\epsilon}^2}$$

yields the ANOVA estimator of the intraclass correlation:

$$\rho_A = \frac{F_{\text{obs}} - 1}{F_{\text{obs}} - 1 + g}$$

$F_{\text{obs}}$  is the observed value of the  $F$  statistic from the ANOVA table. For no weights and equal  $n_i$ ,  $\rho_A = \text{roh}$ , which is the intragroup correlation defined by Kish (1965). Two slightly different estimators are available through the mean and median options (Gleason 1997). If either of these options is specified, the estimate of  $\rho$  becomes

$$\rho = \frac{F_{\text{obs}} - F_m}{F_{\text{obs}} + (g - 1)F_m}$$

For the mean option,  $F_m = E(F_{k-1, N-K}) = (N - k) / (N - k - 2)$ , that is, the expected value of the ANOVA table's  $F$  statistic. For the median option,  $F_m$  is simply the median of the  $F$  statistic. Setting  $F_m$  to 1 gives  $\rho_A$ , so for large samples, these different point estimators are essentially the same. Also, because the intraclass correlation of the random-effects model is by definition nonnegative, for any of the three possible point estimators,  $\rho$  is truncated to zero if  $F_{\text{obs}}$  is less than  $F_m$ .

For no weighting, interval estimators for  $\rho_A$  are computed. If the groups are equal sized (all  $n_i$  equal) and the `exact` option is specified, the following exact (assuming that the  $y_{ij}$  are normally distributed)  $100(1 - \alpha)\%$  confidence interval is computed:

$$\left\{ \frac{F_{\text{obs}} - F_m F_u}{F_{\text{obs}} + (g - 1) F_m F_u}, \frac{F_{\text{obs}} - F_m F_l}{F_{\text{obs}} + (g - 1) F_m F_l} \right\}$$

with  $F_m = 1$ ,  $F_l = F_{\alpha/2, k-1, N-k}$ , and  $F_u = F_{1-\alpha/2, k-1, N-k}$ ,  $F_{\cdot, k-1, N-k}$  being the cumulative distribution function for the  $F$  distribution with  $k - 1$  and  $N - k$  degrees of freedom. If `mean` or `median` is specified,  $F_m$  is defined as above. If the groups are equal sized and `exact` is not specified, the following asymptotic  $100(1 - \alpha)\%$  confidence interval for  $\rho_A$  is computed,

$$\left[ \rho_A - z_{\alpha/2} \sqrt{V(\rho_A)}, \rho_A + z_{\alpha/2} \sqrt{V(\rho_A)} \right]$$

where  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the standard normal distribution and  $\sqrt{V(\rho_A)}$  is the asymptotic standard error of  $\rho$  defined below. This confidence interval is also available for unequal groups. It is not applicable and, therefore, not computed for the estimates of  $\rho$  provided by the `mean` and `median` options. Again, because the intraclass coefficient is nonnegative, if the lower bound is negative for either confidence interval, it is truncated to zero. As might be expected, the coverage probability of a truncated interval is higher than its nominal value.

The asymptotic standard error of  $\rho_A$ , assuming that the  $y_{ij}$  are normally distributed, is also computed when appropriate, namely, for unweighted data and when  $\rho_A$  is computed (neither the `mean` option nor the `median` option is specified):

$$V(\rho_A) = \frac{2(1 - \rho)^2}{g^2} (A + B + C)$$

with

$$\begin{aligned} A &= \frac{\{1 + \rho(g - 1)\}^2}{N - k} \\ B &= \frac{(1 - \rho)\{1 + \rho(2g - 1)\}}{k - 1} \\ C &= \frac{\rho^2\{\sum n_i^2 - 2N^{-1}\sum n_i^3 + N^{-2}(\sum n_i^2)^2\}}{(k - 1)^2} \end{aligned}$$

and  $\rho_A$  is substituted for  $\rho$  (Donner 1986).

The estimated reliability of the group-averaged score, known as the Spearman–Brown prediction formula in the psychometric literature (Winer, Brown, and Michels 1991, 1014), is

$$\rho_t = \frac{t\rho}{1 + (t - 1)\rho}$$

for group size  $t$ . `loneway` computes  $\rho_t$  for  $t = g$ .

The estimated standard deviation of the group effect is  $\sigma_\alpha = \sqrt{(\text{MS}_\alpha - \text{MS}_\epsilon)/g}$ . This deviation comes from the assumption that an observation is derived by adding a group effect to a within-group effect.

The estimated standard deviation within group is the square root of the mean square due to error, or  $\sqrt{\text{MS}_\epsilon}$ .

## Acknowledgment

We thank John Gleason (retired) of Syracuse University for his contributions to improving `loneway`.

## Description

`lowess` carries out a locally weighted regression of *yvar* on *xvar*, displays the graph, and optionally saves the smoothed variable.

Warning: `lowess` is computationally intensive and may therefore take a long time to run on a slow computer. Lowess calculations on 1,000 observations, for instance, require performing 1,000 regressions.

## Quick start

Locally weighted regression of *y1* on *x*

```
lowess y1 x
```

Same as above, but with a bandwidth of 0.4

```
lowess y1 x, bwidth(.4)
```

With running-mean smoothing

```
lowess y1 x, mean
```

Without the tricube weighting function

```
lowess y1 x, noweight
```

Generate a new variable *v* containing the smoothed values of *y1*

```
lowess y1 x, generate(v)
```

Adjust the mean of the smoothed values to equal the mean of the unsmoothed values

```
lowess y1 x, adjust
```

Lowess smoothing of categorical variable *y2* on *x* in terms of the log of the odds ratio

```
lowess y2 x, logit
```

## Menu

Statistics > Nonparametric analysis > Lowess smoothing

## Syntax

```
lowess yvar xvar [if] [in] [, options]
```

<i>options</i>	Description
<b>Main</b>	
<u>mean</u>	running-mean smooth; default is running-line least squares
<u>nweight</u>	suppress weighted regressions; default is tricube weighting function
<u>bwidth</u> (#)	use # for the bandwidth; default is <code>bwidth(0.8)</code>
<u>logit</u>	transform dependent variable to logits
<u>adjust</u>	adjust smoothed mean to equal mean of dependent variable
<u>nograph</u>	suppress graph
<u>generate</u> ( <i>newvar</i> )	create <i>newvar</i> containing smoothed values of <i>yvar</i>
<b>Plot</b>	
<u>marker_options</u>	change look of markers (color, size, etc.)
<u>marker_label_options</u>	add marker labels; change look or position
<b>Smoothed line</b>	
<u>lineopts</u> ( <i>cline_options</i> )	affect rendition of the smoothed line
<b>Add plots</b>	
<u>addplot</u> ( <i>plot</i> )	add other plots to generated graph
<b>Y axis, X axis, Titles, Legend, Overall, By</b>	
<u>twoway_options</u>	any of the options documented in [G-3] <i>twoway_options</i>

*yvar* and *xvar* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

## Options

### Main

**mean** specifies running-mean smoothing; the default is running-line least-squares smoothing.

**nweight** prevents the use of Cleveland's (1979) tricube weighting function; the default is to use the weighting function.

**bwidth**(#) specifies the bandwidth. Centered subsets of `bwidth() × N` observations are used for calculating smoothed values for each point in the data except for the end points, where smaller, uncentered subsets are used. The greater the `bwidth()`, the greater the smoothing. The default is 0.8.

**logit** transforms the smoothed *yvar* into logits. Predicted values less than 0.0001 or greater than 0.9999 are set to  $1/N$  and  $1 - 1/N$ , respectively, before taking logits.

**adjust** adjusts the mean of the smoothed *yvar* to equal the mean of *yvar* by multiplying by an appropriate factor. This option is useful when smoothing binary (0/1) data.

**nograph** suppresses displaying the graph.

**generate**(*newvar*) creates *newvar* containing the smoothed values of *yvar*.

## Plot

*marker\_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker\_options*.

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] *marker\_label\_options*.

## Smoothed line

*lineopts*(*cline\_options*) affects the rendition of the lowess-smoothed line; see [G-3] *cline\_options*.

## Add plots

*addplot*(*plot*) provides a way to add other plots to the generated graph; see [G-3] *addplot\_option*.

## Y axis, X axis, Titles, Legend, Overall, By

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*. These include options for titling the graph (see [G-3] *title\_options*), options for saving the graph to disk (see [G-3] *saving\_option*), and the *by*() option (see [G-3] *by\_option*).

## Remarks and examples

By default, **lowess** provides locally weighted scatterplot smoothing. The basic idea is to create a new variable (*newvar*) that, for each *yvar*  $y_i$ , contains the corresponding smoothed value. The smoothed values are obtained by running a regression of *yvar* on *xvar* by using only the data  $(x_i, y_i)$  and a few of the data near this point. In **lowess**, the regression is weighted so that the central point  $(x_i, y_i)$  gets the highest weight and points that are farther away (based on the distance  $|x_j - x_i|$ ) receive less weight. The estimated regression line is then used to predict the smoothed value  $\hat{y}_i$  for  $y_i$  only. The procedure is repeated to obtain the remaining smoothed values, which means that a separate weighted regression is performed for every point in the data.

Lowess is a desirable smoother because of its locality—it tends to follow the data. Polynomial smoothing methods, for instance, are global in that what happens on the extreme left of a scatterplot can affect the fitted values on the extreme right.

### ► Example 1

The amount of smoothing is affected by **bwidth**(#). You are warned to experiment with different values. For instance,

```
. use https://www.stata-press.com/data/r18/lowess1
(Example data for lowess)
. lowess h1 depth
```

Now compare that with

```
. lowess h1 depth, bwidth(.4)
```

In the first case, the default bandwidth of 0.8 is used, meaning that 80% of the data are used in smoothing each point. In the second case, we explicitly specified a bandwidth of 0.4. Smaller bandwidths follow the original data more closely. ◀

## ▶ Example 2

Two lowess options are especially useful with binary (0/1) data: `adjust` and `logit`. `adjust` adjusts the resulting curve (by multiplication) so that the mean of the smoothed values is equal to the mean of the unsmoothed values. `logit` specifies that the smoothed curve be in terms of the log of the odds ratio:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
```

```
. lowess foreign mpg, ylabel(0 "Domestic" 1 "Foreign") jitter(5) adjust
```

```
. lowess foreign mpg, logit yline(0)
```

With binary data, if you do not use the `logit` option, it is a good idea to specify `graph's jitter()` option; see [G-2] [graph twoway scatter](#). Because the underlying data (whether the car was manufactured outside the United States here) take on only two values, raw data points are more likely to be on top of each other, thus making it impossible to tell how many points there are. `graph's jitter()` option adds some noise to the data to shift the points around. This noise affects only the location of points on the graph, not the lowess curve.

When you specify the `logit` option, the display of the raw data is suppressed.

## □ Technical note

`lowess` can be used for more than just lowess smoothing. Lowess can be usefully thought of as a combination of two smoothing concepts: the use of predicted values from regression (rather than means) for imputing a smoothed value and the use of the tricube weighting function (rather than a constant weighting function). `lowess` allows you to combine these concepts freely. You can use line smoothing without weighting (specify `noweight`), mean smoothing with tricube weighting (specify `mean`), or mean smoothing without weighting (specify `mean` and `noweight`).

□

## Methods and formulas

Let  $y_i$  and  $x_i$  be the two variables, and assume that the data are ordered so that  $x_i \leq x_{i+1}$  for  $i = 1, \dots, N - 1$ . For each  $y_i$ , a smoothed value  $y_i^s$  is calculated.

The subset used in calculating  $y_i^s$  is indices  $i_- = \max(1, i - k)$  through  $i_+ = \min(i + k, N)$ , where  $k = \lfloor (N \times \text{bwidth} - 0.5) / 2 \rfloor$ . The weights for each of the observations between  $j = i_-, \dots, i_+$  are either 1 (`noweight`) or the tricube (default),

$$w_j = \left\{ 1 - \left( \frac{|x_j - x_i|}{\Delta} \right)^3 \right\}^3$$

where  $\Delta = 1.0001 \max(x_{i_+} - x_i, x_i - x_{i_-})$ . The smoothed value  $y_i^s$  is then the (weighted) mean or the (weighted) regression prediction at  $x_i$ .

William Swain Cleveland (1943–) studied mathematics and statistics at Princeton and Yale. He worked for several years at Bell Labs in New Jersey and now teaches statistics and computer science at Purdue. He has made key contributions in many areas of statistics, including graphics and data visualization, time series, environmental applications, and analysis of Internet traffic data.

## Acknowledgment

## Description

`lpoly` performs a kernel-weighted local polynomial regression of  $yvar$  on  $xvar$  and displays a graph of the smoothed values with (optional) confidence bands.

## Quick start

Kernel-weighted local polynomial regression of  $y$  on  $x$

```
lpoly y x
```

Same as above, but specify a bandwidth of 2

```
lpoly y x, bwidth(2)
```

Same as above, but specify a degree of 1

```
lpoly y x, bwidth(2) degree(1)
```

Same as above, but use the alternative Epanechnikov kernel

```
lpoly y x, bwidth(2) degree(1) kernel(epan2)
```

Same as above, but create a new variable for the smoothing grid  $g$  and smoothed values  $s$

```
lpoly y x, bwidth(2) degree(1) kernel(epan2) generate(g s)
```

With 95% confidence bands

```
lpoly y x, ci
```

Use `twoway` to graph multiple local polynomial fits

```
twoway scatter y x || //  
      lpoly y x, degree(1) kernel(epan2) || //  
      lpoly y x, degree(1) kernel(epan2) bwidth(1) || //  
      lpoly y x, degree(1) kernel(epan2) bwidth(7) ||
```

## Menu

Statistics > Nonparametric analysis > Local polynomial smoothing

## Syntax

```
lpoly yvar xvar [if] [in] [weight] [, options]
```

<i>options</i>	Description
<b>Main</b>	
<u>k</u> kernel( <i>kernel</i> )	specify kernel function; default is kernel(epanechnikov)
<u>b</u> width(#   <i>varname</i> )	specify kernel bandwidth
<u>d</u> egree(#)	specify degree of the polynomial smooth; default is degree(0)
<u>g</u> enerate([ <i>newvar</i> <sub>x</sub> ] <i>newvar</i> <sub>s</sub> )	store smoothing grid in <i>newvar</i> <sub>x</sub> and smoothed points in <i>newvar</i> <sub>s</sub>
<u>n</u> (#)	obtain the smooth at # points; default is min( <i>N</i> , 50)
<u>a</u> t( <i>varname</i> )	obtain the smooth at the values specified by <i>varname</i>
<u>n</u> ograph	suppress graph
<u>n</u> oscat	suppress scatterplot only
<b>SE/CI</b>	
<u>c</u> i	plot confidence bands
<u>l</u> evel(#)	set confidence level; default is level(95)
<u>s</u> e( <i>newvar</i> )	store standard errors in <i>newvar</i>
<u>p</u> width(#)	specify pilot bandwidth for standard error calculation
<u>v</u> ar(#   <i>varname</i> )	specify estimates of residual variance
<b>Scatterplot</b>	
<u>m</u> arker_ <i>options</i>	change look of markers (color, size, etc.)

<i>kernel</i>	Description
<code>epanechnikov</code>	Epanechnikov kernel function; the default
<code>epan2</code>	alternative Epanechnikov kernel function
<code>biweight</code>	biweight kernel function
<code>cosine</code>	cosine trace kernel function
<code>gaussian</code>	Gaussian kernel function
<code>parzen</code>	Parzen kernel function
<code>rectangle</code>	rectangle kernel function
<code>triangle</code>	triangle kernel function

`collect` is allowed; see [U] 11.1.10 Prefix commands.

`fweights` and `aweights` are allowed; see [U] 11.1.6 weight.

## Options

### Main

`kernel(kernel)` specifies the kernel function for use in calculating the weighted local polynomial estimate. The default is `kernel(epanechnikov)`.

`bwidth(#|varname)` specifies the half-width of the kernel—the width of the smoothing window around each point. If `bwidth()` is not specified, a rule-of-thumb (ROT) bandwidth estimator is calculated and used. A local variable bandwidth may be specified in *varname*, in conjunction with an explicit smoothing grid using the `at()` option.

`degree(#)` specifies the degree of the polynomial to be used in the smoothing. The default is `degree(0)`, meaning local-mean smoothing.

`generate([newvarx] newvars)` stores the smoothing grid in *newvar<sub>x</sub>* and the smoothed values in *newvar<sub>s</sub>*. If `at()` is not specified, then both *newvar<sub>x</sub>* and *newvar<sub>s</sub>* must be specified. Otherwise, only *newvar<sub>s</sub>* is to be specified.

`n(#)` specifies the number of points at which the smooth is to be calculated. The default is  $\min(N, 50)$ , where  $N$  is the number of observations.

`at(varname)` specifies a variable that contains the values at which the smooth should be calculated. By default, the smoothing is done on an equally spaced grid, but you can use `at()` to instead perform the smoothing at the observed  $x$ 's, for example. This option also allows you to more easily obtain smooths for different variables or different subsamples of a variable and then overlay the estimates for comparison.

`nograph` suppresses drawing the graph of the estimated smooth. This option is often used with the `generate()` option.

`noscatter` suppresses superimposing a scatterplot of the observed data over the smooth. This option is useful when the number of resulting points would be so large as to clutter the graph.

### SE/CI

`ci` plots confidence bands, using the confidence level specified in `level()`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals.

`se(newvar)` stores the estimates of the standard errors in *newvar*. This option requires specifying `generate()` or `at()`.

`pwidht(#)` specifies the pilot bandwidth to be used for standard error computations. The default is chosen to be 1.5 times the value of the ROT bandwidth selector. If you specify `pwidht()` without specifying `se()` or `ci`, then the `ci` option is assumed.

`var(# | varname)` specifies an estimate of a constant residual variance or a variable containing estimates of the residual variances at each grid point required for standard error computation. By default, the residual variance at each smoothing point is estimated by the normalized weighted residual sum of squares obtained from locally fitting a polynomial of order  $p + 2$ , where  $p$  is the degree specified in `degree()`. `var(varname)` is allowed only if `at()` is specified. If you specify `var()` without specifying `se()` or `ci`, then the `ci` option is assumed.

#### Scatterplot

`marker_options` affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

`marker_label_options` specify if and how the markers are to be labeled; see [G-3] [marker\\_label\\_options](#).

#### Smoothed line

`lineopts(cline_options)` affects the rendition of the smoothed line; see [G-3] [cline\\_options](#).

#### CI plot

`ciopts(cline_options)` affects the rendition of the confidence bands; see [G-3] [cline\\_options](#).

#### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] [addplot\\_option](#).

#### Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)  
[Local polynomial smoothing](#)  
[Choice of a bandwidth](#)  
[Confidence bands](#)

## Introduction

The last 25 years or so has seen a significant outgrowth in the literature on scatterplot smoothing, otherwise known as univariate nonparametric regression. Of most appeal is the idea of making no assumptions about the functional form for the expected value of a response given a regressor, but instead allowing the data to “speak for themselves”. Various methods and estimators fall into the category of nonparametric regression, including local mean smoothing as described independently by Nadaraya (1964) and Watson (1964), the Gasser and Müller (1979) estimator, locally weighted scatterplot smoothing (LOWESS) as described by Cleveland (1979), wavelets (for example, Donoho

[1995]), and splines (Eubank 1999), to name a few. Much of the vast literature focuses on automating the amount of smoothing to be performed and dealing with the bias/variance tradeoff inherent to this type of estimation. For example, for Nadaraya–Watson the amount of smoothing is controlled by choosing a *bandwidth*.

Smoothing via local polynomials is by no means a new idea but instead one that has been rediscovered in recent years in articles such as Fan (1992). A natural extension of the local mean smoothing of Nadaraya–Watson, local polynomial regression involves fitting the response to a polynomial form of the regressor via locally weighted least squares. Higher-order polynomials have better bias properties than the zero-degree local polynomials of the Nadaraya–Watson estimator; in general, higher-order polynomials do not require bias adjustment at the boundary of the regression space. For a definitive reference on local polynomial smoothing, see Fan and Gijbels (1996).

## Local polynomial smoothing

Consider a set of scatterplot data  $\{(x_1, y_1), \dots, (x_n, y_n)\}$  from the model

$$y_i = m(x_i) + \sigma(x_i)\epsilon_i \quad (1)$$

for some unknown mean and variance functions  $m(\cdot)$  and  $\sigma^2(\cdot)$ , and symmetric errors  $\epsilon_i$  with  $E(\epsilon_i) = 0$  and  $\text{Var}(\epsilon_i) = 1$ . The goal is to estimate  $m(x_0) = E[Y|X = x_0]$ , making no assumption about the functional form of  $m(\cdot)$ .

`lpoly` estimates  $m(x_0)$  as the constant term (intercept) of a regression, weighted by the kernel function specified in `kernel()`, of  $yvar$  on the polynomial terms  $(xvar - x_0), (xvar - x_0)^2, \dots, (xvar - x_0)^p$  for each smoothing point  $x_0$ . The degree of the polynomial,  $p$ , is specified in `degree()`, the amount of smoothing is controlled by the bandwidth specified in `bwidth()`, and the chosen kernel function is specified in `kernel()`.

### ► Example 1

Consider the motorcycle data as examined (among other places) in Fan and Gijbels (1996). The data consist of 133 observations and measure the acceleration (`accl` measured in grams [g]) of a dummy's head during impact over time (`time` measured in milliseconds). For these data, we use `lpoly` to fit a local cubic polynomial with the default bandwidth (obtained using the ROT method) and the default Epanechnikov kernel.

```
. use https://www.stata-press.com/data/r18/motorcycle
(Motorcycle data from Fan & Gijbels (1996))
. lpoly accel time, degree(3)
```

The default bandwidth and kernel settings do not provide a satisfactory fit in this example. To improve the fit, we can either supply a different bandwidth by using the `bwidth()` option or specify a different kernel by using the `kernel()` option. For example, using the alternative Epanechnikov kernel, `kernel(epan2)`, below provides a better fit for these data.

```
. lpoly accel time, degree(3) kernel(epan2)
```

## □ Technical note

`lpoly` allows specifying in `degree()` both odd and even orders of the polynomial to be used for the smoothing. However, the odd-order,  $2k + 1$ , polynomial approximations are preferable. They have an extra parameter compared with the even-order,  $2k$ , approximations, which leads to a significant bias reduction and there is no increase of variability associated with adding this extra parameter. Using an odd order when estimating the regression function is therefore usually sufficient. For a more thorough discussion, see [Fan and Gijbels \(1996\)](#).

## Choice of a bandwidth

The choice of a bandwidth is crucial for many smoothing techniques, including local polynomial smoothing. In general, using a large bandwidth gives smooths with a large bias, whereas a small bandwidth may result in highly variable smoothed values. Various techniques exist for optimal bandwidth selection. By default, `lpoly` uses the ROT method to estimate the bandwidth used for the smoothing; see *Methods and formulas* for details.

### ► Example 2

Using the `motorcycle` data, we demonstrate how a local linear polynomial fit changes using different bandwidths.

```
. lpoly accel time, degree(1) kernel(epan2) bwidth(1)
> generate(at smooth1) nograph
. lpoly accel time, degree(1) kernel(epan2) bwidth(7) at(at)
> generate(smooth2) nograph
. label variable smooth1 "Smooth: width = 1"
. label variable smooth2 "Smooth: width = 7"
. lpoly accel time, degree(1) kernel(epan2) at(at) addplot(line smooth* at)
> legend(label(2 "Smooth: width = 3.42 (ROT)") cols(2) pos(6))
> note("kernel = epan2, degree = 1")
```

From this graph, we can see that the local linear polynomial fit with larger bandwidth (`width = 7`) corresponds to a smoother line but fails to fit the curvature of the scatterplot data. The smooth obtained using the width equal to one seems to fit most data points, but the corresponding line has several spikes indicating larger variability. The smooth obtained using the ROT bandwidth estimator seems to have a good tradeoff between the fit and variability in this example.

In the above, we also demonstrated how the `generate()` and `addplot()` options may be used to produce overlaid plots obtained from `lpoly` with different options. The `nograph` option saves time when you need to save only results with `generate()`.

However, to avoid generating variables manually, one can use `twoway lpoly` instead; see [G-2] [graph twoway lpoly](#) for more details.

```
. twoway scatter accel time ||
> lpoly accel time, degree(1) kernel(epan2) lpattern(solid) ||
> lpoly accel time, degree(1) kernel(epan2) bwidth(1) ||
> lpoly accel time, degree(1) kernel(epan2) bwidth(7) ||
> , legend(label(2 "Smooth: width = 3.42 (ROT)")
> label(3 "Smooth: width = 1")
> label(4 "Smooth: width = 7") cols(2) pos(6))
> title("Local polynomial smooth") note("kernel = epan2, degree = 1")
> xtitle("Time (msec)") ytitle("Acceleration (g)")
```

The ROT estimate is commonly used as an initial guess for the amount of smoothing; this approach may be sufficient when the choice of a bandwidth is less important. In other cases, you can pick your own bandwidth.

When the shape of the regression function has a combination of peaked and flat regions, a variable bandwidth may be preferable over the constant bandwidth to allow for different degrees of smoothness in different regions. The `bwidth()` option allows you to specify the values of the local variable bandwidths as those stored in a variable in your data.

Similar issues with bias and variability arise when choosing a pilot bandwidth (the `pwidh()` option) used to compute standard errors of the local polynomial smoother. The default value is chosen to be  $1.5 \times \text{ROT}$ . For a review of methods for pilot bandwidth selection, see [Fan and Gijbels \(1996\)](#).

## Confidence bands

The established asymptotic normality of the local polynomial estimators under certain conditions allows the construction of approximate confidence bands. `lpoly` offers the `ci` option to plot these bands.

### Example 3

Let us plot the confidence bands for the local polynomial fit from [example 1](#).

```
. lpoly accel time, degree(3) kernel(epan2) ci legend(cols(2) pos(6))
```

You can obtain graphs with overlaid confidence bands by using `twoway lpolyci`; see [\[G-2\] graph twoway lpolyci](#) for examples.

Constructing the confidence intervals involves computing standard errors obtained by taking a square root of the estimate of the conditional variance of the local polynomial estimator at each grid point  $x_0$ . Estimating the conditional variance requires fitting a polynomial of a higher order locally by using a different bandwidth, the pilot bandwidth. The value of the pilot bandwidth may be supplied by using `pwidth()`. By default, the value of  $1.5 \times \text{ROT}$  is used. Also, estimates of the residual variance  $\sigma^2(x_0)$  at each grid point,  $x_0$ , are required to obtain the estimates of the conditional variances. These estimates may be supplied by using the `var()` option. By default, they are computed using the normalized weighted residual sum of squares from a local polynomial fit of a higher order. See [Methods and formulas](#) for details. The standard errors may be saved by using `se()`.

## Stored results

`lpoly` stores the following in `r()`:

#### Scalars

<code>r(degree)</code>	smoothing polynomial degree	<code>r(bwidth)</code>	bandwidth of the smooth
<code>r(ngrid)</code>	number of successful regressions	<code>r(pwidth)</code>	pilot bandwidth
<code>r(N)</code>	sample size		

#### Macros

<code>r(kernel)</code>	name of kernel
------------------------	----------------

## Methods and formulas

Consider model (1), written in matrix notation,

$$\mathbf{y} = m(\mathbf{x}) + \epsilon$$

where  $\mathbf{y}$  and  $\mathbf{x}$  are the  $n \times 1$  vectors of scatterplot values,  $\epsilon$  is the  $n \times 1$  vector of errors with zero mean and covariance matrix  $\Sigma = \text{diag}\{\sigma(x_i)\}\mathbf{I}_n$ , and  $m(\cdot)$  and  $\sigma(\cdot)$  are some unknown functions. Define  $m(x_0) = E[Y|X = x_0]$  and  $\sigma^2(x_0) = \text{Var}[Y|X = x_0]$  to be the conditional mean and conditional variance of random variable  $Y$  (residual variance), respectively, for some realization  $x_0$  of random variable  $X$ .

The method of local polynomial smoothing is based on the approximation of  $m(x)$  locally by a  $p$ th order polynomial in  $(x - x_0)$  for some  $x$  in the neighborhood of  $x_0$ . For the scatterplot data  $\{(x_1, y_1), \dots, (x_n, y_n)\}$ , the  $p$ th-order local polynomial smooth  $\hat{m}(x_0)$  is equal to  $\hat{\beta}_0$ , an estimate of the intercept of the weighted linear regression,

$$\hat{\beta} = (\mathbf{X}^T \mathbf{W} \mathbf{X})^{-1} \mathbf{X}^T \mathbf{W} \mathbf{y} \quad (2)$$

where  $\hat{\beta} = (\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_p)^T$  is the vector of estimated regression coefficients (with  $\{\hat{\beta}_j = (j!)^{-1} \hat{m}^{(j)}(x)|_{x=x_0}, j = 0, \dots, p\}$  also representing estimated coefficients from a corresponding Taylor expansion);  $\mathbf{X} = \{(x_i - x_0)^j\}_{i,j=1,0}^{n,p}$  is a design matrix; and  $\mathbf{W} = \text{diag}\{K_h(x_i - x_0)\}_{n \times n}$  is a weighting matrix with weights  $K_h(\cdot)$  defined as  $K_h(x) = h^{-1}K(x/h)$ , with  $K(\cdot)$  being a kernel function and  $h$  defining a bandwidth. The kernels are defined in [Methods and formulas of \[R\] kdensity](#).

The default bandwidth is obtained using the ROT method of bandwidth selection. The ROT bandwidth is the plugin estimator of the asymptotically optimal constant bandwidth. This is the bandwidth that minimizes the conditional weighted mean integrated squared error. The ROT plugin bandwidth selector for the smoothing bandwidth  $h$  is defined as follows; assuming constant residual variance  $\sigma^2(x_0) = \sigma^2$  and odd degree  $p$ :

$$\hat{h} = C_{0,p}(K) \left[ \frac{\hat{\sigma}^2 \int w_0(x) dx}{n \int \{\hat{m}^{(p+1)}(x)\}^2 w_0(x) f(x) dx} \right]^{1/(2p+3)} \quad (3)$$

where  $C_{0,p}(K)$  is a constant, as defined in [Fan and Gijbels \(1996\)](#), that depends on the kernel function  $K(\cdot)$ , and the degree of a polynomial  $p$  and  $w_0$  is chosen to be an indicator function on the interval  $[\min_{\mathbf{x}} + 0.05 \times \text{range}_{\mathbf{x}}, \max_{\mathbf{x}} - 0.05 \times \text{range}_{\mathbf{x}}]$  with  $\min_{\mathbf{x}}$ ,  $\max_{\mathbf{x}}$ , and  $\text{range}_{\mathbf{x}}$  being, respectively, the minimum, maximum, and the range of  $\mathbf{x}$ . To obtain the estimates of a constant residual variance,  $\hat{\sigma}^2$ , and  $(p + 1)$ th order derivative of  $m(x)$ , denoted as  $\hat{m}^{(p+1)}(x)$ , a polynomial in  $\mathbf{x}$  of order  $(p + 3)$  is fit globally to  $\mathbf{y}$ .  $\hat{\sigma}^2$  is estimated as a standardized residual sum of squares from this fit.

The expression for the asymptotically optimal constant bandwidth used in constructing the ROT bandwidth estimator is derived for the odd-order polynomial approximations. For even-order polynomial fits the expression would depend not only on  $m^{(p+1)}(x)$  but also on  $m^{(p+2)}(x)$  and the design density and its derivative,  $f(x)$  and  $f'(x)$ . Therefore, the ROT bandwidth selector would require estimation of these additional quantities. Instead, for an even-degree  $p$  of the local polynomial, `lpolynomial` uses the value of the ROT estimator (3) computed using degree  $p + 1$ . As such, for even degrees this is not a plugin estimator of the asymptotically optimal constant bandwidth.

The estimates of the conditional variance of local polynomial estimators are obtained using

$$\widehat{\text{Var}}\{\hat{m}(x_0)|X = x_0\} = \hat{\sigma}_m^2(x_0) = (\mathbf{X}^T \mathbf{W} \mathbf{X})^{-1} (\mathbf{X}^T \mathbf{W}^2 \mathbf{X}) (\mathbf{X}^T \mathbf{W} \mathbf{X})^{-1} \hat{\sigma}^2(x_0) \quad (4)$$

where  $\hat{\sigma}^2(x_0)$  is estimated by the normalized weighted residual sum of squares from the  $(p + 2)$ th order polynomial fit using pilot bandwidth  $h^*$ .

When the bias is negligible the normal-approximation method yields a  $(1 - \alpha) \times 100\%$  confidence interval for  $m(x_0)$ ,

$$\{\hat{m}(x_0) - z_{(1-\alpha/2)}\hat{\sigma}_m(x_0), \hat{m}(x_0) + z_{(1-\alpha/2)}\hat{\sigma}_m(x_0)\}$$

where  $z_{(1-\alpha/2)}$  is the  $(1 - \alpha/2)$ th quantile of the standard Gaussian distribution, and  $\hat{m}(x_0)$  and  $\hat{\sigma}_m(x_0)$  are as defined in (2) and (4), respectively.

## Description

`lroc` graphs the ROC curve and calculates the area under the curve.

`lroc` requires that the current estimation results be from `logistic`, `logit`, `probit`, or `ivprobit`; see [\[R\] logistic](#), [\[R\] logit](#), [\[R\] probit](#), or [\[R\] ivprobit](#).

## Quick start

Graph and compute area under ROC curve for current estimation results

```
lroc
```

Add “My Title” as title of graph

```
lroc, title(My Title)
```

Suppress graph

```
lroc, nograph
```

## Menu

Statistics > Binary outcomes > Postestimation > ROC curve after logistic/logit/probit/ivprobit

## Syntax

```
lroc [depvar] [if] [in] [weight] [, options]
```

<i>options</i>	Description
<b>Main</b>	
<code>all</code>	compute area under ROC curve and graph curve for all observations
<code>nograph</code>	suppress graph
<b>Advanced</b>	
<code>beta(<i>matname</i>)</code>	row vector containing model coefficients
<b>Plot</b>	
<code><i>cline_options</i></code>	change look of the line
<code><i>marker_options</i></code>	change look of markers (color, size, etc.)
<code><i>marker_label_options</i></code>	add marker labels; change look or position
<b>Reference line</b>	
<code><i>rlopts</i>(<i>cline_options</i>)</code>	affect rendition of the reference line
<b>Add plots</b>	
<code>addplot(<i>plot</i>)</code>	add other plots to the generated graph
<b>Y axis, X axis, Titles, Legend, Overall</b>	
<code><i>twoway_options</i></code>	any options other than <code>by()</code> documented in [G-3] <code><i>twoway_options</i></code>

`collect` is allowed; see [U] 11.1.10 **Prefix commands**.

`fweights` are allowed; see [U] 11.1.6 **weight**.

`lroc` is not appropriate with `svy` estimation results.

## Options

### Main

`all` requests that the statistic be computed for all observations in the data, ignoring any `if` or `in` restrictions specified by the estimation command.

`nograph` suppresses graphical output.

### Advanced

`beta(matname)` specifies a row vector containing model coefficients. The columns of the row vector must be labeled with the corresponding names of the independent variables in the data. The dependent variable `depvar` must be specified immediately after the command name. See *Models other than the last fitted model* later in this entry.

### Plot

`cline_options`, `marker_options`, and `marker_label_options` affect the rendition of the ROC curve—the plotted points connected by lines. These options affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] `cline_options`, [G-3] `marker_options`, and [G-3] `marker_label_options`.

## Reference line

`rlopts(cline_options)` affects the rendition of the reference line; see [G-3] *cline\_options*.

## Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] *addplot\_option*.

## Y axis, X axis, Titles, Legend, Overall

*tway\_options* are any of the options documented in [G-3] *tway\_options*, excluding `by()`. These include options for titling the graph (see [G-3] *title\_options*) and for saving the graph to disk (see [G-3] *saving\_option*).

## Remarks and examples

Remarks are presented under the following headings:

*Introduction*

*Samples other than the estimation sample*

*Models other than the last fitted model*

## Introduction

Stata also has a suite of commands for performing both parametric and nonparametric receiver operating characteristic (ROC) analysis. See [R] **roc** for an overview of these commands.

`lroc` graphs the ROC curve—a graph of sensitivity versus one minus specificity as the cutoff  $c$  is varied—and calculates the area under it. Sensitivity is the fraction of observed positive-outcome cases that are correctly classified; specificity is the fraction of observed negative-outcome cases that are correctly classified. When the purpose of the analysis is classification, you must choose a cutoff.

The curve starts at  $(0, 0)$ , corresponding to  $c = 1$ , and continues to  $(1, 1)$ , corresponding to  $c = 0$ . A model with no predictive power would be a  $45^\circ$  line. The greater the predictive power, the more bowed the curve, and hence the area beneath the curve is often used as a measure of the predictive power. A model with no predictive power has area 0.5; a perfect model has area 1.

The ROC curve was first discussed in signal detection theory (Peterson, Birdsall, and Fox 1954) and then was quickly introduced into psychology (Tanner and Swets 1954). It has since been applied in other fields, particularly medicine (for instance, Metz [1978]). For a classic text on ROC techniques, see Green and Swets (1966).

`lsens` also plots sensitivity and specificity; see [R] **lsens**.

### ► Example 1

Hardin and Hilbe (2018) examine data from the National Canadian Registry of Cardiovascular Disease (FASTRAK), sponsored by Hoffman-La Roche Canada. They model death within 48 hours based on whether a patient suffers an anterior infarct (heart attack) rather than an inferior infarct using a logistic regression and evaluate the model using an ROC curve. We replicate their analysis here.

Both anterior and inferior refer to sites on the heart where damage occurs. The model is also adjusted for `hcabg`, whether the subject has had a cardiac bypass surgery (CABG); `age`, a four-category age-group indicator; and `killip`, a four-level risk indicator.

We load the data and then estimate the parameters of the logistic regression with `logistic`. Factor-variable notation is used for each predictor, because they are categorical; see [U] 11.4.3 Factor variables.

```
. use https://www.stata-press.com/data/r18/heart
(Heart attacks)
. logistic death i.site i.hcabg i.killip i.age
Logistic regression
Log likelihood = -636.62553
```

Number of obs = 4,483  
LR chi2(8) = 211.37  
Prob > chi2 = 0.0000  
Pseudo R2 = 0.1424

death	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
site						
Anterior	1.901333	.3185757	3.83	0.000	1.369103	2.640464
1.hcabg	2.105275	.7430694	2.11	0.035	1.054076	4.204801
killip						
2	2.251732	.4064423	4.50	0.000	1.580786	3.207453
3	2.172105	.584427	2.88	0.004	1.281907	3.680487
4	14.29137	5.087654	7.47	0.000	7.112964	28.71423
age						
60-69	1.63726	.5078582	1.59	0.112	.8914261	3.007115
70-79	4.532029	1.206534	5.68	0.000	2.689568	7.636647
>=80	8.893222	2.41752	8.04	0.000	5.219991	15.15125
_cons	.0063961	.0016541	-19.54	0.000	.0038529	.010618

Note: `_cons` estimates baseline odds.

The odds ratios for a unit change in each covariate are reported by `logistic`. At fixed values of the other covariates, patients who enter Canadian hospitals with an anterior infarct have nearly twice the odds of death within 48 hours than those with an inferior infarct. Those who have had a previous CABG have approximately twice the risk of death of those who have not. Those with higher Killip risks and those who are older are also at greater risk of death.

We use `lroc` to draw the ROC curve for the model. The area under the curve of approximately 0.8 indicates acceptable discrimination for the model.

```
. lroc
Logistic model for death
Number of observations = 4483
Area under ROC curve = 0.7965
```

## Samples other than the estimation sample

`lroc` can be used with samples other than the estimation sample. By default, `lroc` remembers the estimation sample used with the last `logistic`, `logit`, `probit`, or `ivprobit` command. To override this, simply use an `if` or `in` restriction to select another set of observations, or specify the `all` option to force the command to use all the observations in the dataset.

See [example 3](#) in [\[R\] estat gof](#) for an example of using `lroc` with a sample other than the estimation sample.

## Models other than the last fitted model

By default, `lroc` uses the last model fit by `logistic`, `logit`, `probit`, or `ivprobit`. You may also directly specify the model to `lroc` by inputting a vector of coefficients with the `beta()` option and passing the name of the dependent variable `depvar` to `lroc`.

### ► Example 2

Suppose that someone publishes the following logistic model of low birthweight:

$$\Pr(\text{low} = 1) = F(-0.02 \text{ age} - 0.01 \text{ lwt} + 1.3 \text{ black} + 1.1 \text{ smoke} + 0.5 \text{ pt1} + 1.8 \text{ ht} + 0.8 \text{ ui} + 0.5)$$

where  $F$  is the cumulative logistic distribution. These coefficients are not odds ratios; they are the equivalent of what `logit` produces.

We can see whether this model fits our data. First, we enter the coefficients as a row vector and label its columns with the names of the independent variables plus `_cons` for the constant (see [\[P\] matrix define](#) and [\[P\] matrix rownames](#)).

```
. use https://www.stata-press.com/data/r18/lbw3, clear
(Hosmer & Lemeshow data)
. matrix input b = (-.02, -.01, 1.3, 1.1, .5, 1.8, .8, .5)
. matrix colnames b = age lwt black smoke ptl ht ui _cons
```

Here we use `lroc` to examine the predictive ability of the model:

```
. lroc low, beta(b) nograph
Logistic model for low
Number of observations =      189
Area under ROC curve   =   0.7275
```

The area under the curve indicates that this model does have some predictive power. We can obtain a graph of sensitivity and specificity as a function of the cutoff probability by typing

```
. lsens low, beta(b)
```

See [R] `lsens`.

4

## Stored results

`lroc` stores the following in `r()`:

Scalars

<code>r(N)</code>	number of observations
<code>r(area)</code>	area under the ROC curve

## Methods and formulas

The ROC curve is a graph of *sensitivity* against  $(1 - \textit{specificity})$ . This is guaranteed to be a monotone nondecreasing function because the number of correctly predicted successes increases and the number of correctly predicted failures decreases as the classification cutoff  $c$  decreases.

The area under the ROC curve is the area on the bottom of this graph and is determined by integrating the curve. The vertices of the curve are determined by sorting the data according to the predicted index, and the integral is computed using the trapezoidal rule.

# Title

**lrtest** — Likelihood-ratio test after estimation

<a href="#">Description</a>	<a href="#">Quick start</a>	<a href="#">Menu</a>	<a href="#">Syntax</a>
<a href="#">Options</a>	<a href="#">Remarks and examples</a>	<a href="#">Stored results</a>	<a href="#">Methods and formulas</a>
<a href="#">References</a>	<a href="#">Also see</a>		

## Description

`lrtest` performs a likelihood-ratio test of the null hypothesis that the parameter vector of a statistical model satisfies some smooth constraint. To conduct the test, both the unrestricted and the restricted models must be fit using the maximum likelihood method (or some equivalent method), and the results of at least one must be stored using [estimates store](#).

`lrtest` also supports composite models. In a composite model, we assume that the log likelihood and dimension (number of free parameters) of the full model are obtained as the sum of the log-likelihood values and dimensions of the constituting models.

## Quick start

Likelihood-ratio test that the coefficients for `x2` and `x3` are equal to 0

```
logit y x1 x2 x3
estimates store full
logit y x1 if e(sample)
estimates store restricted
lrtest full restricted
```

Display additional information, including AIC and BIC

```
lrtest full restricted, stats
```

Likelihood-ratio test that the coefficients for `x1` and `x3` are equal

```
constraint 1 x1=x3
logit y x1 x2 x3, constraints(1)
estimates store constrained
lrtest full constrained
```

Compare stored estimates `full` with the last model run

```
lrtest full
```

## Menu

Statistics > Postestimation

## Syntax

```
lrtest modelspec1 [modelspec2] [, options]
```

*modelspec*<sub>1</sub> and *modelspec*<sub>2</sub> specify the restricted and unrestricted model in any order. *modelspec*<sub>#</sub> is *name* | . | (*namelist*)

*name* is the name under which estimation results were stored using `estimates store` (see [\[R\] estimates store](#)), and “.” refers to the last estimation results, whether or not these were already stored. If *modelspec*<sub>2</sub> is not specified, the last estimation result is used; this is equivalent to specifying *modelspec*<sub>2</sub> as “.”.

If *namelist* is specified for a composite model, *modelspec*<sub>1</sub> and *modelspec*<sub>2</sub> cannot have names in common; for example, `lrtest (A B C) (C D E)` is not allowed because both model specifications include C.

<i>options</i>	Description
<code>stats</code>	display statistical information about the two models
<code>dir</code>	display descriptive information about the two models
<code>df(#)</code>	override the automatic degrees-of-freedom calculation; seldom used
<code>force</code>	force testing even when apparently invalid

`collect` is allowed; see [\[U\] 11.1.10 Prefix commands](#).

## Options

`stats` displays statistical information about the unrestricted and restricted models, including the information indices of Akaike and Schwarz.

`dir` displays descriptive information about the unrestricted and restricted models; see `estimates dir` in [\[R\] estimates store](#).

`df(#)` is seldom specified; it overrides the automatic degrees-of-freedom calculation.

`force` forces the likelihood-ratio test calculations to take place in situations where `lrtest` would normally refuse to do so and issue an error. Such situations arise when one or more assumptions of the test are violated, for example, if the models were fit with `vce(robust)`, `vce(cluster clustvar)`, or `pweights`; when the dependent variables in the two models differ; when the null log likelihoods differ; when the samples differ; or when the estimation commands differ. If you use the `force` option, there is no guarantee as to the validity or interpretability of the resulting test.

## Remarks and examples

The standard way to use `lrtest` is to do the following:

1. Fit either the restricted model or the unrestricted model by using one of Stata’s estimation commands and then store the results using `estimates store name`.
2. Fit the alternative model (the unrestricted or restricted model) and then type `‘lrtest name .’`. `lrtest` determines for itself which of the two models is the restricted model by comparing the degrees of freedom.

Often, you may want to store the alternative model with `estimates store name2`, for instance, if you plan additional tests against models yet to be fit. The likelihood-ratio test is then obtained as `lrtest name name2`.

Remarks are presented under the following headings:

*Nested models*  
*Composite models*

## Nested models

`lrtest` may be used with any estimation command that reports a log likelihood, including `heckman`, `logit`, `poisson`, `stcox`, and `streg`. You must check that one of the model specifications implies a statistical model that is *nested within* the model implied by the other specification. Usually, this means that both models are fit with the same estimation command (for example, both are fit by `logit`, with the same dependent variables) and that the set of covariates of one model is a subset of the covariates of the other model. Second, `lrtest` is valid only for models that are fit by maximum likelihood or by some equivalent method, so it does not apply to models that were fit with probability weights or clusters. Specifying the `vce(robust)` option similarly would indicate that you are worried about the valid specification of the model, so you would not use `lrtest`. Third, `lrtest` assumes that under the null hypothesis, the test statistic is (approximately) distributed as  $\chi^2$ . This assumption is not true for likelihood-ratio tests of “boundary conditions”, such as tests for the presence of overdispersion or random effects (Gutierrez, Carter, and Drukker 2001).

### ▷ Example 1

We have data on infants born with low birthweights along with the characteristics of the mother (Hosmer, Lemeshow, and Sturdivant 2013; see also [R] [logistic](#)). We fit the following model:

```
. use https://www.stata-press.com/data/r18/lbw
(Hosmer & Lemeshow data)
. logistic low age lwt i.race smoke ptl ht ui
Logistic regression                                Number of obs =   189
                                                    LR chi2(8)      =   33.22
                                                    Prob > chi2    = 0.0001
                                                    Pseudo R2     = 0.1416
Log likelihood = -100.724
```

low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
age	.9732636	.0354759	-0.74	0.457	.9061578	1.045339
lwt	.9849634	.0068217	-2.19	0.029	.9716834	.9984249
race						
Black	3.534767	1.860737	2.40	0.016	1.259736	9.918406
Other	2.368079	1.039949	1.96	0.050	1.001356	5.600207
smoke	2.517698	1.00916	2.30	0.021	1.147676	5.523162
ptl	1.719161	.5952579	1.56	0.118	.8721455	3.388787
ht	6.249602	4.322408	2.65	0.008	1.611152	24.24199
ui	2.1351	.9808153	1.65	0.099	.8677528	5.2534
_cons	1.586014	1.910496	0.38	0.702	.1496092	16.8134

Note: `_cons` estimates baseline odds.

We now wish to test the constraint that the coefficients on `age`, `lwt`, `ptl`, and `ht` are all zero or, equivalently here, that the odds ratios are all 1. One solution is to type

```
. test age lwt ptl ht
( 1) [low]age = 0
( 2) [low]lwt = 0
( 3) [low]ptl = 0
( 4) [low]ht = 0
      chi2( 4) = 12.38
      Prob > chi2 = 0.0147
```

This test is based on the inverse of the information matrix and is therefore based on a quadratic approximation to the likelihood function; see [R] [test](#). A more precise test would be to refit the model, applying the proposed constraints, and then calculate the likelihood-ratio test.

We first save the current model:

```
. estimates store full
```

We then fit the constrained model, which here is the model omitting `age`, `lwt`, `ptl`, and `ht`:

```
. logistic low i.race smoke ui
Logistic regression
Log likelihood = -107.93404
Number of obs = 189
LR chi2(4) = 18.80
Prob > chi2 = 0.0009
Pseudo R2 = 0.0801
```

low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
race						
Black	3.052746	1.498087	2.27	0.023	1.166747	7.987382
Other	2.922593	1.189229	2.64	0.008	1.316457	6.488285
smoke						
ui	2.419131	1.047359	2.04	0.041	1.035459	5.651788
_cons	.1402209	.0512295	-5.38	0.000	.0685216	.2869447

Note: `_cons` estimates baseline odds.

That done, `lrtest` compares this model with the model we previously stored:

```
. lrtest full .
Likelihood-ratio test
Assumption: . nested within full
LR chi2(4) = 14.42
Prob > chi2 = 0.0061
```

Let's compare results. `test` reported that `age`, `lwt`, `ptl`, and `ht` were jointly significant at the 1.5% level; `lrtest` reports that they are significant at the 0.6% level. Given the quadratic approximation made by `test`, we could argue that `lrtest`'s results are more accurate.

`lrtest` explicates the assumption that, from a comparison of the degrees of freedom, it has assessed that the last fit model (`.`) is nested within the model stored as `full`. In other words, `full` is the unconstrained model and `.` is the constrained model.

The names in “(Assumption: `.` nested in `full`)” are actually links. Click on a name, and the results for that model are replayed.

◀

Aside: The `nestreg` command provides a simple syntax for performing likelihood-ratio tests for nested model specifications; see [R] [nestreg](#). In the [previous example](#), we fit a full logistic model, used `estimates store` to store the full model, fit a constrained logistic model, and used `lrtest` to report a likelihood-ratio test between two models. To do this with one call to `nestreg`, use the `ltable` option.

## □ Technical note

`lrtest` determines the degrees of freedom of a model as the rank of the (co)variance matrix  $e(V)$ . There are two issues here. First, the *numerical* determination of the rank of a matrix is a subtle problem that can, for instance, be affected by the scaling of the variables in the model. The rank of a matrix depends on the number of (independent) linear combinations of coefficients that sum exactly to zero. In the world of numerical mathematics, it is hard to tell whether a very small number is really nonzero or is a real zero that happens to be slightly off because of roundoff error from the finite precision with which computers make floating-point calculations. Whether a small number is being classified as one or the other, typically on the basis of a threshold, affects the determined degrees of freedom. Although Stata generally makes sensible choices, it is bound to make mistakes occasionally. The moral of this story is to make sure that the calculated degrees of freedom is as you expect before interpreting the results.

□

## □ Technical note

A second issue involves `regress` and related commands such as `anova`. Mainly for historical reasons, `regress` does not treat the residual variance,  $\sigma^2$ , the same way that it treats the regression coefficients. Type `estat vce` after `regress`, and you will see the regression coefficients, not  $\hat{\sigma}^2$ . Most estimation commands for models with ancillary parameters (for example, `streg` and `heckman`) treat all parameters as equals. There is nothing technically wrong with `regress` here; we are usually focused on the regression coefficients, and their estimators are uncorrelated with  $\hat{\sigma}^2$ . But, formally,  $\sigma^2$  adds a degree of freedom to the model, which does not matter if you are comparing two regression models by a likelihood-ratio test. This test depends on the difference in the degrees of freedom, and hence being “off by 1” in each does not matter. But, if you are comparing a regression model with a larger model—for example, a heteroskedastic regression model fit by `arch`—the automatic determination of the degrees of freedom is incorrect, and you must specify the `df(#)` option.

□

## ▷ Example 2

Returning to the low-birthweight data in [example 1](#), we now wish to test that the coefficient on `2.race` (black) is equal to that on `3.race` (other). The base model is still stored under the name `full`, so we need only fit the constrained model and perform the test. With  $z$  as the index of the logit model, the base model is

$$z = \beta_0 + \beta_1 \text{age} + \beta_2 \text{1wt} + \beta_3 \text{2.race} + \beta_4 \text{3.race} + \dots$$

If  $\beta_3 = \beta_4$ , this can be written as

$$z = \beta_0 + \beta_1 \text{age} + \beta_2 \text{1wt} + \beta_3 (\text{2.race} + \text{3.race}) + \dots$$

We can fit the constrained model as follows:

```
. constraint 1 2.race = 3.race
. logistic low age lwt i.race smoke ptl ht ui, constraints(1)
Logistic regression                               Number of obs =   189
                                                    Wald chi2(7) = 25.17
Log likelihood = -100.9997                         Prob > chi2 = 0.0007
( 1) [low]2.race - [low]3.race = 0
```

	low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
age		.9716799	.0352638	-0.79	0.429	.9049649	1.043313
lwt		.9864971	.0064627	-2.08	0.038	.9739114	.9992453
race

Comparing this model with our original model, we obtain

```
. lrtest full .
Likelihood-ratio test
Assumption: . nested within full
LR chi2(1) = 0.55
Prob > chi2 = 0.4577
```

By comparison, typing `test 2.race=3.race` after fitting our base model results in a significance level of 0.4572. Alternatively, we can first store the restricted model, here using the name `equal`. Next, `lrtest` is invoked specifying the names of the restricted and unrestricted models (we do not care about the order). This time, we also add the option `stats` requesting a table of model statistics, including the model selection indices AIC and BIC.

```
. estimates store equal
. lrtest equal full, stats
Likelihood-ratio test
Assumption: equal nested within full
LR chi2(1) = 0.55
Prob > chi2 = 0.4577
Akaike's information criterion and Bayesian information criterion
```

Model	N	ll(null)	ll(model)	df	AIC	BIC
equal	189	.	-100.9997	8	217.9994	243.9334
full	189	-117.336	-100.724	9	219.448	248.6237

Note: BIC uses N = number of observations. See [\[R\] IC note](#).

## Composite models

lrtest supports composite models; that is, models that can be fit by fitting a series of simpler models or by fitting models on subsets of the data. Theoretically, a composite model is one in which the likelihood function,  $L(\theta)$ , of the parameter vector,  $\theta$ , can be written as the product

$$L(\theta) = L_1(\theta_1) \times L_2(\theta_2) \times \cdots \times L_k(\theta_k)$$

of likelihood terms with  $\theta = (\theta_1, \dots, \theta_k)$  a partitioning of the full parameter vector. In such a case, the full-model likelihood  $L(\theta)$  is maximized by maximizing the likelihood terms  $L_j(\theta_j)$  in turn. Obviously,  $\log L(\hat{\theta}) = \sum_{j=1}^k \log L_j(\hat{\theta}_j)$ . The degrees of freedom for the composite model is obtained as the sum of the degrees of freedom of the constituting models.

### ► Example 3

As an example of the application of composite models, we consider a test of the hypothesis that the coefficients of a statistical model do not differ between different portions (“regimes”) of the covariate space. Economists call a test for such a hypothesis a *Chow test*.

We continue the analysis of the data on children of low birthweight by using logistic regression modeling and study whether the regression coefficients are the same among the three races: white, black, and other. A likelihood-ratio Chow test can be obtained by fitting the logistic regression model for each of the races and then comparing the combined results with those of the model previously stored as full. Because the full model included dummies for the three races, this version of the Chow test allows the intercept of the logistic regression model to vary between the regimes (races).

```
. logistic low age lwt smoke ptl ht ui if 1.race, nolog

. estimates store other
```

We are now ready to perform the likelihood-ratio Chow test:

```
. lrtest (full) (white black other), stats
Likelihood-ratio test
Assumption: full nested within (white, black, other)
LR chi2(12) = 9.83
Prob > chi2 = 0.6310
Akaike's information criterion and Bayesian information criterion
```

Model	N	ll(null)	ll(model)	df	AIC	BIC
full	189	-117.336	-100.724	9	219.448	248.6237
white	96	-52.85752	-45.92706	7	105.8541	123.8046
black	26	-17.71291	-12.65416	7	39.30831	48.11499
other	67	-44.26039	-37.22844	7	88.45689	103.8897

Note: BIC uses N = number of observations. See [\[R\] IC note](#).

We cannot reject the hypothesis that the logistic regression model applies to each of the races at any reasonable significance level. By specifying the **stats** option, we can verify the degrees of freedom of the test:  $12 = 7 + 7 + 7 - 9$ . We can obtain the same test by fitting an expanded model with interactions between all covariates and race.

```
. logistic low race##c.(age lwt smoke ptl ht ui)

```
. lrtest full .
```

```
Likelihood-ratio test
```

```
Assumption: full nested within .
```

```
LR chi2(12) = 9.83
```

```
Prob > chi2 = 0.6310
```

Applying `lrtest` for the full model against the model with all interactions yields the same test statistic and  $p$ -value as for the full model against the composite model for the three regimes. Here the specification of the model with interactions was convenient, and `logistic` had no problem computing the estimates for the expanded model. In models with more complicated likelihoods, such as Heckman's selection model (see [R] [heckman](#)) or complicated survival-time models (see [ST] [streg](#)), fitting the models with all interactions may be numerically demanding and may be much more time consuming than fitting a series of models separately for each regime.

Given the model with all interactions, we could also test the hypothesis of no differences among the regions (races) by a Wald version of the Chow test by using the `testparm` command; see [R] [test](#).

```
. testparm race#c.(age lwt smoke ptl ht ui)
( 1) [low]2.race#c.age = 0
( 2) [low]3.race#c.age = 0
( 3) [low]2.race#c.lwt = 0
( 4) [low]3.race#c.lwt = 0
( 5) [low]2.race#c.smoke = 0
( 6) [low]3.race#c.smoke = 0
( 7) [low]2.race#c.ptl = 0
( 8) [low]3.race#c.ptl = 0
( 9) [low]2.race#c.ht = 0
(10) [low]3.race#c.ht = 0
(11) [low]2.race#c.ui = 0
(12) [low]3.race#c.ui = 0

      chi2( 12) =      8.24
      Prob > chi2 =    0.7663
```

We conclude that, here, the Wald version of the Chow test is similar to the likelihood-ratio version of the Chow test.

◀

## Stored results

`lrtest` stores the following in `r()`:

Scalars

<code>r(p)</code>	<i>p</i> -value for likelihood-ratio test
<code>r(df)</code>	degrees of freedom
<code>r(chi2)</code>	LR test statistic

Programmers wishing their estimation commands to be compatible with `lrtest` should note that `lrtest` requires that the following results be returned:

<code>e(cmd)</code>	name of estimation command
<code>e(ll)</code>	log likelihood
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(N)</code>	number of observations

`lrtest` also verifies that `e(N)`, `e(ll_0)`, and `e(depvar)` are consistent between two noncomposite models.

## Methods and formulas

Let  $L_0$  and  $L_1$  be the log-likelihood values associated with the full and constrained models, respectively. The test statistic of the likelihood-ratio test is  $LR = -2(L_1 - L_0)$ . If the constrained model is true, LR is approximately  $\chi^2$  distributed with  $d_0 - d_1$  degrees of freedom, where  $d_0$  and  $d_1$  are the model degrees of freedom associated with the full and constrained models, respectively (Greene 2018, 554–555).

`lrtest` determines the degrees of freedom of a model as the rank of `e(V)`, computed as the number of nonzero diagonal elements of `invsym(e(V))`.

# Title

**lsens** — Graph sensitivity and specificity versus probability cutoff

[Description](#)  
[Options](#)  
[Reference](#)

[Quick start](#)  
[Remarks and examples](#)  
[Also see](#)

[Menu](#)  
[Stored results](#)

[Syntax](#)  
[Methods and formulas](#)

## Description

`lsens` graphs sensitivity and specificity versus probability cutoff and optionally creates new variables containing these data.

`lsens` requires that the current estimation results be from `logistic`, `logit`, `probit`, or `ivprobit`; see [\[R\] logistic](#), [\[R\] logit](#), [\[R\] probit](#), or [\[R\] ivprobit](#).

## Quick start

Graph sensitivity and specificity versus a probability cutoff using current estimation results

```
lsens
```

Generate variables `v1`, `v2`, and `v3` to contain probability cutoffs, sensitivity, and specificity

```
lsens, genprob(v1) gensens(v2) genspec(v3)
```

Add “My Title” to graph

```
lsens, genprob(v1) gensens(v2) genspec(v3) title(My Title)
```

## Menu

Statistics > Binary outcomes > Postestimation > Sensitivity/specificity plot

## Syntax

```
lsens [deivar] [if] [in] [weight] [, options]
```

<i>options</i>	Description
Main	
<code>all</code>	graph all observations in the data
<code>genprob(<i>varname</i>)</code>	create variable containing probability cutoffs
<code>gensens(<i>varname</i>)</code>	create variable containing sensitivity
<code>genspec(<i>varname</i>)</code>	create variable containing specificity
<code>replace</code>	overwrite existing variables
<code>nograph</code>	suppress the graph
Advanced	
<code>beta(<i>matname</i>)</code>	row vector containing model coefficients
Plot	
<code>connect_options</code>	affect rendition of the plotted points connected by lines
Add plots	
<code>addplot(<i>plot</i>)</code>	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
<code>twoway_options</code>	any options other than <code>by()</code> documented in [G-3] <code>twoway_options</code>

`collect` is allowed; see [U] 11.1.10 Prefix commands.

`fweights` are allowed; see [U] 11.1.6 weight.

`lsens` is not appropriate with `svy` estimation results.

## Options

### Main

`all` requests that the statistic be computed for all observations in the data, ignoring any `if` or `in` restrictions specified by the estimation command.

`genprob(varname)`, `gensens(varname)`, and `genspec(varname)` specify the names of new variables created to contain, respectively, the probability cutoffs and the corresponding sensitivity and specificity.

`replace` requests that existing variables specified for `genprob()`, `gensens()`, or `genspec()` be overwritten.

`nograph` suppresses graphical output.

### Advanced

`beta(matname)` specifies a row vector containing model coefficients. The columns of the row vector must be labeled with the corresponding names of the independent variables in the data. The dependent variable *deivar* must be specified immediately after the command name. See *Models other than the last fitted model* later in this entry.

## Plot

*connect\_options* affect the rendition of the plotted points connected by lines; see *connect\_options* in [G-2] [graph twoway scatter](#).

## Add plots

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

## Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Models other than the last fitted model](#)

### Introduction

`lsens` plots sensitivity and specificity; it plots both sensitivity and specificity versus probability cutoff  $c$ . The graph is equivalent to what you would get from `estat classification` (see [R] [estat classification](#)) if you varied the cutoff probability  $c$  from 0 to 1.

### ► Example 1

We illustrate `lsens` after `logistic`; see [R] [logistic](#).

```
. use https://www.stata-press.com/data/r18/lbw
(Hosmer & Lemeshow data)
. logistic low age i.race smoke ui
(output omitted)
. lsens
```

lsens optionally creates new variables containing the probability cutoff, sensitivity, and specificity.

```
. lsens, genprob(p) gensens(sens) genspec(spec) nograph
```

The variables created will have  $M + 2$  distinct nonmissing values: one for each of the  $M$  covariate patterns, one for  $c = 0$ , and another for  $c = 1$ . Values are recorded for  $p = 0$ , for each of the observed predicted probabilities, and for  $p = 1$ . The total number of observations required to do this can be fewer than  $\_N$ , the same as  $\_N$ , or  $\_N + 1$ , or  $\_N + 2$ . If more observations are added, they are added at the end of the dataset and the values of the original variables are set to missing in the added observations. How the values added align with existing observations is irrelevant.

◀

## □ Technical note

logistic, logit, probit, or ivprobit and lsens keep track of the estimation sample. If you type, for instance, `logistic ... if x==1`, then when you type `lsens`, the statistics will be calculated on the `x==1` subsample of the data automatically.

You should specify `if` or `in` with `lsens` only when you wish to produce graphs and calculate statistics for a set of observations other than the estimation sample.

If the `logistic` model was fit with `fweights`, `lsens` properly accounts for the weights in its calculations. You do not have to specify the weights when you run `lsens`. Weights should be specified with `lsens` only when you wish to use a different set of weights.

□

## Models other than the last fitted model

By default, `lsens` uses the last model fit. You may also directly specify the model to `lsens` by inputting a vector of coefficients with the `beta()` option and passing the name of the dependent variable `devar` to `lsens`.

## ▷ Example 2

Suppose that someone publishes the following logistic model of low birthweight:

$$\Pr(\text{low} = 1) = F(-0.02 \text{ age} - 0.01 \text{ lwt} + 1.3 \text{ black} + 1.1 \text{ smoke} + 0.5 \text{ pt1} + 1.8 \text{ ht} + 0.8 \text{ ui} + 0.5)$$

where  $F$  is the cumulative logistic distribution. These coefficients are not odds ratios; they are the equivalent of what `logit` produces.

We can see whether this model fits our data. First, we enter the coefficients as a row vector and label its columns with the names of the independent variables plus `_cons` for the constant (see [P] [matrix define](#) and [P] [matrix rownames](#)).

```
. use https://www.stata-press.com/data/r18/lbw3, clear
(Hosmer & Lemeshow data)
. matrix input b = (-0.02, -.01, 1.3, 1.1, .5, 1.8, .8, .5)
. matrix colnames b = age lwt black smoke pt1 ht ui _cons
```

We can use `lroc` (see [R] [lroc](#)) to examine the predictive ability of the model:

```
. lroc low, beta(b) nograph
Logistic model for low
Number of observations =      189
Area under ROC curve   =   0.7275
```

The area under the curve indicates that this model does have some predictive power. We can obtain a graph of sensitivity and specificity as a function of the cutoff probability by typing

```
. lsens low, beta(b)
```

4

## Stored results

`lsens` stores the following in `r()`:

```
Scalars
      r(N)      number of observations
```

## Methods and formulas

Let  $j$  index observations and  $c$  be the cutoff probability. Let  $p_j$  be the predicted probability of a positive outcome and  $y_j$  be the actual outcome, which we will treat as 0 or 1, although Stata treats it as 0 and non-0, excluding missing observations.

A prediction is classified as *positive* if  $p_j \geq c$  and otherwise is classified as *negative*. The classification is *correct* if it is *positive* and  $y_j = 1$  or if it is *negative* and  $y_j = 0$ .

*Sensitivity* is the fraction of  $y_j = 1$  observations that are correctly classified. *Specificity* is the percentage of  $y_j = 0$  observations that are correctly classified.

# Title

## lv — Letter-value displays

<a href="#">Description</a>	<a href="#">Quick start</a>	<a href="#">Menu</a>	<a href="#">Syntax</a>
<a href="#">Options</a>	<a href="#">Remarks and examples</a>	<a href="#">Stored results</a>	<a href="#">Methods and formulas</a>
<a href="#">References</a>	<a href="#">Also see</a>		

## Description

`lv` shows a letter-value display (Tukey 1977, 44–49; Hoaglin 1983) for each variable in *varlist*. If no variables are specified, letter-value displays are shown for each numeric variable in the data.

## Quick start

Letter-value display for all numeric variables in the dataset

```
lv
```

Letter-value display for `v1`

```
lv v1
```

Also generate new variables `_mid`, `_spread`, `_psigma`, and `_z2` containing midsummaries, spreads, pseudosigmias, and  $z^2$  values

```
lv v1, generate
```

Letter-value displays for `v1` separately for each value of `v2`

```
bysort v2: lv v1
```

## Menu

Statistics > Summaries, tables, and tests > Distributional plots and tests > Letter-value display

## Syntax

```
lv [ varlist ] [ if ] [ in ] [ , generate tail(#) ]
```

by and collect are allowed; see [U] 11.1.10 Prefix commands.

## Options

### Main

**generate** adds four new variables to the data: `_mid`, containing the midsummaries; `_spread`, containing the spreads; `_psigma`, containing the pseudosigmias; and `_z2`, containing the squared values from a standard normal distribution corresponding to the particular letter value. If the variables `_mid`, `_spread`, `_psigma`, and `_z2` already exist, their contents are replaced. At most, only the first 11 observations of each variable are used; the remaining observations contain missing. If *varlist* specifies more than one variable, the newly created variables contain results for the last variable specified. The **generate** option may not be used with the **by** prefix.

**tail**(#) indicates the inverse of the tail density through which letter values are to be displayed: 2 corresponds to the median (meaning half in each tail), 4 to the fourths (roughly the 25th and 75th percentiles), 8 to the eighths, and so on. # may be specified as 4, 8, 16, 32, 64, 128, 256, 512, or 1,024 and defaults to a value of # that has corresponding depth just greater than 1. The default is taken as 1,024 if the calculation results in a number larger than 1,024. Given the intelligent default, this option is rarely specified.

## Remarks and examples

Letter-value displays are a collection of observations drawn systematically from the data, focusing especially on the tails rather than the middle of the distribution. The displays are called letter-value displays because letters have been (almost arbitrarily) assigned to tail densities:

Letter	Tail area	Letter	Tail area
M	1/2	B	1/64
F	1/4	A	1/128
E	1/8	Z	1/256
D	1/16	Y	1/512
C	1/32	X	1/1024

## ▷ Example 1

We have data on the mileage ratings of 74 automobiles. To obtain a letter-value display, we type

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. lv mpg
```

#	74	Mileage (mpg)			spread	pseudosigma
M	37.5		20			
F	19	18	21.5	25	7	5.216359
E	10	15	21.5	28	13	5.771728
D	5.5	14	22.25	30.5	16.5	5.576303
C	3	14	24.5	35	21	5.831039
B	2	12	23.5	35	23	5.732448
A	1.5	12	25	38	26	6.040635
	1	12	26.5	41	29	6.16562
inner fence		7.5		35.5	# below	# above
outer fence		-3		46	0	1
					0	0

The decimal points can be made to line up and thus the output made more readable by specifying a display format for the variable; see [U] 12.5 Formats: Controlling how data are displayed.

```
. format mpg %9.2f
. lv mpg
```

#	74	Mileage (mpg)			spread	pseudosigma
M	37.5		20.00			
F	19	18.00	21.50	25.00	7.00	5.22
E	10	15.00	21.50	28.00	13.00	5.77
D	5.5	14.00	22.25	30.50	16.50	5.58
C	3	14.00	24.50	35.00	21.00	5.83
B	2	12.00	23.50	35.00	23.00	5.73
A	1.5	12.00	25.00	38.00	26.00	6.04
	1	12.00	26.50	41.00	29.00	6.17
inner fence		7.50		35.50	# below	# above
outer fence		-3.00		46.00	0	1
					0	0

At the top, the number of observations is indicated as 74. The first line shows the statistics associated with M, the letter value that puts half the density in each tail, or the median. The median has *depth* 37.5 (that is, in the ordered data, M is 37.5 observations in from the extremes) and has value 20. The next line shows the statistics associated with F or the fourths. The fourths have depth 19 (that is, in the ordered data, the lower fourth is observation 19, and the upper fourth is observation  $74 - 19 + 1$ ), and the values of the lower and upper fourths are 18 and 25. The number in the middle is the point halfway between the fourths—called a midsummary. If the distribution were perfectly symmetric, the midsummary would equal the median. The spread is the difference between the lower and upper summaries ( $25 - 18 = 7$ ). For fourths, half the data lie within a 7-mpg band. The pseudosigma is a calculation of the standard deviation using only the lower and upper summaries and assuming that the variable is normally distributed. If the data really were normally distributed, all the pseudosigmas would be roughly equal.

After the letter values, the line labeled with depth 1 reports the minimum and maximum values. Here the halfway point between the extremes is 26.5, which is greater than the median, indicating that 41 is more extreme than 12, at least relative to the median. And with each letter value, the midsummaries are increasing—our data are skewed. The pseudosigmas are also increasing, indicating

that the data are spreading out relative to a normal distribution, although, given the evident skewness, this elongation may be an artifact of the skewness.

At the end is an attempt to identify outliers, although the points so identified are merely outside some predetermined cutoff. Points outside the inner fence are called *outside values* or *mild outliers*. Points outside the outer fence are called *severe outliers*. The inner fence is defined as  $(3/2)\text{IQR}$  and the outer fence as  $3\text{IQR}$  above and below the F summaries, where the interquartile range (IQR) is the spread of the fourths.

◀

## □ Technical note

The form of the letter-value display has varied slightly with different authors.  $1v$  displays appear as described by Hoaglin (1983) but as modified by Emerson and Stoto (1983), where they included the midpoint of each of the spreads. This format was later adopted by Hoaglin (1985). If the distribution is symmetric, the midpoints will all be roughly equal. On the other hand, if the midpoints vary systematically, the distribution is skewed.

The pseudosigmas are obtained from the lower and upper summaries for each letter value. For each letter value, they are the standard deviation a normal distribution would have if its spread for the given letter value were to equal the observed spread. If the pseudosigmas are all roughly equal, the data are said to have *neutral elongation*. If the pseudosigmas increase systematically, the data are said to be more elongated than a normal, that is, have thicker tails. If the pseudosigmas decrease systematically, the data are said to be less elongated than a normal, that is, have thinner tails.

Interpretation of the number of mild and severe outliers is more problematic. The following discussion is drawn from Hamilton (1991):

Obviously, the presence of any such outliers does not rule out that the data have been drawn from a normal distribution; in large datasets, there will most certainly be observations outside  $(3/2)\text{IQR}$  and  $3\text{IQR}$ . Severe outliers, however, make up about two per million (0.0002%) of a normal population. In samples, they lie far enough out to have substantial effects on means, standard deviations, and other classical statistics. The 0.0002%, however, should be interpreted carefully; outliers appear more often in small samples than one might expect from population proportions because of sampling variation in estimated quartiles. Monte Carlo simulation by Hoaglin, Iglewicz, and Tukey (1986) obtained these results on the percentages and numbers of outliers in random samples from a normal population:

n	percentage		number	
	any outliers	severe	any outliers	severe
10	2.83	.362	.283	.0362
20	1.66	.074	.332	.0148
50	1.15	.011	.575	.0055
100	.95	.002	.95	.002
200	.79	.001	1.58	.002
300	.75	.001	2.25	.003
$\infty$	.70	.0002	$\infty$	$\infty$

Thus, the presence of any severe outliers in samples of less than 300 is sufficient to reject normality. Hoaglin, Iglewicz, and Tukey (1981) suggested the approximation  $0.00698 + 0.4/n$  for the fraction of mild outliers in a sample of size  $n$  or, equivalently,  $0.00698n + 0.4$  for the number of outliers.

□

## ▷ Example 2

The `generate` option adds the `_mid`, `_spread`, `_psigma`, and `_z2` variables to our data, making possible many of the diagnostic graphs suggested by [Hoaglin \(1985\)](#).

```
. lv mpg, generate
  (output omitted)
. list _mid _spread _psigma _z2 in 1/12
```

	<code>_mid</code>	<code>_spread</code>	<code>_psigma</code>	<code>_z2</code>
1.	20	.	.	.
2.	21.5	7	5.216359	.4501955
3.	21.5	13	5.771728	1.26828
4.	22.25	16.5	5.576303	2.188846
5.	24.5	21	5.831039	3.24255
6.	23.5	23	5.732448	4.024532
7.	25	26	6.040635	4.631499
8.	.	.	.	.
9.	.	.	.	.
10.	.	.	.	.
11.	26.5	29	6.16562	5.53073
12.	.	.	.	.

Observations 12 through the end are missing for these new variables. The definition of the observations is always the same. The first observation contains the M summary; the second, the F; the third, the E; and so on. Observation 11 always contains the summary for depth 1. Observations 8–10—corresponding to letter values Z, Y, and X—contain missing because these statistics were not calculated. We have only 74 observations, and their depth would be 1.

[Hoaglin \(1985\)](#) suggests graphing the midsummary against  $z^2$ . If the distribution is not skewed, the points in the resulting graph will be along a horizontal line:

```
. scatter _mid _z2
```

The graph clearly indicates the skewness of the distribution. We might also graph `_psigma` against `_z2` to examine elongation.

## Stored results

lv stores the following in `r()`:

Scalars

<code>r(N)</code>	number of observations	<code>r(u_C)</code>	upper 32nd
<code>r(min)</code>	minimum	<code>r(l_B)</code>	lower 64th
<code>r(max)</code>	maximum	<code>r(u_B)</code>	upper 64th
<code>r(median)</code>	median	<code>r(l_A)</code>	lower 128th
<code>r(l_F)</code>	lower 4th	<code>r(u_A)</code>	upper 128th
<code>r(u_F)</code>	upper 4th	<code>r(l_Z)</code>	lower 256th
<code>r(l_E)</code>	lower 8th	<code>r(u_Z)</code>	upper 256th
<code>r(u_E)</code>	upper 8th	<code>r(l_Y)</code>	lower 512th
<code>r(l_D)</code>	lower 16th	<code>r(u_Y)</code>	upper 512th
<code>r(u_D)</code>	upper 16th	<code>r(l_X)</code>	lower 1024th
<code>r(l_C)</code>	lower 32nd	<code>r(u_X)</code>	upper 1024th

The lower/upper 8ths, 16ths, . . . , 1024ths will be defined only if there are sufficient data.

## Methods and formulas

Let  $N$  be the number of (nonmissing) observations on  $x$ , and let  $x_{(i)}$  refer to the ordered data when  $i$  is an integer. Define  $x_{(i+0.5)} = (x_{(i)} + x_{(i+1)})/2$ ; the median is defined as  $x_{\{(N+1)/2\}}$ .

Define  $x_{[d]}$  as the pair of numbers  $x_{(d)}$  and  $x_{(N+1-d)}$ , where  $d$  is called the *depth*. Thus,  $x_{[1]}$  refers to the minimum and maximum of the data. Define  $m = (N + 1)/2$  as the depth of the median,  $f = (\lfloor m \rfloor + 1)/2$  as the depth of the fourths,  $e = (\lfloor f \rfloor + 1)/2$  as the depth of the eighths, and so on. Depths are reported on the far left of the letter-value display. The corresponding fourths of the data are  $x_{[f]}$ , the eighths are  $x_{[e]}$ , and so on. These values are reported inside the display. The middle value is defined as the corresponding midpoint of  $x_{[.]}$ . The spreads are defined as the difference in  $x_{[.]}$ .

The corresponding point  $z_i$  on a standard normal distribution is obtained as (Hoaglin 1985, 456–457)

$$z_i = \begin{cases} F^{-1}\{(d_i - 1/3)/(N + 1/3)\} & \text{if } d_i > 1 \\ F^{-1}\{0.695/(N + 0.390)\} & \text{otherwise} \end{cases}$$

where  $d_i$  is the depth of the letter value. The corresponding pseudosigma is obtained as the ratio of the spread to  $-2z_i$  (Hoaglin 1985, 431).

Define  $(F_l, F_u) = x_{[f]}$ . The inner fence has cutoffs  $F_l - \frac{3}{2}(F_u - F_l)$  and  $F_u + \frac{3}{2}(F_u - F_l)$ . The outer fence has cutoffs  $F_l - 3(F_u - F_l)$  and  $F_u + 3(F_u - F_l)$ .

The inner-fence values reported by `lv` are almost equal to those used by `graph`, `box` to identify outside points. The only difference is that `graph` uses a slightly different definition of fourths, namely, the 25th and 75th percentiles as defined by `summarize`; see [R] [summarize](#).

# Title

**makespline** — Spline generation

<a href="#">Description</a>	<a href="#">Quick start</a>	<a href="#">Menu</a>	<a href="#">Syntax</a>
<a href="#">Options</a>	<a href="#">Remarks and examples</a>	<a href="#">Stored results</a>	<a href="#">Methods and formulas</a>
<a href="#">References</a>	<a href="#">Also see</a>		

## Description

`makespline` generates a set of variables that form B-spline, piecewise polynomial spline, and restricted cubic spline basis functions from a list of existing variables. B-spline and piecewise polynomial spline bases may be first, second, or third order, with knots at percentiles of the data or uniformly spaced over the range of the variables. Restricted cubic splines, also known as natural splines, may only be of third order.

## Quick start

Generate variables from `x1` and `x2` that form third-order B-spline basis functions, with one knot at the median of each variable

```
makespline bspline x1 x2
```

Same as above, but with three knots at the 25th, 50th, and 75th percentiles

```
makespline bspline x1 x2, knots(3)
```

Same as above, but use second-order B-splines

```
makespline bspline x1 x2, knots(3) order(2)
```

Generate variables that form a linear spline for `x1` with knots at 10 and 20

```
makespline piecewise x1, knotslist(10 20) order(1)
```

Same as above, but do not rescale `x1` before creating spline variables

```
makespline piecewise x1, knotslist(10 20) order(1) norescalevars
```

Generate variables that form third-order piecewise polynomial splines for `x1` and `x2`, with knots at their 25th, 50th, and 75th percentiles

```
makespline piecewise x1 x2, knots(3)
```

Same as above, but with three knots at evenly spaced points over the range of `x1` and of `x2`

```
makespline piecewise x1 x2, knots(3) uniformknots
```

Specify values of knots in matrix `K` to generate variables forming restricted cubic splines

```
makespline rcs x1 x2, knotsmat(K)
```

Generate variables that form a linear spline for `x1` without rescaling the values of `x1`

```
makespline linear x1
```

## Menu

Data > Create or change data > Other variable-creation commands > Spline generation

## Syntax

```
makespline basis varlist [if] [in] [weight] [, options]
```

<i>basis</i>	Description
<b>bspline</b>	B-spline
<b>piecewise</b>	piecewise polynomial spline
<b>rcs</b>	restricted cubic spline
<b>linear</b>	linear spline— <b>piecewise</b> basis of order 1 without rescaling variables

<i>options</i>	Description
<b>Main</b>	
<b>bsepsilon(#)</b>	specify the distance (#) from the variable's boundary for B-spline knot placement; default is <b>bsepsilon(0.01)</b>
<b>local</b>	generate first-order polynomial spline variables centered around adjacent knots
<b>harrell</b>	place knots according to percentiles in <a href="#">Harrell (2001)</a> ; only for <b>rcs</b> basis
<b>order(#)</b>	use a spline basis of order #; default is <b>order(3)</b>
<b>knots(#)</b>	use a spline basis function with # knots
<b>knotslist(<i>knotvals</i>)</b>	use knots specified in <i>knotvals</i>
<b>knotsmat(<i>matname</i>)</b>	use knots in matrix <i>matname</i>
<b>distinct(#)</b>	set minimum number of distinct values required for variables used to construct splines to #; default is <b>distinct(10)</b>
<b>replace</b>	replace existing variables having the same names as the new basis and rescaled variables, if they exist
<b>nore scalevars</b>	do not rescale variables before generating spline basis
<b>uniformknots</b>	place knots at evenly spaced points over the range of each variable; default is placement at percentiles
<b>float</b>	set type for generated variables to float instead of double
<b>basis(<i>stub</i>   <i>newvarlist</i>)</b>	store elements of spline basis function using <i>stub</i> or <i>newvarlist</i>

collect is allowed; see [U] [11.1.10 Prefix commands](#).

fweights, aweights, and iweights are allowed; see [U] [11.1.6 weight](#).

## Options

### Main

**bsepsilon(#)** specifies the distance from the boundary of the variable where B-spline knots may be placed. The default is **bsepsilon(0.01)**.

**local** specifies that a basis function for a first-order piecewise polynomial be generated with variables centered around adjacent knots. When splines are generated for only one variable and used in estimation, the regression coefficients measure slopes for the intervals defined by knots.

**harrell** specifies that knots be placed according to the percentiles recommended in [Harrell \(2001, 23\)](#). This option may be used only with *basis* **rcs** and when specifying 3 to 7 knots.

`order(#)` specifies that a spline of order `#` be used as the basis. `order()` may be 1, 2, or 3 for *basis bspline* and *basis piecewise*. `order()` may only be 3 for *basis rcs*. For *basis linear* or when the `local` option is specified, `order()` may only be 1. The default is `order(3)`, cubic splines.

`knots(#)` specifies that a spline or B-spline basis function with `#` interior knots be used. The number of knots must be an integer greater than or equal to 1. The maximum number of knots is either 4,096 or two-thirds of the sample size, whichever is smaller. Also, the number of knots must be less than the number of distinct values in the variable used to generate the basis function. The default is `knots(1)` if exact knot values are not specified using `knotslist()` or `knotsmat()`. For *basis rcs*, the default is `knots(3)`, and the number of knots must be 3 or greater.

`knotslist(knotvals)` specifies in *knotvals* the values of knots to be used for each variable. The knot values must be specified in the order of *varlist*, and a backslash (`\`) must be used to separate knots for different variables. For example, if splines are generated for `x1` and `x2`, the knots may be specified as `knotslist(20 40 60 \ 5 10 15)`.

`knotsmat(matname)` specifies that, in *matname*, the knots for each variable be the values in each row. The number of knots should be the same for each variable, and there must be as many rows as there are variables. If rows of *matname* are not labeled with *varnames*, then rows are assumed to be in the order of *varlist*.

`distinct(#)` specifies the minimum number of distinct values required for the variables used to construct the basis functions. Intuitively, using discrete variables for continuous interpolation is difficult to justify. `#` specifies the number of distinct values necessary for a variable to be considered continuous. The default is `distinct(10)`.

`replace` specifies that the variables generated to form the basis function be replaced. If `basis(stub|newvarlist)` or `rescale(stub|newvarlist)` are specified, the variables named with *stub*, or those listed in *newvarlist*, are replaced. Otherwise, variables with the default names are replaced.

`norescalevars` specifies that the original values of the variables in *varlist* be used to generate the basis function. By default, variables are first rescaled to  $[0, 1]$ . `norescalevars` may not be used with *basis bspline* or *basis linear*.

`uniformknots` specifies that knots be placed at evenly spaced points over the range of each variable. The default is placement at percentiles of each of the specified variables.

`float` specifies that variables be generated as floats. Because of numerical precision and stability, the default is `double`.

`basis(stub|newvarlist)` specifies that the elements of the basis function be generated with the specified names.

When *stub* is specified, this prefix is used to generate enumerated variables for each element of the basis function.

When *newvarlist* is specified, variables with these names are generated for the elements of the basis function.

`rescale(stub|newvarlist)` specifies that the rescaled variables used to generate the basis function be stored with the specified names. This option applies only to *basis piecewise* and *basis rcs*.

When *stub* is specified, this prefix is used to generate enumerated variables for the rescaled variables.

When *newvarlist* is specified, variables with these names are generated for the rescaled variables.

## Remarks and examples

`makespline` generates new variables that form B-splines, piecewise polynomial splines, and restricted cubic splines from existing variables. Splines allow for different low-order polynomials in different regions of the original variables, and they approximate a smooth function by continuously connecting these low-order polynomials. Knots define the boundaries of the regions.

The standard piecewise polynomial variables created by `makespline` `piecewise` allow the functions to be linear, quadratic, or cubic in each region. `makespline` `linear` provides a convenient method for creating linear splines from the original variables, without rescaling. This is useful when you wish to directly interpret regression coefficients in the metric of the original variables. The terms in the standard piecewise polynomial spline function can be highly collinear and may be numerically unstable when used in estimation. B-splines, which can be created by `makespline` `bspline`, avoid this problem by creating orthogonal spline terms. For an introduction to piecewise polynomial splines and B-splines, see *Piecewise polynomial splines and B-splines* in [R] [npregress intro](#). `makespline` `rCs` creates restricted cubic splines, also known as natural splines, in which the function is linear before the first knot, cubic between adjacent knots, and linear again after the last knot. This can improve performance in the tails over the standard cubic spline.

In addition to selecting the type of spline, `makespline` allows you to specify the location of knots—the locations where the function changes. You can specify the number of knots you wish to allow, and `makespline` will place the knots based on percentiles of the data or uniformly spaced across the range of values in the data. Alternatively, you can specify the exact values at which you wish the knots to be placed.

Regardless of the type of spline, we can refer to our newly created variables as a spline basis function. A basis is a collection of terms that can approximate a smooth function arbitrarily well. A basis function, such as one of the spline functions created by `makespline`, is a subset of the basis terms that can be used to approximate the mean function.

The basis function variables generated by `makespline` are useful for nonparametric and semi-parametric estimation. For instance, `makespline` can be used when we want to fit models such as

$$\mathbf{y} = \mathbf{x}_1\beta + g(\mathbf{x}_2, \mathbf{x}_3, \dots, \mathbf{x}_k) + \epsilon \quad (1)$$

In the expression above, the outcome  $\mathbf{y}$ , the covariates  $\mathbf{x}_1, \dots, \mathbf{x}_k$ , and the unobservable  $\epsilon$  are  $n \times 1$  vectors of covariates. The function  $g(\cdot)$  is unknown and  $\mathbf{x}_1$  enters the model linearly. These types of models are commonly used when we are interested in estimating the effect of  $\mathbf{x}_1$  on the mean of  $\mathbf{y}$ . We are agnostic about the functional form in which the controls,  $\mathbf{x}_2, \dots, \mathbf{x}_k$ , enter the model, but to get a precise estimate of the effect of  $\mathbf{x}_1$ , we need a reliable approximation of  $g(\cdot)$ . We may use `makespline` to generate the basis functions that best approximate  $g(\cdot)$  and then use the basis functions to fit the model in (1).

For instance, we can generate basis functions with `basis` as the stub name:

```
makespline bspline x2-x5, basis(basis)
```

This would generate a third-order B-spline basis function for each of the variables in `x2-x5`, with knots at the medians of `x2-x5`. Each of the basis functions would consist of five variables; see *Methods and formulas* in [R] [npregress series](#) for details.

Once we have these basis functions, we can fit the model in (1) by typing

```
regress y x1 c.(basis*)##c.(basis*)
```

where `c.(basis*)##c.(basis*)` specifies that the terms in the basis functions be included in the model on their own as well as interacted with each of the other terms.

Above, we are assuming that we constructed a good approximation of the unknown function  $g(\cdot)$ . We could go further and select from among these spline basis terms by using a technique such as lasso for prediction, described in [LASSO] [lasso](#), or, if we are interested in inferences on estimated effects, a technique such as the partialing-out or double-selection lasso method, described in [LASSO] [Lasso inference intro](#).

Let's say we are interested in getting a reliable estimate of the effect of  $x_1$  on the mean of the outcome. We would type

```
poregress y x1, controls(c.(basis*)##c.(basis*))
```

The method used by the above command is partialing-out lasso, which selects from the elements of the basis function to provide an optimal approximation of  $g(\cdot)$  while accounting for the implied model selection error. The result is an estimate of the effect of  $x_1$  on the outcome with reliable standard errors.

Of course, the model does not have to be like the one presented in (1). It could be

$$\mathbf{y} = g(\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_k) + \epsilon$$

or

$$\mathbf{y} = g(\mathbf{x}_1) + g(\mathbf{x}_2) + \dots + g(\mathbf{x}_k) + \epsilon$$

or we might instead be interested in using the basis functions for visualization.

## ► Example 1: Generating and naming B-spline basis functions

Below, we generate a third-order B-spline basis function with one knot placed at the median. The basis function is constructed from the variable `price`.

```
. sysuse auto
(1978 automobile data)
. makespline bspline price
```

The basis function consists of these five variables:

```
. describe _*
```

Variable name	Storage type	Display format	Value label	Variable label
<code>_bsp_1_1</code>	double	%10.0g		B-spline basis term 1 for price
<code>_bsp_1_2</code>	double	%10.0g		B-spline basis term 2 for price
<code>_bsp_1_3</code>	double	%10.0g		B-spline basis term 3 for price
<code>_bsp_1_4</code>	double	%10.0g		B-spline basis term 4 for price
<code>_bsp_1_5</code>	double	%10.0g		B-spline basis term 5 for price

The default naming convention is to give the elements of the basis function a name that starts with `_bsp` and two subscripts. The first subscript enumerates the basis functions, and the second subscript enumerates the elements within the basis function. For example, if we created basis functions for two variables, we would obtain the following:

```
. makespline bspline price mpg, replace
. describe _*
```

Variable name	Storage type	Display format	Value label	Variable label
<code>_bsp_1_1</code>	double	%10.0g		B-spline basis term 1 for price
<code>_bsp_1_2</code>	double	%10.0g		B-spline basis term 2 for price
<code>_bsp_1_3</code>	double	%10.0g		B-spline basis term 3 for price
<code>_bsp_1_4</code>	double	%10.0g		B-spline basis term 4 for price
<code>_bsp_1_5</code>	double	%10.0g		B-spline basis term 5 for price
<code>_bsp_2_1</code>	double	%10.0g		B-spline basis term 1 for mpg
<code>_bsp_2_2</code>	double	%10.0g		B-spline basis term 2 for mpg
<code>_bsp_2_3</code>	double	%10.0g		B-spline basis term 3 for mpg
<code>_bsp_2_4</code>	double	%10.0g		B-spline basis term 4 for mpg
<code>_bsp_2_5</code>	double	%10.0g		B-spline basis term 5 for mpg

If we want to change the stub name `_bsp` to `autobasis`, we could use the `basis()` option as follows:

```
. makespline bspline price mpg, basis(autobasis)
. describe auto*
```

Variable name	Storage type	Display format	Value label	Variable label
<code>autobasis_1_1</code>	double	%10.0g		B-spline basis term 1 for price
<code>autobasis_1_2</code>	double	%10.0g		B-spline basis term 2 for price
<code>autobasis_1_3</code>	double	%10.0g		B-spline basis term 3 for price
<code>autobasis_1_4</code>	double	%10.0g		B-spline basis term 4 for price
<code>autobasis_1_5</code>	double	%10.0g		B-spline basis term 5 for price
<code>autobasis_2_1</code>	double	%10.0g		B-spline basis term 1 for mpg
<code>autobasis_2_2</code>	double	%10.0g		B-spline basis term 2 for mpg
<code>autobasis_2_3</code>	double	%10.0g		B-spline basis term 3 for mpg
<code>autobasis_2_4</code>	double	%10.0g		B-spline basis term 4 for mpg
<code>autobasis_2_5</code>	double	%10.0g		B-spline basis term 5 for mpg

Alternatively, we could provide names for each of the variables that form a basis function. For example,

```
. makespline bspline mpg, basis(mpg1 mpg2 mpg3 mpg4 mpg5)
. describe mpg1-mpg5
```

Variable name	Storage type	Display format	Value label	Variable label
<code>mpg1</code>	double	%10.0g		B-spline basis term 1 for mpg
<code>mpg2</code>	double	%10.0g		B-spline basis term 2 for mpg
<code>mpg3</code>	double	%10.0g		B-spline basis term 3 for mpg
<code>mpg4</code>	double	%10.0g		B-spline basis term 4 for mpg
<code>mpg5</code>	double	%10.0g		B-spline basis term 5 for mpg

## ▷ Example 2: Generating and naming piecewise polynomial spline basis functions

Below, we generate a third-order piecewise polynomial spline with one knot at the median and show the variables we generated:

```
. makespline piecewise mpg
. describe *_sp*
```

Variable name	Storage type	Display format	Value label	Variable label
_rs_sp_1	double	%10.0g		mpg rescaled to [0,1]
_sp_1_1	double	%10.0g		Piecewise polynomial basis term 1 for mpg

The only syntactical difference is that, after `makespline`, we specify `piecewise` instead of `bspline` to be the basis. `makespline` generates two variables in this case. They are the elements that are necessary to construct a basis function.

The default naming convention is to give the elements of the spline function a name that starts with `_sp` and has two subscripts. The first subscript enumerates the piecewise polynomial spline for a given variable, and the second subscript denotes the knot number. The rescaled variable starts with `_rs_sp` followed by a subscript denoting the element in the variable list.

Again, we may use a stub to modify the names that precede the subscripts, or we may specify a name for each new variable. Below, we also specified the names for the rescaled variables:

```
. makespline piecewise mpg price, basis(mpgsp pricesp) rescale(mpgrs pricers)
. describe mpgsp mpgrs pricesp pricers
```

Variable name	Storage type	Display format	Value label	Variable label
mpgsp	double	%10.0g		Piecewise polynomial basis term 1 for mpg
mpgrs	double	%10.0g		mpg rescaled to [0,1]
pricesp	double	%10.0g		Piecewise polynomial basis term 1 for price
pricers	double	%10.0g		price rescaled to [0,1]

The logic behind the variables generated is that they consist of all the elements needed to approximate the unknown function  $g(\cdot)$  of the specified variables nonparametrically. In this case, a third-order piecewise polynomial spline approximation of  $g(\cdot)$  consists of the levels, square, and cube of `mpgsp`, `mpgrs`, `pricesp`, and `pricers`. Specifically, to include the fully interacted basis functions in a model, we would need to include the term below in our specification:

```
c.(c.mpgrs##c.mpgrs##c.mpgrs mpgsp)##c.(c.pricers##c.pricers##c.pricers pricesp)
```

`makespline` simplifies this task by returning a local macro with the terms needed to fit  $g(\cdot)$ . The local macro has the name `r(regressors)`. In this case, it expands to the following:

```
. display "r(regressors)"
c.(c.mpgrs##c.mpgrs##c.mpgrs mpgsp)##c.(c.pricers##c.pricers##c.pricers pricesp)
```

Note that when you generate basis functions for more than one variable, as we did above, `r(regressors)` fully interacts these basis functions. These fully interacted basis functions can be included when fitting a model by adding `'r(regressors)'` to your list of covariates.

### ▷ Example 3: Using makespline in semiparametric estimation

As we mentioned previously, basis functions are particularly useful for approximating unknown functions. For example, say we want to obtain the average marginal effect of  $x_1$  on the conditional mean of the continuous outcome  $y$ . We have two controls,  $x_2$  and  $x_3$ , but it is unclear whether they enter the model linearly or with another functional form.

To approximate the unknown function of  $x_2$  and  $x_3$ , we construct two B-spline basis functions with eight knots each. We use the simulated dataset and then the `makespline bspline` command:

```
. use https://www.stata-press.com/data/r18/splines, clear
(Simulated data)
. makespline bspline x2 x3, knots(8)
```

This yields basis functions with 12 elements. Once you fully interact the two basis functions, you get 168 regressors. Using all of them to approximate the unknown function would not be a sound idea. Thus, we will use `poregress` to perform partialing-out lasso linear regression. This estimator will select from the 168 covariates to provide a good approximation to the unknown function and at the same time provide a reliable estimate of the marginal effect of interest.

Rather than interact the basis terms manually, we can simply refer to the macro `r(regressors)`, which contains the full interaction of the basis functions:

```
. poregress y x1, controls('r(regressors)')
Estimating lasso for y using plugin
Estimating lasso for x1 using plugin
Partialing-out linear model
```

Number of obs	=	5,000
Number of controls	=	168
Number of selected controls	=	19
Wald chi2(1)	=	3535.78
Prob > chi2	=	0.0000

y	Robust		z	P> z	[95% conf. interval]	
	Coefficient	std. err.				
x1	2.951242	.049632	59.46	0.000	2.853965	3.048519

Note: Chi-squared test is a Wald test of the coefficients of the variables of interest jointly equal to zero. Lasso select controls for model estimation. Type `lassoinfo` to see number of selected variables in each lasso.

We obtain an average marginal effect of 2.95.

A researcher does not know the true value of the effect; however, we do. These are simulated data. The model is given by

$$y = 3x_1 + 3\sin\{3(x_2 - x_3)\} + \epsilon$$

The unknown function of  $x_2$  and  $x_3$  is complex, yet we obtained a precise estimate of the average marginal effect.

## ► Example 4: Using makespline for estimation and graphing

It is common to use linear splines to create a graph after estimation. The knots of a regressor define a piecewise polynomial that can be visualized conditional on the values of other covariates.

Below, we study the effect of mileage in miles per gallon (mpg) on car prices (price). We regress price on mpg, three linear polynomial basis terms defined by knots at the quartiles of mpg, and a dummy variable, foreign (1 if cars are foreign).

We first generate the variables that form the polynomial basis and then fit the regression.

```
. sysuse auto, clear
(1978 automobile data)
. makespline linear mpg, knots(3) basis(mpg)
. regress price mpg mpg*_ i.foreign
```

Source	SS	df	MS	Number of obs	=	74
Model	316201619	5	63240323.8	F(5, 68)	=	13.49
Residual	318863777	68	4689173.19	Prob > F	=	0.0000
				R-squared	=	0.4979
				Adj R-squared	=	0.4610
Total	635065396	73	8699525.97	Root MSE	=	2165.4

price	Coefficient	Std. err.	t	P> t	[95% conf. interval]
mpg	-1330.299	213.0425	-6.24	0.000	-1755.419 -905.1798
mpg_1_1	1698.953	622.5153	2.73	0.008	456.7432 2941.163
mpg_1_2	-622.9298	651.5686	-0.96	0.342	-1923.115 677.2551
mpg_1_3	139.4188	277.0762	0.50	0.616	-413.4783 692.3158
foreign					
Foreign	1676.381	609.4723	2.75	0.008	460.1983 2892.564
_cons	28796.47	3449.408	8.35	0.000	21913.28 35679.65

The regression line for our model is given by the following command:

```
generate double xb = _b[_cons] + _b[1.foreign]*foreign + ///
mpg*_b[mpg] + (mpg>18)*(mpg-18)*_b[mpg_1_1] + ///
(mpg>20)*(mpg-20)*_b[mpg_1_2] + ///
(mpg>25)*(mpg-25)*_b[mpg_1_3]
```

The effect of mpg changes at the knots. If mpg is less than or equal to 18, it is `_b[mpg]`; if it is greater than 18 but less than or equal to 20, it is `(_b[mpg] + _b[mpg_1_1])`; if it is greater than 20 but less than or equal to 25, it is `(_b[mpg] + _b[mpg_1_1] + _b[mpg_1_2])`; and if it is greater than 25, it is `(_b[mpg] + _b[mpg_1_1] + _b[mpg_1_2] + _b[mpg_1_3])`.

We can plot regression lines for foreign and domestic cars. We first generate the predictions for foreign and domestic cars.

```
. generate xb_domestic = _b[_cons] + mpg*_b[mpg]
> + (mpg>18)*(mpg-18)*_b[mpg_1_1]
> + (mpg>20)*(mpg-20)*_b[mpg_1_2]
> + (mpg>25)*(mpg-25)*_b[mpg_1_3]
. generate xb_foreign = _b[_cons] + _b[1.foreign] + mpg*_b[mpg]
> + (mpg>18)*(mpg-18)*_b[mpg_1_1]
> + (mpg>20)*(mpg-20)*_b[mpg_1_2]
> + (mpg>25)*(mpg-25)*_b[mpg_1_3]
```

Then we plot both regression lines referencing the placement of the knots with vertical lines. In the graph, we also include the values of the dependent variable. We can inspect graphically how the effect of mpg differs across the regions defined by the knots.

```

. twoway line xb_domestic mpg,
>   lcolor(blue) lpattern(dash) sort           ||
>   line xb_foreign mpg,
>   lcolor(red) lpatter(dash_dot) sort         ||
>   scatter price mpg if foreign==0, mcolor(blue%30) ||
>   scatter price mpg if foreign==1, mcolor(red%30)
>   xline(18 20 25)
>   title(Fitted values for domestic and foreign cars)
>   subtitle(Spline regression with knots at quartiles of mpg)

```

4

## Stored results

`makespline` stores the following in `r()`:

### Scalars

<code>r(N_knots)</code>	number of knots
<code>r(local)</code>	1 if <code>local</code> was specified, 0 otherwise
<code>r(bsepsilon)</code>	distance from variable's boundary for B-spline knot placement

### Macros

<code>r(basis)</code>	spline type used to generate basis function
<code>r(regressors)</code>	regressors formed from basis functions
<code>r(basisnames#)</code>	variable names of basis function for variable #
<code>r(wtype)</code>	weight type
<code>r(wexp)</code>	weight expression

### Matrices

<code>r(minmax)</code>	minimum and maximum of all variables
<code>r(knots)</code>	matrix of knots

## Methods and formulas

See *Methods and formulas* in [R] [npregress series](#) for piecewise polynomial spline and B-spline computation.

When the `local` option is specified, let  $V_i$ ,  $i = 1, \dots, n$ , be the variables to be created;  $k_i$ ,  $i = 1, \dots, n - 1$ , be the corresponding knots; and  $\mathcal{V}$  be the original variable rescaled to be in  $[0, 1]$ . Then

$$\begin{aligned} V_1 &= \min(\mathcal{V}, k_1) \\ V_i &= \max\left\{\min(\mathcal{V}, k_i), k_{i-1}\right\} - k_{i-1} \quad i = 2, \dots, n - 1 \\ V_n &= \max(\mathcal{V}, k_{n-1}) - k_{n-1} \end{aligned}$$

When the `rbs` basis is specified, let  $k_i$ ,  $i = 1, \dots, n$ , be the knot values;  $V_i$ ,  $i = 1, \dots, n - 1$ , be the variables to be created; and  $\mathcal{V}$  be the original variable rescaled to be in  $[0, 1]$ . Then

$$\begin{aligned} V_1 &= \mathcal{V} \\ V_{i+1} &= \frac{(\mathcal{V} - k_i)_+^3 - (k_n - k_{n-1})^{-1}\{(\mathcal{V} - k_{n-1})_+^3(k_n - k_i) - (\mathcal{V} - k_n)_+^3(k_{n-1} - k_i)\}}{(k_n - k_1)^2} \\ & \quad i = 1, \dots, n - 2 \end{aligned}$$

where

$$(u)_+ = \begin{cases} u, & \text{if } u > 0 \\ 0, & \text{if } u \leq 0 \end{cases}$$

When the `harrell` option is specified, the knots are placed using the percentiles recommended in [Harrell \(2001, 23\)](#). These percentiles are based on the chosen number of knots as follows:

No. of knots	Percentiles						
3	10	50	90				
4	5	35	65	95			
5	5	27.5	50	72.5	95		
6	5	23	41	59	77	95	
7	2.5	18.33	34.17	50	65.83	81.67	97.5

## Description

Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates.

The `margins` command estimates margins of responses for specified values of covariates and presents the results as a table.

Capabilities include estimated marginal means, least-squares means, average and conditional marginal and partial effects (which may be reported as derivatives or as elasticities), average and conditional adjusted predictions, and predictive margins.

## Quick start

*Estimated marginal means (least-squares means)*

Estimated marginal mean of  $y$  for each level of  $a$  after `anova y a##b`

```
margins a, asbalanced
```

Estimated marginal mean of  $y$  for each level of the interaction of  $a$  and  $b$  after `anova y a##b##c`

```
margins a#b, asbalanced
```

Estimated marginal means of  $y_1$ ,  $y_2$ , and  $y_3$  for each level of  $a$  after `manova y1 y2 y3 = a##b`

```
margins a, asbalanced
```

*Adjusted means and adjusted predictions*

Adjusted mean of  $y$  for each level of  $a$  when  $x$  is at its mean after `regress y i.a x`

```
margins a, atmeans
```

Same as above, but set  $x$  to 10 rather than to its mean

```
margins a, at(x=10)
```

Same as above, and also report adjusted means for  $x = 20$ ,  $x = 30$ , and  $x = 40$

```
margins a, at(x=(10(10)40))
```

Adjusted predicted probability of  $y = 1$  for each level of  $a$  when  $x$  is at its mean after

```
logit y a##c.x
```

```
margins a, atmeans
```

Adjusted predicted probability for each level of the interaction of  $a$  and  $b$ , holding  $x$  at 25, after

```
logit y a##b##c.x
```

```
margins a#b, at(x=25)
```

Adjusted prediction for each level of  $a$  when  $x = 25$  and  $b = 1$

```
margins a, at(x=25 b=1)
```

*Predictive margins and potential-outcome means*

Overall predictive margin, the average predicted probability of  $y = 1$ , after `logit y a##b x1 x2`  
`margins`

Predictive margins (potential-outcome means) for each level of `a`  
`margins a`

Predictive margins for `a`, when `x1` is set to 10, 20, 30, and 40  
`margins a, at(x1=(10(10)40))`

Predictive margins for levels of the interaction of `a` and `b`  
`margins a#b`

Predictive margins for `a` for all combinations of `x1 = 10, 20, 30` and `x2 = 50, 100, 150`  
`margins a, at(x1=(10(10)30) x2=(50(50)150))`

Predictive margins for `a`, first for `x1 = 10, 20, 30` with `x2` at its observed values, then for `x2 = 50, 100, 150` with `x1` at its observed values  
`margins a, at(x1=(10(10)30)) at(x2=(50(50)150))`

Predictive margins for `a` after `svy:logit y a##b x1 x2`  
`margins a, vce(unconditional)`

Average predicted probabilities of  $y = 1, y = 2, \dots$  after `mlogit y x1 x2 i.a`  
`margins`

Predictive margins for each level of `a` for each outcome of `y`  
`margins a`

*Average marginal effects and average partial effects*

Average marginal effect of `x1` on the predicted probability of  $y = 1$  after `probit y c.x1##c.x2##a` with continuous `x1` and `x2` and binary `a`  
`margins, dydx(x1)`

Average marginal effect (average partial effect) of binary `a`  
`margins, dydx(a)`

Average marginal effect of `x1` when `x2` is set to 10, 20, 30, and 40  
`margins, dydx(x1) at(x2=(10(10)40))`

Average marginal effect of `x1` when `a` is set to 0 and then to 1  
`margins a, dydx(x1)`

Average marginal effect of each variable in the model  
`margins, dydx(*)`

Average marginal effect of all variables on the truncated expected value of  $y$ ,  $e(0, \cdot)$ , after `tobit y x1 x2 x3, ll(0)`  
`margins, dydx(*) predict(e(0, .))`

Same as above, and report marginal effects for censored expected value of  $y$ , `ystar(0,.)`, and for the linear prediction, `xb`

```
margins, dydx(*) predict(e(0,.) predict(ystar(0,.) predict(xb)
```

### Conditional marginal effects and conditional partial effects

Marginal effect of  $x_1$  on the predicted probability of  $y = 1$ , setting all variables to their means, after `probit y c.x1##c.x2##a` with continuous  $x_1$  and  $x_2$  and binary  $a$

```
margins, dydx(x1) atmeans
```

Marginal effect (partial effect) of  $a$  when all variables are set to their means

```
margins, dydx(a) atmeans
```

Marginal effect of  $x_1$  when  $a = 0$  and  $x_1$  and  $x_2$  are set to their means

```
margins, dydx(x1) at(a=0 (mean) x1 x2)
```

Same as above

```
margins, dydx(x1) at(a=0) atmeans
```

Marginal effect of  $x_1$  when for all possible combinations of  $a = 0, 1$ ,  $x_1 = 50, 100$ , and  $x_2 = 10, 20, 30, 40$

```
margins a, dydx(x1) at(x1=(50 100) x2=(10(10)40))
```

Marginal effects of  $x_1$ ,  $x_2$ , and  $a$  with all variables set to their means

```
margins, dydx(*) atmeans
```

## Menu

Statistics > Postestimation

## Syntax

```
margins [marginlist] [if] [in] [weight] [, response_options options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without the `i.` prefix, and you may use any factor-variable syntax:

```
. margins i.sex i.group i.sex#i.group
. margins sex group sex#i.group
. margins sex##group
```

<i>response_options</i>	Description
-------------------------	-------------

Main

<code>predict(<i>pred_opt</i>)</code>	estimate margins for <code>predict</code> , <i>pred_opt</i>
<code>expression(<i>pnl_exp</i>)</code>	estimate margins for <i>pnl_exp</i>
<code>dydx(<i>varlist</i>)</code>	estimate marginal effect of variables in <i>varlist</i>
<code>eyex(<i>varlist</i>)</code>	estimate elasticities of variables in <i>varlist</i>
<code>dyex(<i>varlist</i>)</code>	estimate semielasticity— $d(\hat{y})/d(\ln x)$
<code>eydx(<i>varlist</i>)</code>	estimate semielasticity— $d(\ln \hat{y})/d(x)$
<code>continuous</code>	treat factor-level indicators as continuous

---

<i>options</i>	Description
Main	
<b>grand</b>	add the overall margin; default if no <i>marginlist</i>
At	
<b>at</b> ( <i>atspec</i> )	estimate margins at specified values of covariates
<b>atmeans</b>	estimate margins at the means of covariates
<b>asbalanced</b>	treat all factor variables as balanced
if/in/over	
<b>over</b> ( <i>varlist</i> )	estimate margins at unique values of <i>varlist</i>
<b>subpop</b> ( <i>subspec</i> )	estimate margins for subpopulation
Within	
<b>within</b> ( <i>varlist</i> )	estimate margins at unique values of the nesting factors in <i>varlist</i>
Contrast	
<b>contrast_options</b>	any options documented in [R] <b>margins, contrast</b>
Pairwise comparisons	
<b>pwcompare_options</b>	any options documented in [R] <b>margins, pwcompare</b>
SE	
<b>vce(delta)</b>	estimate SEs using delta method; the default
<b>vce(unconditional)</b>	estimate SEs allowing for sampling of covariates
<b>nose</b>	do not estimate SEs
Advanced	
<b>noweights</b>	ignore weights specified in estimation
<b>noesample</b>	do not restrict margins to the estimation sample
<b>emptycells</b> ( <i>empspec</i> )	treatment of empty cells for balanced factors
<b>estimtolerance</b> ( <i>tol</i> )	specify numerical tolerance used to determine estimable functions; default is <code>estimtolerance(1e-5)</code>
<b>noestimcheck</b>	suppress estimability checks
<b>force</b>	estimate margins despite potential problems
<b>chainrule</b>	use the chain rule when computing derivatives
<b>nochainrule</b>	do not use the chain rule
Reporting	
<b>level</b> (#)	set confidence level; default is <code>level(95)</code>
<b>mcompare</b> ( <i>method</i> )	adjust for multiple comparisons; default is <code>mcompare(noadjust)</code>
<b>noatlegend</b>	suppress legend of fixed covariate values
<b>post</b>	post margins and their VCE as estimation results
<b>display_options</b>	control columns and column formats, row spacing, line width and factor-variable labeling
<b>df</b> (#)	use <i>t</i> distribution with # degrees of freedom for computing <i>p</i> -values and confidence intervals

---

<i>method</i>	Description
<code>noadjust</code>	do not adjust for multiple comparisons; the default
<code>bonferroni [adjustall]</code>	Bonferroni's method; adjust across all terms
<code>sidak [adjustall]</code>	Šidák's method; adjust across all terms
<code>scheffe</code>	Scheffé's method

Time-series operators are allowed if they were used in the estimation.

See `at()` under *Options* for a description of *atspec*.

`collect` is allowed; see [U] 11.1.10 **Prefix commands**.

`fweights`, `awweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`df(#)` does not appear in the dialog box.

## Options

*Warning: The option descriptions are brief and use jargon. Skip to [Remarks and examples](#) if you are reading about margins for the first time.*

### Main

`predict(pred_opt)` and `expression(pnl_exp)` are mutually exclusive; they specify the response. If neither is specified, the response will be the default prediction that would be produced by `predict` after the underlying estimation command. Some estimation commands, such as `mlogit`, document a different default prediction for margins than for `predict`.

`predict(pred_opt)` specifies the option(s) to be specified with the `predict` command to produce the variable that will be used as the response. After estimation by `logistic`, you could specify `predict(xb)` to obtain linear predictions rather than the `predict` command's default, the probabilities.

Multiple `predict()` options can be specified to compute margins of multiple predictions simultaneously.

`expression(pnl_exp)` specifies the response as an expression. See [R] **predictnl** for a full description of *pnl\_exp*. After estimation by `logistic`, you might specify `expression(exp(predict(xb)))` to use relative odds rather than probabilities as the response. For examples, see [Example 12: Margins of a specified expression](#).

`dydx(varlist)`, `eyex(varlist)`, `dyex(varlist)`, and `eydx(varlist)` request that margins report derivatives of the response with respect to *varlist* rather than on the response itself. `eyex()`, `dyex()`, and `eydx()` report derivatives as elasticities; see [Expressing derivatives as elasticities](#).

`continuous` is relevant only when one of `dydx()` or `eydx()` is also specified. It specifies that the levels of factor variables be treated as continuous; see [Derivatives versus discrete differences](#). This option is implied if there is a single-level factor variable specified in `dydx()` or `eydx()`.

`grand` specifies that the overall margin be reported. `grand` is assumed when *marginlist* is empty.

### At

`at(atspec)` specifies values for covariates to be treated as fixed.

`at(age=20)` fixes covariate `age` to the value specified. `at()` may be used to fix continuous or factor covariates.

`at(age=20 sex=1)` simultaneously fixes covariates `age` and `sex` at the values specified.

`at(age=(20 30 40 50))` fixes age first at 20, then at 30, . . . `margins` produces separate results for each specified value.

`at(age=(20(10)50))` does the same as `at(age=(20 30 40 50))`; that is, you may specify a `numlist`.

`at((mean) age (median) distance)` fixes the covariates at the summary statistics specified. `at((p25) _all)` fixes all covariates at their 25th percentile values. See *Syntax of at()* for the full list of summary-statistic modifiers.

`at((mean) _all (median) x x2=1.2 z=(1 2 3))` is processed from general to specific, with settings for named covariates overriding general settings specified via `_all`. Thus, all covariates are fixed at their means except for `x` (fixed at its median), `x2` (fixed at 1.2), and `z` (fixed first at 1, then at 2, and finally at 3).

`at((means) _all (asobserved) x2)` is a convenient way to set all covariates except `x2` to the mean.

Multiple `at()` options can be specified, and each will produce a different set of margins.

See *Syntax of at()* for more information.

`atmeans` specifies that covariates be fixed at their means and is shorthand for `at((mean) _all)`. `atmeans` differs from `at((mean) _all)` in that `atmeans` will affect subsequent `at()` options. For instance,

```
. margins ..., atmeans at((p25) x) at((p75) x)
```

produces two sets of margins with both sets evaluated at the means of all covariates except `x`.

`asbalanced` is shorthand for `at((asbalanced) _factor)` and specifies that factor covariates be evaluated as though there were an equal number of observations in each level; see *Obtaining margins as though the data were balanced*. `asbalanced` differs from `at((asbalanced) _factor)` in that `asbalanced` will affect subsequent `at()` options in the same way as `atmeans` does.

if/in/over

`over(varlist)` specifies that separate sets of margins be estimated for the groups defined by `varlist`. The variables in `varlist` must contain nonnegative integer (or missing) values. The variables need not be covariates in your model. When `over()` is combined with the `vce(unconditional)` option, each group is treated as a subpopulation; see [SVY] [Subpopulation estimation](#).

`subpop([varname] [if])` is intended for use with the `vce(unconditional)` option. It specifies that margins be estimated for the single subpopulation identified by the indicator variable or by the `if` expression or by both. Zero or missing indicates that the observation be excluded; nonzero or nonmissing, that it be included. See [SVY] [Subpopulation estimation](#) for why `subpop()` is preferred to `if` expressions and `in` ranges when also using `vce(unconditional)`. If `subpop()` is used without `vce(unconditional)`, it is treated merely as an additional `if` qualifier.

Within

`within(varlist)` allows for nested designs. `varlist` contains the nesting variable(s) over which margins are to be estimated. See *Obtaining margins with nested designs*. As with `over(varlist)`, when `within(varlist)` is combined with `vce(unconditional)`, each level of the variables in `varlist` is treated as a subpopulation.

Contrast

`contrast_options` are any of the options documented in [R] [margins, contrast](#).

## Pairwise comparisons

`pwcompare_options` are any of the options documented in [R] [margins](#), [pwcompare](#).

## SE

`vce(delta)` and `vce(unconditional)` specify how the VCE and, correspondingly, standard errors are calculated.

`vce(delta)` is the default. The delta method is applied to the formula for the response and the VCE of the estimation command. This method assumes that values of the covariates used to calculate the response are given or, if all covariates are not fixed using `at()`, that the data are given.

`vce(unconditional)` specifies that the covariates that are not fixed be treated in a way that accounts for their having been sampled. The VCE is estimated using the linearization method. This method allows for heteroskedasticity or other violations of distributional assumptions and allows for correlation among the observations in the same manner as `vce(robust)` and `vce(cluster ...)`, which may have been specified with the estimation command. This method also accounts for complex survey designs if the data are `svyset`. See [Obtaining margins with survey data and representative samples](#). When you use complex survey data, this method requires that the linearized variance estimation method be used for the model. See [SVY] [svy postestimation](#) for an [example of margins](#) with replication-based methods.

`nose` suppresses calculation of the VCE and standard errors. See [Requirements for model specification](#) for an example of the use of this option.

## Advanced

`noweights` specifies that any weights specified on the previous estimation command be ignored by `margins`. By default, `margins` uses the weights specified on the estimator to average responses and to compute summary statistics. If weights are specified on the `margins` command, they override previously specified weights, making it unnecessary to specify `noweights`. The `noweights` option is not allowed after `svy:` estimation when the `vce(unconditional)` option is specified.

For multilevel models, such as `meglm`, the default behavior is to construct a single weight value for each observation by multiplying the corresponding multilevel weights within the given observation.

`noesample` specifies that `margins` not restrict its computations to the estimation sample used by the previous estimation command. See [Example 15: Margins evaluated out of sample](#).

With the default delta-method VCE, `noesample` margins may be estimated on samples other than the estimation sample; such results are valid under the assumption that the data used are treated as being given.

You can specify `noesample` and `vce(unconditional)` together, but if you do, you should be sure that the data in memory correspond to the original `e(sample)`. To show that you understand that, you must also specify the `force` option. Be aware that making the `vce(unconditional)` calculation on a sample different from the estimation sample would be equivalent to estimating the coefficients on one set of data and computing the scores used by the linearization on another set; see [P] [\\_robust](#).

`emptycells(strict)` and `emptycells(rewrite)` are relevant only when the `asbalanced` option is also specified. `emptycells()` specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced; see [Obtaining margins as though the data were balanced](#).

`emptycells(strict)` is the default; it specifies that margins involving empty cells be treated as not estimable.

`emptycells(reweight)` specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the margin estimable but changes its interpretation. `emptycells(reweight)` is implied when the `within()` option is specified.

`estimtolerance(tol)` specifies the numerical tolerance used to determine estimable functions. The default is `estimtolerance(1e-5)`.

A linear combination of the model coefficients  $z$  is found to be not estimable if

$$\text{mreldif}(z, z \times H) > \text{tol}$$

where  $H$  is defined in *Methods and formulas*.

`noestimcheck` specifies that `margins` not check for estimability. By default, the requested margins are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If `noestimcheck` is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations. See *Estimability of margins*.

`force` instructs `margins` to proceed in some situations where it would otherwise issue an error message because of apparent violations of assumptions. Do not be casual about specifying `force`. You need to understand and fully evaluate the statistical issues. For an example of the use of `force`, see *Using margins after the estimates use command*.

`chainrule` and `nochainrule` specify whether `margins` uses the chain rule when numerically computing derivatives. You need not specify these options when using `margins` after any official Stata estimator; `margins` will choose the appropriate method automatically.

Specify `nochainrule` after estimation by a community-contributed command. We recommend using `nochainrule`, even though `chainrule` is usually safe and is always faster. `nochainrule` is safer because it makes no assumptions about how the parameters and covariates join to form the response.

`nochainrule` is implied when the `expression()` option is specified.

#### Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.8 Specifying the width of confidence intervals**.

`mcompare(method)` specifies the method for computing  $p$ -values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate,  $\alpha_c$ , to achieve a prespecified experimentwise error rate,  $\alpha_e$ .

`mcompare(noadjust)` is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

`mcompare(bonferroni)` adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality

$$\alpha_e \leq m\alpha_c$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \alpha_e/m$$

`mcompare(sidak)` adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the  $m$  comparisons are independent.

`mcompare(scheffe)` controls the experimentwise error rate using the  $F$  or  $\chi^2$  distribution with degrees of freedom equal to the rank of the term.

`mcompare(method adjustall)` specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in *marginslist*. This option is compatible only with the `bonferroni` and `sidak` methods.

`noatlegend` specifies that the legend showing the fixed values of covariates be suppressed.

`post` causes `margins` to behave like a Stata estimation (e-class) command. `margins` posts the vector of estimated margins along with the estimated variance–covariance matrix to `e()`, so you can treat the estimated margins just as you would results from any other estimation command. For example, you could use `test` to perform simultaneous tests of hypotheses on the margins, or you could use `lincom` to create linear combinations. See [Example 10: Testing margins—contrasts of margins](#).

*display\_options*: `noci`, `nopvalues`, `vsquish`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nostretch`.

`noci` suppresses confidence intervals from being reported in the coefficient table.

`nopvalues` suppresses  $p$ -values and their test statistics from being reported in the coefficient table.

`vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

`nofvlabel` displays factor-variable level values rather than attached value labels. This option overrides the `fvlabel` setting; see [\[R\] set showbaselevels](#).

`fvwrap(#)` allows long value labels to wrap the first  $\#$  lines in the coefficient table. This option overrides the `fvwrap` setting; see [\[R\] set showbaselevels](#).

`fvwrapon(style)` specifies whether value labels that wrap will break at word boundaries or break based on available space.

`fvwrapon(word)`, the default, specifies that value labels break at word boundaries.

`fvwrapon(width)` specifies that value labels break based on available space.

This option overrides the `fvwrapon` setting; see [\[R\] set showbaselevels](#).

`cformat(%fmt)` specifies how to format margins, standard errors, and confidence limits in the table of estimated margins.

`pformat(%fmt)` specifies how to format  $p$ -values in the table of estimated margins.

`sformat(%fmt)` specifies how to format test statistics in the table of estimated margins.

`nostretch` specifies that the width of the table of estimated margins not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the table of estimated margins up to the width of the Results window. Specifying `lstretch` or `nostretch` overrides the setting given by `set lstretch`. If `set lstretch` has not been set, the default is `lstretch`. `nostretch` is not shown in the dialog box.

The following option is available with `margins` but is not shown in the dialog box:

`df(#)` specifies that the  $t$  distribution with `#` degrees of freedom be used for computing  $p$ -values and confidence intervals. The default typically is to use the standard normal distribution. However, if the estimation command computes the residual degrees of freedom (`e(df_r)`) and `predict(xb)` is specified with `margins`, the default is to use the  $t$  distribution with `e(df_r)` degrees of freedom.

## Introduction

`margins` is a postestimation command, a command for use after you have fit a model using an estimation command such as `regress` or `logistic`, or using almost any other estimation command.

`margins` estimates and reports margins of responses and margins of derivatives of responses, also known as marginal effects. A margin is a statistic based on a fitted model in which some of or all the covariates are fixed. Marginal effects are changes in the response for change in a covariate, which can be reported as a derivative, elasticity, or semielasticity.

For a brief overview of `margins`, see [Williams \(2012\)](#).

## Obtaining margins of responses

What we call margins of responses are also known as predictive margins, adjusted predictions, and recycled predictions. When applied to balanced data, margins of responses are also called estimated marginal means and least-squares means.

A margin is a statistic based on a fitted model calculated over a dataset in which some of or all the covariates are fixed at values different from what they really are. For instance, after a linear regression fit on males and females, the marginal mean (margin of mean) for males is the predicted mean of the dependent variable, where every observation is treated as if it represents a male; thus, those observations that in fact do represent males are included, as well as those observations that represent females. The marginal mean for females would be similarly obtained by treating all observations as if they represented females.

In making the calculation, `sex` is treated as male or female everywhere it appears in the model. The model might be

```
. regress y age bp i.sex sex#c.age sex#c.bp
```

and then, in making the marginal calculation of the mean for males and females, `margins` not only accounts for the direct effect of `i.sex` but also for the indirect effects of `sex#c.age` and `sex#c.bp`.

The response being margined can be any statistic produced by **[R] predict**, or any expression of those statistics.

Standard errors are obtained by the delta method, at least by default. The delta method assumes that the values at which the covariates are evaluated to obtain the marginal responses are fixed. When your sample represents a population, whether you are using `svy` or not (see [\[SVY\] svy](#)), you can specify `margins' vce(unconditional)` option and `margins` will produce standard errors that account for the sampling variability of the covariates. Some researchers reserve the term predictive margins to describe this.

The best way to understand `margins` is to see some examples. You can run the following examples yourself if you type

```
. use https://www.stata-press.com/data/r18/margex
(Artificial data for margins)
```

**Example 1: A simple case after regress**

```
. regress y i.sex i.group
(output omitted)
. margins sex
Predictive margins                                Number of obs = 3,000
Model VCE: OLS
Expression: Linear prediction, predict()
```

	Delta-method				
	Margin	std. err.	t	P> t	[95% conf. interval]
sex					
Male	60.56034	.5781782	104.74	0.000	59.42668 61.69401
Female	78.88236	.5772578	136.65	0.000	77.7505 80.01422

The numbers reported in the Margin column are average values of the linear prediction of *y*, as noted above the output table after `Expression:.` Based on a linear regression of *y* on *sex* and *group*, 60.6 would be the average value of the linear prediction of *y* if everyone in the data were treated as if they were male, and 78.9 would be the average value if everyone were treated as if they were female.

**Example 2: A simple case after logistic**

`margins` may be used after almost any estimation command.

```
. logistic outcome i.sex i.group
(output omitted)
. margins sex
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	Delta-method				
	Margin	std. err.	z	P> z	[95% conf. interval]
sex					
Male	.1286796	.0111424	11.55	0.000	.106841 .1505182
Female	.1905087	.0089719	21.23	0.000	.1729241 .2080933

The numbers reported in the Margin column are average predicted probabilities. Based on a logistic regression of *outcome* on *sex* and *group*, 0.13 would be the average probability of *outcome* if everyone in the data were treated as if they were male, and 0.19 would be the average probability if everyone were treated as if they were female.

`margins` reports average values after `regress` and average probabilities after `logistic`. By default, `margins` makes tables of whatever it is that `predict` (see [R] [predict](#)) predicts by default. Alternatively, `margins` can make tables of anything that `predict` can produce if you use `margins' predict()` option; see [Example 11: Margins of a specified prediction](#).

**Example 3: Average response versus response at average**

In [example 2](#), margins reported average probabilities of outcome for `sex = 0` and `sex = 1`. If we instead wanted the predicted probabilities evaluated at the mean of the covariates, we would specify margins' `atmeans` option. We previously typed

```
. logistic outcome i.sex i.group
(output omitted)
. margins sex
(output omitted)
```

and now we type

```
. margins sex, atmeans
Adjusted predictions                               Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
At: 0.sex = .4993333 (mean)
    1.sex = .5006667 (mean)
    1.group = .3996667 (mean)
    2.group = .3726667 (mean)
    3.group = .2276667 (mean)
```

	Delta-method				[95% conf. interval]	
	Margin	std. err.	z	P> z		
sex						
Male	.0966105	.0089561	10.79	0.000	.0790569	.1141641
Female	.1508362	.0118064	12.78	0.000	.127696	.1739764

The prediction at the average of the covariates is different from the average of the predictions. The first is the expected probability of a person with average characteristics, a person who, in another problem, might be 3/4 married and have 1.2 children. The second is the average of the probability among actual persons in the data.

When you specify `atmeans` or any other `at` option, margins reports the values used for the covariates in the legend above the table. margins lists the values for all the covariates, including values it may not use, in the results that follow. In this example, margins reported means for `sex` even though those means were not used. They were not used because we asked for the margins of `sex`, so `sex` was fixed first at 0 and then at 1.

If you wish to suppress this legend, specify the `nolegend` option.

**Example 4: Multiple margins from one command**

More than one margin can be reported by just one margins command. You can type

```
. margins sex group
```

and doing that is equivalent in terms of the output to typing

```
. margins sex
. margins group
```

When multiple margins are requested on the same command, each is estimated separately. There is, however, a difference when you also specify margins' `post` option. Then, the variance–covariance matrix for all margins requested is posted, and that is what allows you to test, for example, equality of margins. Testing equality of margins is covered in [Example 10: Testing margins—contrasts of margins](#).

In any case, below we request margins for `sex` and for `group`.

```
. margins sex group
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	Delta-method		z	P> z	[95% conf. interval]	
	Margin	std. err.				
<b>sex</b>						
Male	.1286796	.0111424	11.55	0.000	.106841	.1505182
Female	.1905087	.0089719	21.23	0.000	.1729241	.2080933
<b>group</b>						
1	.2826207	.0146234	19.33	0.000	.2539593	.311282
2	.1074814	.0094901	11.33	0.000	.0888812	.1260817
3	.0291065	.0073417	3.96	0.000	.0147169	.043496

### Example 5: Margins with interaction terms

The estimation command on which `margins` bases its calculations may contain interaction terms, such as an interaction of `sex` and `group`:

```
. logistic outcome i.sex i.group sex#group
(output omitted)
. margins sex group
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	Delta-method		z	P> z	[95% conf. interval]	
	Margin	std. err.				
<b>sex</b>						
Male	.1561738	.0132774	11.76	0.000	.1301506	.182197
Female	.1983749	.0101546	19.54	0.000	.1784723	.2182776
<b>group</b>						
1	.3211001	.0176403	18.20	0.000	.2865257	.3556744
2	.1152127	.0099854	11.54	0.000	.0956417	.1347838
3	.0265018	.0109802	2.41	0.016	.0049811	.0480226

We fit the model by typing `logistic outcome i.sex i.group sex#group`, but the meaning would have been the same had we typed `logistic outcome sex##group`.

As mentioned in [example 4](#), the results for `sex` and the results for `group` are calculated independently, and we would have obtained the same results had we typed `margins sex` followed by `margins group`.

The margin for male (`sex = 0`) is 0.16. The probability 0.16 is the average probability if everyone in the data were treated as if `sex = 0`, including `sex = 0` in the main effect and `sex = 0` in the interaction of `sex` with `group`.

Had we specified `margins sex, atmeans`, we would have obtained not average probabilities but the probabilities evaluated at the average. Rather than obtaining 0.16, we would have obtained 0.10

for  $sex = 0$ . The 0.10 is calculated by taking the fitted model, plugging in  $sex = 0$  everywhere, and plugging in the average value of the group indicator variables everywhere they are used. That is, rather than treating the group indicators as being (1, 0, 0), (0, 1, 0), or (0, 0, 1) depending on observation, the group indicators are treated as being (0.40, 0.37, 0.23), which are the average values of  $group = 1$ ,  $group = 2$ , and  $group = 3$ .

### Example 6: Margins with continuous variables

To the [above example](#), we will add the continuous covariate `age` to the model and then rerun `margins sex group`.

```
. logistic outcome i.sex i.group sex#group age
  (output omitted)
. margins sex group
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	Delta-method		z	P> z	[95% conf. interval]	
	Margin	std. err.				
<b>sex</b>						
Male	.1600644	.0125653	12.74	0.000	.1354368	.184692
Female	.1966902	.0100043	19.66	0.000	.1770821	.2162983
<b>group</b>						
1	.2251302	.0123233	18.27	0.000	.200977	.2492834
2	.150603	.0116505	12.93	0.000	.1277685	.1734376
3	.0736157	.0337256	2.18	0.029	.0075147	.1397167

Compared with the results presented in [example 5](#), results for `sex` change little, but results for `groups 1` and `3` change markedly. The tables differ because now we are adjusting for the continuous covariate `age`, as well as for `sex` and `group`.

We will continue examining interactions in [example 8](#). Because we have added a continuous variable, let's take a detour to explain how to obtain margins for continuous variables and to explain their interpretation.

### Example 7: Margins of continuous variables

Continuing with our example of

```
. logistic outcome i.sex i.group sex#group age
```

let's examine the continuous covariate `age`.

You are not allowed to type `margins age`; doing that will produce an error:

```
. margins age
factor age not found in list of covariates
r(322);
```

The message “`age` not found in list of covariates” is `margins`’ way of saying, “Yes, `age` might be in the model, but if it is, it is not included as a factor variable; it is in as a continuous variable.” Sometimes, Stata is overly terse. `margins` might also say that because `age` is continuous there are an infinite number of values at which it could evaluate the margins. At what value(s) should `age` be fixed? `margins` requires more guidance with continuous covariates. We can provide that guidance by using the `at()` option and typing

```
. margins, at(age=40)
```

To understand why that yields the desired result, let us tell you that if you were to type

```
. margins
```

`margins` would report the overall margin—the margin that holds nothing constant. Because our model is logistic, the average value of the predicted probabilities would be reported. The `at()` option fixes one or more covariates to the value(s) specified and can be used with both factor and continuous variables. Thus, if you typed `margins, at(age=40)`, then `margins` would average over the data the responses for everybody, setting `age=40`. Here is what happens when you type that:

```
. margins, at(age=40)
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
At: age = 40
```

	Delta-method				[95% conf. interval]	
	Margin	std. err.	z	P> z		
_cons	.1133603	.0070731	16.03	0.000	.0994972	.1272234

Reported is the margin for `age = 40`, adjusted for the other covariates in our model.

If we wanted to obtain the margins for `age 30, 35, 40, 45, and 50`, we could type

```
. margins, at(age=(30 35 40 45 50))
```

or, equivalently,

```
. margins, at(age=(30(5)50))
```

## Example 8: Margins of interactions

Our model is

```
. logistic outcome i.sex i.group sex#group age
```

We can obtain the margins of all possible combinations of the levels of `sex` and the levels of `group` by typing

```
. margins sex#group
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	Delta-method		z	P> z	[95% conf. interval]	
	Margin	std. err.				
sex#group						
Male#1	.2379605	.0237178	10.03	0.000	.1914745	.2844465
Male#2	.0658294	.0105278	6.25	0.000	.0451953	.0864636
Male#3	.0538001	.0136561	3.94	0.000	.0270347	.0805656
Female#1	.2158632	.0112968	19.11	0.000	.1937218	.2380045
Female#2	.2054406	.0183486	11.20	0.000	.1694781	.2414032
Female#3	.085448	.0533914	1.60	0.110	-.0191973	.1900932

The first line in the table reports the marginal probability for `sex = 0` (male) and `group = 1`. That is, it reports the estimated probability if everyone in the data were treated as if they were `sex = 0` and `group = 1`.

Also reported are all the other combinations of `sex` and `group`.

By the way, we could have typed `margins sex#group` even if our fitted model did not include `sex#group`. Estimation is one thing, and asking questions about the nature of the estimates is another. `margins` does, however, require that `i.sex` and `i.group` appear somewhere in the model, because fixing a value outside the model would just produce the grand margin, and you can separately ask for that if you want it by typing `margins` without arguments.

### Example 9: Decomposing margins

We have the model

```
. logistic outcome i.sex i.group sex#group age
```

In [example 6](#), we typed `margins sex` and obtained 0.160 for males and 0.197 for females. We are going to decompose each of those numbers. Let us explain:

1. The margin for males, 0.160, treats everyone as if they were male, and that amounts to simultaneously
  - 1a. treating males as males and
  - 1b. treating females as males.
2. The margin for females, 0.197, treats everyone as if they were female, and that amounts to simultaneously
  - 2a. treating males as females and
  - 2b. treating females as females.

The margins 1a and 1b are the decomposition of 1, and the margins 2a and 2b are the decomposition of 2.

We could obtain 1a and 2a by typing

```
. margins if sex==0, at(sex=(0 1))
```

because the qualifier `if sex==0` would restrict margins to running on only the males. Similarly, we could obtain [1b](#) and [2b](#) by typing

```
. margins if sex==1, at(sex=(0 1))
```

We run these examples below:

```
. margins if sex==0, at(sex=(0 1))
Predictive margins                                Number of obs = 1,498
Model VCE: OIM
Expression: Pr(outcome), predict()
1._at: sex = 0
2._at: sex = 1
```

	Delta-method				
	Margin	std. err.	z	P> z	[95% conf. interval]
_at					
1	.0794393	.0062147	12.78	0.000	.0672586 .0916199
2	.1335584	.0127351	10.49	0.000	.1085981 .1585187

```
. margins if sex==1, at(sex=(0 1))
Predictive margins                                Number of obs = 1,502
Model VCE: OIM
Expression: Pr(outcome), predict()
1._at: sex = 0
2._at: sex = 1
```

	Delta-method				
	Margin	std. err.	z	P> z	[95% conf. interval]
_at					
1	.2404749	.0199709	12.04	0.000	.2013326 .2796171
2	.2596538	.0104756	24.79	0.000	.2391219 .2801857

Putting together the results from [example 6](#) and the results above, we have

Margin treating individuals as themselves	0.170
Margin treating individuals as male	0.160
Margin treating male as male	0.079
Margin treating female as male	0.240
Margin treating individuals as female	0.197
Margin treating male as female	0.134
Margin treating female as female	0.260

### Example 10: Testing margins—contrasts of margins

Continuing with the previous example, it would be interesting to test the equality of [2b](#) and [1b](#), to test whether the average probability of a positive outcome for females treated as females is equal to that for females treated as males. That test would be different from testing the overall significance of `sex` in our model. The test performed on our model would be a test of whether the probability of a positive outcome differs between males and females when they have equal values of the other covariates. The test of equality of margins is a test of whether the average probabilities differ given the different pattern of values of the other covariates that the two sexes have in our data.

We can also perform such tests by treating the results from `margins` as estimation results. There are three steps required to perform tests on margins. First, you must arrange it so that all the margins of interest are reported by just one `margins` command. Second, you must specify margins' `post` option. Third, you perform the test with the `test` command.

Such tests and comparisons can be readily performed by contrasting margins; see [R] [margins, contrast](#). Also see *Contrasts of margins—effects (discrete marginal effects)* in [R] [marginsplot](#).

In the [previous example](#), we used two commands to obtain our results, namely,

```
. margins if sex==0, at(sex=(0 1))
. margins if sex==1, at(sex=(0 1))
```

We could, however, have obtained the same results by typing just one command:

```
. margins, over(sex) at(sex=(0 1))
```

Performing `margins, over(sex)` first restricts the sample to `sex==0` and then restricts it to `sex==1`, and that is equivalent to the two different `if` conditions that we specified before.

To test whether females treated as females is equal to females treated as males, we will need to type

```
. margins, over(sex) at(sex=(0 1)) post
. test _b[2._at#1.sex] = _b[1._at#1.sex]
```

We admit that the second command may seem to have come out of nowhere. When we specify `post` on the `margins` command, `margins` behaves as if it were an estimation command, which means that 1) it posts its estimates and full VCE to `e()`, 2) it gains the ability to replay results just as any estimation command can, and 3) it gains access to the standard postestimation commands. Item 3 explains why we could use `test`. We learned that we wanted to test `_b[2._at#1.sex]` and `_b[1._at#1.sex]` by replaying the estimation results, but this time with the standard estimation command `coeflegend` option. So, what we typed was

```
. margins, over(sex) at(sex=(0 1)) post
. margins, coeflegend
. test _b[2._at#1.sex] = _b[1._at#1.sex]
```

We will let you try `margins`, `coeflegend` for yourself. The results of running the other two commands are

```
. margins, over(sex) at(sex=(0 1)) post
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over:      sex
1._at: 0.sex
      sex = 0
      1.sex
      sex = 0
2._at: 0.sex
      sex = 1
      1.sex
      sex = 1
```

	Delta-method			z	P> z	[95% conf. interval]	
	Margin	std. err.					
_at#sex							
1#Male	.0794393	.0062147	12.78	0.000	.0672586	.0916199	
1#Female	.2404749	.0199709	12.04	0.000	.2013326	.2796171	
2#Male	.1335584	.0127351	10.49	0.000	.1085981	.1585187	
2#Female	.2596538	.0104756	24.79	0.000	.2391219	.2801857	

```
. test _b[2._at#1.sex] = _b[1._at#1.sex]
( 1) - 1bn._at#1.sex + 2._at#1.sex = 0
      chi2( 1) =    0.72
      Prob > chi2 =    0.3951
```

We can perform the same test in one command using contrasts of margins:

```
. logistic outcome i.sex i.group sex#group age
(output omitted)
. margins, over(sex) at(sex=(0 1)) contrast(atcontrast(r._at) wald)
Contrasts of predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over:      sex
1._at: 0.sex
      sex = 0
      1.sex
      sex = 0
2._at: 0.sex
      sex = 1
      1.sex
      sex = 1
```

	df	chi2	P>chi2
_at@sex			
(2 vs 1) Male	1	14.59	0.0001
(2 vs 1) Female	1	0.72	0.3951
Joint	2	16.13	0.0003

	Delta-method			
	Contrast	std. err.	[95% conf. interval]	
_at@sex				
(2 vs 1) Male	.0541192	.0141706	.0263453	.081893
(2 vs 1) Female	.0191789	.0225516	-.0250215	.0633793

We refit our logistic model because its estimation results were replaced when we posted our margins. The syntax to perform the contrast we want is admittedly not obvious. Contrasting (testing) across `at()` groups is more difficult than contrasting across the margins themselves or across `over()` groups, because we have no natural place for the contrast operators (`r.`, in our case). We also explicitly requested Wald tests of the contrasts, which are not provided by default. Nevertheless, the  $\chi^2$  statistic and its *p*-value for (2 vs 1) for `female` matches the results of our `test` command. We also obtain the test of whether the response of males treated as males is equal to the response of males treated as females.

For a gentler introduction to contrasts of margins, see [\[R\] margins, contrast](#).

### Example 11: Margins of a specified prediction

We will fit the model

```
. use https://www.stata-press.com/data/r18/margex
. tobit ycn i.sex i.group sex#group age, ul(90)
```

and we will tell the following story about the variables: We run a peach orchard where we allow people to pick their own peaches. A person receives one empty basket in exchange for \$20, along with the right to enter the orchard. There is no official limit on how many peaches a person can pick, but only 90 peaches will fit into a basket. The dependent variable in the above tobit model, `ycn`, is the number of peaches picked. We use tobit, a special case of censored-normal regression, because `ycn` is censored at 90.

After fitting this model, if we typed

```
. margins sex
```

we would obtain the margins for males and for females of the uncensored number of peaches picked. We would obtain that because `predict` after `tobit` produces the uncensored number by default. To obtain the censored prediction, we would have to specify `predict's ystar(.,90)` option. If we want the margins based on that response, we type

```
. margins sex, predict(ystar(.,90))
```

The results of typing that are

```
. tobit ycn i.sex i.group sex#group age, ul(90)
  (output omitted)
. margins sex, predict(ystar(.,90))
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: E(ycn*|ycn<90), predict(ystar(.,90))
```

	Delta-method				[95% conf. interval]	
	Margin	std. err.	z	P> z		
sex						
Male	62.21804	.5996952	103.75	0.000	61.04266	63.39342
Female	78.34272	.4555278	171.98	0.000	77.4499	79.23553

In our previous examples, `sex = 1` has designated females, so evidently the females visiting our orchard are better at filling baskets than the men.

### Example 12: Margins of a specified expression

Continuing with our peach orchard example and the previously fit model

```
. use https://www.stata-press.com/data/r18/margex
. tobit ycn i.sex i.group sex#group age, ul(90)
```

let's examine how well our baskets are working for us. What is the proportion of the number of peaches actually picked to the number that would have been picked were the baskets larger? As mentioned in [example 11](#), `predict, ystar(.,90)` produces the expected number picked given the limit of basket size. `predict, xb` would predict the expected number without a limit. We want the ratio of those two predictions. That ratio will measure as a proportion how well the baskets work. Thus, we could type

```
. margins sex, expression(predict(ystar(.,90))/predict(xb))
```

That would give us the proportion for everyone treated as male and everyone treated as female, but what we want to know is how well baskets work for true males and true females, so we will type

```
. margins, over(sex) expression(predict(ystar(0,90))/predict(xb))
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: predict(ystar(0,90))/predict(xb)
Over:      sex
```

	Delta-method				[95% conf. interval]	
	Margin	std. err.	z	P> z		
sex						
Male	.9811785	.0013037	752.60	0.000	.9786233	.9837338
Female	.9419962	.0026175	359.88	0.000	.9368659	.9471265

By the way, we could count the number of peaches saved by the limited basket size during the period of data collection by typing

```
. count
    3,000
. margins, expression(3000*(predict(xb)-predict(ystar(.,90))))
(output omitted)
```

The number of peaches saved turns out to be 9,183.

### Example 13: Margins with multiple outcomes (responses)

Estimation commands such as `mlogit` and `mprobit` (see [R] [mlogit](#) and [R] [mprobit](#)) calculate multiple responses, and those multiple responses are reflected in the options available with `predict` after estimation. Obtaining margins for such estimators is thus the same as obtaining margins of a specified prediction, which was demonstrated in [example 11](#). The solution is to include the `predict_opt` that selects the desired response in margins' `predict(predict_opt)` option.

If we fit the multinomial logistic model

```
. mlogit group i.sex age
```

then to obtain the margins for the probability that `group = 1`, we would type

```
. margins sex, predict(outcome(1))
```

and to obtain the margins for the probability that `group = 3`, we would type

```
. margins sex, predict(outcome(3))
```

To obtain the margins for each of these outcomes simultaneously, type

```
. margins sex, predict(outcome(1)) predict(outcome(3))
```

We learned about the `outcome(1)` and `outcome(3)` options by looking in [R] [mlogit postestimation](#). For an example using margins with a multiple-outcome estimator, see [example 4](#) in [R] [mlogit postestimation](#).

### Example 14: Margins with multiple equations

Estimation commands such as `mvreg`, `manova`, `sureg`, and `reg3` (see [MV] [mvreg](#), [MV] [manova](#), [R] [sureg](#), and [R] [reg3](#)) fit multiple equations. Obtaining margins for such estimators is the same as obtaining margins with multiple outcomes (see [example 13](#)), which in turn is the same as obtaining margins of a specified prediction (see [example 11](#)). You place the relevant option from the estimator's `predict` command into margins' `predict(predict_opt)` option.

If we fit the seemingly unrelated regression model

```
. sureg (y = i.sex age) (distance = i.sex i.group)
```

we can obtain the marginal means of `y` for males and females by typing

```
. margins sex, predict(equation(y))
```

and we can obtain the marginal means of `distance` by typing

```
. margins sex, predict(equation(distance))
```

We could obtain the difference between the margins of `y` and `distance` by typing

```
. margins sex, expression(predict(equation(y)) -
> predict(equation(distance)))
```

More examples can be found in [MV] [manova](#) and [MV] [manova postestimation](#).

**Example 15: Margins evaluated out of sample**

You can fit your model on one dataset and use `margins` on another if you specify `margins' noesample` option. Remember that `margins` reports estimated average responses, and, unless you lock all the covariates at fixed values by using the `at()` option, the remaining variables are allowed to vary as they are observed to vary in the data. That is indeed the point of using `margins`. The fitted model provides the basis for adjusting for the remaining variables, and the data provide their values. The predictions produced by `margins` are of interest assuming the data used by `margins` are in some sense interesting or representative. In some cases, you might need to fit your model on one set of data and perform `margins` on another.

In [example 11](#), we fit the model

```
. tobit ycn i.sex i.group sex#group age, ul(90)
```

and we told a story about our peach orchard in which we charged people \$20 to collect a basket of peaches, where baskets could hold at most 90 peaches. Let us now tell you that we believe the data on which we estimated those margins were unrepresentative, or at least, we have a more representative sample stored in another `.dta` file. That dataset includes the demographics of our customers but does not include counts of peaches picked. It is a lot of work counting those peaches.

Thus, we will fit our model just as we did previously using the detailed data, but we will bring the other, more representative dataset into memory before issuing the `margins sex, predict(ystar(.,90))` command, and we will add `noesample` to it.

```
. use https://www.stata-press.com/data/r18/margex
(Artificial data for margins)
. tobit ycn i.sex i.group sex#group age, ul(90)
(output omitted)
. use https://www.stata-press.com/data/r18/peach
. margins sex, predict(ystar(.,90)) noesample
Predictive margins                                Number of obs = 2,727
Model VCE: OIM
Expression: E(ycn|ycn<90), predict(ystar(.,90))
```

	Delta-method				
	Margin	std. err.	z	P> z	[95% conf. interval]
sex					
0	56.79774	1.003731	56.59	0.000	54.83046 58.76502
1	75.02146	.6437446	116.54	0.000	73.75974 76.28317

In [example 12](#), we produced an estimate of the number of peaches saved by the limited-size baskets. We can update that estimate using the new demographic data by typing

```
. count
2,727
. margins, exp(2727*(predict(xb)-predict(ystar(.,90)))) noesample
(output omitted)
```

By running the above, we find that the updated number of peaches saved is 6,408.

## Obtaining margins of derivatives of responses (a.k.a. marginal effects)

Derivatives of responses are themselves responses, so everything said above in *Obtaining margins of responses* is equally true of derivatives of responses, and every example above could be repeated here substituting the derivative of the response for the response.

Derivatives are of interest because they are an informative way of summarizing fitted results. The change in a response for a change in the covariate is easy to understand and to explain. In simple models, one hardly needs margins to assist in obtaining such margins. Consider the simple linear regression

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \epsilon$$

The derivatives of the responses are

$$dy/d(\text{sex}) = \beta_1$$

$$dy/d(\text{age}) = \beta_2$$

margins computes these derivatives using  $\hat{\beta}_1$  and  $\hat{\beta}_2$ , the coefficients from the linear predictor of  $y$ . How does the linear predictor  $\hat{y}$  change between males and females? It changes by  $\hat{\beta}_1$ . How does  $\hat{y}$  change with age? It changes by  $\hat{\beta}_2$  per year.

If you make the model a little more complicated, however, the need for margins arises. Consider the model

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \epsilon$$

Now, the derivative with respect to age is

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age}$$

The change in  $y$  for a change in age itself changes with age, and so to better understand the fitted results, you might want to make a table of the change in  $y$  for a change in age for age = 30, age = 40, and age = 50. margins can do that.

Consider an even more complicated model, such as

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon \quad (1)$$

The derivatives are

$$dy/d(\text{sex}) = \beta_1 + \beta_5 \times \text{bp}$$

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age}$$

$$dy/d(\text{bp}) = \beta_4 + \beta_5 \times \text{sex}$$

$$dy/d(\text{tmt}) = \beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2$$

At this point, margins becomes indispensable.

**Use at() freely, especially with continuous variables**

An option one tends to use frequently with derivatives of responses is `at()`. Such use is often to better understand or to communicate how the response varies, or, in technical jargon, to explore the nature of the response surface.

For instance, the effect  $dy/d(\text{tmt})$  in (1) is equal to  $\beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2$ , and so simply to understand how treatment varies with age, we may want to fix age at various values. We might type

```
. margins, dydx(tmt) at(age=(30 40 50))
```

**Expressing derivatives as elasticities**

You specify the `dydx(varname)` option on the `margins` command to use  $dy/d(\text{varname})$  as the response variable. If you want that derivative expressed as an elasticity, you can specify `eyex(varname)`, `eydx(varname)`, or `dyex(varname)`. You substitute `e` for `d` where you want an elasticity. In the discussion below, when we talk about  $y$ , we are referring to the linear predictions from the model.

The formulas are

$$\text{dydx}() = dy/dx$$

$$\text{eyex}() = dy/dx \times (x/y)$$

$$\text{eydx}() = dy/dx \times (1/y) = d \ln(y)/dx$$

$$\text{dyex}() = dy/dx \times (x) = dy/d \ln(x)$$

and the interpretations are

<code>dydx()</code> :	change in $y$ for a	change in $x$
<code>eyex()</code> :	proportional change in $y$ for a	proportional change in $x$
<code>eydx()</code> :	proportional change in $y$ for a	change in $x$
<code>dyex()</code> :	change in $y$ for a	proportional change in $x$

As `margins` always does with response functions, calculations are made at the observational level and are then averaged. Let's assume that in observation 5,  $dy/dx = 0.5$ ,  $y = 15$ , and  $x = 30$ ; then

$$\text{dydx}() = 0.5$$

$$\text{eyex}() = 1.0$$

$$\text{eydx}() = 0.03$$

$$\text{dyex}() = 15.0$$

Many social scientists would informally explain the meaning of `eyex() = 1` as “ $y$  increases 100% when  $x$  increases 100%” or as “ $y$  doubles when  $x$  doubles”, although neither statement is literally true. `eyex()`, `eydx()`, and `dyex()` are rates evaluated at a point, just as `dydx()` is a rate, and all such interpretations are valid only for small (infinitesimal) changes in  $x$ . It is true that `eyex() = 1` means  $y$  increases with  $x$  at a rate such that, if the rate were constant,  $y$  would double if  $x$  doubled. This issue of casual interpretation is no different from casually interpreting `dydx()` as if it represents the response to a unit change. It is not necessarily true that `dydx() = 0.5` means that “ $y$  increases by 0.5 if  $x$  increases by 1”. It is true that “ $y$  increases with  $x$  at a rate such that, if the rate were constant,  $y$  would increase by 0.5 if  $x$  increased by 1”.

`dydx()`, `eyex()`, `eydx()`, and `dyex()` may be used with continuous  $x$  variables. `dydx()` and `eydx()` may also be used with factor variables. For `eydx()`, effects are based on  $d\ln(y)/dx$  for continuous covariates and on differences of  $\ln(y)$  for discrete covariates. Estimates based on logarithms have better computational properties and allow us to think of semielasticities as coefficients in a regression with log dependent variables. As we discuss next, when we are analyzing marginal effects of categorical variables, we think in terms of discrete differences instead of derivatives.

## Derivatives versus discrete differences

In (1),

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon$$

Let us call your attention to the derivatives of  $y$  with respect to age and sex:

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age} \quad (2)$$

$$dy/d(\text{sex}) = \beta_1 + \beta_5 \times \text{bp} \quad (3)$$

`age` is presumably a continuous variable, and (2) is precisely how `margins` calculates its derivatives when you type `margins, dydx(age)`. `sex`, however, is presumably a factor variable, and `margins` does not necessarily make the calculation using (3) were you to type `margins, dydx(sex)`. We will explain, but let us first clarify what we mean by a continuous and a factor variable. Say that you fit (1) by typing

```
. regress y i.sex age c.age#c.age i.bp bp#sex
> i.tmt tmt#c.age tmt#c.age#c.age
```

It is important that `sex` entered the model as a factor variable. It would not do to type `regress y sex . . .` because then `sex` would be a continuous variable, or at least it would be a continuous variable from Stata's point of view. The model estimates would be the same, but `margins'` understanding of those estimates would be a little different. With the model fit using `i.sex`, `margins` understands that either `sex` is 0 or `sex` is 1. With the model fit using `sex`, `margins` thinks `sex` is continuous and, for instance, `sex = 1.5` is a possibility.

`margins` calculates `dydx()` differently for continuous and for factor variables. For continuous variables, `margins` calculates  $dy/dx$  using the fitted values from `regress`. For factor variables, `margins` calculates the discrete first difference from the base category. To obtain that for `sex`, write down the model and then subtract from it the model evaluated at the base category for `sex`, which is `sex = 0`. If you do that, you will get the same formula as we obtained for the derivative, namely,

$$\text{discrete difference}\{(\text{sex} = 1) - (\text{sex} = 0)\} = \beta_1 + \beta_5 \times \text{bp}$$

We obtain the same formula because our model is linear regression. Outside of linear regression, and outside of linear response functions generally, the discrete difference is not equal to the derivative. The discrete difference is not equal to the derivative for logistic regression, probit, etc. The discrete difference calculation is generally viewed as better for factor variables than the derivative calculation because the discrete difference is what would actually be observed.

If you want the derivative calculation for your factor variables, specify the `continuous` option on the `margins` command.

**Example 16: Average marginal effect (partial effects)**

Concerning the title of this example, the way we use the term marginal effect, the effects of factor variables are calculated using discrete first differences. If you wanted the continuous calculation, you would specify margins' continuous option in what follows.

```
. use https://www.stata-press.com/data/r18/margex
(Artificial data for margins)
. logistic outcome treatment##group age c.age#c.age treatment#c.age
(output omitted)
. margins, dydx(treatment)
Average marginal effects                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
dy/dx wrt: 1.treatment
```

	Delta-method		z	P> z	[95% conf. interval]	
	dy/dx	std. err.				
1.treatment	.0385625	.0162848	2.37	0.018	.0066449	.0704801

Note: dy/dx for factor levels is the discrete change from the base level.

The average marginal effect of treatment on the probability of a positive outcome is 0.039.

**Example 17: Average marginal effect of all covariates**

We will continue with the model

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
```

if we wanted the average marginal effects for all covariates, we would type margins, dydx(\*) or margins, dydx(\_all); they mean the same thing. This is probably the most common way margins, dydx() is used.

```
. margins, dydx(*)
Average marginal effects                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
dy/dx wrt: 1.treatment 2.group 3.group age
```

	Delta-method		z	P> z	[95% conf. interval]	
	dy/dx	std. err.				
1.treatment	.0385625	.0162848	2.37	0.018	.0066449	.0704801
group						
2	-.0776906	.0181584	-4.28	0.000	-.1132805	-.0421007
3	-.1505652	.0400882	-3.76	0.000	-.2291366	-.0719937
age	.0095868	.0007796	12.30	0.000	.0080589	.0111148

Note: dy/dx for factor levels is the discrete change from the base level.

### Example 18: Evaluating marginal effects over the response surface

Continuing with the model

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
```

What follows maps out the entire response surface of our fitted model. We report the marginal effect of treatment evaluated at age = 20, 30, . . . , 60, by each level of group.

```
. margins group, dydx(treatment) at(age=(20(10)60))
Conditional marginal effects                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
dy/dx wrt: 1.treatment
1._at: age = 20
2._at: age = 30
3._at: age = 40
4._at: age = 50
5._at: age = 60
```

	Delta-method		z	P> z	[95% conf. interval]	
	dy/dx	std. err.				
0.treatment	(base outcome)					
1.treatment						
_at#group						
1 1	-.0208409	.0152862	-1.36	0.173	-.0508013	.0091196
1 2	.009324	.0059896	1.56	0.120	-.0024155	.0210635
1 3	.0006558	.0048682	0.13	0.893	-.0088856	.0101972
2 1	-.0436964	.0279271	-1.56	0.118	-.0984325	.0110397
2 2	.0382959	.0120405	3.18	0.001	.014697	.0618949
2 3	.0064564	.0166581	0.39	0.698	-.0261929	.0391057
3 1	-.055676	.0363191	-1.53	0.125	-.1268601	.015508
3 2	.1152235	.0209858	5.49	0.000	.074092	.156355
3 3	.0284808	.0471293	0.60	0.546	-.0638908	.1208524
4 1	-.0271101	.0395501	-0.69	0.493	-.1046177	.0504158
4 2	.2447682	.0362623	6.75	0.000	.1736954	.315841
4 3	.0824401	.1025028	0.80	0.421	-.1184616	.2833418
5 1	.0292732	.0587751	0.50	0.618	-.0859239	.1444703
5 2	.3757777	.0578106	6.50	0.000	.2624709	.4890844
5 3	.1688268	.1642191	1.03	0.304	-.1530368	.4906904

Note: dy/dx for factor levels is the discrete change from the base level.

### Obtaining margins with survey data and representative samples

The standard errors and confidence intervals produced by margins are based by default on the delta method applied to the VCE of the current estimates. Delta-method standard errors treat the covariates at which the response is evaluated as given or fixed. Such standard errors are appropriate if you specify at() to fix the covariates, and they are appropriate when you are making inferences about groups exactly like your sample whether you specify at() or not.

On the other hand, if you have a representative sample of the population or if you have complex survey data and if you want to make inferences about the underlying population, you need to account for the variation in the covariates that would arise in repeated sampling. You do that using vce(unconditional), which invokes a different standard error calculation based on Korn and Graubard (1999). Syntactically, there are three cases. They all involve specifying the vce(unconditional) option on the margins command:

1. *You have a representative random sample, and you have not svyset your data.*  
When you fit the model, you need to specify the `vce(robust)` or `vce(cluster clustvar)` option. When you issue the `margins` command, you need to specify the `vce(unconditional)` option.
2. *You have a weighted sample, and you have not svyset your data.*  
You need to specify `[pw=weight]` when you fit the model and, of course, specify the `vce(unconditional)` option on the `margins` command. You do not need to specify the weights on the `margins` command because `margins` will obtain them from the estimation results.
3. *You have svyset your data, whether it be a simple random sample or something more complex including weights, strata, sampling units, or poststratification, and you are using the linearized variance estimator.*  
You need to use the `svy` prefix when you fit the model. You need to specify `vce(unconditional)` when you issue the `margins` command. You do not need to respecify the weights.

Even though the data are `svyset`, and even though the estimation was `svy` estimation, `margins` does not default to `vce(unconditional)`. It does not default to `vce(unconditional)` because there are valid reasons to want the data-specific, `vce(delta)` standard-error estimates. Whether you specify `vce(unconditional)` or not, `margins` uses the weights, so you do not need to respecify them even if you are using `vce(unconditional)`.

`vce(unconditional)` is allowed only after estimation with `vce(robust)`, `vce(cluster ...)`, or the `svy` prefix with the linearized variance estimator. If the VCE of the current estimates was specified as clustered, so will be the VCE estimates of `margins`. If the estimates were from a survey estimation, the survey settings in the dataset will be used by `margins`.

When you use `vce(unconditional)`, never specify `if exp` or `in range` on the `margins` command; instead, specify the `subpop(if exp)` option. You do that for the usual reasons; see [\[SVY\] Subpopulation estimation](#). If you specify `over(varlist)` to examine subgroups, the subgroups will automatically be treated as subpopulations.

If you are using a replication-based variance estimator, you may want to use this method to estimate the variance of your margins; see [\[SVY\] svy postestimation](#).

### Example 19: Inferences for populations, margins of response

In [example 6](#), we fit the model

```
. logistic outcome i.sex i.group sex#group age
```

and we obtained margins by sex and margins by group,

```
. margins sex group
```

If our data were randomly drawn from the population of interest and we wanted to account for this, we would have typed

```
. logistic outcome i.sex i.group sex#group age, vce(robust)
. margins sex group, vce(unconditional)
```

We do that below:

```
. logistic outcome i.sex i.group sex#group age, vce(robust)
  (output omitted)
. margins sex group, vce(unconditional)
Predictive margins                                Number of obs = 3,000
Expression: Pr(outcome), predict()
```

	Unconditional		z	P> z	[95% conf. interval]	
	Margin	std. err.				
sex						
Male	.1600644	.0131685	12.16	0.000	.1342546	.1858743
Female	.1966902	.0104563	18.81	0.000	.1761963	.2171841
group						
1	.2251302	.0127069	17.72	0.000	.200225	.2500354
2	.150603	.0118399	12.72	0.000	.1273972	.1738088
3	.0736157	.0343188	2.15	0.032	.0063522	.1408793

The estimated margins are the same as they were in [example 6](#), but the standard errors and confidence intervals differ, although not by much. Given that we have 3,000 observations in our randomly drawn sample, we should expect this.

### Example 20: Inferences for populations, marginal effects

In [example 17](#), we fit a logistic model and then obtained the average marginal effects for all covariates by typing

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
. margins, dydx(*)
```

To repeat that and also obtain standard errors for our population, we would type

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age,
> vce(robust)
. margins, dydx(*) vce(unconditional)
```

The results are

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age, vce(robust)
  (output omitted)
. margins, dydx(*) vce(unconditional)
Average marginal effects                                Number of obs = 3,000
Expression: Pr(outcome), predict()
dy/dx wrt: 1.treatment 2.group 3.group age
```

	Unconditional		z	P> z	[95% conf. interval]	
	dy/dx	std. err.				
1.treatment	.0385625	.0163872	2.35	0.019	.0064442	.0706808
group						
2	-.0776906	.0179573	-4.33	0.000	-.1128863	-.0424949
3	-.1505652	.0411842	-3.66	0.000	-.2312848	-.0698456
age	.0095868	.0007814	12.27	0.000	.0080553	.0111183

Note: dy/dx for factor levels is the discrete change from the base level.

## Example 21: Inferences for populations with svyset data

See [example 3](#) in `[SVY] svy postestimation`.

### Standardizing margins

A standardized margin is the margin calculated on data different from the data used to fit the model. Typically, the word `standardized` is reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

Say that you work for a hospital and have fit a model of mortality on the demographic characteristics of the hospital's patients. At this stage, were you to type

```
. margins
```

you would obtain the mortality rate for your hospital. You have another dataset, `hstandard.dta`, that contains demographic characteristics of patients across all hospitals along with the population of each hospital recorded in the `pop` variable. You could obtain the expected mortality rate at your hospital if your patients matched the characteristics of the standard population by typing

```
. use https://www.stata-press.com/data/r18/hstandard, clear  
. margins [fw=pop], noesample
```

You specified `noesample` because the margin is being calculated on data other than the data used to fit the model. You specified `[fw=pop]` because the reference dataset you are using included population counts, as many reference datasets do.

### Obtaining margins as though the data were balanced

Here we discuss what are commonly called estimated marginal means or least-squares means. These are margins assuming that all levels of factor variables are equally likely or, equivalently, that the design is balanced. The seminal reference on these margins is [Searle, Speed, and Milliken \(1980\)](#).

In designed experiments, observations are often allocated in a balanced way so that the variances can be easily compared and decomposed. At the Acme Portable Widget Company, they are experimenting with a new machine. The machine has three temperature settings and two pressure settings; a combination of settings will be optimal on any particular day, determined by the weather. At start-up, one runs a quick test and chooses the optimal setting for the day. Across different days, each setting will be used about equally, says the manufacturer.

In experiments with the machine, 10 widgets were collected for stress testing at each of the settings over a six-week period. We wish to know the average stress-test value that can be expected from these machines over a long period.

### Balancing using `asbalanced`

The data were intended to be balanced, but unfortunately, the stress test sometimes destroys samples before the stress can be measured. Thus, even though the experiment was designed to be balanced, the data are not balanced. You specify the `asbalanced` option to estimate the margins as if the data were balanced. So that you can compare the `asbalanced` results with the observed results, we will also include `margins` without the `asbalanced` option in what follows:

```
. use https://www.stata-press.com/data/r18/acmemanuf
. regress y pressure##temp
  (output omitted)
. margins
Predictive margins                                Number of obs = 49
Model VCE: OLS
Expression: Linear prediction, predict()
```

	Delta-method		t	P> t	[95% conf. interval]	
	Margin	std. err.				
_cons	109.9214	1.422629	77.27	0.000	107.0524	112.7904

```
. margins, asbalanced
Adjusted predictions                                Number of obs = 49
Model VCE: OLS
Expression: Linear prediction, predict()
At: pressure (asbalanced)
    temp      (asbalanced)
```

	Delta-method		t	P> t	[95% conf. interval]	
	Margin	std. err.				
_cons	115.3758	1.530199	75.40	0.000	112.2899	118.4618

□ Technical note

Concerning how `asbalanced` calculations are performed, if a factor variable has  $l$  levels, then each level’s coefficient contributes to the response weighted by  $1/l$ . If two factors,  $a$  and  $b$ , interact, then each coefficient associated with their interaction is weighted by  $1/(l_a \times l_b)$ .

If a balanced factor interacts with a continuous variable, then each coefficient in the interaction is applied to the value of the continuous variable, and the results are weighted equally. So, if the factor being interacted has  $l_a$  levels, the effect of each coefficient on the value of the continuous covariate is weighted by  $1/l_a$ .

**Balancing by standardization**

To better understand the balanced results, we can perform the balancing ourselves by using the standardizing method shown in [Standardizing margins](#). To do that, we will input a balanced dataset and then type `margins, noesample`.

```

. use https://www.stata-press.com/data/r18/acmemanuf
. regress y pressure##temp
  (output omitted)
. drop _all
. input pressure temp
      pressure      temp
1.  1  1
2.  1  2
3.  1  3
4.  2  1
5.  2  2
6.  2  3
7.  end
. margins, noesample
Predictive margins                                Number of obs = 6
Model VCE: OLS
Expression: Linear prediction, predict()

```

	Delta-method		t	P> t	[95% conf. interval]	
	Margin	std. err.				
._cons	115.3758	1.530199	75.40	0.000	112.2899	118.4618

We obtain the same results as previously.

## Balancing nonlinear responses

If our testing had produced a binary outcome, say, acceptable/unacceptable, rather than a continuous variable, we would type

```

. use https://www.stata-press.com/data/r18/acmemanuf, clear
. logistic acceptable pressure##temp
. margins, asbalanced

```

The result of doing that would be 0.680. If we omitted the `asbalanced` option, the result would have been 0.667. The two results are so similar because `acmemanuf.dta` is nearly balanced.

Even though the `asbalanced` option can be used on both linear and nonlinear responses, such as probabilities, there is an issue of which you should be aware. The most widely used formulas for balancing responses apply the balancing to the linear prediction, average that as if it were balanced, and then apply the nonlinear transform. That is the calculation that produced 0.680.

An alternative would be to apply the standardization method. That amounts to making the linear predictions observation by observation, applying the nonlinear transform to each, and then averaging the nonlinear result as if it were balanced. You could do that by typing

```

. use https://www.stata-press.com/data/r18/acmemanuf, clear
. logistic acceptable pressure##temp
. clear
. input pressure temp
  (see above for entered data)
. margins, noesample

```

The result from the standardization procedure would be 0.672. These two ways of averaging nonlinear responses are discussed in detail in [Lane and Nelder \(1982\)](#) within the context of general linear models.

Concerning the method used by the `asbalanced` option, if your data start balanced and you have a nonlinear response, you will get different results with and without the `asbalanced` option!

## Treating a subset of covariates as balanced

So far, we have treated all the covariates as if they were balanced. `margins` will allow you to treat a subset of the covariates as balanced, too. For instance, you might be performing an experiment in which you are randomly allocating patients to a treatment arm and so want to balance on arm, but you do not want to balance the other characteristics because you want mean effects for the experiment's population.

In this example, we will imagine that the outcome of the experiment is continuous. We type

```
. use https://www.stata-press.com/data/r18/margex, clear
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm)
```

If we wanted results balanced on `agegroup` as well, we could type

```
. margins, at((asbalanced) arm agegroup)
```

If we wanted results balanced on all three covariates, we could type

```
. margins, at((asbalanced) arm agegroup sex)
```

or we could type

```
. margins, at((asbalanced) _factor)
```

or we could type

```
. margins, asbalanced
```

## Using `fvset` design

As a convenience feature, equivalent to

```
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm sex)
```

is

```
. fvset design asbalanced arm sex
. regress y arm##sex sex##agegroup
. margins
```

The advantage of the latter is that you have to set the variables as balanced only once. This is useful when balancing is a design characteristic of certain variables and you wish to avoid accidentally treating them as unbalanced.

If you save your data after `fvsetting`, the settings will be remembered in future sessions. If you want to clear the setting(s), type

```
. fvset clear varlist
```

See [\[R\] fvset](#).

**Balancing in the presence of empty cells**

The issue of empty cells is not exclusively an issue of balancing, but there are special considerations when balancing. Empty cells are discussed generally in *Estimability of margins*.

An empty cell is an interaction of levels of two or more factor variables for which you have no data. Usually, margins involving empty cells cannot be estimated. When balancing, there is an alternate definition of the margin that allows the margin to be estimated. `margins` makes the alternate calculation when you specify the `emptycells(reweight)` option. By default, `margins` uses the `emptycells(strict)` option.

If you have empty cells in your data and you request margins involving the empty cells, those margins will be marked as not estimable even if you specify the `asbalanced` option.

```
. use https://www.stata-press.com/data/r18/estimability, clear
(margins estimability)
. regress y sex##group
(output omitted)
. margins sex, asbalanced

Adjusted predictions                                Number of obs = 69
Model VCE: OLS

Expression: Linear prediction, predict()
At: sex      (asbalanced)
    group    (asbalanced)
```

	Delta-method				[95% conf. interval]	
	Margin	std. err.	t	P> t		
sex						
Male	21.91389	1.119295	19.58	0.000	19.67572	24.15206
Female	.	(not estimable)				

This example is discussed in *Estimability of margins*, although without the `asbalanced` option. What is said there is equally relevant to the `asbalanced` case. For reasons explained there, the margin for `sex = 1` (female) cannot be estimated.

The margin for `sex = 1` can be estimated in the `asbalanced` case if you are willing to make an assumption. Remember that `margins` makes the balanced calculation by summing the responses associated with the levels and then dividing by the number of levels. If you specify `emptycells(reweight)`, `margins` sums what is available and divides by the number available. Thus, you are assuming that, whatever the responses in the empty cells, those responses are such that they would not change the overall mean of what is observed.

The results of specifying `emptycells(reweight)` are

```
. margins sex, asbalanced emptycells(reweight)
Adjusted predictions                               Number of obs = 69
Model VCE: OLS
Expression:   Linear prediction, predict()
Empty cells: reweight
At: sex      (asbalanced)
      group  (asbalanced)
```

	Delta-method					[95% conf. interval]
	Margin	std. err.	t	P> t		
sex						
Male	21.91389	1.119295	19.58	0.000	19.67572	24.15206
Female	24.85185	1.232304	20.17	0.000	22.38771	27.316

## Obtaining margins with nested designs

### Introduction to nested designs

Factors whose meaning depends on other factors are called nested factors, and the factors on which their meaning depends are called the nesting factors. For instance, assume that we have a sample of patients and each patient is assigned to one doctor. Then, patient is nested within doctor. Let the identifiers of the first 5 observations of our data be

Doctor	Patient	Name
1	1	Fred
1	2	Mary
1	3	Bob
2	1	Karen
2	2	Hank

The first patient on one doctor’s list has nothing whatsoever to do with the first patient on another doctor’s list. The meaning of `patient = 1` is defined only when the value of `doctor` is supplied.

Nested factors enter into models as interactions of nesting and nested; the nested factor does not appear by itself. We might estimate a model such as

```
. regress y ... i.doctor doctor#patient ...
```

You do not include `i.patient` because the coding for patient has no meaning except within doctor. Patient 1 is Fred for doctor 1 and Karen for doctor 2, etc.

`margins` provides an option to help account for the structure of nested models. The `within(varlist)` option specifies that `margins` estimate and report a set of margins for the value combinations of `varlist`. We might type

```
. margins, within(doctor)
```

Margin calculations are performed first for `doctor = 1`, then for `doctor = 2`, and so on.

Sometimes you need to specify `within()`, and other times you do not. Let’s consider the particular model

```
. regress y i.doctor doctor#patient i.sex sex#doctor#patient
```

The guidelines are the following:

1. You may compute overall margins by typing `margins`.
2. You may compute overall margins within levels of a nesting factor by typing `margins, within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing `margins patient, within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing `margins sex`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

For examples using `within()`, see [\[R\] anova](#).

### **Margins with nested designs as though the data were balanced**

To obtain margins with nested designs as though the data were balanced, the guidelines are the same as above except that 1) you add the `asbalanced` option and 2) whenever you do not specify `within()`, you specify `emptycells(reweight)`. The updated guidelines are

1. You may compute overall margins by typing `margins, asbalanced emptycells(reweight)`.
2. You may compute overall margins within levels of a nesting factor by typing `margins, asbalanced within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing `margins patient, asbalanced within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing `margins sex, asbalanced emptycells(reweight)`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

Just as explained in *Using fvset design*, rather than specifying the `asbalanced` option, you may set the balancing characteristic on the factor variables once and for all by using the command `fvset design asbalanced varlist`.

#### Technical note

Specifying either `emptycells(reweight)` or `within(varlist)` causes `margins` to rebalance over all empty cells in your model. If you have interactions in your model that are not involved in the nesting, `margins` will lose its ability to detect estimability.

#### Technical note

Careful readers will note that the description of `within(varlist)` matches closely the description of `over(varlist)`. The concept of nesting is similar to the concept of subpopulations. `within()` differs from `over()` in that it gracefully handles the missing cells when margins are computed as balanced.

## Coding of nested designs

In the *Introduction* to this section, we showed a coding of the nested variable `patient`, where the coding started over with each doctor:

Doctor	Patient	Name
1	1	Fred
1	2	Mary
1	3	Bob
2	1	Karen
2	2	Hank

That coding style is not required. The data could just as well have been coded

Doctor	Patient	Name
1	1	Fred
1	2	Mary
1	3	Bob
2	4	Karen
2	5	Hank

or even

Doctor	Patient	Name
1	1037239	Fred
1	2223942	Mary
1	0611393	Bob
2	4433329	Karen
2	6110271	Hank

Actually, either of the above two alternatives is better than the first one because `margins` will be better able to give you feedback about estimability should you make a mistake following the guidelines. On the other hand, both of these alternatives require more memory at the estimation step. If you run short of memory, you will need to recode your patient ID to the first coding style, which you could do by typing

```
. sort doctor patient
. by doctor: generate newpatient = _n
```

Alternatively, you can `set emptycells drop` and continue to use your patient ID variable just as it is coded. If you do this, we recommend that you remember to type `set emptycells keep` when you are finished; `margins` is better able to determine estimability that way. If you regularly work with large nested models, you can `set emptycells keep`, permanently so that the setting persists across sessions. See [\[R\] set emptycells](#).

## Special topics

### Requirements for model specification

The results that `margins` reports are based on the most recently fit model or, in Stata jargon, the most recently issued estimation command. Here we discuss 1) mechanical requirements for how you specify that estimation command, 2) workarounds to use when those restrictions prove impossible, and 3) requirements for `margins`' `predict(pred_opt)` option to work.

Concerning 1, when you specify the estimation command, covariates that are logically factor variables must be Stata factor variables, and that includes indicator variables, binary variables, and dummies. It will not do to type

```
. regress y ... sex ...
```

even if `sex` is a 0/1 variable. You must type

```
. regress y ... i.sex ...
```

If you violate this rule, you will not get incorrect results, but you will discover that you will be unable to obtain margins on `sex`:

```
. margins sex
factor sex not found in list of covariates
r(111);
```

It is also important that if the same continuous variable appears in your model more than once, differently transformed, those transforms be performed via Stata's factor-variable notation. It will not do to type

```
. generate age2 = age^2
. regress y ... age age2 ...
```

You must type

```
. regress y ... age c.age#c.age ...
```

You must do that because `margins` needs to know everywhere that variable appears in the model if it is to be able to set covariates to fixed values.

Concerning 2, sometimes the transformations you desire may not be achievable using the factor-variable notation; in those situations, there is a workaround. Let's assume you wish to estimate

```
. generate age1_5 = age^1.5
. regress y ... age age1_5 ...
```

There is no factor-variable notation for including `age` and `age1.5` in a model, so obviously you are going to obtain the estimates by typing just what we have shown. In what follows, it would be okay if there are interactions of `age` and `age1_5` with other variables specified by the factor-variable notation, so the model could just as well be

```
. regress y ... age age1_5 sex#c.age sex#c.age1_5 ...
```

Let's assume you have fit one of these two models. On any subsequent `margins` command where you leave `age` free to vary, there will be no issue. You can type

```
. margins sex
```

and results will be correct. Issues arise when you attempt to fix `age` at predetermined values. The following would produce incorrect results:

```
. margins sex, at(age=20)
```

The results would be incorrect because they leave `age1_5` free to vary, and, logically, fixing `age` implies that `age1_5` should also be fixed. Because we were unable to state the relationship between `age` and `age1_5` using the factor-variable notation, `margins` does not know to fix `age1_5` at  $20^{1.5}$  when it fixes `age` at 20. To get the correct results, you must fix the value of `age1_5` yourself:

```
. margins sex, at(age=20 age1_5=89.442719)
```

That command produces correct results. In the command, 89.442719 is  $20^{1.5}$ .

In summary, when there is a functional relationship between covariates of your model and that functional relationship is not communicated to `margins` via the factor-variable notation, then it becomes your responsibility to ensure that all variables that are functionally related are set to the appropriate fixed values when any one of them is set to a fixed value.

Concerning 3, we wish to amend our claim that you can calculate margins for anything that `predict` will produce. We need to add a qualifier. Let us show you an example where the statement is not true. After `regress`, `predict` will predict something it calls  $\text{pr}(a, b)$ , which is the probability  $a \leq y \leq b$ . Yet if we attempted to use `pr()` with `margins` after estimation by `regress`, we would obtain

```
. margins sex, predict(pr(10,20))
prediction is a function of possibly stochastic quantities other than e(b)
r(498);
```

What we should have stated was that you can calculate margins for anything that `predict` will produce for which all the estimated quantities used in its calculation appear in  $e(V)$ , the estimated VCE. `pr()` is a function of  $\beta$ , the estimated coefficients, and of  $s^2$ , the estimated variance of the residual. `regress` does not post the variance of the residual variance (`sic`) in  $e(V)$ , or even estimate it, and therefore, `predict(pr(10,20))` cannot be specified with `margins` after estimation by `regress`.

It is unlikely that you will ever encounter these kinds of problems because there are so few predictions where the components are not posted to  $e(V)$ . If you do encounter the problem, the solution may be to specify `nose` to suppress the standard error calculation. If the problem is not with computing the margin, but with computing its standard error, `margins` will report the result:

```
. margins sex, predict(pr(10,20)) nose
(output appears with SEs, tests, and CIs left blank)
```

## □ Technical note

Programmers: If you run into this after running an estimation command that you have written, be aware that as of Stata 11, you are supposed to set in `e(marginsok)` the list of options allowed with `predict` that are okay to use with `margins`. When that list is not set, `margins` looks for violations of its assumptions and, if it finds any, refuses to proceed.

□

## Estimability of margins

Sometimes `margins` will report that a margin cannot be estimated:

```
. use https://www.stata-press.com/data/r18/estimability, clear
(margins estimability)
. regress y sex##group
(output omitted)
. margins sex

Predictive margins                                Number of obs = 69
Model VCE: OLS
Expression: Linear prediction, predict()
```

	Delta-method				
	Margin	std. err.	t	P> t	[95% conf. interval]
sex					
Male	21	.8500245	24.71	0.000	19.30027 22.69973
Female	.	(not estimable)			

In the above output, the margin for `sex = 0` (male) is estimated, but the margin for `sex = 1` (female) is not estimable. This occurs because of empty cells. An empty cell is an interaction of levels of two or more factor variables for which you have no data. In the example, the lack of estimability arises because we have two empty cells:

```
. table sex group, nototals
```

	Group				
	1	2	3	4	5
Sex					
Male	2	9	27	8	2
Female	9	9	3		

To calculate the marginal mean response for `sex = 1`, we have no responses to average over for `group = 4` and `group = 5`. We obviously could calculate that mean for the observations that really are `sex = 1`, but remember, the marginal calculation for `sex = 1` treats everyone as if female, and we will thus have 8 and 2 observations for which we have no basis for estimating the response.

There is no solution for this problem unless you are willing to treat the data as if it were balanced and adjust your definition of a margin; see [Balancing in the presence of empty cells](#).

## Manipulability of tests

Manipulability is a problem that arises with some tests, and in particular, arises with Wald tests. Tests of margins are based on Wald tests, hence our interest. This is a generic issue and not specific to the `margins` command.

Let's understand the problem. Consider performing a test of whether some statistic  $\phi$  is 0. Whatever the outcome of that test, it would be desirable if the outcome were the same were we to test whether the  $\text{sqrt}(\phi)$  were 0, or whether  $\phi^2$  were 0, or whether any other monotonic transform of  $\phi$  were 0 (for  $\phi^2$ , we were considering only the positive half of the number line). If a test does not have that property, it is manipulable.

Wald tests are manipulable, and that means the tests produced by `margins` are manipulable. You can see this for yourself by typing

```
. use https://www.stata-press.com/data/r18/margex, clear
. replace y = y - 65
. regress y sex##group
. margins, df(.)
. margins, expression(predict(xb)^2)
```

To compare the results from the two `margins` commands, we added the `df(.)` option to the first one, forcing it to report a  $z$  statistic even though a  $t$  statistic would have been appropriate in this case. We would prefer if the test against zero produced by `margins, df(.)` was equal to the test produced by `margins, expression(predict(xb)^2)`. But alas, they produce different results. The first produces  $z = 12.93$ , and the second produces  $z = 12.57$ .

The difference is not much in our example, but behind the scenes, we worked to make it small. We subtracted 65 from  $y$  so that the experiment would be for a case where it might be reasonable that you would be testing against 0. One does not typically test whether the mean income in the United States is zero or whether the mean blood pressure of live patients is zero. Had we left  $y$  as it was originally, we would have obtained  $z = 190$  and  $z = 96$ . We did not want to show that comparison to you first because the mean of  $y$  is so far from 0 that you probably would never be testing it. The corresponding difference in  $\phi$  is tiny.

Regardless of the example, it is important that you base your tests in the metric where the likelihood surface is most quadratic. For further discussion on manipulability, see [Manipulability in \[R\] predictnl](#).

This manipulability is not limited to Wald tests after estimation; you can also see the manipulability of results produced by linear regression just by applying nonlinear transforms to a covariate ([Phillips and Park 1988](#); [Gould 1996](#)).

## Using margins after the estimates use command

Assume you fit and used `estimates save` (see [\[R\] estimates save](#)) to save the estimation results:

```
. regress y sex##group age c.age*c.age if site==1
. ...
. estimates save mymodel
file mymodel.ster saved
```

Later, perhaps in a different Stata session, you reload the estimation results by typing

```
. estimates use mymodel
```

You plan to use `margins` with the reloaded results. You must remember that `margins` bases its results not only on the current estimation results but also on the current data in memory. Before you can use `margins`, you must reload the dataset on which you fit the model or, if you wish to produce standardized margins, some other dataset.

```
. use mydata, clear
(data for fitting models)
```

If the dataset you loaded contained the data for standardization, you can stop reading; you know that to produce standardized margins, you need to specify the `noesample` option.

We reloaded the original data and want to produce margins for the estimation sample. In addition to the data, `margins` requires that `e(sample)` be set, as `margins` will remind us:

```
. margins sex
e(sample) does not identify the estimation sample
r(322);
```

The best solution is to use `estimates esample` to rebuild `e(sample)`:

```
. estimates esample: y sex group age if site==1
```

If we knew we had no missing values in `y` and the covariates, we could type

```
. estimates esample: if site==1
```

Either way, `margins` would now work:

```
. margins sex  
(usual output appears)
```

There is an alternative. We do not recommend it, but we admit that we have used it. Rather than rebuilding `e(sample)`, you can use `margins`' `noesample` option to tell `margins` to skip using `e(sample)`. You could then specify the appropriate `if` statement (if necessary) to identify the estimation sample:

```
. estimates use mymodel  
. use mydata, clear  
(data for fitting models)  
. margins sex if !missing(y, sex, group age) & site==1, noesample  
(usual output appears)
```

In the above, we are not really running on a sample different from the estimation sample; we are merely using `noesample` to fool `margins`, and then we are specifying on the `margins` command the conditions equivalent to re-create `e(sample)`.

If we wish to obtain `vce(unconditional)` results, however, `noesample` will be insufficient. We must also specify the `force` option,

```
. margins sex if !missing(y, sex, group age) & site==1,  
> vce(unconditional) noesample force  
(usual output appears)
```

Regardless of the approach you choose—resetting `e(sample)` or specifying `noesample` and possibly `force`—make sure you are right. In the `vce(delta)` case, you want to be right to ensure that you obtain the results you want. In the `vce(unconditional)` case, you need to be right because otherwise results will be statistically invalid.

## Syntax of `at()`

In `at(atspec)`, `atspec` may contain one or more of the following specifications:

```
varlist  
(stat) varlist  
varname = #  
varname = (numlist)  
varname = generate(exp)
```

where

1. *varnames* must be covariates in the previously fit model (estimation command).
2. Variable names (whether in *varname* or *varlist*) may be continuous variables, factor variables, or specific level variables, such as `age`, `group`, or `3.group`.

3. *varlist* may also be one of three standard lists:
  - a. `_all` (all covariates),
  - b. `_factor` (all factor-variable covariates), or
  - c. `_continuous` (all continuous covariates).
4. *stat* can be any of the following:

<i>stat</i>	Description	Variables allowed
<code>asobserved</code>	at observed values in the sample (default)	all
<code>mean</code>	means (default for <i>varlist</i> )	all
<code>median</code>	medians	continuous
<code>p1</code>	1st percentile	continuous
<code>p2</code>	2nd percentile	continuous
<code>...</code>	3rd–49th percentiles	continuous
<code>p50</code>	50th percentile (same as <code>median</code> )	continuous
<code>...</code>	51st–97th percentiles	continuous
<code>p98</code>	98th percentile	continuous
<code>p99</code>	99th percentile	continuous
<code>min</code>	minimums	continuous
<code>max</code>	maximums	continuous
<code>zero</code>	fixed at zero	continuous
<code>base</code>	base level	factors
<code>asbalanced</code>	all levels equally probable and sum to 1	factors

Any *stat* except `zero`, `base`, and `asbalanced` may be prefixed with an `o` to get the overall statistic—the sample over all `over()` groups. For example, `omean`, `omedian`, and `op25`. Overall statistics differ from their correspondingly named statistics only when the `over()` or `within()` option is specified. When no *stat* is specified, `mean` is assumed. If *stat* is not followed by a *varlist*, *stat* is ignored.

*atspec* can involve multiple settings for one covariate as well as settings for multiple covariates. The following rules are applied when more than one covariate or value is included:

1. When more than one covariate is referenced in *atspec* but each covariate is set to only one value, all settings are applied in combination. For example, `at(x1=5 x2=0)` results in `margins` being estimated under one scenario, with `x1` set to 5, `x2` set to 0, and all other covariates set to their observed values (the default).
2. When multiple values are specified for a covariate, the covariate will be set to each of the values in turn. For example, `at(x1=5 x1=10)` or, equivalently, `at(x1=(5 10))` specifies that `x1` be set first to 5 and then to 10.
3. When multiple values are specified for more than one covariate, all possible combinations of settings are applied in turn. For example, `at(x1=(5 10) x2=(0 1))` results in `margins` being estimated under four scenarios: (`x1 = 5 x2 = 0`), (`x1 = 5 x2 = 1`), (`x1 = 10 x2 = 0`), and (`x1 = 10 x2 = 1`).
4. Settings may be specified for groups of covariates using three general *varlists*—`_all`, `_factor`, and `_continuous`. When *atspec* includes both specifications with general *varlists* and specifications with named covariates, the specifications for named covariates take precedence over general ones. For example, `at(x1=10 (means) _all)` sets `x1` to 10 while setting all other covariates to their means.

5. Only one (*stat*) *varlist* specification can be applied to a covariate. If more than one is specified, the rightmost specification is respected. For example, `at((means) x1 x2 (medians) x1 x2)` sets both `x1` and `x2` to their medians.
6. When both a (*stat*) specification and another specification are included for a named covariate, the other specification takes precedence. For example, `at(x1=5 (means) x1)` sets `x1` to 5.

In addition, `at()` can be repeated. When multiple `at()` options are specified, *atspecs* are processed sequentially. For instance, `at(x1=5) at(x2=0)` results in `margins` being estimated under two scenarios. The first sets `x1` to 5 and all other covariates, including `x2`, to their observed values. The second sets `x2` to 0 and all other covariates to their observed values. Note that this is different from the single `at(x1=5 x2=0)` specification, which sets `x1` and `x2` to the specified values simultaneously.

## Estimation commands that may be used with margins

`margins` may be used after most estimation commands.

`margins` cannot be used after estimation commands that do not produce full variance matrices, such as `exlogistic` and `expoisson` (see [\[R\] exlogistic](#) and [\[R\] expoission](#)).

`margins` is all about covariates and cannot be used after estimation commands that do not post the covariates, which eliminates `gmm` (see [\[R\] gmm](#)).

`margins` cannot be used after some estimation commands that have an odd data organization, such as `nlogit`. However, `margins` has been specially adapted to work with many choice model estimation commands; see [\[CM\] margins](#).

## Glossary

**adjusted mean.** A *margin* when the response is the linear predictor from linear regression, ANOVA, etc. For some authors, adjusting also implies adjusting for unbalanced data. See [Obtaining margins of responses](#) and see [Obtaining margins as though the data were balanced](#).

**average marginal effect.** See [marginal effect and average marginal effect](#).

**average partial effect.** See [partial effect and average partial effect](#).

**conditional margin.** A *margin* when the response is evaluated at fixed values of all the covariates. If any covariates are left to vary, the margin is called a predictive margin.

**effect.** The effect of *x* is the derivative of the *response* with respect to covariate *x*, or it is the difference in responses caused by a discrete change in *x*. Also see [marginal effect](#).

The effect of *x* measures the change in the response for a change in *x*. Derivatives or differences might be reported as elasticities. If *x* is continuous, the effect is measured continuously. If *x* is a factor, the effect is measured with respect to each level of the factor and may be calculated as a discrete difference or as a continuous change, as measured by the derivative. `margins` calculates the discrete difference by default and calculates the derivative if the `continuous` option is specified.

**elasticity and semielasticity.** The elasticity of  $y$  with respect to  $x$  is  $d(\ln y)/d(\ln x) = (x/y) \times (dy/dx)$ , which is approximately equal to the proportional change in  $y$  for a proportional change in  $x$ .

The semielasticity of  $y$  with respect to  $x$  is either 1)  $dy/d(\ln x) = x \times (dy/dx)$  or 2)  $d(\ln y)/dx = (1/y) \times (dy/dx)$ , which is approximately 1) the change in  $y$  for a proportional change in  $x$  or 2) the proportional change in  $y$  for a change in  $x$ .

`margins` uses model predictions or user-specified statistics in `expression()` in place of  $y$  above.

**empty cell.** An interaction of levels of two or more factor variables for which you have no data. For instance, you have sex interacted with group in your model, and in your data there are no females in group 1. Empty cells affect which margins can be estimated; see [Estimability of margins](#).

**estimability.** Estimability concerns whether a margin can be uniquely estimated (identified); see [Estimability of margins](#).

**estimated marginal mean.** This is one of the few terms that has the same meaning across authors. An estimated marginal mean is a margin assuming the levels of each factor covariate are equally likely (balanced), including interaction terms. This is obtained using `margins`' `asbalanced` option. In addition, there is an alternate definition of estimated marginal mean in which margins involving empty cells are redefined so that they become estimable. This is invoked by `margins`' `emptycells(rewrite)` option. See [Balancing in the presence of empty cells](#).

**least-squares mean.** Synonym for *estimated marginal mean*.

**margin.** A statistic calculated from predictions or other statistics of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. The prediction or other statistic on which the margin is based is called the response.

If all the covariates are fixed, then the margin is called a conditional margin. If any covariates are left to vary, the margin is called a predictive margin.

In this documentation, we divide margins on the basis of whether the statistic is a response or a derivative of a response; see [Obtaining margins of responses](#) and [Obtaining margins of derivatives of responses](#).

**marginal effect and average marginal effect.** The marginal effect of  $x$  is the *margin of the effect* of  $x$ . The term is popular with social scientists, and because of that, you might think the word marginal in marginal effect means derivative because of terms like marginal cost and marginal revenue. Marginal used in that way, however, refers to the derivative of revenue and the derivative of cost; it refers to the numerator, whereas marginal effect refers to the denominator. Moreover, *effect* is already a derivative or difference.

Some researchers interpret marginal in marginal effect to mean instantaneous, and thus a marginal effect is the instantaneous derivative rather than the discrete first difference, corresponding to `margins`' `continuous` option. Researchers who use marginal in this way refer to the discrete difference calculation of an effect as a partial effect.

Other researchers define marginal effect to be the margin when all covariates are held fixed and the average marginal effect when some covariates are not fixed.

**out-of-sample prediction.** Predictions made in one dataset using the results from a model fit on another. Sample here refers to the sample on which the model was fit, and out-of-sample refers to the dataset on which the predictions are made.

**partial effect and average partial effect.** Some authors restrict the term *marginal effect* to mean derivatives and use the term partial effect to denote discrete differences; see [marginal effect and average marginal effect](#).

**population marginal mean.** The theoretical (true) value that is estimated by *estimated marginal mean*.

We avoid this term because it can be confused with the concept of a population in survey statistics, with which the population marginal mean has no connection.

**posting results, posting margins.** A Stata concept having to do with storing the results from the `margins` command in `e()` so that those results can be used as if they were estimation results, thus allowing the subsequent use of postestimation commands, such as `test`, `testnl`, `lincom`, and `nlcom` (see [R] `test`, [R] `testnl`, [R] `lincom`, and [R] `nlcom`). This is achieved by specifying `margins' post` option. See *Example 10: Testing margins—contrasts of margins*.

**predictive margin.** A *margin* in which all the covariates are not fixed. When all covariates are fixed, it is called a *conditional margin*.

**recycled prediction.** A synonym for *predictive margin*.

**response.** A prediction or other statistic derived from combining the parameter estimates of a fitted model with data or specified values on covariates. Derivatives of responses are themselves responses. Responses are what we take *margins* of.

**standardized margin.** The margin calculated on data different from the data used to fit the model. The term *standardized* is usually reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

**subpopulation.** A subset of your sample that represents a subset of the population, such as the males in a sample of people. In survey contexts when it is desired to account for sampling of the covariates, standard errors for marginal statistics and effects need to account for both the population and the subpopulation. This is accomplished by specifying the `vce(unconditional)` option and one of the `subpop()` or `over()` options. In fact, the above is allowed even when your data are not `svyset` because `vce(unconditional)` implies that the sample represents a population.

## Stored results

`margins` stores the following in `r()`:

### Scalars

<code>r(N)</code>	number of observations
<code>r(N_sub)</code>	subpopulation observations
<code>r(N_clust)</code>	number of clusters
<code>r(N_psu)</code>	number of sampled PSUs, survey data only
<code>r(N_strata)</code>	number of strata, survey data only
<code>r(df_r)</code>	variance degrees of freedom, survey data only
<code>r(N_poststrata)</code>	number of post strata, survey data only
<code>r(k_predict)</code>	number of <code>predict()</code> options
<code>r(k_margins)</code>	number of terms in <i>marginlist</i>
<code>r(k_by)</code>	number of subpopulations
<code>r(k_at)</code>	number of <code>at()</code> options
<code>r(level)</code>	confidence level of confidence intervals

### Macros

<code>r(cmd)</code>	<code>margins</code>
<code>r(cmdline)</code>	command as typed

------------------------	-------------------------

## Methods and formulas

Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. There are many names for the different statistics that `margins` can compute: estimates marginal means (see [Searle](#),

Speed, and Milliken [1980]), predictive margins (see Graubard and Korn [2004]), marginal effects (see Greene [2018]), and average marginal/partial effects (see Wooldridge [2010] and Bartus [2005]).

Methods and formulas are presented under the following headings:

- Notation*
- Marginal effects*
- Fixing covariates and balancing factors*
- Estimable functions*
- Standard errors conditional on the covariates*
- Unconditional standard errors*

## Notation

Let  $\theta$  be the vector of parameters in the current model fit, let  $\mathbf{z}$  be a vector of covariate values, and let  $f(\mathbf{z}, \theta)$  be a scalar-valued function returning the value of the predictions of interest. The following table illustrates the parameters and default prediction for several of Stata's estimation commands.

Command	$\theta$	$\mathbf{z}$	$f(\mathbf{z}, \theta)$
regress	$\beta$	$\mathbf{x}$	$\mathbf{x}\beta$
cloglog	$\beta$	$\mathbf{x}$	$1 - e^{-e^{x\beta}}$
logit	$\beta$	$\mathbf{x}$	$1/(1 + e^{-x\beta})$
poisson	$\beta$	$\mathbf{x}$	$e^{x\beta}$
probit	$\beta$	$\mathbf{x}$	$\Phi(\mathbf{x}\beta)$
biprobit	$\beta_1, \beta_2, \rho$	$\mathbf{x}_1, \mathbf{x}_2$	$\Phi_2(\mathbf{x}_1\beta_1, \mathbf{x}_2\beta_2, \rho)$
mlogit	$\beta_1, \beta_2, \dots, \beta_k$	$\mathbf{x}$	$e^{-x\beta_1} / (\sum_i e^{-x\beta_i})$
nbreg	$\beta, \ln\alpha$	$\mathbf{x}$	$e^{x\beta}$

$\Phi()$  and  $\Phi_2()$  are cumulative distribution functions:  $\Phi()$  for the standard normal distribution and  $\Phi_2()$  for the standard bivariate normal distribution.

`margins` computes estimates of

$$p(\theta) = \frac{1}{M_{S_p}} \sum_{j=1}^M \delta_j(S_p) f(\mathbf{z}_j, \theta)$$

where  $\delta_j(S_p)$  identifies elements within the subpopulation  $S_p$  (for the prediction of interest),

$$\delta_j(S_p) = \begin{cases} 1, & j \in S_p \\ 0, & j \notin S_p \end{cases}$$

$M_{S_p}$  is the subpopulation size,

$$M_{S_p} = \sum_{j=1}^M \delta_j(S_p)$$

and  $M$  is the population size.

Let  $\widehat{\boldsymbol{\theta}}$  be the vector of parameter estimates. Then, `margins` estimates  $p(\boldsymbol{\theta})$  via

$$\widehat{p} = \frac{1}{w.} \sum_{j=1}^N \delta_j(S_p) w_j f(\mathbf{z}_j, \widehat{\boldsymbol{\theta}})$$

where

$$w. = \sum_{j=1}^N \delta_j(S_p) w_j$$

$\delta_j(S_p)$  indicates whether observation  $j$  is in subpopulation  $S_p$ ,  $w_j$  is the weight for the  $j$ th observation, and  $N$  is the sample size.

## Marginal effects

`margins` also computes marginal and partial effects. For the marginal effect of continuous covariate  $x$ , `margins` computes

$$\widehat{p} = \frac{1}{w.} \sum_{j=1}^N \delta_j(S_p) w_j h(\mathbf{z}_j, \widehat{\boldsymbol{\theta}})$$

where

$$h(\mathbf{z}, \boldsymbol{\theta}) = \frac{\partial f(\mathbf{z}, \boldsymbol{\theta})}{\partial x}$$

The marginal effect for level  $k$  of factor variable  $A$  is the simple contrast (also known as difference) comparing its margin with the margin at the base level.

$$h(\mathbf{z}, \boldsymbol{\theta}) = f(\mathbf{z}, \boldsymbol{\theta} | A = k) - f(\mathbf{z}, \boldsymbol{\theta} | A = \text{base})$$

Elasticities and semielasticities given by `eyex()` and `dyex()` are only available for continuous covariates. Elasticities are computed using

$$h(\mathbf{z}, \boldsymbol{\theta}) = \frac{\partial \ln\{f(\mathbf{z}, \boldsymbol{\theta})\}}{\partial \ln(x)}$$

and semielasticities, `dyex()`, using

$$h(\mathbf{z}, \boldsymbol{\theta}) = \frac{\partial f(\mathbf{z}, \boldsymbol{\theta})}{\partial \ln(x)}$$

Semielasticities of the form `eydx()` for continuous covariates are computed using

$$h(\mathbf{z}, \boldsymbol{\theta}) = \frac{\partial \ln\{f(\mathbf{z}, \boldsymbol{\theta})\}}{\partial x}$$

and for discrete covariates using

$$h(\mathbf{z}, \boldsymbol{\theta}) = \ln\{f(\mathbf{z}, \boldsymbol{\theta} | A = k)\} - \ln\{f(\mathbf{z}, \boldsymbol{\theta} | A = \text{base})\}$$

## Fixing covariates and balancing factors

`margins` controls the values in each  $\mathbf{z}$  vector through the `marginlist`, the `at()` option, the `atmeans` option, and the `asbalanced` and `emptycells()` options. Suppose  $\mathbf{z}$  is composed of the elements from the equation specification

$$\mathbf{A}\#\#\mathbf{B} \ x$$

where  $\mathbf{A}$  is a factor variable with  $a$  levels,  $\mathbf{B}$  is a factor variable with  $b$  levels, and  $x$  is a continuous covariate. To simplify the notation for this discussion, assume the levels of  $\mathbf{A}$  and  $\mathbf{B}$  start with 1 and are contiguous. Then

$$\mathbf{z} = (A_1, \dots, A_a, B_1, \dots, B_b, A_1B_1, A_1B_2, \dots, A_aB_b, x, 1)$$

where  $A_i$ ,  $B_j$ , and  $A_iB_j$  represent the indicator values for the factor variables  $\mathbf{A}$  and  $\mathbf{B}$  and the interaction  $\mathbf{A}\#\mathbf{B}$ .

When factor  $\mathbf{A}$  is in the `marginlist`, `margins` replaces  $\mathbf{A}$  with  $i$  and then computes the mean of the subsequent prediction, for  $i = 1, \dots, a$ . When the interaction term  $\mathbf{A}\#\mathbf{B}$  is in the `marginlist`, `margins` replaces  $\mathbf{A}$  with  $i$  and  $\mathbf{B}$  with  $j$ , and then computes the mean of the subsequent prediction, for all combinations of  $i = 1, \dots, a$  and  $j = 1, \dots, b$ .

The `at()` option sets model covariates to fixed values. For example, `at(x=15)` causes `margins` to temporarily set  $x$  to 15 for each observation in the dataset before computing any predictions. Similarly, `at((median) x)` causes `margins` to temporarily set  $x$  to the median of  $x$  using the current dataset.

When factor variable  $\mathbf{A}$  is specified as `asbalanced`, `margins` sets each  $A_i$  to  $1/a$ . Thus, each  $\mathbf{z}$  vector will look like

$$\mathbf{z} = (1/a, \dots, 1/a, B_1, \dots, B_b, B_1/a, B_2/a, \dots, B_b/a, x, 1)$$

If  $\mathbf{B}$  is also specified as `asbalanced`, then each  $B_j$  is set to  $1/b$ , and each  $\mathbf{z}$  vector will look like

$$\mathbf{z} = (1/a, \dots, 1/a, 1/b, \dots, 1/b, 1/ab, 1/ab, \dots, 1/ab, x, 1)$$

If `emptycells(reweight)` is also specified, then `margins` uses a different balancing weight for each element of  $\mathbf{z}$ , depending on how many empty cells the element is associated with. Let  $\delta_{ij}$  indicate that the  $ij$ th cell of  $\mathbf{A}\#\mathbf{B}$  was observed in the estimation sample.

$$\delta_{ij} = \begin{cases} 0, & \mathbf{A} = i \text{ and } \mathbf{B} = j \text{ was an empty cell} \\ 1, & \text{otherwise} \end{cases}$$

For the grand margin, the affected elements of  $\mathbf{z}$  and their corresponding balancing weights are

$$A_i = \frac{\sum_j \delta_{ij}}{\sum_k \sum_j \delta_{kj}}$$

$$B_j = \frac{\sum_i \delta_{ij}}{\sum_i \sum_k \delta_{ik}}$$

$$A_i B_j = \frac{\delta_{ij}}{\sum_k \sum_l \delta_{kl}}$$

For the  $j$ th margin of  $\mathbf{B}$ , the affected elements of  $\mathbf{z}$  and their corresponding balancing weights are

$$A_i = \frac{\delta_{ij}}{\sum_k \delta_{kj}}$$

$$B_l = \begin{cases} 1, & \text{if } l = j \text{ and not all } \delta_{ij} \text{ are zero} \\ 0, & \text{otherwise} \end{cases}$$

$$A_i B_l = \frac{\delta_{il}}{\sum_k \delta_{kl}} B_l$$

## Estimable functions

The fundamental idea behind estimable functions is clearly defined in the statistical literature for linear models; see [Searle and Gruber \(2017\)](#). Assume that we are working with the following linear model:

$$\mathbf{y} = \mathbf{X}\mathbf{b} + \mathbf{e}$$

where  $\mathbf{y}$  is an  $N \times 1$  vector of responses,  $\mathbf{X}$  is an  $N \times p$  matrix of covariate values,  $\mathbf{b}$  is a  $p \times 1$  vector of coefficients, and  $\mathbf{e}$  is a vector of random errors. Assuming a constant variance for the random errors, the normal equations for the least-squares estimator,  $\hat{\mathbf{b}}$ , are

$$\mathbf{X}'\mathbf{X}\hat{\mathbf{b}} = \mathbf{X}'\mathbf{y}$$

When  $\mathbf{X}$  is not of full column rank, we will need a generalized inverse (g-inverse) of  $\mathbf{X}'\mathbf{X}$  to solve for  $\hat{\mathbf{b}}$ . Let  $\mathbf{G}$  be a g-inverse of  $\mathbf{X}'\mathbf{X}$ .

[Searle and Gruber \(2017\)](#) defines a linear function of the parameters as *estimable* if it is identically equal to some linear function of the expected values of the  $\mathbf{y}$  vector. Let  $\mathbf{H} = \mathbf{G}\mathbf{X}'\mathbf{X}$ . Then this definition simplifies to the following rule:

$$\mathbf{z}\mathbf{b} \text{ is estimable if } \mathbf{z} = \mathbf{z}\mathbf{H}$$

`margins` generalizes this to nonlinear functions by assuming the prediction function  $f(\mathbf{z}, \boldsymbol{\theta})$  is a function of one or more of the linear predictions from the equations in the model that  $\boldsymbol{\theta}$  represents.

$$f(\mathbf{z}, \boldsymbol{\theta}) = h(\mathbf{z}_1\boldsymbol{\beta}_1, \mathbf{z}_2\boldsymbol{\beta}_2, \dots, \mathbf{z}_k\boldsymbol{\beta}_k)$$

$\mathbf{z}_i\boldsymbol{\beta}_i$  is considered estimable if  $\mathbf{z}_i = \mathbf{z}_i\mathbf{H}_i$ , where  $\mathbf{H}_i = \mathbf{G}_i\mathbf{X}'_i\mathbf{X}_i$ ,  $\mathbf{G}_i$  is a g-inverse for  $\mathbf{X}'_i\mathbf{X}_i$ , and  $\mathbf{X}_i$  is the matrix of covariates from the  $i$ th equation of the fitted model. `margins` considers  $p(\boldsymbol{\theta})$  to be estimable if every  $\mathbf{z}_i\boldsymbol{\beta}_i$  is estimable.

## Standard errors conditional on the covariates

By default, `margins` uses the delta method to estimate the variance of  $\widehat{p}$ .

$$\widehat{\text{Var}}(\widehat{p} | \mathbf{z}) = \mathbf{v}' \mathbf{V} \mathbf{v}$$

where  $\mathbf{V}$  is a variance estimate for  $\widehat{\boldsymbol{\theta}}$  and

$$\mathbf{v} = \left. \frac{\partial \widehat{p}}{\partial \boldsymbol{\theta}} \right|_{\boldsymbol{\theta} = \widehat{\boldsymbol{\theta}}}$$

This variance estimate is conditional on the  $\mathbf{z}$  vectors used to compute the marginalized predictions.

## Unconditional standard errors

`margins` with the `vce(unconditional)` option uses linearization to estimate the unconditional variance of  $\widehat{\boldsymbol{\theta}}$ . Linearization uses the variance estimator for the total of a score variable for  $\widehat{p}$  as an approximate estimator for  $\text{Var}(\widehat{p})$ ; see [SVY] **Variance estimation**. `margins` requires that the model was fit using some form of linearized variance estimator and that `predict`, `scores` computes the appropriate score values for the linearized variance estimator.

The score for  $\widehat{p}$  from the  $j$ th observation is given by

$$s_j = \frac{\partial \widehat{p}}{\partial w_j} = -\frac{\delta_j(S_p)}{w} \widehat{p} + \frac{\delta_j(S_p)}{w} f(\mathbf{z}_j, \widehat{\boldsymbol{\theta}}) + \frac{1}{w} \sum_{i=1}^N \delta_i(S_p) w_i \frac{\partial f(\mathbf{z}_i, \widehat{\boldsymbol{\theta}})}{\partial w_j}$$

The remaining partial derivative can be decomposed using the chain rule.

$$\frac{\partial f(\mathbf{z}_i, \widehat{\boldsymbol{\theta}})}{\partial w_j} = \left( \left. \frac{\partial f(\mathbf{z}_i, \boldsymbol{\theta})}{\partial \boldsymbol{\theta}} \right|_{\boldsymbol{\theta} = \widehat{\boldsymbol{\theta}}} \right) \left( \frac{\partial \widehat{\boldsymbol{\theta}}}{\partial w_j} \right)'$$

This is the inner product of two vectors, the second of which is not a function of the  $i$  index. Thus, the score is

$$s_j = -\frac{\delta_j(S_p)}{w} \widehat{p} + \frac{\delta_j(S_p)}{w} f(\mathbf{z}_j, \widehat{\boldsymbol{\theta}}) + \left( \left. \frac{\partial \widehat{p}}{\partial \boldsymbol{\theta}} \right|_{\boldsymbol{\theta} = \widehat{\boldsymbol{\theta}}} \right) \left( \frac{\partial \widehat{\boldsymbol{\theta}}}{\partial w_j} \right)'$$

If  $\widehat{\boldsymbol{\theta}}$  was derived from a system of equations (such as in linear regression or maximum likelihood estimation), then  $\widehat{\boldsymbol{\theta}}$  is the solution to

$$\mathbf{G}(\boldsymbol{\theta}) = \sum_{j=1}^N \delta_j(S_m) w_j \mathbf{g}(\boldsymbol{\theta}, \mathbf{y}_j, \mathbf{x}_j) = \mathbf{0}$$

where  $S_m$  identifies the subpopulation used to fit the model,  $\mathbf{g}(\cdot)$  is the model's gradient function, and  $\mathbf{y}_j$  and  $\mathbf{x}_j$  are the values of the dependent and independent variables for the  $j$ th observation. We can use linearization to derive a first-order approximation for  $\partial \widehat{\boldsymbol{\theta}} / \partial w_j$ .

$$\mathbf{G}(\hat{\boldsymbol{\theta}}) \approx \mathbf{G}(\boldsymbol{\theta}_0) + \left. \frac{\partial \mathbf{G}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} \right|_{\boldsymbol{\theta}=\boldsymbol{\theta}_0} (\hat{\boldsymbol{\theta}} - \boldsymbol{\theta}_0)$$

Let  $\mathbf{H}$  be the Hessian matrix

$$\mathbf{H} = \left. \frac{\partial \mathbf{G}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}} \right|_{\boldsymbol{\theta}=\boldsymbol{\theta}_0}$$

Then

$$\hat{\boldsymbol{\theta}} \approx \boldsymbol{\theta}_0 + (-\mathbf{H})^{-1} \mathbf{G}(\boldsymbol{\theta}_0)$$

and

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial w_j} \approx (-\mathbf{H})^{-1} \left. \frac{\partial \mathbf{G}(\boldsymbol{\theta})}{\partial w_j} \right|_{\boldsymbol{\theta}=\hat{\boldsymbol{\theta}}} = (-\mathbf{H})^{-1} \delta_j(S_m) \mathbf{g}(\hat{\boldsymbol{\theta}}, \mathbf{y}_j, \mathbf{x}_j)$$

The computed value of the score for  $\hat{p}$  for the  $j$ th observation is

$$s_j = \mathbf{v}' \mathbf{u}_j$$

where

$$\mathbf{v} = \begin{bmatrix} -\frac{\hat{p}}{w} \\ \frac{1}{w} \\ \frac{\partial \hat{p}}{\partial \boldsymbol{\theta}} (-\mathbf{H})^{-1} \end{bmatrix}$$

and

$$\mathbf{u}_j = \begin{bmatrix} \delta_j(S_p) \\ \delta_j(S_p) f(\mathbf{z}_j, \hat{\boldsymbol{\theta}}) \\ \delta_j(S_m) \mathbf{g}(\hat{\boldsymbol{\theta}}, \mathbf{y}_j, \mathbf{x}_j) \end{bmatrix}$$

Thus, the variance estimate for  $\hat{p}$  is

$$\widehat{\text{Var}}(\hat{p}) = \mathbf{v}' \widehat{\text{Var}}(\hat{\mathbf{U}}) \mathbf{v}$$

where

$$\hat{\mathbf{U}} = \sum_{j=1}^N w_j \mathbf{u}_j$$

`margins` uses the model-based variance estimates for  $(-\mathbf{H})^{-1}$  and the scores from `predict` for  $\mathbf{g}(\hat{\boldsymbol{\theta}}, \mathbf{y}_j, \mathbf{x}_j)$ .

## Postestimation commands

The following standard postestimation command is available after `margins`:

Command	Description
<code>marginsplot</code>	graph the results from <code>margins</code> —profile plots, interaction plots, etc.

For information on `marginsplot`, see [R] [marginsplot](#).

The following standard postestimation commands are available after `margins`, `post`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

## Remarks and examples

Continuing with the example from *Example 8: Margins of interactions* in [R] [margins](#), we use the dataset and refit the logistic model of outcome:

```
. use https://www.stata-press.com/data/r18/margex
(Artificial data for margins)
. logistic outcome sex##group age
(output omitted)
```

We then estimate the margins for males and females and post the margins as estimation results with a full VCE.

```
. margins sex, post
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	Delta-method		z	P> z	[95% conf. interval]	
	Margin	std. err.				
sex						
Male	.1600644	.0125653	12.74	0.000	.1354368	.184692
Female	.1966902	.0100043	19.66	0.000	.1770821	.2162983

We can now use `nlcom` (see [R] [nlcom](#)) to estimate a risk ratio of females to males using the average probabilities for females and males posted by `margins`:

```
. nlcom (risk_ratio: _b[1.sex] / _b[0.sex])
risk_ratio: _b[1.sex] / _b[0.sex]
```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
risk_ratio	1.228819	.1149538	10.69	0.000	1.003514	1.454124

We could similarly estimate the average risk difference between females and males:

```
. nlcom (risk_diff: _b[1.sex] - _b[0.sex])
risk_diff: _b[1.sex] - _b[0.sex]
```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
risk_diff	.0366258	.0160632	2.28	0.023	.0051425	.068109

## Description

`margins` with the `contrast` option or with contrast operators performs contrasts of margins. This extends the capabilities of `contrast` to any of the nonlinear responses, predictive margins, or other margins that can be estimated by `margins`.

## Quick start

Reference category contrasts of the predictive margins for `a` after `logit y a##b x1`  
`margins r.a`

Contrasts of predictive margins for `a` with the previous level  
`margins ar.a`

Test the equality of predictive margins for `a`  
`margins a, contrast`

Reference category contrasts of predictive margins for `x1 = 10` and `x1 = 20` with `x1 = 0`  
`margins, at(x1=(0 10 20)) contrast(atcontrast(r))`

Average partial effect of increasing `x1` by 100 for each observation after `probit y x1 x2`  
`margins, at((asobserved) _all) at(x1=generate(x1+100)) ///  
contrast(atcontrast(r))`

## Menu

Statistics > Postestimation

## Syntax

```
margins [marginlist] [if] [in] [weight] [, contrast margins_options]
```

```
margins [marginlist] [if] [in] [weight] [, contrast(suboptions) margins_options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without [contrast operators](#), and you may use any factor-variable syntax:

```
. margins sex##group, contrast
. margins sex##g.group, contrast
. margins sex@group, contrast
```

See the [operators \(op.\)](#) table in [\[R\] contrast](#) for the list of contrast operators. Contrast operators may also be specified on the variables in `margins`'s `over()` and `within()` options to perform contrasts across the levels of those variables.

<i>suboptions</i>	Description
Contrast	
<code>overall</code>	add a joint hypothesis test for all specified contrasts
<code>lincom</code>	treat user-defined contrasts as linear combinations
<code>predict(op[. _predict])</code>	apply the <i>op.</i> contrast operator to the groups defined by multiple <code>predict()</code> options
<code>atcontrast(op[. _at])</code>	apply the <i>op.</i> contrast operator to the groups defined by <code>at()</code>
<code>predictjoint</code>	test jointly across all groups defined by multiple <code>predict()</code> options
<code>atjoint</code>	test jointly across all groups defined by <code>at()</code>
<code>overjoint</code>	test jointly across all levels of the unoperated <code>over()</code> variables
<code>withinjoint</code>	test jointly across all levels of the unoperated <code>within()</code> variables
<code>marginswithin</code>	perform contrasts within the levels of the unoperated terms in <i>marginlist</i>
<code>cieffects</code>	show effects table with confidence intervals
<code>pveffects</code>	show effects table with <i>p</i> -values
<code>effects</code>	show effects table with confidence intervals and <i>p</i> -values
<code>nowald</code>	suppress table of Wald tests
<code>noatlevels</code>	report only the overall Wald test for terms that use the <code>within @</code> or nested <code> </code> operator
<code>nosvyadjust</code>	compute unadjusted Wald tests for survey results

`collect` is allowed; see [\[U\] 11.1.10 Prefix commands](#).

`fweights`, `awweights`, `iweights`, and `pweights` are allowed; see [\[U\] 11.1.6 weight](#).

## Suboptions

Contrast

`overall` specifies that a joint hypothesis test over all terms be performed.

- `lincom` specifies that user-defined contrasts be treated as linear combinations. The default is to require that all user-defined contrasts sum to zero. (Summing to zero is part of the definition of a contrast.)
- `predict(op[. _at])` specifies that the *op.* contrast operator be applied to the groups defined by multiple specifications of `margins`'s `predict()` option. The default behavior, by comparison, is to perform tests and contrasts within these groups.
- `atcontrast(op[. _at])` specifies that the *op.* contrast operator be applied to the groups defined by the `at()` option(s). The default behavior, by comparison, is to perform tests and contrasts within the groups defined by the `at()` option(s).
- See [example 6](#) in *Remarks and examples*.
- `predictjoint` specifies that joint tests be performed across all groups defined by multiple specifications of `margins`'s `predict()` option. The default behavior, by comparison, is to perform contrasts and tests within each group.
- `atjoint` specifies that joint tests be performed across all groups defined by the `at()` option. The default behavior, by comparison, is to perform contrasts and tests within each group.
- See [example 5](#) in *Remarks and examples*.
- `overjoint` specifies how unoperated variables in the `over()` option are treated.
- Each variable in the `over()` option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.
- `overjoint` specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.
- See [example 3](#) in *Remarks and examples*.
- `withinjoint` specifies how unoperated variables in the `within()` option are treated.
- Each variable in the `within()` option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.
- `withinjoint` specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.
- `marginswithin` specifies how unoperated variables in *marginlist* are treated.
- Each variable in *marginlist* may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.
- `marginswithin` specifies that contrasts and tests be performed within each combination of levels of the unoperated variables. The default behavior, by comparison, is to perform joint tests across all levels of the unoperated variables.
- See [example 4](#) in *Remarks and examples*.
- `cieffects` specifies that a table containing a confidence interval for each individual contrast be reported.
- `pveffects` specifies that a table containing a *p*-value for each individual contrast be reported.
- `effects` specifies that a single table containing a confidence interval and *p*-value for each individual contrast be reported.
- `nowald` suppresses the table of Wald tests.

`noatlevels` indicates that only the overall Wald test be reported for each term containing within or nested (`@` or `|`) operators.

`nosvyadjust` is for use with `svy` estimation commands. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is to say the test is carried out as  $W/k \sim F(k, d)$  rather than as  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ , where  $k$  is the dimension of the test and  $d$  is the total number of sampled PSUs minus the total number of strata.

## Remarks and examples

Remarks are presented under the following headings:

- [Contrasts of margins](#)
- [Contrasts and the `over\(\)` option](#)
- [The `overjoint` suboption](#)
- [The `marginswithin` suboption](#)
- [Contrasts and the `at\(\)` option](#)
- [Estimating treatment effects with margins](#)
- [Conclusion](#)

## Contrasts of margins

### ► Example 1

Estimating contrasts of margins is as easy as adding a contrast operator to the variable name. Let's review [Example 2: A simple case after logistic](#) of [R] [margins](#). Variable `sex` is coded 0 for males and 1 for females.

```
. use https://www.stata-press.com/data/r18/margex
(Artificial data for margins)
. logistic outcome i.sex i.group
(output omitted)
. margins sex
Predictive margins                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	Delta-method				
	Margin	std. err.	z	P> z	[95% conf. interval]
sex					
Male	.1286796	.0111424	11.55	0.000	.106841 .1505182
Female	.1905087	.0089719	21.23	0.000	.1729241 .2080933

The first margin, 0.13, is the average probability of a positive outcome, treating everyone as if they were male. The second margin, 0.19, is the average probability of a positive outcome, treating everyone as if they were female. We can compare females with males by rerunning `margins` and adding a contrast operator:

```
. margins r.sex
Contrasts of predictive margins          Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	df	chi2	P>chi2	
sex	1	16.61	0.0000	

	Contrast	Delta-method std. err.	[95% conf. interval]	
sex (Female vs Male)	.0618291	.0151719	.0320927	.0915656

The `r.` prefix for `sex` is the reference-category contrast operator—see [\[R\] contrast](#). (The default reference category is zero, the lowest value of `sex`.) Contrast operators in a *marginlist* work just as they do in the *termlist* of a `contrast` command.

The contrast estimate of 0.06 says that unconditional on group, females on average are about 6% more likely than males to have a positive outcome. The  $\chi^2$  statistic of 16.61 shows that the contrast is significantly different from zero.

You may be surprised that we did not need to include the `contrast` option to estimate our contrast. If we had included the option, our output would not have changed:

```
. margins r.sex, contrast
Contrasts of predictive margins          Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	df	chi2	P>chi2	
sex	1	16.61	0.0000	

	Contrast	Delta-method std. err.	[95% conf. interval]	
sex (Female vs Male)	.0618291	.0151719	.0320927	.0915656

The `contrast` option is useful mostly for its suboptions, which control the output and how contrasts are estimated in more complicated situations. But `contrast` may be specified on its own (without contrast operators or suboptions) if we do not need estimates or confidence intervals:

```
. margins sex group, contrast
Contrasts of predictive margins          Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	df	chi2	P>chi2	
sex	1	16.61	0.0000	
group	2	225.76	0.0000	

Each  $\chi^2$  statistic is a joint test of constituent contrasts. The test for group has two degrees of freedom because group has three levels.

◀

## Contrasts and the over() option

### ▷ Example 2

It is common to estimate margins at combinations of factor levels, and `margins, contrast` includes several suboptions for contrasting such margins. Let's fit a model with two categorical predictors and their interaction:

```
. logistic outcome agegroup##group
Logistic regression                               Number of obs = 3,000
                                                LR chi2(8)      = 520.64
                                                Prob > chi2    = 0.0000
Log likelihood = -1105.7504                    Pseudo R2     = 0.1906
```

outcome	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
agegroup						
30-39	3.54191	2.226951	2.01	0.044	1.032882	12.14576
40+	16.23351	9.611879	4.71	0.000	5.086452	51.80955

3	.2146739	.1772903	-1.86	0.062	.042541	1.083306
agegroup#group						
30-39#2	.4426927	.3358505	-1.07	0.283	.1000772	1.958257
30-39#3	1.16088	1.103521	0.16	0.875	.1801538	7.480508
40+#2	.440672	.3049393	-1.18	0.236	.1135259	1.71055
40+#3	.4407892	.4034666	-0.89	0.371	.0732998	2.650693
_cons	.0379747	.0223371	-5.56	0.000	.0119897	.1202762

Note: `_cons` estimates baseline odds.

Each of `agegroup` and `group` has three levels. To compare each age group with the reference category on the probability scale, we can again use `margins` with the `r. contrast` operator.

```
. margins r.agegroup
Contrasts of predictive margins          Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
```

	df	chi2	P>chi2
agegroup			
(30-39 vs 20-29)	1	10.04	0.0015
(40+ vs 20-29)	1	224.44	0.0000
Joint	2	238.21	0.0000

	Delta-method		
	Contrast	std. err.	[95% conf. interval]
agegroup			
(30-39 vs 20-29)	.044498	.0140448	.0169706 .0720253
(40+ vs 20-29)	.2059281	.0137455	.1789874 .2328688

Our model includes an interaction, though, so it would be nice to estimate the contrasts separately for each value of group. We need the `over()` option:

```
. margins r.agegroup, over(group)
Contrasts of predictive margins          Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over:      group
```

	df	chi2	P>chi2
agegroup@group			
(30-39 vs 20-29) 1	1	6.94	0.0084
(30-39 vs 20-29) 2	1	1.18	0.2783
(30-39 vs 20-29) 3	1	3.10	0.0783
(40+ vs 20-29) 1	1	173.42	0.0000
(40+ vs 20-29) 2	1	57.77	0.0000
(40+ vs 20-29) 3	1	5.12	0.0236
Joint	6	266.84	0.0000

	Delta-method		
	Contrast	std. err.	[95% conf. interval]
agegroup@group			
(30-39 vs 20-29) 1	.0819713	.0311208	.0209757 .142967
(30-39 vs 20-29) 2	.0166206	.0153309	-.0134275 .0466686
(30-39 vs 20-29) 3	.0243462	.0138291	-.0027584 .0514507
(40+ vs 20-29) 1	.3447797	.0261811	.2934658 .3960937
(40+ vs 20-29) 2	.1540882	.0202722	.1143554 .193821
(40+ vs 20-29) 3	.0470319	.0207774	.006309 .0877548

The effect of `agegroup` appears to be greatest for the first level of `group`.

Including a variable in the `over()` option is not equivalent to including the variable in the main *marginlist*. The variables in the *marginlist* are manipulated in the analysis, so that we can measure, for example, the effect of being in age group 3 and not age group 1. (The manipulation could be mimicked by running `replace` and then `predict`, but the manipulations actually performed by `margins` do not

change the data in memory.) The variables in the `over()` option are not so manipulated—the values of the `over()` variables are left as they were observed, and the *marginlist* variables are manipulated separately for each observed `over()` group.

◀

## The overjoint suboption

### ▷ Example 3

Each variable in an `over()` option may be specified with or without contrast operators. Our option `over(group)` did not include a contrast operator, so margins estimated the contrasts separately for each level of `group`. If we had instead specified `over(r.group)`, we would have received differences of the contrasts:

```
. margins r.agegroup, over(r.group)
Contrasts of predictive margins                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over:      group
```

	df	chi2	P>chi2
group#agegroup			
(2 vs 1) (30-39 vs 20-29)	1	3.55	0.0596
(2 vs 1) (40+ vs 20-29)	1	33.17	0.0000
(3 vs 1) (30-39 vs 20-29)	1	2.86	0.0906
(3 vs 1) (40+ vs 20-29)	1	79.36	0.0000
Joint	4	83.88	0.0000

	Delta-method		
	Contrast	std. err.	[95% conf. interval]
group#agegroup			
(2 vs 1) (30-39 vs 20-29)	-.0653508	.0346921	-.133346 .0026445
(2 vs 1) (40+ vs 20-29)	-.1906915	.0331121	-.25559 -.1257931
(3 vs 1) (30-39 vs 20-29)	-.0576252	.0340551	-.1243719 .0091216
(3 vs 1) (40+ vs 20-29)	-.2977479	.0334237	-.3632572 -.2322386

The contrasts are double differences: the estimate of  $-0.19$ , for example, says that the difference in the probability of success between age group 3 and age group 1 is smaller in group 2 than in group 1. We can jointly test pairs of the double differences with the `overjoint` suboption:

```
. margins r.agegroup, over(group) contrast(overjoint)
Contrasts of predictive margins                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over:      group
```

	df	chi2	P>chi2
group#agegroup			
(joint) (30-39 vs 20-29)	2	3.62	0.1641
(joint) (40+ vs 20-29)	2	79.45	0.0000
Joint	4	83.88	0.0000

The `contrast(overjoint)` option overrides the default behavior of `over()` and requests joint tests over the levels of the unoperated variable `group`. The  $\chi^2$  statistic of 3.62 tests that the first and third contrasts from the previous table are jointly zero. The  $\chi^2$  statistic of 79.45 jointly tests the other pair of contrasts.

## The marginswithin suboption

### Example 4

Another suboption that may usefully be combined with `over()` is `marginswithin`. `marginswithin` requests that contrasts be performed within the levels of unoperated variables in the main *marginlist*, instead of performing them jointly across the levels. `marginswithin` affects only unoperated variables because contrast operators take precedence over suboptions.

Let's first look at the default behavior, which occurs when `marginswithin` is not specified:

```
. margins agegroup, over(r.group) contrast(effects)
Contrasts of predictive margins          Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over:      group
```

	df	chi2	P>chi2
group#agegroup			
(2 vs 1) (joint)	2	33.94	0.0000
(3 vs 1) (joint)	2	83.38	0.0000
Joint	4	83.88	0.0000

	Delta-method				
	Contrast	std. err.	z	P> z	[95% conf. interval]
group# agegroup (2 vs 1) (30-39 vs base)	-.0653508	.0346921	-1.88	0.060	-.133346 .0026445
(2 vs 1) (40+ vs base)	-.1906915	.0331121	-5.76	0.000	-.25559 -.1257931
(3 vs 1) (30-39 vs base)	-.0576252	.0340551	-1.69	0.091	-.1243719 .0091216
(3 vs 1) (40+ vs base)	-.2977479	.0334237	-8.91	0.000	-.3632572 -.2322386

Here `agegroup` in the main *marginlist* is an unoperated variable, so `margins` by default performs joint tests across the levels of `agegroup`: the  $\chi^2$  statistic of 33.94, for example, jointly tests whether the first two contrast estimates in the lower table differ significantly from zero.

When we specify `marginswithin`, the contrasts will instead be performed within the levels of `agegroup`:

```
. margins agegroup, over(r.group) contrast(marginswithin effects)
Contrasts of predictive margins                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
Over:      group
```

	df	chi2	P>chi2
group@agegroup			
(2 vs 1) 20-29	1	0.06	0.7991
(2 vs 1) 30-39	1	7.55	0.0060
(2 vs 1) 40+	1	68.39	0.0000
(3 vs 1) 20-29	1	1.80	0.1798
(3 vs 1) 30-39	1	10.47	0.0012
(3 vs 1) 40+	1	159.89	0.0000
Joint	6	186.87	0.0000

	Delta-method				[95% conf. interval]	
	Contrast	std. err.	z	P> z		
group@agegroup						
(2 vs 1) 20-29	-.0058686	.0230533	-0.25	0.799	-.0510523	.039315
(2 vs 1) 30-39	-.0712194	.0259246	-2.75	0.006	-.1220308	-.0204081
(2 vs 1) 40+	-.1965602	.0237688	-8.27	0.000	-.2431461	-.1499742
(3 vs 1) 20-29	-.0284991	.0212476	-1.34	0.180	-.0701436	.0131454
(3 vs 1) 30-39	-.0861243	.0266137	-3.24	0.001	-.1382862	-.0339624
(3 vs 1) 40+	-.326247	.0258009	-12.64	0.000	-.3768159	-.2756781

The joint tests in the top table have been replaced by one-degree-of-freedom tests, one for each combination of the two reference comparisons and three levels of `agegroup`. The reference-category contrasts for `group` have been performed within levels of `agegroup`.

◀

## Contrasts and the `at()` option

### ▷ Example 5

The `at()` option of `margins` is used to set predictors to particular values. When `at()` is used, contrasts are by default performed within each `at()` level:

```
. margins r.agegroup, at(group=(1/3))
```

```
Contrasts of adjusted predictions                                Number of obs = 3,000
Expression: Pr(outcome), predict()
1._at: group = 1
2._at: group = 2
3._at: group = 3
```

	df	chi2	P>chi2
agegroup@_at			
(30-39 vs 20-29) 1	1	6.94	0.0084
(30-39 vs 20-29) 2	1	1.18	0.2783
(30-39 vs 20-29) 3	1	3.10	0.0783
(40+ vs 20-29) 1	1	173.42	0.0000
(40+ vs 20-29) 2	1	57.77	0.0000
(40+ vs 20-29) 3	1	5.12	0.0236
Joint	6	266.84	0.0000

	Delta-method		
	Contrast	std. err.	[95% conf. interval]
agegroup@_at			
(30-39 vs 20-29) 1	.0819713	.0311208	.0209757 .142967
(30-39 vs 20-29) 2	.0166206	.0153309	-.0134275 .0466686
(30-39 vs 20-29) 3	.0243462	.0138291	-.0027584 .0514507
(40+ vs 20-29) 1	.3447797	.0261811	.2934658 .3960937
(40+ vs 20-29) 2	.1540882	.0202722	.1143554 .193821
(40+ vs 20-29) 3	.0470319	.0207774	.006309 .0877548

Our option `at(group=(1/3))` manipulates the values of `group` and is therefore not equivalent to `over(group)`. We see that the reference-category contrasts for `agegroup` have been performed within each `at()` level. For a similar example that uses the `._at` operator instead of the `at()` option, see [Contrasts of at\(\) groups—discrete effects](#) in [R] [marginsplot](#).

The default within behavior of `at()` may be changed to joint behavior with the `atjoint` suboption:

```
. margins r.agegroup, at(group=(1/3)) contrast(atjoint)
```

```
Contrasts of adjusted predictions                                Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
1._at: group = 1
2._at: group = 2
3._at: group = 3
```

	df	chi2	P>chi2
_at#agegroup			
(joint) (30-39 vs 20-29)	2	3.62	0.1641
(joint) (40+ vs 20-29)	2	79.45	0.0000
Joint	4	83.88	0.0000

Now, the tests are performed jointly over the levels of `group`, the `at()` variable. The `atjoint` suboption is the analogue for `at()` of the `overjoint` suboption from [example 3](#).

## ► Example 6

What if we would like to apply a contrast operator, like `r.`, to the `at()` levels? It is not possible to specify the operator inside the `at()` option. Instead, we need a new suboption, `atcontrast()`:

```
. margins r.agegroup, at(group=(1/3)) contrast(atcontrast(r))
Contrasts of adjusted predictions          Number of obs = 3,000
Model VCE: OIM
Expression: Pr(outcome), predict()
1._at: group = 1
2._at: group = 2
3._at: group = 3
```

	df	chi2	P>chi2
_at#agegroup			
(2 vs 1) (30-39 vs 20-29)	1	3.55	0.0596
(2 vs 1) (40+ vs 20-29)	1	33.17	0.0000
(3 vs 1) (30-39 vs 20-29)	1	2.86	0.0906
(3 vs 1) (40+ vs 20-29)	1	79.36	0.0000
Joint	4	83.88	0.0000

	Delta-method		
	Contrast	std. err.	[95% conf. interval]
_at#agegroup			
(2 vs 1) (30-39 vs 20-29)	-.0653508	.0346921	-.133346 .0026445
(2 vs 1) (40+ vs 20-29)	-.1906915	.0331121	-.25559 -.1257931
(3 vs 1) (30-39 vs 20-29)	-.0576252	.0340551	-.1243719 .0091216
(3 vs 1) (40+ vs 20-29)	-.2977479	.0334237	-.3632572 -.2322386

When we specify `contrast(atcontrast(r))`, `margins` will apply the `r.` reference-category operator to the levels of `group`, the variable specified inside `at()`. The default reference category is 1, the lowest level of `group`.

## Estimating treatment effects with margins

`margins` with the `contrast` option can also be used to estimate treatment effects in certain cases. A treatment effect represents the change in an outcome variable that is attributable to a particular event, controlling for all other factors that could affect the outcome. For example, we might want to know how a person's wage changes as a result of being in a union. Here the outcome variable is the person's wage, and the "event" is membership in a union. The treatment effect measures the difference in a person's wage as a result of being or not being in a union once we control for the person's educational background, level of experience, industry, and other factors.

In fact, Stata has an entire manual dedicated to estimators designed specifically for estimating treatment effects; see the [Stata Causal Inference and Treatment-Effects Estimation Reference Manual](#). Here we show how `margins` can be used to estimate treatment effects using the regression-adjustment estimator when the conditional independence assumption is met; see [\[CAUSAL\] teffects intro](#). Regression adjustment simply means that we are going to use a regression model to predict the outcome variable, controlling for treatment status and other characteristics. The conditional independence assumption implies that we have enough variables in our dataset so that once we control for them in our regression model, the outcomes one would obtain with and without treatment are independent of how treatment status is determined.

► Example 7: Regression adjustment with a binary treatment variable

nlsw88.dta contains women's wages (wage) in dollars per hour, a binary variable indicating their union status (union), years of experience (ttl\_exp), and a variable, grade, indicating the number of years of schooling completed. We want to know how being in a union (the treatment) affects women's wages. Traditionally, a wage equation of the form

$$\ln \text{wage}_i = \beta_0 + \beta_1 \text{union}_i + \beta_2 \text{grade}_i + \beta_3 \text{ttl\_exp} + \beta_4 \text{ttl\_exp}^2 + \epsilon_i$$

would be fit. However, there are two shortcomings that we will improve upon. First, to avoid the problem of predicting the level of a log-transformed dependent variable, we will use poisson with the vce(robust) option to fit an exponential regression model; see Wooldridge (2010, sec. 18.2) for background on this approach. Second, the previous equation implies that factors other than union status have the same impact on wages for both union and nonunion workers. Regression-adjustment estimators allow all the variables to have different impacts depending on the level of the treatment variable, and we can accomplish that here using factor-variable notation. In Stata, we fit our model by typing

```
. use https://www.stata-press.com/data/r18/nlsw88
(NLSW, 1988 extract)

. poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
note: noncount dependent variable encountered; results correspond to an
      exponential-mean model rather than a poisson model.

Iteration 0:  Log pseudolikelihood = -4770.7957
Iteration 1:  Log pseudolikelihood = -4770.7693
Iteration 2:  Log pseudolikelihood = -4770.7693

Poisson regression                                Number of obs =   1,876
                                                    Wald chi2(7)    = 1047.11
                                                    Prob > chi2     = 0.0000
                                                    Pseudo R2      = 0.1195

Log pseudolikelihood = -4770.7693
```

wage	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
union						
Union	.8638376	.168233	5.13	0.000	.534107	1.193568
grade	.0895252	.0056874	15.74	0.000	.0783782	.1006722
ttl_exp	.0805737	.0114534	7.03	0.000	.0581255	.103022
c.ttl_exp#						
c.ttl_exp	-.0015502	.0004612	-3.36	0.001	-.0024541	-.0006463
union#						
c.grade						
Union	-.0310298	.0088259	-3.52	0.000	-.0483282	-.0137314
union#						
c.ttl_exp						
Union	-.0404226	.0230113	-1.76	0.079	-.085524	.0046788
union#						
c.ttl_exp#						
c.ttl_exp						
Union	.0011808	.0008428	1.40	0.161	-.0004711	.0028327
_cons	.017488	.0893602	0.20	0.845	-.1576547	.1926308

To see how union status affects wages, we can use margins:

```
. margins r.union, vce(unconditional)
Contrasts of predictive margins                Number of obs = 1,876
Expression: Predicted number of events, predict()
```

	df	chi2	P>chi2
union	1	26.22	0.0000

	Unconditional			
	Contrast	std. err.	[95% conf. interval]	
union (Union vs Nonunion)	1.004119	.1960944	.6197815	1.388457

The estimated contrast 1.004 indicates that on average, belonging to a union causes a woman's wage to be slightly more than a dollar higher than if she were not in the union. This estimated contrast is called the average treatment effect (ATE). Conceptually, we predicted the wage of each woman in the estimation sample assuming she was in a union and obtained the sample mean. We then predicted each woman's wage assuming she was not in a union and obtained that sample mean. The difference between these two sample means represents the ATE.

We obtain essentially the same results by using `teffects ra`:

```
. teffects ra (wage c.grade c.ttl_exp##c.ttl_exp, poisson) (union)
Iteration 0: EE criterion = 2.611e-13
Iteration 1: EE criterion = 1.112e-26
Treatment-effects estimation                Number of obs    =    1,876
Estimator      : regression adjustment
Outcome model  : Poisson
Treatment model: none
```

wage	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
ATE union (Union vs Nonunion)	1.004119	.1960421	5.12	0.000	.619884	1.388355
POmean union Nonunion	7.346493	.1096182	67.02	0.000	7.131645	7.561341

The point estimates of the ATE are identical to those we obtained using `margins`, though the standard errors differ slightly from those reported by `margins`. The standard errors from the two estimators are, however, asymptotically equivalent, meaning they would coincide with a sufficiently large dataset. The last statistic in this output table indicates the untreated potential-outcome mean (untreated POM), which is the mean predicted wage assuming each woman did not belong to a union.

If we specify the `pomeans` option with `teffects ra`, we can obtain both the treated and the untreated POMs, which represent the predicted mean wages assuming all women were or were not in the union:

```
. teffects ra (wage c.grade c.ttl_exp##c.ttl_exp, poisson) (union), pomeans
Iteration 0: EE criterion = 2.611e-13
Iteration 1: EE criterion = 1.112e-26
Treatment-effects estimation      Number of obs      =      1,876
Estimator      : regression adjustment
Outcome model  : Poisson
Treatment model: none
```

wage	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
P0means						
union						
Nonunion	7.346493	.1096182	67.02	0.000	7.131645	7.561341
Union	8.350612	.1757346	47.52	0.000	8.006179	8.695046

Notice that the difference between these two POMs equals 1.004119, which is the ATE we obtained earlier.

In some applications, the average treatment effect of the treated (ATET) is more germane than the ATE. For example, if the untreated subjects in the sample could not possibly receive treatment (perhaps because a medical condition precludes their taking an experimental drug), then considering the counterfactual outcome had those subjects taken the drug may not be relevant. In these cases, the ATET is a better statistic because it measures the effect of the treatment only for those subjects who actually did receive treatment. Like the ATE, the ATET involves computing predicted outcomes for each treatment level, obtaining the sample means, and computing the difference between those two means. Unlike the ATE, however, we use only observations corresponding to treated subjects.

### ► Example 8: Regression adjustment with a binary treatment variable (continued)

Here we calculate the ATET of union membership, first using margins. Because `teffects ra` overwrote our estimation results, we first quietly refit our `poisson` model. We then call `margins` to obtain the ATET:

```
. quietly poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
. margins r.union, subpop(union) vce(unconditional)
Contrasts of predictive margins      Number of obs      =      1,876
                                      Subpop. no. obs =      460

Expression: Predicted number of events, predict()
```

	df	chi2	P>chi2
union	1	18.86	0.0000

	Unconditional Contrast	std. err.	[95% conf. interval]	
union (Union vs Nonunion)	.901419	.2075863	.4945574	1.308281

The key here was specifying the `subpop(union)` option to restrict `margin`'s computations to those women who are union members. The results indicate that being in the union causes the union members' wages to be about 90 cents higher than they would otherwise be.

To replicate these results using `teffects ra`, we include the `atet` option to obtain ATETs:

```
. teffects ra (wage c.grade c.ttl_exp##c.ttl_exp, poisson) (union), atet
Iteration 0: EE criterion = 2.611e-13
Iteration 1: EE criterion = 9.347e-27
Treatment-effects estimation      Number of obs      =      1,876
Estimator      : regression adjustment
Outcome model  : Poisson
Treatment model: none
```

wage		Robust		z	P> z	[95% conf. interval]	
	Coefficient	std. err.					
ATET							
	union						
	(Union						
	vs						
	Nonunion)	.901419	.2075309	4.34	0.000	.4946658	1.308172
POmean							
	union						
	Nonunion	7.776417	.162121	47.97	0.000	7.458665	8.094168

We obtain the same point estimate of the effect of union status as with `margins`. As before, the standard errors differ slightly between the two estimators, but they are asymptotically equivalent. The output also indicates that among the women who are in a union, their average wage would be \$7.78 if they were not in a union.

◀

## □ Technical note

One advantage of the ATET over the ATE is that the ATET can be consistently estimated with slightly weaker assumptions than are required to consistently estimate the ATE. See [Comparing the ATE and ATET](#) in *Remarks and examples of [CAUSAL] teffects intro advanced*.

□

Both `margins` and `teffects` can estimate treatment effects using regression adjustment, so which should you use? In addition to regression adjustment, the `teffects` command implements other estimators of treatment effects; some of these estimators possess desirable robustness properties that we cannot replicate using `margins`. Moreover, all the `teffects` estimators use a common syntax and automatically present the estimated treatment effects, whereas we must first fit our own regression model and then call `margins` to obtain the treatment effects.

On the other hand, particularly with the `at()` option, `margins` gives us more flexibility in specifying our scenarios. The `teffects` commands allow us to measure the effect of a single binary or multinomial treatment, but we can have `margins` compute the effects of arbitrary interventions, as we illustrate in the next example.

## ▷ Example 9: Interventions involving multiple variables

Suppose we want to see how women's wages would be affected if we could increase each woman's education level by one year. That is, we want to measure the treatment effect of an additional year of schooling. We assume that if a woman attains another year of schooling, she cannot simultaneously work. Thus, an additional year of education implies her total work experience must decrease by a year. The flexible `at()` option of `margins` allows us to manipulate both variables at once:

```

. quietly poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
. margins, at((asobserved) _all)
> at(grade=generate(grade+1) ttl_exp=generate(ttl_exp-1))
> contrast(atcontrast(r._at))

Contrasts of predictive margins                                Number of obs = 1,876
Model VCE: Robust

Expression: Predicted number of events, predict()
1._at: (asobserved)
2._at: grade = grade+1
      ttl_exp = ttl_exp-1

```

	df	chi2	P>chi2
_at	1	58.53	0.0000

	Delta-method		
	Contrast	std. err.	[95% conf. interval]
_at (2 vs 1)	.3390392	.0443161	.2521813 .4258971

The first `at()` option instructs `margins` to obtain predicted wages for all women in the sample using their existing values for `grade` and `ttl_exp` and to record the mean of those predictions. The second `at()` option instructs `margins` to obtain the mean predicted wage under the counterfactual scenario where each woman's education level is increased by one year and total work experience is simultaneously decreased by one year. The `contrast()` option instructs `margins` to compute the difference between the two means. The output indicates that increasing education by one year, which will necessarily decrease work experience by the same amount, will cause the average wage to increase by about 34 cents per hour, a statistically significant amount.

◀

## Conclusion

`margins, contrast` is a powerful command, and its abundance of suboptions may seem daunting. The suboptions are in the service of only three goals, however. There are three things that `margins, contrast` can do with a factor variable or a set of `at()` definitions:

1. Perform contrasts across the levels of the factor or set (as in [example 1](#)).
2. Perform a joint test across the levels of the factor or set (as in [example 5](#)).
3. Perform other tests and contrasts within each level of the factor or set (as in [example 4](#)).

The default behavior for variables specified inside `at()`, `over()`, and `within()` is to perform contrasts within groups; the default behavior for variables in the *marginlist* is to perform joint tests across groups.

◀

## Stored results

`margins, contrast` stores the following additional results in `r()`:

### Scalars

`r(k_terms)`                      number of terms participating in contrasts

### Macros

`r(cmd)`                              `contrast`

`r(cmd2)`                             `margins`

`r(overall)`                         `overall` or empty

### Matrices

`r(L)`                                 matrix of contrasts applied to the margins

`r(chi2)`                             vector of  $\chi^2$  statistics

`r(p)`                                 vector of  $p$ -values corresponding to `r(chi2)`

`r(df)`                                vector of degrees of freedom corresponding to `r(p)`

`margins, contrast` with the `post` option also stores the following additional results in `e()`:

### Scalars

`e(k_terms)`                         number of terms participating in contrasts

### Macros

`e(cmd)`                              `contrast`

`e(cmd2)`                             `margins`

`e(overall)`                         `overall` or empty

### Matrices

`e(L)`                                 matrix of contrasts applied to the margins

`e(chi2)`                             vector of  $\chi^2$  statistics

`e(p)`                                 vector of  $p$ -values corresponding to `e(chi2)`

`e(df)`                                vector of degrees of freedom corresponding to `e(p)`

## Description

`margins` with the `pwcompare` option performs pairwise comparisons of margins. `margins, pwcompare` extends the capabilities of `pwcompare` to any of the nonlinear responses, predictive margins, or other margins that can be estimated by `margins`.

## Quick start

All pairwise comparisons of the predictive margins for `a` after `logit y a##b x1`  
`margins a, pwcompare`

Same as above, but report both tests and confidence intervals for differences in predictive margins  
`margins a, pwcompare(effects)`

Same as above, but adjust  $p$ -values and confidence intervals for multiple comparisons using Bonferroni's method  
`margins a, pwcompare(effects) mcompare(bonferroni)`

Report predictive margins for the levels of `a`, and group those that are not significantly different  
`margins a, pwcompare(groups)`

All pairwise comparisons of the predictive margins for combinations of levels of `a` and `b`  
`margins a#b, pwcompare`

## Menu

Statistics > Postestimation

## Syntax

```
margins [marginlist] [if] [in] [weight] [, pwcompare margins_options]
```

```
margins [marginlist] [if] [in] [weight] [, pwcompare(suboptions) margins_options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without the *i.* prefix, and you may use any factor-variable syntax:

- . margins *i.sex i.group i.sex#i.group*, pwcompare
- . margins *sex group sex#i.group*, pwcompare
- . margins *sex##group*, pwcompare

<i>suboptions</i>	Description
-------------------	-------------

Pairwise comparisons

<b>ci</b> effects	show effects table with confidence intervals; the default
<b>p</b> effects	show effects table with <i>p</i> -values
<b>e</b> ffects	show effects table with confidence intervals and <i>p</i> -values
<b>ci</b> margins	show table of margins and confidence intervals
<b>g</b> roups	show table of margins and group codes
<b>s</b> ort	sort the margins or contrasts in each term

collect is allowed; see [U] 11.1.10 Prefix commands.

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

## Suboptions

Pairwise comparisons

**ci**effects specifies that a table of the pairwise comparisons with their standard errors and confidence intervals be reported. This is the default.

**p**effects specifies that a table of the pairwise comparisons with their standard errors, test statistics, and *p*-values be reported.

**e**ffects specifies that a table of the pairwise comparisons with their standard errors, test statistics, *p*-values, and confidence intervals be reported.

**ci**margins specifies that a table of the margins with their standard errors and confidence intervals be reported.

**g**roups specifies that a table of the margins with their standard errors and group codes be reported. Margins with the same letter in the group code are not significantly different at the specified significance level.

**s**ort specifies that the reported tables be sorted on the margins or contrasts in each term.

## Remarks and examples

You should be familiar with the concepts and syntax of both `margins` and `pwcompare` before using the `pwcompare` option of `margins`. These remarks build on those in [R] [margins](#) and [R] [pwcompare](#).

`margins` can perform pairwise comparisons of any of the margins that it estimates.

We begin by fitting a logistic regression model using the NHANES II dataset, ignoring the complex survey nature of the data. Our dependent variable is `highbp`, an indicator for whether a person has high blood pressure. We fit an interacted model including two factor variables representing the region of the country as well as the continuous covariate `bmi`.

```
. use https://www.stata-press.com/data/r18/nhanes2
. logistic highbp region#c.bmi
  (output omitted)
```

By default, `margins` will compute the predictive margins of the probability of a positive outcome for each of the terms in `marginlist` after logistic regression. We will margin on `region` so that `margins` will estimate the average predicted probabilities of having high blood pressure conditional on being in each of the four regions and unconditional on BMI. We can specify the `pwcompare` option to obtain all possible pairwise comparisons of these predictive margins:

```
. margins region, pwcompare
Pairwise comparisons of predictive margins      Number of obs = 10,351
Model VCE: OIM
Expression: Pr(highbp), predict()
```

	Delta-method		Unadjusted	
	Contrast	std. err.	[95% conf. interval]	
region				
MW vs NE	-.0377194	.0133571	-.0638987	-.01154
S vs NE	-.0156843	.0133986	-.041945	.0105764
W vs NE	-.006873	.0136595	-.0336451	.019899
S vs MW	.0220351	.0124564	-.0023789	.0464492
W vs MW	.0308463	.0127366	.0058831	.0558096
W vs S	.0088112	.0127801	-.0162373	.0338598

This table gives each of the pairwise differences with confidence intervals. We can see that the confidence interval in the row labeled `MW vs NE` does not include 0. At the 5% level, the predictive margins for the first and second regions, the Northeast and the Midwest, are significantly different. The same is true of the second and fourth regions, the Midwest and the West. With many pairwise comparisons, output in this format can be difficult to sort through. We can organize it by adding the `group` suboption:

```
. margins region, pwcompare(group)
Pairwise comparisons of predictive margins      Number of obs = 10,351
Model VCE: OIM
Expression: Pr(highbp), predict()
```

	Delta-method Margin	Unadjusted std. err.	Unadjusted groups
region			
NE	.4388358	.010069	B
MW	.4011164	.0087764	A
S	.4231516	.0088395	AB
W	.4319628	.0092301	B

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

The group output includes the predictive margins for each region and letters denoting margins that are not significantly different from one another. In this case, the Northeast (NE), South (S), and West (W) regions have the letter B in the “Unadjusted Groups” column. The letter B indicates that the average predicted probability for the Northeast region is not significantly different from the average predicted probabilities for the South and West regions at the 5% significance level. The Midwest (MW) region does not share a letter with the Northeast region nor the West region, which indicates that the average predicted probability for the Midwest region is significantly different for each of the other two regions at our 5% level.

We can also include the `mcompare(bonferroni)` option to perform tests using Bonferroni’s method to account for making multiple comparisons.

```
. margins region, pwcompare(group) mcompare(bonferroni)
Pairwise comparisons of predictive margins      Number of obs = 10,351
Model VCE: OIM
Expression: Pr(highbp), predict()
```

	Number of comparisons
region	6

	Delta-method Margin	Bonferroni std. err.	Bonferroni groups
region			
NE	.4388358	.010069	B
MW	.4011164	.0087764	A
S	.4231516	.0088395	AB
W	.4319628	.0092301	AB

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

We now see the letter A on the row corresponding to the West region. At the 5% level and with Bonferroni’s adjustment, the predictive margins for the probability in the Midwest and West regions are not significantly different.

## Stored results

`margins`, `pwcompare` stores the following additional results in `r()`:

Scalars	
<code>r(k_terms)</code>	number of terms participating in pairwise comparisons
Macros	
<code>r(cmd)</code>	<code>pwcompare</code>
<code>r(cmd2)</code>	<code>margins</code>
<code>r(group#)</code>	group code for the #th margin in <code>r(b)</code>
<code>r(mcmethod_vs)</code>	<i>method</i> from <code>mcompare()</code>
<code>r(mctitle_vs)</code>	title for <i>method</i> from <code>mcompare()</code>
<code>r(mcadjustall_vs)</code>	<code>adjustall</code> or empty
Matrices	
<code>r(b)</code>	margin estimates
<code>r(V)</code>	variance–covariance matrix of the margin estimates
<code>r(b_vs)</code>	margin difference estimates
<code>r(V_vs)</code>	variance–covariance matrix of the margin difference estimates
<code>r(error_vs)</code>	margin difference estimability codes; 0 means estimable, 8 means not estimable
<code>r(table_vs)</code>	matrix containing the margin differences with their standard errors, test statistics, <i>p</i> -values, and confidence intervals
<code>r(L)</code>	matrix that produces the margin differences

`margins`, `pwcompare` with the `post` option also stores the following additional results in `e()`:

Scalars	
<code>e(k_terms)</code>	number of terms participating in pairwise comparisons
Macros	
<code>e(cmd)</code>	<code>pwcompare</code>
<code>e(cmd2)</code>	<code>margins</code>
Matrices	
<code>e(b)</code>	margin estimates
<code>e(V)</code>	variance–covariance matrix of the margin estimates
<code>e(b_vs)</code>	margin difference estimates
<code>e(V_vs)</code>	variance–covariance matrix of the margin difference estimates
<code>e(error_vs)</code>	margin difference estimability codes; 0 means estimable, 8 means not estimable
<code>e(L)</code>	matrix that produces the margin differences

<code>sidak [adjustall]</code>	Šidák's method; adjust across all terms
<code>scheffe</code>	Scheffé's method

## Options

### Main

`xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()` specify the variables from the preceding `margins` command whose group levels will be used for the graph's  $x$  axis, plots, `by()` subgraphs, and graphs.

`marginsplot` chooses default dimensions based on the `margins` command. In most cases, the first variable appearing in an `at()` option and evaluated over more than one value is used for the  $x$  axis. If no `at()` variable meets this condition, the first variable in the `marginlist` is usually used for the  $x$  axis and the remaining variables determine the plotted lines or markers. Pairwise comparisons and graphs of marginal effects (derivatives) have different defaults. In all cases, you may override the defaults and explicitly control which variables are used on each dimension of the graph by using these dimension options.

Each of these options supports [suboptions](#) that control the labeling of the dimension—axis labels for `xdimension()`, plot labels for `plotdimension()`, subgraph titles for `bydimension()`, and graph titles for `graphdimension()` titles.

For examples using the dimension options, see [Controlling the graph's dimensions](#).

`xdimension(dimlist [, dimopts])` specifies the variables for the  $x$  axis in *dimlist* and controls the content of those labels with *dimopts*.

`plotdimension(dimlist [, dimopts])` specifies in *dimlist* the variables whose group levels determine the plots and optionally specifies in *dimopts* the content of the plots' labels.

`bydimension(dimlist [, dimopts])` specifies in *dimlist* the variables whose group levels determine the `by()` subgraphs and optionally specifies in *dimopts* the content of the subgraphs' titles. For an example using `by()`, see [Three-way interactions](#).

`graphdimension(dimlist [, dimopts])` specifies in *dimlist* the variables whose group levels determine the graphs and optionally specifies in *dimopts* the content of the graphs' titles.

`horizontal` reverses the default  $x$  and  $y$  axes. By default, the  $y$  axis represents the estimates of the margins and the  $x$  axis represents one or more factors or continuous covariates. Specifying `horizontal` swaps the axes so that the  $x$  axis represents the estimates of the margins. This option can be useful if the labels on the factor or continuous covariates are long.

The `horizontal` option is discussed in [Horizontal is sometimes better](#).

`noci` removes plots of the pointwise confidence intervals. The default is to plot the confidence intervals.

`derivlabels` specifies that variable labels attached to marginal-effects variables be used in place of the variable names in titles and legends. Marginal-effects variables are the ones specified in `margins`'s option `dydx()`, `dyex()`, `eydx()`, or `eyex()`.

`name(name | stub [ , replace ])` specifies the name of the graph or graphs. If the `graphdimension()` option is specified, or if the default action is to produce multiple graphs, then the argument of `name()` is taken to be `stub` and graphs named `stub1`, `stub2`, ... are created.

The `replace` suboption causes existing graphs with the specified name or names to be replaced.

If `name()` is not specified, default names are used and the graphs may be replaced by subsequent `marginsplot` or other graphing commands.

### Labels

With the exception of `allxlabel`s, all of these options may be specified either directly as options or as *dimopts* within options `xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()`. When specified in one of the dimension options, only the labels for that dimension are affected. When specified outside the dimension options, all labels on all dimensions are affected. Specifications within the dimension options take precedence.

`allxlabel`s specifies that tick marks and labels be placed on the  $x$  axis for each value of the  $x$ -dimension variables. By default, if there are more than 25 ticks, default graph axis labeling rules are applied. Labeling may also be specified using the standard graph `twoway`  $x$ -axis label rules and options—`xlabel()`; see [G-3] [axis\\_label\\_options](#).

`noylabel`s specifies that value labels not be used to construct graph labels and titles for the group levels in the dimension. By default, if a variable in a dimension has value labels, those labels are used to construct labels and titles for axis ticks, plots, subgraphs, and graphs.

Graphs of contrasts and pairwise comparisons are an exception to this rule and are always labeled with values rather than value labels.

`allsimplelabels` and `nosimplelabels` control whether graphs' labels and titles include just the values of the variables or include variable names and equal signs. The default is to use just the value label for variables that have value labels and to use variable names and equal signs for variables that do not have value labels. An example of the former is “Female” and the latter is “country=2”.

Sometimes, value labels are universally descriptive, and sometimes they have meaning only when considered in relation to their variable. For example, “Male” and “Female” are typically universal, regardless of the variable from which they are taken. “High” and “Low” may not have meaning unless you know they are in relation to a specific measure, say, blood-pressure level. The `allsimplelabels` and `nosimplelabels` options let you override the default labeling.

`allsimplelabels` specifies that all titles and labels use just the value or value label of the variable.

`nosimplelabels` specifies that all titles and labels include `varname=` before the value or value label of the variable.

`separator(string)` and `noseparator` control the separator between label sections when more than one variable is used to specify a dimension. The default separator is a comma followed by a space, but no separator may be requested with `noseparator` or the default may be changed to any string with `separator()`.

For example, if `plotdimension(a b)` is specified, the plot labels in our graph legend might be “a=1, b=1”, “a=1, b=2”, .... Specifying `separator(:)` would create labels “a=1:b=1”, “a=1:b=2”, ....

## Plot

`plotopts(plot_options)` affects the rendition of all margin plots. The *plot\_options* can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] [marker\\_options](#), [G-3] [marker\\_label\\_options](#), and [G-3] [cline\\_options](#).

These settings may be overridden for specific plots by using the `plot#opts()` option.

`plot#opts(plot_options)` affects the rendition of the #th margin plot. The *plot\_options* can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] [marker\\_options](#), [G-3] [marker\\_label\\_options](#), and [G-3] [cline\\_options](#).

`recast(plottype)` specifies that margins be plotted using *plottype*. *plottype* may be `scatter`, `line`, `connected`, `bar`, `area`, `spike`, `dropline`, or `dot`; see [G-2] [graph twoway](#). When `recast()` is specified, the plot-rendition options appropriate to the specified *plottype* may be used in lieu of *plot\_options*. For details on those options, follow the appropriate link from [G-2] [graph twoway](#).

For an example using `recast()`, see [Continuous covariates](#).

You may specify `recast()` within a `plotopts()` or `plot#opts()` option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified *plottype*.

## CI plot

`ciopts(rcap_options)` affects the rendition of all confidence interval plots; see [G-3] [rcap\\_options](#).

These settings may be overridden for specific confidence interval plots with the `ci#opts()` option.

`ci#opts(rcap_options)` affects the rendition of the #th confidence interval; see [G-3] [rcap\\_options](#).

`recastci(plottype)` specifies that confidence intervals be plotted using *plottype*. *plottype* may be `rarea`, `rbar`, `rspike`, `rcap`, `rcapsym`, `rline`, `rconnected`, or `rscatter`; see [G-2] [graph twoway](#). When `recastci()` is specified, the plot-rendition options appropriate to the specified *plottype* may be used in lieu of *rcap\_options*. For details on those options, follow the appropriate link from [G-2] [graph twoway](#).

For an example using `recastci()`, see [Continuous covariates](#).

You may specify `recastci()` within a `ciopts()` or `ci#opts()` option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified *plottype*.

`mcompare(method)` specifies the method for confidence intervals that account for multiple comparisons within a factor-variable term. The default is determined by the margins results stored in `r()`. If `marginsplot` is working from margins results stored in `e()`, the default is `mcompare(noadjust)`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is determined by the margins results stored in `r()`. If `marginsplot` is working from margins results stored in `e()`, the default is `level(95)` or as set by `set level`; see [U] [20.8 Specifying the width of confidence intervals](#).

## Pairwise

These options have an effect only when the `pwcompare` option was specified on the preceding margins command.

`unique` specifies that only unique pairwise comparisons be plotted. The default is to plot all pairwise comparisons, including those that are mirror images of each other—“male” versus “female” and “female” versus “male”. `margins` reports only the unique pairwise comparisons. `unique`

also changes the default `xdimension()` for graphs of pairwise comparisons from the reference categories (`_pw0`) to the comparisons of each pairwise category (`_pw`).

Unique comparisons are often preferred with horizontal graphs that put all pairwise comparisons on the  $x$  axis, whereas including the full matrix of comparisons is preferred for charts showing the reference groups on an axis and the comparison groups as plots; see [Pairwise comparisons](#) and [Horizontal is sometimes better](#).

`csort` specifies that comparison categories are sorted first, and then reference categories are sorted within comparison category. The default is to sort reference categories first, and then sort comparison categories within reference categories. This option has an observable effect only when `_pw` is also specified in one of the dimension options. It then determines the order of the labeling in the dimension where `_pw` is specified.

---

#### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [\[G-3\] addplot\\_option](#).

For an example using `addplot()`, see [Adding scatterplots of the data](#).

If multiple graphs are drawn by a single `marginsplot` command or if `plot` specifies plots with multiple  $y$  variables, for example, `scatter y1 y2 x`, then the graph's legend will not clearly identify all the plots and will require customization using the `legend()` option; see [\[G-3\] legend\\_options](#).

---

#### Y axis, X axis, Titles, Legend, Overall, By

`twoway_options` are any of the options documented in [\[G-3\] twoway\\_options](#). These include options for titling the graph (see [\[G-3\] title\\_options](#)); for saving the graph to disk (see [\[G-3\] saving\\_option](#)); for controlling the labeling and look of the axes (see [\[G-3\] axis\\_options](#)); for controlling the look, contents, position, and organization of the legend (see [\[G-3\] legend\\_options](#)); for adding lines (see [\[G-3\] added\\_line\\_options](#)) and text (see [\[G-3\] added\\_text\\_options](#)); and for controlling other aspects of the graph's appearance (see [\[G-3\] twoway\\_options](#)).

The `label()` suboption of the `legend()` option has no effect on `marginsplot`. Use the `order()` suboption instead.

`byopts(byopts)` affects the appearance of the combined graph when `bydimension()` is specified or when the default graph has subgraphs, including the overall graph title, the position of the legend, and the organization of subgraphs. See [\[G-3\] by\\_option](#).

## Remarks and examples

Remarks are presented under the following headings:

- Introduction*
- Dataset*
- Profile plots*
- Interaction plots*
- Contrasts of margins—effects (discrete marginal effects)*
- Three-way interactions*
- Continuous covariates*
- Plots at every value of a continuous covariate*
- Contrasts of at() groups—discrete effects*
- Controlling the graph's dimensions*
- Pairwise comparisons*
- Horizontal is sometimes better*
- Marginal effects*
- Plotting a subset of the results from margins*
- Advanced usage*
  - Plots with multiple terms*
  - Plots with multiple at() options*
  - Adding scatterplots of the data*
  - Video examples*

## Introduction

`marginsplot` is a post-`margins` command. It graphs the results of the `margins` command, whether those results are marginal means, predictive margins, marginal effects, contrasts, pairwise comparisons, or other statistics; see [R] [margins](#).

By default, the margins are plotted on the  $y$  axis, and all continuous and factor covariates specified in the `margins` command will usually be placed on the  $x$  axis or used to identify plots. Exceptions are discussed in the following sections and in *Addendum: Advanced uses of `dimlist`* below.

`marginsplot` produces classic plots, such as profile plots and interaction plots. Beyond that, anything that `margins` can compute, `marginsplot` can graph.

We will be using some relatively complicated `margins` commands with little explanation of the syntax. We will also avoid lengthy interpretations of the results of `margins`. See [R] [margins](#) for the complete syntax of `margins` and discussions of its results.

All graphs in this entry were drawn using the `s2gcolor` scheme; see [G-4] [Scheme s2](#).

[Mitchell \(2021\)](#) and [Baldwin \(2019\)](#) show in many examples how to use `marginsplot` to understand a fitted model.

## Dataset

For continuity, we will use one dataset for most examples—the Second National Health and Nutrition Examination Survey (NHANES II) ([McDowell et al. 1981](#)). NHANES II is part of a study to assess the health and nutritional status of adults and children in the United States. It is designed to be a nationally representative sample of the U.S. population. This particular sample is from 1976 to 1980.

The survey nature of the dataset—weights, strata, and sampling units—will be ignored in our analyses. We are discussing graphing, not survey statistics. If you would like to see the results with the appropriate adjustments for the survey design, just add `svy:` before each estimation command, and if you wish, add `vce(unconditional)` as an option to each `margins` command. See [R] [margins](#), particularly the discussion and examples under *Obtaining margins with survey data and representative*

*samples*, for reasons why you probably would want to add `vce(unconditional)` when analyzing survey data. For the most part, adjusting for survey design produces moderately larger confidence intervals and relatively small changes in point estimates.

## Profile plots

What does my estimation say about how my response varies as one (or more) of my covariates changes? That is the question that is answered by profile plots. Profile plots are also referred to as plots of estimated (or expected, or least-squares) means, though that is unnecessarily restrictive when considering models of binary, count, and ordered outcomes. In the latter cases, we might prefer to say they plot conditional expectations of responses, where a response might be a probability.

What we do with the other covariates depends on the questions we wish to answer. Sometimes, we wish to hold other covariates at fixed values, and sometimes we wish to average the response over their values. `margins` can do either, so you can graph either.

We can fit a fully factorial two-way ANOVA of systolic blood pressure on age group and sex using the NHANES II data.

```
. use https://www.stata-press.com/data/r18/nhanes2
. anova bpsystol agegrp##sex
```

	Number of obs =	10,351	R-squared =	0.2497	
	Root MSE =	20.2209	Adj R-squared =	0.2489	
Source	Partial SS	df	MS	F	Prob>F
Model	1407229.3	11	127929.93	312.88	0.0000
agegrp	1243037.8	5	248607.56	608.02	0.0000
sex	27728.379	1	27728.379	67.81	0.0000
agegrp#sex	88675.043	5	17735.009	43.37	0.0000
Residual	4227440.7	10,339	408.88294		
Total	5634670	10,350	544.41256		

If you are more comfortable with regression than ANOVA, then type

```
. regress bpsystol agegrp##sex
```

The `anova` and `regress` commands fit identical models. The output from `anova` displays all the terms in the model and thus tends to be more conducive to exploration with `margins` and `marginsplot`.

We estimate the predictive margins of systolic blood pressure for each age group using `margins`.

```
. margins agegrp
Predictive margins                                Number of obs = 10,351
Expression: Linear prediction, predict()
```

	Delta-method		t	P> t	[95% conf. interval]	
	Margin	std. err.				
agegrp						
20-29	117.2684	.419845	279.31	0.000	116.4454	118.0914
30-39	120.2383	.5020813	239.48	0.000	119.2541	121.2225
40-49	126.9255	.56699	223.86	0.000	125.8141	128.0369
50-59	135.682	.5628593	241.06	0.000	134.5787	136.7853
60-69	141.5285	.3781197	374.30	0.000	140.7873	142.2696
70+	148.1096	.6445073	229.80	0.000	146.8463	149.373

The six predictive margins are just the averages of the predictions over the estimation sample, holding `agegrp` to each of its six levels. If this were a designed experiment rather than survey data, we might wish to assume the cells are balanced—that they have the same number of observations—and thus estimate what are often called expected means or least-squares means. To do that, we would simply add the `asbalanced` option to the `margins` command. The NHANES II data are decidedly unbalanced over `sex#agegrp` cells. So much so that it is unreasonable to assume the cells are balanced.

We graph the results:

```
. marginsplot
Variables that uniquely identify margins: agegrp
```

Profile plots are often drawn without confidence intervals (CIs). The CIs may be removed by adding the `nocl` option. We prefer to see the CIs.

Disciplines vary widely in their use of the term profile plot. Some disciplines consider any connected plot of a response over values of other variables to be a profile plot. By that definition, most graphs in this entry are profile plots.

## Interaction plots

Interaction plots are often used to explore the form of an interaction. The interaction term in our ANOVA results is highly significant. Are the interaction effects also large enough to matter? What form do they take? We can answer these questions by fixing `agegrp` and `sex` to each possible combination of the two covariates and estimating the margins for those cells.

```
. margins agegrp#sex
```

Then, we can graph the results:

```
. marginsplot
```

```
Variables that uniquely identify margins: agegrp sex
```

It is clear that the effect of age differs by sex—there is an interaction. If there were no interaction, then the two lines would be parallel.

While males start out with higher systolic blood pressure, females catch up to the males as age increases and may even surpass males in the upper age groups. We say “may” because we cannot tell if the differences are statistically significant. The CIs overlap for the top three age groups. It is tempting to conclude from this overlap that the differences are not statistically significant. Do not fall into this trap. Likewise, do not fall into the trap that the first three age groups are different because their CIs do not overlap. The CIs are for the point estimates, not the differences. There is a covariance between the differences that we must consider if we are to make statements about those differences.

## Contrasts of margins—effects (discrete marginal effects)

To assess the differences, all we need to do is ask `margins` to contrast the sets of effects that we just estimated; see [\[R\] margins, contrast](#). With only two groups in sex, it does not matter much which contrast operator we choose. We will use the reference contrast. It will compare the difference between males and females, with males (the first category) as the reference category.

```
. margins r.sex@agegrp
```

```
Contrasts of adjusted predictions
```

```
Number of obs = 10,351
```

```
Expression: Linear prediction, predict()
```

	df	F	P>F
sex@agegrp			
(Female vs Male) 20-29	1	224.92	0.0000
(Female vs Male) 30-39	1	70.82	0.0000
(Female vs Male) 40-49	1	12.15	0.0005
(Female vs Male) 50-59	1	0.47	0.4949
(Female vs Male) 60-69	1	3.88	0.0488
(Female vs Male) 70+	1	6.37	0.0116
Joint	6	53.10	0.0000
Denominator	10339		

	Contrast	Delta-method std. err.	[95% conf. interval]	
sex@agegrp				
(Female vs Male) 20-29	-12.60132	.8402299	-14.24833	-10.9543
(Female vs Male) 30-39	-8.461161	1.005448	-10.43203	-6.490288
(Female vs Male) 40-49	-3.956451	1.134878	-6.181031	-1.731871
(Female vs Male) 50-59	-.7699782	1.128119	-2.981309	1.441353
(Female vs Male) 60-69	1.491684	.756906	.0080022	2.975367
(Female vs Male) 70+	3.264762	1.293325	.729594	5.79993

Because we are looking for effects that are different from 0, we will add a reference line at 0 to our graph.

```
. marginsplot, yline(0)
```

```
Variables that uniquely identify margins: agegrp
```

We can now say that females' systolic blood pressure is substantially and significantly lower than males' in the first three age groups but is significantly higher in the last two age groups. Despite the overlapping CIs for the last two age groups in the interaction graph, the effect of sex is significant in these age groups.

The terminology for what we just estimated and graphed varies widely across disciplines. Those versed in design of experiments refer to these values as contrasts or effects. Economists and some other social scientists call them marginal or partial effects. The latter groups might be more comfortable if we avoided the whole concept of contrasts and instead estimated the effects by typing

```
. margins agegrp, dydx(sex)
```

This will produce estimates that are identical to those shown above, and we can graph them by typing `marginplot`.

The advantage of using the contrast notation and thinking in contrasts is most evident when we take marginal effects with respect to a categorical covariate with more than two levels. Marginal effects for each level of the covariate will be taken with respect to a specified base level. Contrasts are much more flexible. Using the `r.` operator, we can reproduce the marginal-effects results by taking derivatives with respect to a reference level (as we saw above.) We can also estimate the marginal effect of first moving from level 1 to level 2, then from level 2 to level 3, then from level 3 to level 4, . . . using the `ar.` or “reverse adjacent” operator. Adjacent effects (marginal effects) can be valuable when evaluating an ordinal covariate, such as `agegrp` in our current model. For a discussion of contrasts, see [R] [contrast](#) and [R] [margins, contrast](#).

### Three-way interactions

`marginplot` can handle any number of covariates in your `margins` command. Consider the three-way ANOVA model that results from adding an indicator for whether an individual has been diagnosed with diabetes. We will fully interact the new covariate with the others in the model.

```
. anova bpsystol agegrp##sex##diabetes
```

	Number of obs =	10,349	R-squared =	0.2572	
	Root MSE =	20.131	Adj R-squared =	0.2556	
Source	Partial SS	df	MS	F	Prob>F
Model	1448983.2	23	62999.268	155.45	0.0000
agegrp	107963.58	5	21592.716	53.28	0.0000
sex	1232.7927	1	1232.7927	3.04	0.0812
agegrp#sex	11679.592	5	2335.9185	5.76	0.0000
diabetes	7324.9892	1	7324.9892	18.07	0.0000
agegrp#diabetes	5484.5462	5	1096.9092	2.71	0.0189
sex#diabetes	102.98824	1	102.98824	0.25	0.6142
agegrp#sex#diabetes	4863.1497	5	972.62994	2.40	0.0349
Residual	4184296.9	10,325	405.25878		
Total	5633280	10,348	544.38346		

The three-way interaction is significant, as is the main effect of `diabetes` and its interaction with `agegrp`.

Again, if you are more comfortable with regression than ANOVA, you may type

```
. regress bpsystol agegrp##sex##diabetes
```

The `margins` and `marginplot` results will be the same.

We estimate the expected cell means for each combination of `agegrp`, `sex`, and `diabetes`, and then graph the results by typing

```
. margins agegrp#sex#diabetes
  (output omitted)
. marginsplot
```

Variables that uniquely identify margins: **agegrp sex diabetes**

The graph is busy and difficult to interpret.

We can make it better by putting those with diabetes on one subgraph and those without on another:

```
. marginsplot, by(diabetes)
```

Variables that uniquely identify margins: **agegrp sex diabetes**

We notice much larger CIs for diabetics. That is not surprising because our sample contains only 499 diabetics compared with 9,850 nondiabetics.

A more interesting way to arrange the plots is by grouping the subgraphs on sex:

```
. marginsplot, by(sex)
```

Variables that uniquely identify margins: **agegrp sex diabetes**

Adjusted predictions of agegrp#sex#diabetes with 95% CIs

Aside from increased systolic blood pressure in the upper-age groups, which we saw earlier, it appears that those with diabetes are at greater risk of higher systolic blood pressure for many upper-age groups. We can check that by having margins estimate the differences between diabetics and nondiabetics, and graphing the results.

```
. margins r.diabetes@agegrp#sex  
(output omitted)
```

```
. marginsplot, by(sex) yline(0)
```

Variables that uniquely identify margins: **agegrp sex**

Contrasts of adjusted predictions of diabetes@agegrp#sex with 95% CIs

With CIs above 0 for six of eight age groups over 40, this graph provides evidence that diabetes is related to higher blood pressure in those over 40.

## Continuous covariates

`margins` and `marginsplot` are just as useful with continuous covariates as they are with factor variables. As a variation on our ANOVA/regression models, let's move to a logistic regression, using as our dependent variable an indicator for whether a person has high blood pressure. We introduce a continuous covariate—body mass index (BMI), a measure of weight relative to height. High BMI is often associated with high blood pressure. We will allow the effect of BMI to vary across sexes, age groups, and sex/age combinations by fully interacting the covariates.

```
. logistic highbp sex##agegrp#c.bmi
```

If we wished, we could perform all the analyses above on this model. Instead of estimating margins, contrasts, and marginal effects on the level of systolic blood pressure, we would be estimating margins, contrasts, and marginal effects on the probability of having high blood pressure. You can see those results by repeating any of the prior commands that involve `sex` and `agegrp`. In this section, we will focus on the continuous covariate `bmi`.

With continuous covariates, rather than specify them in the `marginlist` of `margins`, we specify the specific values at which we want the covariate evaluated in an `at()` option. `at()` options are very flexible, and there are many ways to specify values; see [Syntax of at\(\)](#) in [\[R\] margins](#).

BMI in our sample ranges from 12.4 to 61.1. Let's estimate the predictive margins for males and females at levels of BMI from 10 through 65 at intervals of 5 and graph the results:

```
. margins sex, at(bmi=(10(5)65))
(output omitted)
```

```
. marginsplot, xlabel(10(10)60)
```

Variables that uniquely identify margins: **bmi sex**

We added the `xlabel(10(10)60)` option to improve the labeling of the  $x$  axis. You may add any *twoway\_options* (see [\[G-3\] twoway\\_options](#)) to the `marginsplot` command.

For a given BMI, males are generally more susceptible to high blood pressure, though the effect is attenuated by the logistic response when the probabilities approach 0 or 1.

Because `bmi` is continuous, we might prefer to see the response graphed using a line. We might also prefer that the CIs be plotted as areas. We change the plottype of the response by using the `recast()` option and the plottype of the CI by using the `recastci()` option:

```
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
Variables that uniquely identify margins: bmi sex
```

The CIs are a little dark for our tastes. You can dim them a bit by reducing the intensity of their color. Adding `ciopts(color(*.8))` to our `marginsplot` command will do that. Any plot option accepted by `twoway rarea` (see [G-2] [graph twoway rarea](#)) may be specified in a `ciopts()` option.

Given their confidence regions, the male and female profiles appear to be statistically different over most of the range of BMI. As with the profiles of categorical covariates, we can check that assertion by contrasting the two profiles on `sex` and graphing the results. Let's improve the smoothness of the response by specifying intervals of 1 instead of 5.

```
. margins r.sex, at(bmi=(10(1)65))
(output omitted)
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
Variables that uniquely identify margins: bmi
```

We see that the difference between the sexes is largest at a BMI of about 35 and that the sexes respond more similarly with very high and very low BMI. This shape is largely determined by the response of the logistic function, which is attenuated near probabilities 0 and 1, combined with the fact that the lowest measured BMIs are associated with low probabilities of high blood pressure and the highest measured BMIs are associated with high probabilities of high blood pressure.

As when we contrasted profiles of categorical variables, different disciplines will think of this graph differently. Those familiar with designed experiments will be comfortable with the terms used above—this is a contrast of profiles, or a profile of effects, or a profile of a contrast. Many social scientists will prefer to think of this as a graph of marginal or partial effects. For them, this is a plot of the discrete marginal effect of being female for various levels of BMI. They can obtain an identical graph, with labeling more appropriate for the marginal effect's interpretation, by typing

```
. margins, at(bmi=(10(1)65)) dydx(sex)
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
```

We can also plot profiles of the response of BMI by levels of another continuous covariate (rather than by the categorical variable `sex`). To do so, we will need another continuous variable in our model. We have been using age groups as a covariate to emphasize the treatment of categorical variables and to allow the effect of age to be flexible. Our dataset also has age recorded in integer years. We replace `agegrp` with continuous `age` in our logistic regression.

```
. logistic highbp sex##c.age##c.bmi
```

We can now obtain profiles of BMI for different ages by specifying ranges for both `bmi` and `age` in a single `at()` option on the `margins` command:

```
. margins sex, at(bmi=(10(5)60) age=(20(10)70))
```

With six ages specified, we have many profiles, so we will dispense with the CIs by adding the `noci` option:

```
. marginsplot, noci by(sex)
```

Variables that uniquely identify margins: **bmi age sex**

Our model seems to indicate that males have a sharper reaction to body mass indices than do females. Likewise, younger subjects display a sharper response, while older subjects have a more gradual response with earlier onset. That interpretation might be a result of our parametric treatment of `age`. As it turns out, the interpretation holds if we allow age to take more flexible forms or return to our use of age groups, which allows each of seven age groups to have unique BMI profiles. Here are the commands to perform that analysis:

```
. logistic highbp sex##agegrp##c.bmi
(output omitted)
. margins sex#agegrp, at(bmi=(10(5)60))
(output omitted)
. marginsplot, noci by(sex)
Variables that uniquely identify margins: bmi sex agegrp
```

## Plots at every value of a continuous covariate

In some cases, the specific values of a continuous covariate are important, and we want to plot the response at those specific values. Return to our logistic example with age treated as a continuous covariate.

```
. logistic highbp sex##c.age##c.bmi
```

We can use a programming trick to extract all the values of age and then supply them in an `at()` option, just as we would any list of values.

```
. levelsof age
. margins sex, at(age=('r(levels)'))
```

See [\[P\] levelsof](#) for a discussion of the `levelsof` command. `levelsof` returns in `r(levels)` the sorted list of unique values of the specified *varlist*, in our case, `age`.

We can then plot the results using `marginsplot`.

This is not a very interesting trick when using our age variable, which is recorded as integers from 20 to 74, but the approach will work with almost any continuous variable. In our model, `bmi` might seem more interesting, but there are 9,941 unique values of `bmi` in our dataset. A graph cannot resolve so many different values. For that reason, we usually recommend against plotting at every value of a covariate. Instead, graph at reasonable values over the range of the covariate by using the `at()` option, as we did earlier. This trick is best reserved for variables with a few, or at most a few dozen, unique values.

## Contrasts of at() groups—discrete effects

We have previously contrasted across the values of factor variables in our model. Put another way, we have estimated the discrete marginal effects of factor variables. We can do the same for the levels of variables in `at()` specifications and across separate `at()` specifications.

Returning to one of our logistic models and its margins, we earlier estimated the predictive margins of BMI at 5-unit intervals for both sexes. These are the commands we typed:

```
. logistic highbp sex##agegrp##c.bmi
. margins sex, at(bmi=(10(5)65))
. marginsplot, xlabel(10(10)60)
```

We can estimate the discrete effects by `sex` of `bmi` moving from 10 to 15, then from 15 to 20, . . . , and then from 60 to 65 by contrasting the levels of the `at()` groups using the reverse-adjacent contrast operator (`ar.`). We specify the operator within the `atcontrast()` suboption of the `contrast()` option. We need to specify one other option. By default, `margins`, `contrast` will apply a contrast to all variables in its `marginlist` when a contrast has been requested. In this case, we do not want to contrast across sexes but rather to contrast across the levels of BMI within each sex. To prevent margins from contrasting across the sexes, we specify the `marginswithin` option. Our margins command is

```
. margins sex, at(bmi=(10(5)65)) contrast(atcontrast(ar._at) marginswithin)
```

And we graph the results using `marginsplot`:

```
. marginsplot
Variables that uniquely identify margins: bmi sex
```

The graph shows the contrasts (or if you prefer, discrete changes) in the probability of high blood pressure by sex as one increases BMI in 5-unit increments.

We can even estimate contrasts (discrete effects) across `at()` options. To start, let's compare the age-group profiles of the probability of high blood pressure for those in the 25th and 75th percentile of BMI.

```
. margins agegrp, at((p25) bmi) at((p75) bmi)
  (output omitted)
. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
  _atoption=1: (p25) bmi
  _atoption=2: (p75) bmi
```

For each age group, people whose BMI is at the 75th percentile have a much higher probability of high blood pressure than those at the 25th percentile. What is that difference in probability and its CI? To contrast across the percentiles of BMI within age groups, we again specify a contrast operator on the `at()` groups using `atcontrast()`, and we also tell `margins` to perform that contrast within the levels of the *marginlist* by using the `marginswithin` option.

```

. margins agegrp, at((p25) bmi) at((p75) bmi)
> contrast(atcontrast(r._at) marginswithin)
(output omitted)
. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
  _atoption=1: (p25) bmi
  _atoption=2: (p75) bmi

```

The differences in probability between 25th and 75th BMI percentiles are clearly significantly greater than 0. The differences appear to be smallest for those in the youngest and oldest age groups.

## Controlling the graph's dimensions

Thus far, `marginsplot` has miraculously done almost exactly what we want in most cases. The things we want on the  $x$  axis have been there, the choice of plots has made sense, etc. Some of that luck sprang from the relatively simple analyses we were performing, and some was from careful specification of our `margins` command. Sometimes, we will not be so lucky.

Consider the following `regress`, `margins`, and `marginsplot` commands:

```
. regress bpsystol agegrp##sex##c.bmi
(output omitted)

. margins agegrp, over(sex) at(bmi=(10(10)60))
(output omitted)

. marginsplot

Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
  _atoption=1: (p25) bmi
  _atoption=2: (p75) bmi
```

By default, `marginsplot` places the levels of the first multilevel `at()` specification on the  $x$  axis and then usually plots the levels of all remaining variables as connected lines. That is what we see in the graph above—`bmi`, the `at()` variable, is on the  $x$  axis, and each combination of `agegrp` and `sex` is plotted as a separate connected line. If there is no multilevel `at()` specification, then the first variable in `marginlist` becomes the  $x$  axis. There are many more rules, but it is usually best to simply type `marginsplot` and see what happens. If you do not like `marginsplot`'s choices, change them.

What if we wanted `agegrp` on the  $x$  axis instead of BMI? We tell `marginsplot` to make that change by specifying `agegrp` in the `xdimension()` option:

```
. marginsplot, xdimension(agegrp)
Variables that uniquely identify margins: bmi agegrp sex
```

We have been suppressing the Results window output for `marginsplot`, but that output is helpful if we want to change how things are plotted. You may specify any variable used in your `margins` command in any of the dimension options—`xdimension()`, `plottedimension()`, `bydimension()`, and `graphdimension()`. (In fact, there are some pseudovariables that you may also specify in some cases; see [Addendum: Advanced uses of dimlist](#) for details.) `marginsplot` tries to help you narrow your choices by listing a set of variables that uniquely identify all your margins. You are not restricted to this list.

We have a different  $x$  axis and a different set of plots, but our graph is still busy and difficult to read. We can make it better by creating separate graph panels for each sex. We do that by adding a `bydimension()` option with `sex` as the argument.

```
. marginsplot, xdimension(agegrp) bydimension(sex)
Variables that uniquely identify margins: bmi agegrp sex
```

The patterns and the differences between males and females are now easier to see.

If our interest is in comparing males and females, we might even choose to create a separate panel for each level of BMI:

```
. marginsplot, xdimension(agegrp) bydimension(bmi) xlabel(, angle(45))
```

Variables that uniquely identify margins: **bmi agegrp sex**

The  $x$ -axis labels did not fit, so we angled them.

We leave you to explore the use of the `graphdimension()` option. It is much like `bydimension()` but creates separate graphs rather than separate panels. Operationally, the `plotdimension()` option is rarely used. All variables not in the  $x$  dimension and not specified elsewhere become the plotted connected lines.

You will likely use the dimension options frequently. This is one of the rare cases where we recommend using the minimal abbreviations of the options—`x()` for `xdimension()`, `plot()` for `plotdimension()`, `by()` for `bydimension()`, and `graph()` for `graphdimension()`. The abbreviations are easy to read and just as meaningful as the full option names. The full names exist to reinforce the relationship between the dimension options.

## Pairwise comparisons

`marginsplot` can graph the results of `margins`, `pwcompare`; see [R] [margins](#), [pwcompare](#). We return to one of our ANOVA examples. Here we request pairwise comparisons with the `pwcompare` option of `margins`, and we request Bonferroni-adjusted CIs with the `mcompare()` option:

```
. anova bpsystol agegrp##sex
(output omitted)
. margins agegrp, pwcompare mcompare(bonferroni)
(output omitted)
. marginsplot
```

Variables that uniquely identify margins: **\_pw1 \_pw0**

**i\_pw** enumerates all pairwise comparisons; **\_pw0** enumerates the reference categories; **\_pw1** enumerates the comparison categories.

Each connected line plot in the graph represents a reference age-group category for the pairwise comparison. The ticks on the  $x$  axis represent comparison age-group categories. So, each plot is a profile for a reference category showing its comparison to each other category.

## Horizontal is sometimes better

Another interesting way to graph pairwise comparisons is to simply plot each comparison and label the two categories being compared. This type of graph works better if it is oriented horizontally rather than vertically.

Continuing with the example above, we will switch the graph to horizontal. We will also make several changes to display the graph better. We specify that only unique comparisons be plotted. The graph above plotted both 1 versus 2 and 2 versus 1, which are the same comparison with opposite signs. We add a reference line at 0 because we are interested in comparisons that differ from 0. This graph looks better without the connecting lines, so we add the option `recast(scatter)`. We also reverse the  $y$  scale so that the smallest levels of age group appear at the top of the axis.

```
. marginsplot, horizontal unique xline(0) recast(scatter) yscale(reverse)
Variables that uniquely identify margins: _pw1 _pw0
i_pw enumerates all pairwise comparisons; _pw0 enumerates the reference
categories; _pw1 enumerates the comparison categories.
```

All the comparisons differ from 0, so all our age groups are statistically different from each other.

The `horizontal` option can be useful outside of pairwise comparisons. Profile plots are usually oriented vertically. However, when your covariates have long labels or there are many levels at which the margins are being evaluated, the graph may be easier to read when rendered horizontally.

## Marginal effects

We have seen how to graph discrete effects for factor variables and continuous variables by using contrasts, and optionally by using the `dydx()` option of `margins`: *Contrasts of margins—effects (discrete marginal effects)* and *Continuous covariates*. Let's now consider graphing instantaneous marginal effects for continuous covariates. Begin by refitting our logistic model of high blood pressure as a function of sex, age, and BMI:

```
. logistic highbp sex##agegrp##c.bmi
```

We estimate the average marginal effect of BMI on the probability of high blood pressure for each age group and then graph the results by typing

```
. margins agegrp, dydx(bmi)
  (output omitted)
. marginsplot
```

Variables that uniquely identify margins: **agegrp**

These are the conditional expectations of the marginal effects treating everyone in the sample as though they were in each age group. We can estimate fully conditional marginal effects that do not depend on averaging over the sample by also margining on our one remaining covariate—sex.

```
. margins agegrp#sex, dydx(bmi)
  (output omitted)
. marginsplot
```

Variables that uniquely identify margins: **agegrp sex**

The effect of BMI on the probability of high blood pressure looks to increase with age for females. The marginal effect is higher for males than females in the younger age groups but then decreases with age for males after the 40–49 age group.

You may want to test for differences in the marginal effect of BMI for males and females by contrasting across sexes within `agegrp`:

```
. margins r.sex@agegrp, dydx(bmi)
```

## Plotting a subset of the results from margins

`marginsplot` plots all the margins produced by the preceding `margins` command. If you want a graph that does not include all the margins, then enter a `margins` command that produces a reduced set of margins. Obvious ways to reduce the number of margins include not specifying some factors or interactions in the *marginlist* of `margins`, not specifying some `at()` or `over()` options, or reducing the values specified in an `at()` option. A less obvious technique uses selection lists in factor operators to select specific sets of levels from factor variables specified in the *marginlist*.

Instead of typing

```
. margins agegrp
```

which will give you margins for all six age groups in our sample, type

```
. margins i(2/4).agegrp
```

which will give you only three margins—those for groups 2, 3, and 4. See [U] [11.4.3.4 Selecting levels](#).

## Advanced usage

`margins` is incredibly flexible in the statistics it can estimate and in the grouping of those estimates. Many of the estimates that `margins` can produce do not make convincing graphs. `marginsplot` plots the results of any `margins` command, regardless of whether the resulting graph is easily interpreted. Here we demonstrate some options that can make complicated `margins` into graphs that are somewhat more useful than those produced by `marginsplot`'s defaults. Others may find truly useful applications for these approaches.

### Plots with multiple terms

Margins plots are rarely interesting when you specify multiple terms on your `margins` command, for example, `margins a b`. Such plots often compare things that are not comparable. The defaults for `marginsplot` rarely produce useful plots with multiple terms. Perhaps the most interesting graph in such cases puts all the levels of all the terms together on the vertical axis and plots their margins on the horizontal axis. We do that by including the *marginlist* from `margins` in an `xdimension()` option on `marginsplot`. The long labels on such graphs look better with a horizontal orientation, and there is no need to connect the margin estimates, so we specify the `recast(scatter)` option.

Using one of our ANOVA examples from earlier,

```
. anova bpsystol agegrp##sex
(output omitted)

. margins agegrp sex
(output omitted)

. marginsplot, xdimension(agegrp sex) horizontal recast(scatter)
Variables that uniquely identify margins: agegrp sex
```

The “asobserved” notations in the  $y$ -axis labels are informing us that, for example, when the margin for females is evaluated, the values of age group are taken as they are observed in the dataset. The margin is computed as an average over those values.

### Plots with multiple at() options

Some disciplines like to compute margins at the means of other covariates in their model and others like to compute the response for each observation and then take the means of the response. These correspond to the `margins` options `at((mean) _all)` and `at((asobserved) _all)`. For responses that are linear functions of the coefficients, such as `predict` after `regress`, the two computations yield identical results. For responses that are nonlinear functions of the coefficients, the two computations estimate different things.

Using one of our logistic models of high blood pressure,

```
. logistic highbp sex##agegrp##c.bmi
```

and computing both sets of margins for each age group,

```
. margins agegrp, at((mean) _all) at((asobserved) _all)
```

we can use marginsplot to compare the approaches:

```
. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
  _atoption=1: (mean)_all
  _atoption=2: (asobserved) _all
```

For the first three age groups, the probabilities of high blood pressure are lower at the means of `sex` and `bpi` than are the mean probabilities of high blood pressure averaged over the observed values of `sex` and `bpi`. The reverse is true for the last three age groups, although the values are very similar in these older age groups.

Such comparisons come up even more frequently when evaluating marginal effects. We can estimate the marginal effects of sex at each age group and graph the results by adding `dydx(sex)` to our `margins` command:

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
  (output omitted)
. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
  _atoption=1: (mean)_all
  _atoption=2: (asobserved) _all
```

The average marginal effect is smaller for most age groups, but the CIs for both sets of estimates are wide. Can we tell the difference between the estimates? To answer that, we use the now-familiar tactic of taking the contrast of our estimated marginal-effects profiles. That means adding `contrast(atjoint marginswithin)` to our `margins` command. We will also add `mcompare(bonferroni)` to account for the fact that we will be comparing six contrasts.

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
> contrast(atjoint marginswithin) mcompare(bonferroni)
```

We will also add the familiar reference line at 0 to our graph of the contrasts.

```
. marginsplot, yline(0)
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
  _atoption=1: (mean)_all
  _atoption=2: (asobserved) _all
```

While the difference in the estimates of marginal effects is not large, we can distinguish the estimates for the 30–39 and 70+ age groups.

The `at()` option of `margins` provides far more flexibility than demonstrated above. It can be used to evaluate a response or marginal effect at almost any point of interest or combinations of such points. See *Syntax of `at()`* in [R] `margins`.

## Adding scatterplots of the data

We can add scatterplots of the observed data to our plots of the margins. The NHANES II dataset is too large for this to be interesting, so for this example, we will use `auto.dta`. We fit mileage on whether the care is foreign and on a quadratic in the weight of the car. We convert the weight into tons (U.S. definition) to improve the scaling, and we format the new `tons` variable to improve its labels on the graph. For our graph, we create separate variables for mileage of domestic and of foreign cars. We fit a fully interacted model so that the effect of weight on mileage can be different for foreign and for domestic cars.

```
. use https://www.stata-press.com/data/r18/auto
. generate tons = weight/2000
. format tons %6.2f
. separate mpg, by(foreign)
. regress mpg foreign##c.tons##c.tons
```

We then estimate the margins over the range of tons, using the option `over(foreign)` to obtain separate estimates for foreign and domestic cars.

```
. margins, at(tons=(.8(.05)2.4)) over(foreign)
```

Adding scatterplots of mileage for domestic and foreign cars is easy. We insert into an `addplot()` option of `marginsplot` the same scatterplot syntax for `twoway` that we would type to produce a scatterplot of the data:

```
. marginsplot, addplot(scatter mpg0 tons || scatter mpg1 tons) recast(line) noci
Variables that uniquely identify margins: tons foreign
```

Many will be surprised that the mileage profile is higher in 1978 for domestic (U.S. built) cars. Is the difference significant?

```
. margins, at(tons=(.8(.05)2.4)) over(r.for)
(output omitted)
. marginsplot, yline(0)
```

Variables that uniquely identify margins: **tons**

As we did earlier, we contrast the two profiles. We can discern some difference between the two profiles for midweight vehicles, but otherwise there is insufficient information to believe mileage differs across domestic and foreign cars.

## Addendum: Advanced uses of dimlist

*dimlist* specifies the dimensions from the immediately preceding `margins` command that are to be used for the `marginsplot`'s *x* axis, plots, subgraphs, and graphs. *dimlist* may contain:

<i>dim</i>	Description
<i>varname</i>	Any variable referenced in the preceding <code>margins</code> command.
<code>_equation</code>	If the estimation command being analyzed is multivariate and <code>margins</code> automatically produced estimates for more than one dependent-variable equation, then <i>dimlist</i> may contain <code>_equation</code> to enumerate those equations.
<code>_outcome</code>	If the estimation command being analyzed is ordinal and <code>margins</code> automatically produced estimates for more than one outcome level, then <i>dimlist</i> may contain <code>_outcome</code> to enumerate those outcomes.
<code>_predict</code>	If the preceding <code>margins</code> command included multiple <code>predict()</code> options, then <i>dimlist</i> may contain <code>_predict</code> to enumerate those <code>predict()</code> options.
<code>at(varname)</code>	If a variable is specified in both the <i>marginlist</i> or the <code>over()</code> option and in the <code>at()</code> option of <code>margins</code> , then the two uses can be distinguished in <code>marginsplot</code> by typing the <code>at()</code> variables as <code>at(varname)</code> in <i>dimlist</i> .
<code>_deriv</code>	If the preceding <code>margins</code> command included a <code>dydx()</code> , <code>eyex()</code> , <code>dyex()</code> , or <code>eydx()</code> option, <i>dimlist</i> may also contain <code>_deriv</code> to specify all the variables over which derivatives were taken.
<code>_term</code>	If the preceding <code>margins</code> command included multiple terms (for example, <code>margins a b</code> ), then <i>dimlist</i> may contain <code>_term</code> to enumerate those terms.
<code>_atopt</code>	If the preceding <code>margins</code> command included multiple <code>at()</code> options, then <i>dimlist</i> may contain <code>_atopt</code> to enumerate those <code>at()</code> options.

When the `pairwise` option is specified on `margins`, you may specify dimensions that enumerate the pairwise comparisons.

<code>_pw</code>	enumerates all the pairwise comparisons
<code>_pw0</code>	enumerates the reference categories of the comparisons
<code>_pw1</code>	enumerates the comparison categories of the comparisons

## Acknowledgments

## Description

All Stata commands maximize likelihood functions using `moptimize()` and `optimize()`; see *Methods and Formulas* below. Commands use the Newton–Raphson method with step halving and special fixups when they encounter nonconcave regions of the likelihood. For details, see [M-5] `moptimize()` and [M-5] `optimize()`. For more information about programming maximum likelihood estimators in ado-files and Mata, see [R] `ml` and Pitblado, Poi, and Gould (2024).

## Syntax

```
mle_cmd ... [ , options ]
```

<i>options</i>	Description
<code>difficult</code>	use a different stepping algorithm in nonconcave regions
<code>technique(<i>algorithm_spec</i>)</code>	maximization technique
<code>iterate(#)</code>	perform maximum of # iterations; default is <code>iterate(300)</code>
<code>[no]log</code>	display an iteration log of the log likelihood; typically, the default
<code>trace</code>	display current parameter vector in iteration log
<code>gradient</code>	display current gradient vector in iteration log
<code>showstep</code>	report steps within an iteration in iteration log
<code>hessian</code>	display current negative Hessian matrix in iteration log
<code>showtolerance</code>	report the calculated result that is compared to the effective convergence criterion
<code>tolerance(#)</code>	tolerance for the coefficient vector; see <i>Options</i> for the defaults
<code>ltolerance(#)</code>	tolerance for the log likelihood; see <i>Options</i> for the defaults
<code>nrtolerance(#)</code>	tolerance for the scaled gradient; see <i>Options</i> for the defaults
<code>qtolerance(#)</code>	when specified with algorithms <code>bhhh</code> , <code>dfp</code> , or <code>bfgs</code> , the $\mathbf{q} - \mathbf{H}$ matrix is used as the final check for convergence rather than <code>nrtolerance()</code> and the $\mathbf{H}$ matrix; seldom used
<code>nonrtolerance</code>	ignore the <code>nrtolerance()</code> option
<code>from(<i>init_specs</i>)</code>	initial values for the coefficients

*algorithm\_spec* is

```
algorithm [ # [ algorithm [ # ] ]... ]
```

*algorithm* is { *nr* | *bhhh* | *dfp* | *bfgs* }

*init\_specs* is one of

```
matname [ , skip copy]
```

```
{ [ eqname: ] name = # | /eqname = # } [...]
```

```
# [ # ... ], copy
```

## Maximization options

`difficult` specifies that the likelihood function is likely to be difficult to maximize because of nonconcave regions. When the message “not concave” appears repeatedly, `ml`’s standard stepping algorithm may not be working well. `difficult` specifies that a different stepping algorithm be used in nonconcave regions. There is no guarantee that `difficult` will work better than the default; sometimes it is better and sometimes it is worse. You should use the `difficult` option only when the default stepper declares convergence and the last iteration is “not concave” or when the default stepper is repeatedly issuing “not concave” messages and producing only tiny improvements in the log likelihood.

`technique(algorithm_spec)` specifies how the likelihood function is to be maximized. The following algorithms are allowed. For details, see [Pitblado, Poi, and Gould \(2024\)](#).

`technique(nr)` specifies Stata’s modified Newton–Raphson (NR) algorithm.

`technique(bhhh)` specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.

`technique(dfp)` specifies the Davidon–Fletcher–Powell (DFP) algorithm.

`technique(bfgs)` specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is `technique(nr)`.

You can switch between algorithms by specifying more than one in the `technique()` option. By default, an algorithm is used for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the technique in the option. For example, specifying `technique(bhhh 10 nr 1000)` requests that `ml` perform 10 iterations with the BHHH algorithm followed by 1000 iterations with the NR algorithm, and then switch back to BHHH for 10 iterations, and so on. The process continues until convergence or until the maximum number of iterations is reached.

`iterate(#)` specifies the maximum number of iterations. When the number of iterations equals `iterate()`, the optimizer stops and presents the current results. If convergence is declared before this threshold is reached, it will stop when convergence is declared. Specifying `iterate(0)` is useful for viewing results evaluated at the initial value of the coefficient vector. Specifying `iterate(0)` and `from()` together allows you to view results evaluated at a specified coefficient vector; however, not all commands allow the `from()` option. The default value of `iterate(#)` for both estimators programmed internally and estimators programmed with `ml` is the number set using `set maxiter`, which is 300 by default.

`log` and `nolog` specify whether an iteration log showing the progress of the log likelihood is to be displayed. For most commands, the log is displayed by default, and `nolog` suppresses it; see `set iterlog` in [R] *set iter*. For a few commands (such as the `svy` maximum likelihood estimators), you must specify `log` to see the log.

`trace` adds to the iteration log a display of the current parameter vector.

`gradient` adds to the iteration log a display of the current gradient vector.

`showstep` adds to the iteration log a report on the steps within an iteration. This option was added so that developers at StataCorp could view the stepping when they were improving the `ml` optimizer code. At this point, it mainly provides entertainment.

`hessian` adds to the iteration log a display of the current negative Hessian matrix.

`showtolerance` adds to the iteration log the calculated value that is compared with the effective convergence criterion at the end of each iteration. Until convergence is achieved, the smallest calculated value is reported.

`shownrtolerance` is a synonym of `showtolerance`.

Below, we describe the three convergence tolerances. Convergence is declared when the `nrtolerance()` criterion is met and either the `tolerance()` or the `ltolerance()` criterion is also met.

`tolerance(#)` specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to `tolerance()`, the `tolerance()` convergence criterion is satisfied.

`tolerance(1e-4)` is the default for estimators programmed with `ml`.

`tolerance(1e-6)` is the default.

`ltolerance(#)` specifies the tolerance for the log likelihood. When the relative change in the log likelihood from one iteration to the next is less than or equal to `ltolerance()`, the `ltolerance()` convergence is satisfied.

`ltolerance(0)` is the default for estimators programmed with `ml`.

`ltolerance(1e-7)` is the default.

`nrtolerance(#)` specifies the tolerance for the scaled gradient. Convergence is declared when  $\mathbf{g}\mathbf{H}^{-1}\mathbf{g}' < \text{nrtolerance}()$ . The default is `nrtolerance(1e-5)`.

`qtolerance(#)` when specified with algorithms `bhhh`, `dfp`, or `bfgs` uses the  $\mathbf{q} - \mathbf{H}$  matrix as the final check for convergence rather than `nrtolerance()` and the  $\mathbf{H}$  matrix.

Beginning with Stata 12, by default, Stata now computes the  $\mathbf{H}$  matrix when the  $\mathbf{q} - \mathbf{H}$  matrix passes the convergence tolerance, and Stata requires that  $\mathbf{H}$  be concave and pass the `nrtolerance()` criterion before concluding convergence has occurred.

`qtolerance()` provides a way for the user to obtain Stata's earlier behavior.

`nonnrtolerance` specifies that the default `nrtolerance()` criterion be turned off.

`from()` specifies initial values for the coefficients. Not all estimators in Stata support this option. You can specify the initial values in one of three ways: by specifying the name of a vector containing the initial values (for example, `from(b0)`, where `b0` is a properly labeled vector); by specifying coefficient names with the values (for example, `from(age=2.1 /sigma=7.4)`); or by specifying a list of values (for example, `from(2.1 7.4, copy)`). `from()` is intended for use when doing

bootstraps (see [R] [bootstrap](#)) and in other special situations (for example, with `iterate(0)`). Even when the values specified in `from()` are close to the values that maximize the likelihood, only a few iterations may be saved. Poor values in `from()` may lead to convergence problems.

`skip` specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

`copy` specifies that the list of values or the initialization vector be copied into the initial-value vector by position rather than by name.

## Remarks and examples

Only in rare circumstances would you ever need to specify any of these options, except `nolog`. The `nolog` option is useful for reducing the amount of output appearing in log files; also see `set iterlog` in [R] [set iter](#).

The following is an example of an iteration log:

```
Iteration 0: Log likelihood = -3791.0251
Iteration 1: Log likelihood = -3761.738
Iteration 2: Log likelihood = -3758.0632 (not concave)
Iteration 3: Log likelihood = -3758.0447
Iteration 4: Log likelihood = -3757.5861
Iteration 5: Log likelihood = -3757.474
Iteration 6: Log likelihood = -3757.4613
Iteration 7: Log likelihood = -3757.4606
Iteration 8: Log likelihood = -3757.4606
      (table of results omitted)
```

At iteration 8, the model converged. The message “not concave” at the second iteration is notable. This example was produced using the `heckman` command; its likelihood is not globally concave, so it is not surprising that this message sometimes appears. The other message that is occasionally seen is “backed up”. Neither of these messages should be of any concern unless they appear at the final iteration.

If a “not concave” message appears at the last step, there are two possibilities. One is that the result is valid, but there is collinearity in the model that the command did not otherwise catch. Stata checks for obvious collinearity among the independent variables before performing the maximization, but strange collinearities or near collinearities can sometimes arise between coefficients and ancillary parameters. The second, more likely cause for a “not concave” message at the final step is that the optimizer entered a flat region of the likelihood and prematurely declared convergence.

If a “backed up” message appears at the last step, there are also two possibilities. One is that Stata found a perfect maximum and could not step to a better point; if this is the case, all is fine, but this is a highly unlikely occurrence. The second is that the optimizer worked itself into a bad concave spot where the computed gradient and Hessian gave a bad direction for stepping.

If either of these messages appears at the last step, perform the maximization again with the `gradient` option. If the gradient goes to zero, the optimizer has found a maximum that may not be unique but is a maximum. From the standpoint of maximum likelihood estimation, this is a valid result. If the gradient is not zero, it is not a valid result, and you should try tightening up the convergence criterion, or try `ltol(0) to1(1e-7)` to see if the optimizer can work its way out of the bad region.

If you get repeated “not concave” steps with little progress being made at each step, try specifying the `difficult` option. Sometimes `difficult` works wonderfully, reducing the number of iterations and producing convergence at a good (that is, concave) point. Other times, `difficult` works poorly, taking much longer to converge than the default stepper.

## Stored results

Maximum likelihood estimators store the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations	always stored
<code>e(k)</code>	number of parameters	always stored
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>	usually stored
<code>e(k_eq_model)</code>	number of equations in overall model test	usually stored
<code>e(k_dv)</code>	number of dependent variables	usually stored
<code>e(df_m)</code>	model degrees of freedom	always stored
<code>e(r2_p)</code>	pseudo- $R^2$	sometimes stored
<code>e(ll)</code>	log likelihood	always stored
<code>e(ll_0)</code>	log likelihood, constant-only model	stored when constant-only model is fit
<code>e(N_clust)</code>	number of clusters	stored when <code>vce(cluster <i>clustvar</i>)</code> is specified; see <a href="#">[U] 20.22 Obtaining robust variance estimates</a>
<code>e(chi2)</code>	$\chi^2$	usually stored
<code>e(p)</code>	$p$ -value for model test	usually stored
<code>e(rank)</code>	rank of <code>e(V)</code>	always stored
<code>e(rank0)</code>	rank of <code>e(V)</code> for constant-only model	stored when constant-only model is fit
<code>e(ic)</code>	number of iterations	usually stored
<code>e(rc)</code>	return code	usually stored
<code>e(converged)</code>	1 if converged, 0 otherwise	usually stored

### Macros

<code>e(cmd)</code>	name of command	always stored
<code>e(cmdline)</code>	command as typed	always stored
<code>e(depvar)</code>	names of dependent variables	always stored
<code>e(wtype)</code>	weight type	stored when weights are specified or implied
<code>e(wexp)</code>	weight expression	stored when weights are specified or implied
<code>e(title)</code>	title in estimation output	usually stored by commands using <code>ml</code>
<code>e(clustvar)</code>	name of cluster variable	stored when <code>vce(cluster <i>clustvar</i>)</code> is specified; see <a href="#">[U] 20.22 Obtaining robust variance estimates</a>
<code>e(chi2type)</code>	Wald or LR; type of model $\chi^2$ test	usually stored
<code>e(vce)</code>	<i>vce</i> type specified in <code>vce()</code>	stored when command allows <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.	sometimes stored
<code>e(opt)</code>	type of optimization	always stored
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization	always stored
<code>e(ml_method)</code>	type of <code>ml</code> method	always stored by commands using <code>ml</code>
<code>e(user)</code>	name of likelihood-evaluator program	always stored
<code>e(technique)</code>	from <code>technique()</code> option	sometimes stored
<code>e(singularHmethod)</code>	m-marquardt or hybrid; method used when Hessian is singular	sometimes stored <sup>1</sup>
<code>e(crittype)</code>	optimization criterion	always stored <sup>1</sup>
<code>e(properties)</code>	estimator properties	always stored
<code>e(predict)</code>	program used to implement <code>predict</code>	usually stored

Macros, *continued*

<code>e(deriv_useminbound)</code>	off or on; whether minimum bounds are used for step sizes in numerical derivative computations	always stored by <code>ml model</code>
-----------------------------------	--	--

## Matrices

<code>e(b)</code>	coefficient vector	always stored
<code>e(Cns)</code>	constraints matrix	sometimes stored
<code>e(ilog)</code>	iteration log (up to 20 iterations)	usually stored
<code>e(gradient)</code>	gradient vector	usually stored
<code>e(V)</code>	variance–covariance matrix of the estimators	always stored
<code>e(V_modelbased)</code>	model-based variance	only stored when <code>e(V)</code> is robust, cluster–robust, bootstrap, or jackknife variance
<code>e(deriv_minbound)</code>	minimum values for step sizes	only stored when <code>e(deriv_useminbound)</code> is on

## Functions

<code>e(sample)</code>	marks estimation sample	always stored
------------------------	-------------------------	---------------

1. Type `ereturn list, all` to view these results; see [P] [return](#).

See *Stored results* in the manual entry for any maximum likelihood estimator for a list of returned results.

## Methods and formulas

Optimization is currently performed by `moptimize()` and `optimize()`, with the former implemented in terms of the latter; see [M-5] [moptimize\(\)](#) and [M-5] [optimize\(\)](#). Some estimators use `moptimize()` and `optimize()` directly, and others use the `ml` ado-file interface to `moptimize()`.

Prior to Stata 11, Stata had three separate optimization engines: an internal one used by estimation commands implemented in C code; `ml` implemented in ado-code separately from `moptimize()` and used by most estimators; and `moptimize()` and `optimize()` used by a few recently written estimators. These days, the internal optimizer and the old version of `ml` are used only under version control. In addition, `arch` and `arima` (see [TS] [arch](#) and [TS] [arima](#)) are currently implemented using the old `ml`.

Let  $L_1$  be the log likelihood of the full model (that is, the log-likelihood value shown on the output), and let  $L_0$  be the log likelihood of the “constant-only” model. The likelihood-ratio  $\chi^2$  model test is defined as  $2(L_1 - L_0)$ . The pseudo- $R^2$  (McFadden 1974) is defined as  $1 - L_1/L_0$ . This is simply the log likelihood on a scale where 0 corresponds to the “constant-only” model and 1 corresponds to perfect prediction for a discrete model (in which case the overall log likelihood is 0).

Some maximum likelihood routines can report coefficients in an exponentiated form, for example, odds ratios in `logistic`. Let  $b$  be the unexponentiated coefficient,  $s$  its standard error, and  $b_0$  and  $b_1$  the reported confidence interval for  $b$ . In exponentiated form, the point estimate is  $e^b$ , the standard error  $e^b s$ , and the confidence interval  $e^{b_0}$  and  $e^{b_1}$ . The displayed  $Z$  (or  $t$ ) statistics and  $p$ -values are the same as those for the unexponentiated results. This is justified because  $e^b = 1$  and  $b = 0$  are equivalent hypotheses, and normality is more likely to hold in the  $b$  metric.

# Title

**mean** — Estimate means

[Description](#)  
[Options](#)  
[References](#)

[Quick start](#)  
[Remarks and examples](#)  
[Also see](#)

[Menu](#)  
[Stored results](#)

[Syntax](#)  
[Methods and formulas](#)

## Description

`mean` produces estimates of means, along with standard errors.

## Quick start

Mean, standard error, and 95% confidence interval for `v1`

```
mean v1
```

Also compute statistics for `v2`

```
mean v1 v2
```

Same as above, but for each level of categorical variable `catvar1`

```
mean v1 v2, over(catvar1)
```

Weighting by probability weight `wvar`

```
mean v1 v2 [pweight=wvar]
```

Population mean using `svyset` data

```
svy: mean v3
```

Subpopulation means for each level of categorical variable `catvar2` using `svyset` data

```
svy: mean v3, over(catvar2)
```

Test equality of two subpopulation means

```
svy: mean v3, over(catvar2)  
test v3@1.catvar2 = v3@2.catvar2
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Means

## Syntax

```
mean varlist [if] [in] [weight] [, options]
```

<i>options</i>	Description
<b>Model</b>	
<code>stdize(<i>varname</i>)</code>	variable identifying strata for standardization
<code>stdweight(<i>varname</i>)</code>	weight variable for standardization
<code>nostdrescale</code>	do not rescale the standard weight variable
<b>if/in/over</b>	
<code>over(<i>varlist<sub>o</sub></i>)</code>	group over subpopulations defined by <i>varlist<sub>o</sub></i>
<b>SE/Cluster</b>	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>analytic</code> , <code>cluster <i>clustvar</i></code> , <code>bootstrap</code> , or <code>jackknife</code>
<b>Reporting</b>	
<code>level(#)</code>	set confidence level; default is level(95)
<code>noheader</code>	suppress table header
<code>display_options</code>	control column formats, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<code>coeflegend</code>	display legend instead of statistics

*varlist* may contain factor variables; see [U] 11.4.3 **Factor variables**.

`bootstrap`, `collect`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] **mi estimate**.

Weights are not allowed with the `bootstrap` prefix; see [R] **bootstrap**.

`aweight`s are not allowed with the `jackknife` prefix; see [R] **jackknife**.

`vce()` and `weights` are not allowed with the `svy` prefix; see [SVY] **svy**.

`fweights`, `aweight`s, `iweight`s, and `pweight`s are allowed; see [U] 11.1.6 **weight**.

`coeflegend` does not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`stdize(varname)` specifies that the point estimates be adjusted by direct standardization across the strata identified by *varname*. This option requires the `stdweight()` option.

`stdweight(varname)` specifies the weight variable associated with the standard strata identified in the `stdize()` option. The standardization weights must be constant within the standard strata.

`nostdrescale` prevents the standardization weights from being rescaled within the `over()` groups. This option requires `stdize()` but is ignored if the `over()` option is not specified.

### if/in/over

`over(varlisto)` specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist<sub>o</sub>*. Only numeric, nonnegative, integer-valued variables are allowed in `over(varlisto)`.

## SE/Cluster

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`analytic`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(analytic)`, the default, uses the analytically derived variance estimator associated with the sample mean.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`noheader` prevents the table header from being displayed.

`display_options`: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

The following option is available with `mean` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

### ► Example 1

Using the fuel data from [example 3](#) of [R] [ttest](#), we estimate the average mileage of the cars without the fuel treatment (`mpg1`) and those with the fuel treatment (`mpg2`).

```
. use https://www.stata-press.com/data/r18/fuel
. mean mpg1 mpg2
Mean estimation                                     Number of obs = 12
```

	Mean	Std. err.	[95% conf. interval]	
mpg1	21	.7881701	19.26525	22.73475
mpg2	22.75	.9384465	20.68449	24.81551

Using these results, we can test the equality of the mileage between the two groups of cars.

```
. test mpg1 = mpg2
( 1) mpg1 - mpg2 = 0
      F( 1, 11) =      5.04
      Prob > F =      0.0463
```

## ▷ Example 2

In [example 1](#), the joint observations of `mpg1` and `mpg2` were used to estimate a covariance between their means.

```
. matrix list e(V)
symmetric e(V)[2,2]
      mpg1      mpg2
mpg1  .62121212
mpg2  .4469697  .88068182
```

If the data were organized this way out of convenience but the two variables represent independent samples of cars (coincidentally of the same sample size), we should reshape the data and use the `over()` option to ensure that the covariance between the means is zero.

```
. use https://www.stata-press.com/data/r18/fuel
. stack mpg1 mpg2, into(mpg) clear
. rename _stack trt
. label define trt_lab 1 "without" 2 "with"
. label values trt trt_lab
. label var trt "Fuel treatment"
. mean mpg, over(trt)
Mean estimation                                     Number of obs = 24
```

	Mean	Std. err.	[95% conf. interval]	
c.mpg@trt				
without	21	.7881701	19.36955	22.63045
with	22.75	.9384465	20.80868	24.69132

```
. matrix list e(V)
symmetric e(V)[2,2]
      c.mpg@      c.mpg@
      1.trt      2.trt
c.mpg@1.trt  .62121212
c.mpg@2.trt      0  .88068182
```

Now, we can test the equality of the mileage between the two independent groups of cars.

```
. test mpg@1.trt = mpg@2.trt
( 1)  c.mpg@1bn.trt - c.mpg@2.trt = 0
      F( 1, 23) = 2.04
      Prob > F = 0.1667
```

## ▷ Example 3: standardized means

Suppose that we collected the blood pressure data from [example 2](#) of [\[R\] dstdize](#), and we wish to obtain standardized high blood pressure rates for each city in 1990 and 1992, using, as the standard, the age, sex, and race distribution of the four cities and two years combined. Our rate is really the mean of a variable that indicates whether a sampled individual has high blood pressure. First, we generate the strata and weight variables from our standard distribution, and then use `mean` to compute the rates.

```
. use https://www.stata-press.com/data/r18/hbp, clear
. egen strata = group(age race sex) if inlist(year, 1990, 1992)
(675 missing values generated)
. by strata, sort: gen stdw = _N
. mean hbp, over(city year) stdize(strata) stdweight(stdw)
Mean estimation
N. of std strata = 24                                Number of obs = 455
```

	Mean	Std. err.	[95% conf. interval]	
c.hbp@city#year				
1 1990	.058642	.0296273	.0004182	.1168657
1 1992	.0117647	.0113187	-.0104789	.0340083
2 1990	.0488722	.0238958	.0019121	.0958322
2 1992	.014574	.007342	.0001455	.0290025
3 1990	.1011211	.0268566	.0483425	.1538998
3 1992	.0810577	.0227021	.0364435	.1256719
5 1990	.0277778	.0155121	-.0027066	.0582622
5 1992	.0548926	0	.	.

The standard error of the high blood pressure rate estimate is missing for city 5 in 1992 because there was only one individual with high blood pressure; that individual was the only person observed in the stratum of white males 30–35 years old.

By default, `mean` rescales the standard weights within the `over()` groups. In the following, we use the `nostdrescale` option to prevent this, thus reproducing the results in [\[R\] dstdize](#).

```
. mean hbp, over(city year) stdize(strata) stdweight(stdw) nostdrescale
Mean estimation
N. of std strata = 24                                Number of obs = 455
```

	Mean	Std. err.	[95% conf. interval]	
c.hbp@city#year				
1 1990	.0073302	.0037034	.0000523	.0146082
1 1992	.0015432	.0014847	-.0013745	.004461
2 1990	.0078814	.0038536	.0003084	.0154544
2 1992	.0025077	.0012633	.000025	.0049904
3 1990	.0155271	.0041238	.007423	.0236312
3 1992	.0081308	.0022772	.0036556	.012606
5 1990	.0039223	.0021904	-.0003822	.0082268
5 1992	.0088735	0	.	.

## ► Example 4: profile plots and contrasts

The first example in [R] [marginsplot](#) shows how to use margins and marginsplot to get profile plots from a linear regression. We can similarly explore the data using marginsplot after mean with the over() option. Here we use marginsplot to plot the means of systolic blood pressure for each age group.

```
. use https://www.stata-press.com/data/r18/nhanes2, clear
. mean bpsystol, over(agegrp)
Mean estimation                                     Number of obs = 10,351
```

	Mean	Std. err.	[95% conf. interval]	
c.bpsystol@agegrp				
20-29	117.3466	.3247329	116.71	117.9831
30-39	120.2374	.4095845	119.4345	121.0402
40-49	126.9442	.532033	125.9013	127.9871
50-59	135.6754	.6061842	134.4872	136.8637
60-69	141.5227	.4433527	140.6537	142.3918
70+	148.1765	.8321116	146.5454	149.8076

```
. marginsplot
Variables that uniquely identify means: agegrp
```

We see that the mean systolic blood pressure increases with age. We can use `contrast` to formally test whether each mean is different from the mean in the previous age group using the `ar.` `contrast` operator; see [R] [contrast](#) for more information on this command.

```
. contrast ar.agegrp#c.bpsystol, effects nowald
```

```
Contrasts of means
```

	Contrast	Std. err.	t	P> t	[95% conf. interval]	
agegrp# c.bpsystol (30-39 vs 20-29) (40-49 vs 30-39) (50-59 vs 40-49) (60-69 vs 50-59) (70+ vs 60-69)	2.89081	.5226958	5.53	0.000	1.866225	3.915394
	6.706821	.6714302	9.99	0.000	5.390688	8.022954
	8.731263	.8065472	10.83	0.000	7.150275	10.31225
	5.847282	.7510133	7.79	0.000	4.375151	7.319413
	6.653743	.9428528	7.06	0.000	4.80557	8.501917

The first row of the output reports that the mean systolic blood pressure for the 30–39 age group is 2.89 higher than the mean for the 20–29 age group. The mean for the 40–49 age group is 6.71 higher than the mean for the 30–39 age group, and so on. Each of these differences is significantly different from zero.

We can include both `agegrp` and `sex` in the `over()` option to estimate means separately for men and women in each age group.

```
. mean bpsystol, over(agegrp sex)
```

```
Mean estimation
```

```
Number of obs = 10,351
```

	Mean	Std. err.	[95% conf. interval]	
c.bpsystol@agegrp#sex				
20-29#Male	123.8862	.4528516	122.9985	124.7739
20-29#Female	111.2849	.3898972	110.5206	112.0492
30-39#Male	124.6818	.5619855	123.5802	125.7834
30-39#Female	116.2207	.5572103	115.1284	117.3129
40-49#Male	129.0033	.7080788	127.6153	130.3912
40-49#Female	125.0468	.7802558	123.5174	126.5763
50-59#Male	136.0864	.855435	134.4096	137.7632
50-59#Female	135.3164	.8556015	133.6393	136.9935
60-69#Male	140.7451	.6059786	139.5572	141.9329
60-69#Female	142.2368	.6427981	140.9767	143.4968
70+#Male	146.3951	1.141126	144.1583	148.6319
70+#Female	149.6599	1.189975	147.3273	151.9924

```
. marginsplot
```

```
Variables that uniquely identify means: agegrp sex
```

Are the means different for men and women within each age group? We can again perform the tests using `contrast`. This time, we will use `r.sex` to obtain contrasts comparing men and women and use `@agegrp` to request that the tests are performed for each age group.

```
. contrast r.sex#c.bpsystol@agegrp, effects nowald
```

```
Contrasts of means
```

	Contrast	Std. err.	t	P> t	[95% conf. interval]	
sex@agegrp# c.bpsystol (Female vs Male) 20-29	-12.60132	.5975738	-21.09	0.000	-13.77268	-11.42996
(Female vs Male) 30-39	-8.461161	.7913981	-10.69	0.000	-10.01245	-6.909868
(Female vs Male) 40-49	-3.956451	1.053648	-3.76	0.000	-6.021805	-1.891097
(Female vs Male) 50-59	-.7699782	1.209886	-0.64	0.525	-3.141588	1.601631
(Female vs Male) 60-69	1.491684	.8834022	1.69	0.091	-.2399545	3.223323
(Female vs Male) 70+	3.264762	1.648699	1.98	0.048	.0329927	6.496531

Using a 0.05 significance level, we find that the mean systolic blood pressure is different for men and women in all age groups except the fifties and sixties.

## Video example

[Descriptive statistics in Stata](#)

## Stored results

`mean` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(N_over)</code>	number of subpopulations
<code>e(N_stdize)</code>	number of standard strata
<code>e(N_clust)</code>	number of clusters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(df_r)</code>	sample degrees of freedom
<code>e(rank)</code>	rank of <code>e(V)</code>

### Macros

<code>e(cmd)</code>	<code>mean</code>
<code>e(cmdline)</code>	command as typed
<code>e(varlist)</code>	<i>varlist</i>
<code>e(stdize)</code>	<i>varname</i> from <code>stdize()</code>
<code>e(stdweight)</code>	<i>varname</i> from <code>stdweight()</code>
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(over)</code>	<i>varlist</i> from <code>over()</code>
<code>e(vce)</code>	<i>vcetype</i> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(marginsnotok)</code>	predictions disallowed by <code>margins</code>

### Matrices

<code>e(b)</code>	vector of mean estimates
<code>e(V)</code>	(co)variance estimates
<code>e(sd)</code>	vector of standard deviation estimates
<code>e(_N)</code>	vector of numbers of nonmissing observations
<code>e(_N_stdsum)</code>	number of nonmissing observations within the standard strata
<code>e(_p_stdize)</code>	standardizing proportions
<code>e(error)</code>	error code corresponding to <code>e(b)</code>

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

### Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals
-----------------------	--

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

Methods and formulas are presented under the following headings:

*The mean estimator*  
*Survey data*  
*The survey mean estimator*  
*The standardized mean estimator*  
*The poststratified mean estimator*  
*The standardized poststratified mean estimator*  
*Subpopulation estimation*

### The mean estimator

Let  $y$  be the variable on which we want to calculate the mean and  $y_j$  an individual observation on  $y$ , where  $j = 1, \dots, n$  and  $n$  is the sample size. Let  $w_j$  be the weight, and if no weight is specified, define  $w_j = 1$  for all  $j$ . For `aweight`s, the  $w_j$  are normalized to sum to  $n$ . See *The survey mean estimator* for `pweight`d data.

Let  $W$  be the sum of the weights

$$W = \sum_{j=1}^n w_j$$

The mean is defined as

$$\bar{y} = \frac{1}{W} \sum_{j=1}^n w_j y_j$$

The default variance estimator for the mean is

$$\widehat{V}(\bar{y}) = \frac{1}{W(W-1)} \sum_{j=1}^n w_j (y_j - \bar{y})^2$$

The standard error of the mean is the square root of the variance.

If  $x$ ,  $x_j$ , and  $\bar{x}$  are similarly defined for another variable (observed jointly with  $y$ ), the covariance estimator between  $\bar{x}$  and  $\bar{y}$  is

$$\widehat{\text{Cov}}(\bar{x}, \bar{y}) = \frac{1}{W(W-1)} \sum_{j=1}^n w_j (x_j - \bar{x})(y_j - \bar{y})$$

### Survey data

See `[SVY] Variance estimation`, `[SVY] Direct standardization`, and `[SVY] Poststratification` for discussions that provide background information for the following formulas. The following formulas are derived from the fact that the mean is a special case of the ratio estimator where the denominator variable is one,  $x_j = 1$ ; see `[R] ratio`.

## The survey mean estimator

Let  $Y_j$  be a survey item for the  $j$ th individual in the population, where  $j = 1, \dots, M$  and  $M$  is the size of the population. The associated population mean for the item of interest is  $\bar{Y} = Y/M$  where

$$Y = \sum_{j=1}^M Y_j$$

Let  $y_j$  be the survey item for the  $j$ th sampled individual from the population, where  $j = 1, \dots, m$  and  $m$  is the number of observations in the sample.

The estimator for the mean is  $\bar{y} = \hat{Y}/\hat{M}$ , where

$$\hat{Y} = \sum_{j=1}^m w_j y_j \quad \text{and} \quad \hat{M} = \sum_{j=1}^m w_j$$

and  $w_j$  is a sampling weight. The score variable for the mean estimator is

$$z_j(\bar{y}) = \frac{y_j - \bar{y}}{\hat{M}} = \frac{\hat{M}y_j - \hat{Y}}{\hat{M}^2}$$

## The standardized mean estimator

Let  $D_g$  denote the set of sampled observations that belong to the  $g$ th standard stratum and define  $I_{D_g}(j)$  to indicate if the  $j$ th observation is a member of the  $g$ th standard stratum; where  $g = 1, \dots, L_D$  and  $L_D$  is the number of standard strata. Also, let  $\pi_g$  denote the fraction of the population that belongs to the  $g$ th standard stratum, thus  $\pi_1 + \dots + \pi_{L_D} = 1$ .  $\pi_g$  is derived from the `stdweight()` option.

The estimator for the standardized mean is

$$\bar{y}^D = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g}{\hat{M}_g}$$

where

$$\hat{Y}_g = \sum_{j=1}^m I_{D_g}(j) w_j y_j \quad \text{and} \quad \hat{M}_g = \sum_{j=1}^m I_{D_g}(j) w_j$$

The score variable for the standardized mean is

$$z_j(\bar{y}^D) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) \frac{\hat{M}_g y_j - \hat{Y}_g}{\hat{M}_g^2}$$

## The poststratified mean estimator

Let  $P_k$  denote the set of sampled observations that belong to poststratum  $k$  and define  $I_{P_k}(j)$  to indicate if the  $j$ th observation is a member of poststratum  $k$ ; where  $k = 1, \dots, L_P$  and  $L_P$  is the number of poststrata. Also let  $M_k$  denote the population size for poststratum  $k$ .  $P_k$  and  $M_k$  are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [SVY] `svyset`.

The estimator for the poststratified mean is

$$\bar{y}^P = \frac{\hat{Y}^P}{\widehat{M}^P} = \frac{\hat{Y}^P}{M}$$

where

$$\hat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) w_j y_j$$

and

$$\widehat{M}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{M}_k = \sum_{k=1}^{L_P} M_k = M$$

The score variable for the poststratified mean is

$$z_j(\bar{y}^P) = \frac{z_j(\hat{Y}^P)}{M} = \frac{1}{M} \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left( y_j - \frac{\hat{Y}_k}{\widehat{M}_k} \right)$$

## The standardized poststratified mean estimator

The estimator for the standardized poststratified mean is

$$\bar{y}^{DP} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g^P}{\widehat{M}_g^P}$$

where

$$\hat{Y}_g^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \hat{Y}_{g,k} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) w_j y_j$$

and

$$\widehat{M}_g^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{M}_{g,k} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) w_j$$

The score variable for the standardized poststratified mean is

$$z_j(\bar{y}^{DP}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{M}_g^P z_j(\hat{Y}_g^P) - \hat{Y}_g^P z_j(\widehat{M}_g^P)}{(\widehat{M}_g^P)^2}$$

where

$$z_j(\hat{Y}_g^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) y_j - \frac{\hat{Y}_{g,k}}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}_g^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) - \frac{\widehat{M}_{g,k}}{\widehat{M}_k} \right\}$$

## Subpopulation estimation

Let  $S$  denote the set of sampled observations that belong to the subpopulation of interest, and define  $I_S(j)$  to indicate if the  $j$ th observation falls within the subpopulation.

The estimator for the subpopulation mean is  $\bar{y}^S = \widehat{Y}^S / \widehat{M}^S$ , where

$$\widehat{Y}^S = \sum_{j=1}^m I_S(j) w_j y_j \quad \text{and} \quad \widehat{M}^S = \sum_{j=1}^m I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^S) = I_S(j) \frac{y_j - \bar{y}^S}{\widehat{M}^S} = I_S(j) \frac{\widehat{M}^S y_j - \widehat{Y}^S}{(\widehat{M}^S)^2}$$

The estimator for the standardized subpopulation mean is

$$\bar{y}^{DS} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^S}{\widehat{M}_g^S}$$

where

$$\widehat{Y}_g^S = \sum_{j=1}^m I_{D_g}(j) I_S(j) w_j y_j \quad \text{and} \quad \widehat{M}_g^S = \sum_{j=1}^m I_{D_g}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^{DS}) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) I_S(j) \frac{\widehat{M}_g^S y_j - \widehat{Y}_g^S}{(\widehat{M}_g^S)^2}$$

The estimator for the poststratified subpopulation mean is

$$\bar{y}^{PS} = \frac{\widehat{Y}^{PS}}{\widehat{M}^{PS}}$$

where

$$\widehat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) I_S(j) w_j y_j$$

and

$$\widehat{M}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{M}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^{PS}) = \frac{\widehat{M}^{PS} z_j(\widehat{Y}^{PS}) - \widehat{Y}^{PS} z_j(\widehat{M}^{PS})}{(\widehat{M}^{PS})^2}$$

where

$$z_j(\widehat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j) y_j - \frac{\widehat{Y}_k^S}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j) - \frac{\widehat{M}_k^S}{\widehat{M}_k} \right\}$$

The estimator for the standardized poststratified subpopulation mean is

$$\bar{y}^{DPS} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^{PS}}{\widehat{M}_g^{PS}}$$

where

$$\widehat{Y}_g^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{Y}_{g,k}^S = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) I_S(j) w_j y_j$$

and

$$\widehat{M}_g^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{M}_{g,k}^S = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^{DPS}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{M}_g^{PS} z_j(\widehat{Y}_g^{PS}) - \widehat{Y}_g^{PS} z_j(\widehat{M}_g^{PS})}{(\widehat{M}_g^{PS})^2}$$

where

$$z_j(\widehat{Y}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) I_S(j) y_j - \frac{\widehat{Y}_{g,k}^S}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) I_S(j) - \frac{\widehat{M}_{g,k}^S}{\widehat{M}_k} \right\}$$

## Postestimation commands

The following postestimation commands are of special interest after `mean`:

Command	Description
<code>estat sd</code>	standard deviation estimates

The following standard postestimation commands are also available:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>hausman</code>	Hausman’s specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>marginsplot</code>	graph the results from <code>mean</code>
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

## estat sd

### Description for estat sd

`estat sd` reports standard deviations based on the estimation results from `mean`. `estat sd` is not appropriate with estimation results that used direct standardization.

`estat sd` can also report subpopulation standard deviations based on estimation results from `svy: mean`; see [\[SVY\] estat](#).

### Menu for estat sd

Statistics > Postestimation

### Syntax for estat sd

```
estat sd [ , variance ]
```

### Option for estat sd

`variance` requests that the variance be displayed instead of the standard deviation.

### Stored results for estat sd

`estat sd` stores the following in `r()`:

Matrices

<code>r(mean)</code>	vector of mean estimates
<code>r(sd)</code>	vector of standard deviation estimates
<code>r(variance)</code>	vector of variance estimates

# Title

**mfp** — Multivariable fractional polynomial models

<a href="#">Description</a>	<a href="#">Quick start</a>	<a href="#">Menu</a>	<a href="#">Syntax</a>
<a href="#">Options</a>	<a href="#">Remarks and examples</a>	<a href="#">Stored results</a>	<a href="#">Acknowledgments</a>
<a href="#">References</a>	<a href="#">Also see</a>		

## Description

`mfp` selects the multivariable fractional polynomial (MFP) model that best predicts the outcome variable from the right-hand-side variables in `xvarlist`.

For univariate fractional polynomials, `fp` can be used to fit a wider range of models than `mfp`. See [\[R\] fp](#) for more details.

## Quick start

Find optimal MFP model for regression of `y` on fractional polynomials of `x1`, `x2`, and `x3`

```
mfp: regress y x1 x2 x3
```

Same as above, but search only powers of  $-1$ ,  $-0.5$ ,  $1$ , and  $2$

```
mfp, xpowers(-1 -.5 1 2): regress y x1 x2 x3
```

Allow a maximum of 2 degrees of freedom for all covariates

```
mfp, dfdefault(2): regress y x1 x2 x3
```

Allow 4 degrees of freedom for `x1` and 2 degrees of freedom for `x2` and `x3`

```
mfp, dfdefault(2) df(x1:4): regress y x1 x2 x3
```

Same as above

```
mfp, df(x1:4, x2 x3:2): regress y x1 x2 x3
```

Use a 10% significance level when testing between fractional polynomials of different degrees

```
mfp, alpha(0.1): regress y x1 x2 x3
```

Perform backward selection using a nominal  $p$ -value of 0.05 for all variables

```
mfp, select(0.05): regress y x1 x2 x3
```

Same as above, but force `x3` into the model by setting its nominal  $p$ -value to 1

```
mfp, select(0.05, x3:1): regress y x1 x2 x3
```

Note: In the above examples, `regress` could be replaced with any estimation command allowing the `mfp` prefix.

## Menu

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial models

## Syntax

```
mfp [ , options ] : regression_cmd [ yvar1 [ yvar2 ] ] xvarlist [ if ] [ in ] [ weight ]
[ , regression_cmd_options ]
```

*regression\_cmd* may be `clogit`, `glm`, `intreg`, `logistic`, `logit`, `mlogit`, `nbreg`, `ologit`, `oprobit`, `poisson`, `probit`, `qreg`, `regress`, `rreg`, `stcox`, `stcrreg`, `streg`, or `xtgee`.

*yvar1* is not allowed for `streg`, `stcrreg`, and `stcox`. For these commands, you must first `stset` your data.

*yvar1* and *yvar2* must both be specified when *regression\_cmd* is `intreg`.

*xvarlist* has elements of type *varlist* or (*varlist*) or both, for example, `x1 x2 (x3 x4 x5)`. Elements enclosed in parentheses are tested jointly for inclusion in the model and are not eligible for fractional polynomial transformation.

<i>options</i>	Description
Model 2	
<code>sequential</code>	use the Royston and Altman model-selection algorithm; default uses closed-test procedure
<code>cycles(#)</code>	maximum number of iteration cycles; default is <code>cycles(5)</code>
<code>dfdefault(#)</code>	default maximum degrees of freedom; default is <code>dfdefault(4)</code>
<code>center(cent_list)</code>	specification of centering for the independent variables
<code>alpha(alpha_list)</code>	<i>p</i> -values for testing between FP models; default is <code>alpha(0.05)</code>
<code>df(df_list)</code>	degrees of freedom for each predictor
<code>powers(numlist)</code>	list of FP powers to use; default is <code>powers(-2 -1(.5) 1 2 3)</code>
Adv. model	
<code>xorder(+ - n)</code>	order of entry into model-selection algorithm; default is <code>xorder(+)</code>
<code>select(select_list)</code>	nominal <i>p</i> -values for selection on each predictor
<code>xpowers(xp_list)</code>	FP powers for each predictor
<code>zero(varlist)</code>	treat nonpositive values of specified predictors as zero when FP is transformed
<code>catzero(varlist)</code>	add indicator variable for specified predictors
<code>all</code>	include out-of-sample observations in generated variables
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>display_options</code>	control column formats and line width

---

<i>regression_cmd_options</i>	Description
-------------------------------	-------------

---

Adv. model

<i>regression_cmd_options</i>	options appropriate to the regression command in use
-------------------------------	--

---

`collect` is allowed; see [U] 11.1.10 **Prefix commands**.

All weight types supported by *regression\_cmd* are allowed; see [U] 11.1.6 **weight**.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

`fp generate` may be used to create new variables containing fractional polynomial powers. See [R] **fp**.

## Options

Model 2

`sequential` chooses the sequential fractional polynomial (FP) selection algorithm (see [Methods of FP model selection](#)).

`cycles(#)` sets the maximum number of iteration cycles permitted. `cycles(5)` is the default.

`dfdefault(#)` determines the default maximum degrees of freedom (df) for a predictor. The default is `dfdefault(4)` (second-degree FP).

`center(cent_list)` defines the centering of the covariates `xvar1`, `xvar2`, ... of `xvarlist`. The default is `center(mean)`, except for binary covariates, where it is `center(#)`, with # being the lower of the two distinct values of the covariate. A typical item in `cent_list` is `varlist:{mean|#|no}`. Items are separated by commas. The first item is special in that `varlist` is optional, and if it is omitted, the default is reset to the specified value (`mean`, #, or `no`). For example, `center(no, age:mean)` sets the default to `no` (that is, no centering) and the centering of `age` to `mean`.

`alpha(alpha_list)` sets the significance levels for testing between FP models of different degrees. The rules for `alpha_list` are the same as those for `df_list` in the `df()` option (see below). The default nominal *p*-value (significance level, selection level) is 0.05 for all variables.

Example: `alpha(0.01)` specifies that all variables have an FP selection level of 1%.

Example: `alpha(0.05, weight:0.1)` specifies that all variables except `weight` have an FP selection level of 5%; `weight` has a level of 10%.

`df(df_list)` sets the df for each predictor. The df (not counting the regression constant, `_cons`) is twice the degree of the FP, so, for example, an `xvar` fit as a second-degree FP (FP2) has 4 df. The first item in `df_list` may be either # or `varlist:#`. Subsequent items must be `varlist:#`. Items are separated by commas, and `varlist` is specified in the usual way for variables. With the first type of item, the df for all predictors is taken to be #. With the second type of item, all members of `varlist` (which must be a subset of `xvarlist`) have # df.

The default number of degrees of freedom for a predictor of type `varlist` specified in `xvarlist` but not in `df_list` is assigned according to the number of distinct (unique) values of the predictor, as follows:

# of distinct values	Default df
1	(invalid predictor)
2–3	1
4–5	<code>min(2, dfdefault())</code>
≥ 6	<code>dfdefault()</code>

Example: `df(4)`

All variables have 4 df.

Example: `df(2, weight displ:4)`

`weight` and `displ` have 4 df; all other variables have 2 df.

Example: `df(weight displ:4, mpg:2)`

`weight` and `displ` have 4 df, `mpg` has 2 df; all other variables have default df.

`powers(numlist)` is the set of FP powers to be used. The default set is `-2, -1, -0.5, 0, 0.5, 1, 2, 3` (0 means log).

## Adv. model

`xorder(+|-|n)` determines the order of entry of the covariates into the model-selection algorithm.

The default is `xorder(+)`, which enters them in decreasing order of significance in a multiple linear regression (most significant first). `xorder(-)` places them in reverse significance order, whereas `xorder(n)` respects the original order in *xvarlist*.

`select(select_list)` sets the nominal *p*-values (significance levels) for variable selection by backward elimination. A variable is dropped if its removal causes a nonsignificant increase in deviance. The rules for *select\_list* are the same as those for *df\_list* in the `df()` option (see above). Using the default selection level of 1 for all variables forces them all into the model. Setting the nominal *p*-value to be 1 for a given variable forces it into the model, leaving others to be selected or not. The nominal *p*-value for elements of *xvarlist* bound by parentheses is specified by including (*varlist*) in *select\_list*.

Example: `select(0.05)`

All variables have a nominal *p*-value of 5%.

Example: `select(0.05, weight:1)`

All variables except *weight* have a nominal *p*-value of 5%; *weight* is forced into the model.

Example: `select(a (b c):0.05)`

All variables except *a*, *b*, and *c* are forced into the model. *b* and *c* are tested jointly with 2 df at the 5% level, and *a* is tested singly at the 5% level.

`xpowers(xp_list)` sets the permitted FP powers for covariates individually. The rules for *xp\_list* are the same as for *df\_list* in the `df()` option. The default selection is the same as that for the `powers()` option.

Example: `xpowers(-1 0 1)`

All variables have powers  $-1, 0, 1$ .

Example: `xpowers(x5:-1 0 1)`

All variables except *x5* have default powers; *x5* has powers  $-1, 0, 1$ .

`zero(varlist)` treats negative and zero values of members of *varlist* as zero when FP transformations are applied. By default, such variables are subjected to a preliminary linear transformation to avoid negative and zero values, as described in the `scale` option of [R] `fp`. *varlist* must be part of *xvarlist*.

`catzero(varlist)` is a variation on `zero()`; see *Zeros and zero categories* below. *varlist* must be part of *xvarlist*.

*regression\_cmd\_options* may be any of the options appropriate to *regression\_cmd*.

`all` includes out-of-sample observations when generating the FP variables. By default, the generated FP variables contain missing values outside the estimation sample.

## Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] **20.8 Specifying the width of confidence intervals**.

*display\_options*: `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] **Estimation options**.

## Remarks and examples

Remarks are presented under the following headings:

*Iteration report*  
*Estimation algorithm*  
*Methods of FP model selection*  
*Zeros and zero categories*

For elements in *xvarlist* not enclosed in parentheses, `mfp` leaves variables in the data named `Ixvar__1`, `Ixvar__2`, ..., where *xvar* represents the first four letters of the name of *xvar*<sub>1</sub>, and so on, for *xvar*<sub>2</sub>, *xvar*<sub>3</sub>, etc. The new variables contain the best-fitting FP powers of *xvar*<sub>1</sub>, *xvar*<sub>2</sub>, ...

### Iteration report

By default, for each continuous predictor, *x*, `mfp` compares null, linear, and FP1 models for *x* with an FP2 model. The deviance for each of these nested submodels is given in the column labeled “Deviance”. The line labeled “Final” gives the deviance for the selected model and its powers. All the other predictors currently selected are included, with their transformations (if any). For models specified as having 1 df, the only choice is whether the variable enters the model.

### Estimation algorithm

The estimation algorithm in `mfp` processes the *xvars* in turn. Initially, `mfp` silently arranges *xvarlist* in order of increasing *p*-value (that is, of decreasing statistical significance) for omitting each predictor from the model comprising *xvarlist*, with each term linear. The aim is to model relatively important variables before unimportant ones. This approach may help to reduce potential model-fitting difficulties caused by collinearity or, more generally, “concurvity” among the predictors. See the `xorder()` option above for details on how to change the ordering.

At the initial cycle, the best-fitting FP function for *xvar*<sub>1</sub> (the first of *xvarlist*) is determined, with all the other variables assumed to be linear. Either the default or the alternative procedure is used (see *Methods of FP model selection* below). The functional form (but not the estimated regression coefficients) for *xvar*<sub>1</sub> is kept, and the process is repeated for *xvar*<sub>2</sub>, *xvar*<sub>3</sub>, etc. The first iteration concludes when all the variables have been processed in this way. The next cycle is similar, except that the functional forms from the initial cycle are retained for all variables except the one currently being processed.

A variable whose functional form is prespecified to be linear (that is, to have 1 df) is tested for exclusion within the above procedure when its nominal *p*-value (selection level) according to `select()` is less than 1; otherwise, it is included.

Updating of FP functions and candidate variables continues until the functions and variables included in the overall model do not change (convergence). Convergence is usually achieved within 1–4 cycles.

### Methods of FP model selection

`mfp` includes two algorithms for FP model selection, both of which combine backward elimination with the selection of an FP function. For each continuous variable in turn, they start from a most-complex permitted FP model and attempt to simplify the model by reducing the degree. The default algorithm resembles a closed-test procedure, a sequence of tests maintaining the overall type I error rate at a prespecified nominal level, such as 5%. All significance tests are approximate; therefore, the algorithm is not precisely a closed-test procedure (Royston and Sauerbrei 2008, chap. 6).

The closed-test algorithm for choosing an FP model with maximum permitted degree  $m = 2$  (that is, an FP2 model with 4 df) for one continuous predictor,  $x$ , is as follows:

1. Inclusion: Test FP2 against the null model for  $x$  on 4 df at the significance level determined by `select()`. If  $x$  is significant, continue; otherwise, drop  $x$  from the model.
2. Nonlinearity: Test FP2 against a straight line in  $x$  on 3 df at the significance level determined by `alpha()`. If significant, continue; otherwise, stop, with the chosen model for  $x$  being a straight line.
3. Simplification: Test FP2 against FP1 on 2 df at the significance level determined by `alpha()`. If significant, the final model is FP2; otherwise, it is FP1.

The first step is omitted if  $x$  is to be retained in the model, that is, if its nominal  $p$ -value, according to the `select()` option, is 1.

An alternative algorithm is available with the `sequential` option, as originally suggested by [Royston and Altman \(1994\)](#):

1. Test FP2 against FP1 on 2 df at the `alpha()` significance level. If significant, the final model is FP2; otherwise, continue.
2. Test FP1 against a straight line on 1 df at the `alpha()` level. If significant, the final model is FP1; otherwise, continue.
3. Test a straight line against omitting  $x$  on 1 df at the `select()` level. If significant, the final model is a straight line; otherwise, drop  $x$ .

The final step is omitted if  $x$  is to be retained in the model, that is, if its nominal  $p$ -value, according to the `select()` option, is 1.

If  $x$  is uninfluential, the overall type I error rate of this procedure is about double that of the closed-test procedure, for which the rate is close to the nominal value. This inflated type I error rate confers increased apparent power to detect nonlinear relationships.

## Zeros and zero categories

The `zero()` option permits fitting an FP model to the positive values of a covariate, taking nonpositive values as zero. An application is the assessment of the effect of cigarette smoking as a risk factor in an epidemiological study. Nonsmokers may be qualitatively different from smokers, so the effect of smoking (regarded as a continuous variable) may not be continuous between one and zero cigarettes. To allow for this, the risk may be modeled as constant for the nonsmokers and as an FP function of the number of cigarettes for the smokers:

```
. generate byte nonsmokr = cond(n_cigs==0, 1, 0) if n_cigs != .
. mfp, zero(n_cigs) df(4, nonsmokr:1): logit case n_cigs nonsmokr age
```

Omission of `zero(n_cigs)` would cause `n_cigs` to be transformed before analysis by the addition of a suitable constant, probably 1.

A closely related approach involves the `catzero()` option. The command

```
. mfp, catzero(n_cigs): logit case n_cigs age
```

would achieve a similar result to the previous command but with important differences. First, `mfp` would create the equivalent of the binary variable `nonsmokr` automatically and include it in the model. Second, the two smoking variables would be treated as one predictor in the model. With the `select()` option active, the two variables would be tested jointly for inclusion in the model. A modified version is described in [Royston and Sauerbrei \(2008, sec. 4.15\)](#).

## ▷ Example 1

We illustrate two of the analyses performed by [Sauerbrei and Royston \(1999\)](#). We use `brcancer.dta`, which contains prognostic factors data from the German Breast Cancer Study Group of patients with node-positive breast cancer. The response variable is recurrence-free survival time (`rectime`), and the censoring variable is `censrec`. There are 686 patients with 299 events. We use Cox regression to predict the log hazard of recurrence from prognostic factors of which five are continuous (`x1`, `x3`, `x5`, `x6`, `x7`) and three are binary (`x2`, `x4a`, `x4b`). Hormonal therapy (`hormon`) is known to reduce recurrence rates and is forced into the model. We use `mfp` to build a model from the initial set of eight predictors by using the backfitting model-selection algorithm. We set the nominal  $p$ -value for variable and FP selection to 0.05 for all variables except `hormon`, which it is set to 1:

```
. use https://www.stata-press.com/data/r18/brcancer
(German breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
```

```
. mfp, alpha(.05) select(.05, hormon:1): stcox x1 x2 x3 x4a x4b x5 x6 x7 hormon,
> nohr
```

Deviance for model with all terms untransformed = 3471.637, 686 observations

hormon	-.4024169	.1280843	-3.14	0.002	-.6534575	-.1513763

Deviance = 3420.724.

Some explanation of the output from the model-selection algorithm is desirable. Consider the first few lines of output in the iteration log:

1. Deviance for model with all terms untransformed = 3471.637, 686 observations

Variable	Model (vs.)	Deviance	Dev diff.	P	Powers	(vs.)
2. x5	null FP2	3503.610	61.366	0.000*	.	.5 3
3.	lin.	3471.637	29.393	0.000+	1	
4.	FP1	3449.203	6.959	0.031+	0	
5.	Final	3442.244			.5 3	

Line 1 gives the deviance ( $-2 \times \log$  partial likelihood) for the Cox model with all terms linear, the place where the algorithm starts. The model is modified variable by variable in subsequent steps. The most significant linear term turns out to be x5, which is therefore processed first. Line 2 compares the best-fitting FP2 for x5 with a model omitting x5. The FP has powers (0.5, 3), and the test for inclusion of x5 is highly significant. The reported deviance of 3,503.610 is of the null model, not for the FP2 model. The deviance for the FP2 model may be calculated by subtracting the deviance

difference (Dev diff.) from the reported deviance, giving  $3,503.610 - 61.366 = 3,442.244$ . Line 3 shows that the FP2 model is also a significantly better fit than a straight line (`lin.`) and line 4 that FP2 is also somewhat better than FP1 ( $p = 0.031$ ). Thus at this stage in the model-selection procedure, the final model for `x5` (line 5) is FP2 with powers (0.5, 3). The overall model with an FP2 for `x5` and all other terms linear has a deviance of 3,442.244.

After all the variables have been processed (cycle 1) and reprocessed (cycle 2) in this way, convergence is achieved because the functional forms (FP powers and variables included) after cycle 2 are the same as they were after cycle 1. The model finally chosen is Model II as given in tables 3 and 4 of [Sauerbrei and Royston \(1999\)](#). Because of scaling of variables, the regression coefficients reported there are different, but the model and its deviance are identical. The model includes `x1` with powers  $(-2, -0.5)$ , `x4a`, `x5` with powers  $(-2, -1)$ , and `x6` with power 0.5. There is strong evidence of nonlinearity for `x1` and for `x5`, the deviance differences for comparison with a straight-line model (FP2 vs `lin.`) being, respectively, 19.3 and 31.1 at convergence (cycle 2). Predictors `x2`, `x3`, `x4b`, and `x7` are dropped, as may be seen from their status out in the table `Final multivariable fractional polynomial model for _t` (the assumed *depvar* when using `stcox`).

All predictors except `x4a` and `hormon`, which are binary, have been centered on the mean of the original variable. For example, the mean of `x1` (age) is 53.05 years. The first FP-transformed variable for `x1` is `x1^-2` and is created by the expression `generate double Ix1__1 = X^-2-.0355 if e(sample)`. The value 0.0355 is obtained from  $(53.05/10)^{-2}$ . The division by 10 is applied automatically to improve the scaling of the regression coefficient for `Ix1__1`.

According to [Sauerbrei and Royston \(1999\)](#), medical knowledge dictates that the estimated risk function for `x5` (number of positive nodes), which was based on the above FP with powers  $(-2, -1)$ , should be monotonic, but it was not. They improved Model II by estimating a preliminary exponential transformation, `x5e` =  $\exp(-0.12 \cdot x5)$ , for `x5` and fitting a degree 1 FP for `x5e`, thus obtaining a monotonic risk function. The value of  $-0.12$  was estimated univariately using nonlinear Cox regression with the ado-file `boxtid` ([Royston and Ambler 1999b, 1999d](#)). To ensure a negative exponent, [Sauerbrei and Royston \(1999\)](#) restricted the powers for `x5e` to be positive. Their Model III may be fit by using the following command:

```
. mfp, alpha(.05) select(.05, hormon:1) df(x5e:2) xpowers(x5e:0.5 1 2 3):
> stcox x1 x2 x3 x4a x4b x5e x6 x7 hormon
```

Other than the customization for `x5e`, the command is the same as it was before. The resulting model is as reported in table 4 of [Sauerbrei and Royston \(1999\)](#):

```
. use https://www.stata-press.com/data/r18/brcancer, clear
(German breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
. mfp, alpha(.05) select(.05, hormon:1) df(x5e:2) xpowers(x5e:0.5 1 2 3):
> stcox x1 x2 x3 x4a x4b x5e x6 x7 hormon, nohr
(output omitted)
```

## Stored results

In addition to what *regression\_cmd* stores, **mfp** stores the following in `e()`:

### Scalars

<code>e(fp_nx)</code>	number of predictors in <i>xvarlist</i>
<code>e(fp_dev)</code>	deviance of final model fit
<code>e(Fp_id#)</code>	initial degrees of freedom for the #th element of <i>xvarlist</i>
<code>e(Fp_fd#)</code>	final degrees of freedom for the #th element of <i>xvarlist</i>
<code>e(Fp_al#)</code>	FP selection level for the #th element of <i>xvarlist</i>
<code>e(Fp_se#)</code>	backward elimination selection level for the #th element of <i>xvarlist</i>

### Macros

<code>e(fp_cmd)</code>	<code>fracpoly</code>
<code>e(fp_cmd2)</code>	<code>mfp</code>
<code>e(cmdline)</code>	command as typed
<code>e(fracpoly)</code>	command used to fit the selected model using <code>fracpoly</code>
<code>e(fp_fv1)</code>	variables in final model
<code>e(fp_dep1)</code>	<i>yvar</i> <sub>1</sub> ( <i>yvar</i> <sub>2</sub> )
<code>e(fp_opts)</code>	estimation command options
<code>e(fp_x1)</code>	first variable in <i>xvarlist</i>
<code>e(fp_x2)</code>	second variable in <i>xvarlist</i>
...	
<code>e(fp_xN)</code>	last variable in <i>xvarlist</i> , $N=e(fp\_nx)$
<code>e(fp_k1)</code>	power for first variable in <i>xvarlist</i> (*)
<code>e(fp_k2)</code>	power for second variable in <i>xvarlist</i> (*)
...	
<code>e(fp_kN)</code>	power for last var. in <i>xvarlist</i> (*), $N=e(fp\_nx)$

Note: (\*) contains ‘.’ if the variable is not selected in the final model.

In addition to the above, the following is stored in `r()`:

### Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals
-----------------------	--

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

## Acknowledgments

**mfp** is an update of `mfracpol` by [Royston and Ambler \(1998\)](#).

## Postestimation commands

The following postestimation commands are of special interest after `mfp`:

Command	Description
<code>fracplot</code>	plot data and fit from most recently fit fractional polynomial model
<code>fracpred</code>	create variable containing prediction, deviance residuals, or SES of fitted values

The following standard postestimation commands are also available if available after `regression_cmd`:

Command	Description
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>linktest</code>	link test for model specification
<code>lrtest</code>	likelihood-ratio test
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

## fracplot and fracpred

### Description for fracplot and fracpred

`fracplot` plots the data and fit, with 95% confidence limits, from the most recently fit fractional polynomial (FP) model. The data and fit are plotted against *varname*, which may be *xvar*<sub>1</sub> or another of the covariates (*xvar*<sub>2</sub>, ..., or a variable from *xvarlist*). If *varname* is not specified, *xvar*<sub>1</sub> is assumed.

`fracpred` creates *newvar* containing the fitted index or deviance residuals for the whole model, or the fitted index or its standard error for *varname*, which may be *xvar*<sub>1</sub> or another covariate.

### Menu for fracplot and fracpred

#### fracplot

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial plot

#### fracpred

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial prediction

### Syntax for fracplot and fracpred

*Plot data and fit from most recently fit fractional polynomial model*

```
fracplot [varname] [if] [in] [, fracplot_options]
```

*Create variable containing the prediction, deviance residuals, or SEs of fitted values*

```
fracpred newvar [, fracpred_options]
```

<i>fracplot_options</i>	Description
Plot	
<i>marker_options</i>	change look of markers (color, size, etc.)
<i>marker_label_options</i>	add marker labels; change look or position
Fitted line	
<u>lineopts</u> ( <i>cline_options</i> )	affect rendition of the fitted line
CI plot	
<u>ciopts</u> ( <i>area_options</i> )	affect rendition of the confidence bands
Add plots	
<u>addplot</u> ( <i>plot</i> )	add other plots to the generated graph
Y axis, X axis, Titles, Legend, Overall	
<i>twoway_options</i>	any options other than <code>by()</code> documented in [G-3] <i>twoway_options</i>

<i>fracpred_options</i>	Description
<code>for(<i>varname</i>)</code>	compute prediction for <i>varname</i>
<code>dresid</code>	compute deviance residuals
<code>stdp</code>	compute standard errors of the fitted values <i>varname</i>

`fracplot` is not allowed after `mfp` with `clogit`, `mlogit`, or `stcrreg`. `fracpred`, `dresid` is not allowed after `mfp` with `clogit`, `mlogit`, or `stcrreg`.

## Options for fracplot

### Plot

`marker_options` affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

`marker_label_options` specify if and how the markers are to be labeled; see [G-3] [marker\\_label\\_options](#).

### Fitted line

`lineopts(cline_options)` affect the rendition of the fitted line; see [G-3] [cline\\_options](#).

### CI plot

`ciopts(area_options)` affect the rendition of the confidence bands; see [G-3] [area\\_options](#).

### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

### Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Options for fracpred

`for(varname)` specifies (partial) prediction for variable *varname*. The fitted values are adjusted to the value specified by the `center()` option in `mfp`.

`dresid` specifies that deviance residuals be calculated.

`stdp` specifies calculation of the standard errors of the fitted values *varname*, adjusted for all the other predictors at the values specified by `center()`.

## Remarks and examples

`fracplot` actually produces a component-plus-residual plot. For normal-error models with constant weights and one covariate, this amounts to a plot of the observations with the fitted line inscribed. For other normal-error models, weighted residuals are calculated and added to the fitted values.

For models with additional covariates, the line is the partial linear predictor for the variable in question ( $xvar_1$  or a covariate) and includes the intercept  $\beta_0$ .

For generalized linear and Cox models, the fitted values are plotted on the scale of the “index” (linear predictor). Deviance residuals are added to the (partial) linear predictor to give component-plus-residual values. These values are plotted as small circles.

## ▷ Example 1

In [example 1](#) of [\[R\] mfp](#), we used Cox regression to predict the log hazard of breast cancer recurrence from prognostic factors of which five are continuous ( $x_1$ ,  $x_3$ ,  $x_5$ ,  $x_6$ ,  $x_7$ ) and three are binary ( $x_2$ ,  $x_{4a}$ ,  $x_{4b}$ ). We also controlled for hormonal therapy ( $hormon$ ). We used `mfp` to build a model from the initial set of eight predictors by using the backfitting model-selection algorithm. The nominal  $p$ -value for variable and FP selection was set to 0.05 for all variables except  $hormon$ , which is set to 1.

```
. use https://www.stata-press.com/data/r18/brcancer
(German breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
. mfp, alpha(.05) select(.05, hormon:1): stcox x1 x2 x3 x4a x4b x5 x6 x7 hormon,
> nohr
(output omitted)
```

We can use `fracplot` to produce component-plus-residual plots of the continuous variables. We produce the component-plus-residual plot for  $x_1$  with `fracplot` by specifying  $x_1$  after the command name.

```
. fracplot x1
```

We use `fracpred` with the `stdp` option to predict the standard error of the fractional polynomial prediction for  $x_1$ . The standard error prediction will be stored in variable `sepx1`. We specify that prediction is made for  $x_1$  with the `for()` option. After prediction, we use `summarize` to show how the standard error estimate varies over different values of  $x_1$ .

```
. fracpred sepx1, stdp for(x1)
```

```
. summarize sepx1
```

Variable	Obs	Mean	Std. dev.	Min	Max
sepx1	686	.0542654	.0471993	.0003304	.6862065

◀

## Methods and formulas

The general definition of an FP, accommodating possible repeated powers, may be written for functions  $H_1(x), \dots, H_m(x)$  as

$$\beta_0 + \sum_{j=1}^m \beta_j H_j(x)$$

where  $H_1(x) = x^{(p_1)}$  and for  $j = 2, \dots, m$ ,

$$H_j(x) = \begin{cases} x^{(p_j)} & \text{if } p_j \neq p_{j-1} \\ H_{j-1}(x) \log x & \text{if } p_j = p_{j-1} \end{cases}$$

For example, an FP of degree 3 with powers (1, 3, 3) has  $H_1(x) = x$ ,  $H_2(x) = x^3$ , and  $H_3(x) = x^3 \log x$  and equals  $\beta_0 + \beta_1 x + \beta_2 x^3 + \beta_3 x^3 \log x$ .

The component-plus-residual values graphed by `fracplot` are calculated as follows: Let the data consist of triplets  $(y_i, x_i, \mathbf{z}_i)$ ,  $i = 1, \dots, n$ , where  $\mathbf{z}_i$  is the vector of covariates for the  $i$ th observation, after applying possible fractional polynomial transformation and adjustment as described earlier. Let  $\hat{\eta}_i = \hat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}' \hat{\beta} + \mathbf{z}_i' \hat{\gamma}$  be the linear predictor from the FP model, as given by the `fracpred` command or, equivalently, by the `predict` command with the `xb` option, following `mfp`. Here  $\mathbf{H}(x_i) = \{H_1(x_i), \dots, H_m(x_i)\}'$  is the vector of FP functions described above,  $\mathbf{H}(x_0) = \{H_1(x_0), \dots, H_m(x_0)\}'$  is the vector of adjustments to  $x_0$  (often,  $x_0$  is chosen to be the mean of the  $x_i$ ),  $\hat{\beta}$  is the estimated parameter vector, and  $\hat{\gamma}$  is the estimated parameter vector for the covariates. The values  $\hat{\eta}_i^* = \hat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}' \hat{\beta}$  represent the behavior of the FP model for  $x$  at fixed values  $\mathbf{z} = \mathbf{0}$  of the (adjusted) covariates. The  $i$ th component-plus-residual is defined as  $\hat{\eta}_i^* + d_i$ , where  $d_i$  is the deviance residual for the  $i$ th observation. For normal-errors models,  $d_i = \sqrt{w_i}(y_i - \hat{\eta}_i)$ , where  $w_i$  is the case weight (or 1, if `weight` is not specified). For logistic, Cox, and generalized linear regression models, see [R] [logistic](#), [R] [probit](#), [ST] [stcox](#), and [R] [glm](#) for the formula for  $d_i$ . The formula for `poisson` models is the same as that for `glm` with `family(poisson)`. For `stcox`,  $d_i$  is the partial martingale residual (see [ST] [stcox postestimation](#)).

`fracplot` plots the values of  $d_i$  and the curve represented by  $\hat{\eta}_i^*$  against  $x_i$ . The confidence interval for  $\hat{\eta}_i^*$  is obtained from the variance–covariance matrix of the entire model and takes into account the uncertainty in estimating  $\beta_0$ ,  $\beta$ , and  $\gamma$  (but not in estimating the FP powers for  $x$ ).

`fracpred` with the `for(varname)` option calculates the predicted index at  $x_i = x_0$  and  $\mathbf{z}_i = \mathbf{0}$ ; that is,  $\hat{\eta}_i = \hat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}' \hat{\beta}$ . The standard error is calculated from the variance–covariance matrix of  $(\hat{\beta}_0, \hat{\beta})$ , again ignoring estimation of the powers.

## Description

`misstable` makes tables that help you understand the pattern of missing values in your data.

## Quick start

*Tables with counts of missing values*

Missing observations in `v1`, `v2`, and `v3`

```
misstable summarize v1 v2 v3
```

Missing observations in `v1–v3` for cases where `v4 > 10`

```
misstable summarize v1 v2 v3 if v4>10
```

All variables with missing values

```
misstable summarize
```

Include variables with no missing values in the table

```
misstable summarize, all
```

Create 3 missing-data indicator variables with prefix `m` for `v1`, `v2`, and `v3`

```
misstable summarize v1 v2 v3, generate(m)
```

*Tables of missing-value patterns*

Missing-value patterns for `v1`, `v2`, and `v3`

```
misstable patterns v1 v2 v3
```

Same as above, but for all variables with missing values

```
misstable patterns
```

Show variables in the order listed in the command

```
misstable patterns v1 v3 v2, asis
```

Show frequencies, rather than percentages, in the output

```
misstable patterns v1 v2 v3, frequency
```

*Missing-value patterns displayed as trees*

A tree view of missing-value patterns for `v1`, `v2`, and `v3`

```
misstable tree v1 v2 v3
```

For all variables with missing values

```
misstable tree
```

*Nesting patterns of missing values*

Missing values for v1, v2, and v3

```
misstable nested v1 v2 v3
```

Same as above, but for all variables with missing values

```
misstable nested
```

Treat extended missing values (.a, .b, ..., .z) as nonmissing

```
misstable nested v1 v2 v3, exok
```

## Menu

Statistics > Summaries, tables, and tests > Other tables > Tabulate missing values

## Syntax

Report counts of missing values

```
misstable summarize [varlist] [if] [in] [, summarize_options]
```

Report pattern of missing values

```
misstable patterns [varlist] [if] [in] [, patterns_options]
```

Present a tree view of the pattern of missing values

```
misstable tree [varlist] [if] [in] [, tree_options]
```

List the nesting rules that describe the missing-value pattern

```
misstable nested [varlist] [if] [in] [, nested_options]
```

<i>summarize_options</i>	Description
<u>all</u>	show all variables
<u>showzeros</u>	show zeros in table
<u>generate</u> ( <i>stub</i> [, <i>exok</i> ])	generate missing-value indicators

<i>patterns_options</i>	Description
<u>asis</u>	use variables in order given
<u>frequency</u>	report frequencies instead of percentages
<u>exok</u>	treat .a, .b, ..., .z as nonmissing
<u>replace</u>	replace data in memory with dataset of patterns
<u>clear</u>	okay to replace even if original unsaved
<u>bypatterns</u>	list by patterns rather than by frequency

<i>tree_options</i>	Description
<u>asis</u>	use variables in order given
<u>frequency</u>	report frequencies instead of percentages
<u>exok</u>	treat .a, .b, ..., .z as nonmissing

<i>nested_options</i>	Description
<u>exok</u>	treat .a, .b, ..., .z as nonmissing

In addition, programmer's option `nopreserve` is allowed with all syntaxes; see [P] [nopreserve option](#).

`collect` is allowed; see [U] [11.1.10 Prefix commands](#).

## Options

Options are presented under the following headings:

*Options for misstable summarize*  
*Options for misstable patterns*  
*Options for misstable tree*  
*Option for misstable nested*  
*Common options*

### Options for misstable summarize

**all** specifies that the table should include all the variables specified or all the variables in the dataset.

The default is to include only numeric variables that contain missing values.

**showzeros** specifies that zeros in the table should display as 0 rather than being omitted.

**generate**(*stub* [, *exok*]) requests that a missing-value indicator *newvar*, a new binary variable containing 0 for complete observations and 1 for incomplete observations, be generated for every numeric variable in *varlist* containing missing values. If the **all** option is specified, missing-value indicators are created for all the numeric variables specified or for all the numeric variables in the dataset. If *exok* is specified within **generate**(), the extended missing values *.a*, *.b*, ..., *.z* are treated as if they do not designate missing.

For each variable in *varlist*, *newvar* is the corresponding variable name *varname* prefixed with *stub*. If the total length of *stub* and *varname* exceeds 32 characters, *newvar* is abbreviated so that its name does not exceed 32 characters.

### Options for misstable patterns

**asis**, **frequency**, and **exok** – see *Common options* below.

**replace** specifies that the data in memory be replaced with a dataset corresponding to the table just displayed; see *misstable patterns* under *Remarks and examples* below.

**clear** is for use with **replace**; it specifies that it is okay to change the data in memory even if they have not been saved to disk.

**bypatterns** specifies the table be ordered by pattern rather than by frequency. That is, **bypatterns** specifies that patterns containing one incomplete variable be listed first, followed by those for two incomplete variables, and so on. The default is to list the most frequent pattern first, followed by the next most frequent pattern, etc.

### Options for misstable tree

**asis**, **frequency**, and **exok** – see *Common options* below.

### Option for misstable nested

**exok** – see *Common options* below.

## Common options

`asis` specifies that the order of the variables in the table be the same as the order in which they are specified on the `misstable` command. The default is to order the variables by the number of missing values, and within that, by the amount of overlap of missing values.

`frequency` specifies that the table should report frequencies instead of percentages.

`exok` specifies that the extended missing values `.a`, `.b`, ..., `.z` should be treated as if they do not designate missing. Some users use extended missing values to designate values that are missing for a known and valid reason.

`nopreserve` is a programmer's option allowed with all `misstable` commands; see [P] [nopreserve option](#).

## Remarks and examples

Remarks are presented under the following headings:

*misstable summarize*  
*misstable patterns*  
*misstable tree*  
*misstable nested*  
*Execution time of misstable nested*

In what follows, we will use data from a 125-observation, fictional, student-satisfaction survey:

```
. use https://www.stata-press.com/data/r18/studentsurvey
(Student survey)
. summarize
```

Variable	Obs	Mean	Std. dev.	Min	Max
m1	125	2.456	.8376619	1	4
m2	125	2.472	.8089818	1	4
age	122	18.97541	.8763477	17	21
female	122	.5245902	.5014543	0	1
dept	116	2.491379	1.226488	1	4
offcampus	125	.36	.4819316	0	1
comment	0				

The `m1` and `m2` variables record the student's satisfaction with teaching and with academics. `comment` is a string variable recording any comments the student might have had.

## misstable summarize

### ▷ Example 1

misstable summarize reports counts of missing values:

```
. misstable summarize
```

Variable	Obs=.	Obs>.	Obs<.	Unique values	Min	Max
age	3		122	5	17	21
female	3		122	2	0	1
dept	9		116	4	1	4

Stata provides 27 different missing values, namely, ., .a, .b, ..., .z. The first of those, ., is often called system missing. The remaining missing values are called extended missings. The nonmissing and missing values are ordered *nonmissing* < . < .a < .b < ... < .z. Thus, reported in the column “Obs=.” are counts of system missing values; in the column “Obs>.”, extended missing values; and in the column “Obs<.”, nonmissing values.

The rightmost portion of the table is included to remind you how the variables are encoded.

Our data contain seven variables and yet misstable reported only three of them. The omitted variables contain no missing values or are string variables. Even if we specified the varlist explicitly, those variables would not appear in the table unless we specified the all option.

We can also create missing-value indicators for each of the variables above using the generate() option:

```
. quietly misstable summarize, generate(miss_)
. describe miss_*
```

Variable name	Storage type	Display format	Value label	Variable label
miss_age	byte	%8.0g		(age>=.)
miss_female	byte	%8.0g		(female>=.)
miss_dept	byte	%8.0g		(dept>=.)

For each variable containing missing values, the generate() option creates a new binary variable containing 0 for complete observations and 1 for incomplete observations. In our example, three new missing-value indicators are generated, one for each of the incomplete variables age, female, and dept. The naming convention of generate() is to prefix the corresponding variable names with the specified stub, which is miss\_ in this example.

Missing-value indicators are useful, for example, for checking whether data are missing completely at random. They are also often used within the multiple-imputation context to identify the observed and imputed data; see [MI] [Intro substantive](#) for a general introduction to multiple imputation. Within Stata’s multiple-imputation commands, an incomplete value is identified by the system missing value, a dot. By default, misstable summarize, generate() marks the extended missing values as incomplete values, as well. You can use exok within generate() to treat extended missing values as complete when creating missing-value identifiers.

**misstable patterns**

## ▷ Example 2

`misstable patterns` reports the pattern of missing values:

```
. misstable patterns
Missing-value patterns
(1 means complete)

  Percent |      Pattern
          |      1  2  3
-----|-----
    93%  |      1  1  1
         |
         |      1  1  0
         |      0  0  0
-----|-----
    100% |
Variables are (1) age (2) female (3) dept
```

There are three patterns in these data: (1,1,1), (1,1,0), and (0,0,0). By default, the rows of the table are ordered by frequency. In larger tables that have more patterns, it is sometimes useful to order the rows by pattern. We could have obtained that by typing `mi misstable patterns, bypatterns`.

In a pattern, 1 indicates that all values of the variable are nonmissing and 0 indicates that all values are missing. Thus, pattern (1,1,1) means no missing values, and 93% of our data have that pattern. There are two patterns in which variables are missing, (1,1,0) and (0,0,0). Pattern (1,1,0) means that `age` is nonmissing, `female` is nonmissing, and `dept` is missing. The order of the variables in the patterns appears in the key at the bottom of the table. Five percent of the observations have pattern (1,1,0). The remaining 2% have pattern (0,0,0), meaning that all three variables contain missing.

As with `misstable summarize`, only numeric variables that contain missing are listed, so had we typed `misstable patterns comments age female offcampus dept`, we still would have obtained the same table. Variables that are automatically omitted contain no missing values or are string variables.

The variables in the table are ordered from lowest to highest frequency of missing values, although you cannot see that from the information presented in the table. The variables are ordered this way even if you explicitly specify the varlist with a different ordering. Typing `misstable patterns dept female age` would produce the same table as above. Specify the `asis` option if you want the variables in the order in which you specify them.

You can obtain a dataset of the patterns by specifying the `replace` option:

```
. misstable patterns, replace clear
Missing-value patterns
(1 means complete)

  Percent |      Pattern
          |      1  2  3
-----|-----
    93%  |      1  1  1
         |
         |      1  1  0
         |      0  0  0
-----|-----
    100% |
Variables are (1) age (2) female (3) dept
(summary data now in memory)
```

```
. list
```

	_freq	age	female	dept
1.	3	0	Male	0
2.	6	1	Female	0
3.	116	1	Female	1

The differences between the dataset and the printed table are that 1) the dataset always records frequency and 2) the rows are reversed.

◀

## misstable tree

### ▷ Example 3

`misstable tree` presents a tree view of the pattern of missing values:

```
. use https://www.stata-press.com/data/r18/studentsurvey, clear
(Student survey)
. misstable tree, frequency
Nested pattern of missing values
  dept      age      female
-----
      9        3        3
                0
                6
                6
    116        0        0
                0
                116
                    116
-----
(number missing listed first)
```

In this example, we specified the `frequency` option to see the table in frequency rather than percentage terms. In the table, each column sums to the total number of observations in the data, 125. Variables are ordered from those with the most missing values to those with the least. Start with the first column. The `dept` variable is missing in 9 observations and, farther down, the table reports that it is not missing in 116 observations.

Go back to the first row and read across, but only to the second column. The `dept` variable is missing in 9 observations. Within those 9, `age` is missing in 3 of them and is not missing in the remaining 6. Reading down the second column, within the 116 observations that `dept` is not missing, `age` is missing in 0 and not missing in 116.

Reading straight across the first row again, `dept` is missing in 9 observations, and within the 9, `age` is missing in 3, and within the 3, `female` is also missing in 3. Skipping down just a little, within the 6 observations for which `dept` is missing and `age` is not missing, `female` is not missing, too.

◀

## misstable nested

### ▷ Example 4

`misstable nested` lists the nesting rules that describe the missing-value pattern,

```
. misstable nested
  1. female(3) <-> age(3) -> dept(9)
```

This line says that in observations in which `female` is missing, so is `age` missing, and vice versa, and in observations in which `age` (or `female`) is missing, so is `dept`. The numbers in parentheses are counts of the missing values. The `female` variable happens to be missing in 3 observations, and the same is true for `age`; the `dept` variable is missing in 9 observations. Thus, `dept` is missing in the 3 observations for which `age` and `female` are missing, and in 6 more observations, too.

In these data, it turns out that the missing-value pattern can be summarized in one statement. In a larger dataset, you might see something like this:

```
. misstable nested
  1. female(50) <-> age(50) -> dept(120)
  2. female(50) -> m1(58)
  3. offcampus(11)
```

`misstable nested` accounts for every missing value. In the above, in addition to `female <-> age -> dept`, we have that `female -> m1`, and we have `offcampus`, the last all by itself. The last line says that the 11 missing values in `offcampus` are not themselves nested in the missing value of any other variable, nor do they imply the missing values in another variable. In some datasets, all the statements will be of this last form.

In our data, however, we have one statement:

```
. misstable nested
  1. female(3) <-> age(3) -> dept(9)
```

When the missing-value pattern can be summarized in one `misstable nested` statement, the pattern of missing values in the data is said to be monotone.

◀

## Execution time of misstable nested

The execution time of `misstable nested` is affected little by the number of observations but can grow quickly with the number of variables, depending on the fraction of missing values within variable. The execution time of the example above, which has 3 variables containing missing, is instant. In worst-case scenarios, with 500 variables, the time might be 25 seconds; with 1,000 variables, the execution time might be closer to an hour.

In situations where `misstable nested` takes a long time to complete, it will produce thousands of rules that will defy interpretation. A 523-variable dataset we have seen ran in 20 seconds and produced 8,040 rules. Although we spotted a few rules in the output that did not surprise us, such as the year of the date being missing implied that the month and the day were also missing, mostly the output was not helpful.

If you have such a dataset, we recommend you run `misstable` on groups of variables that you have reason to believe the pattern of missing values might be related.

## Stored results

`misstable summarize` stores the following values of the last variable summarized in `r()`:

### Scalars

<code>r(N_eq_dot)</code>	number of observations containing .
<code>r(N_gt_dot)</code>	number of observations containing .a, .b, ..., .z
<code>r(N_lt_dot)</code>	number of observations containing nonmissing
<code>r(K_uniq)</code>	number of unique, nonmissing values
<code>r(min)</code>	variable's minimum value
<code>r(max)</code>	variable's maximum value

### Macros

<code>r(vartype)</code>	numeric, string, or none
-------------------------	--------------------------

`r(K_uniq)` contains . if the number of unique, nonmissing values is greater than 500. `r(vartype)` contains none if no variables are summarized, and in that case, the value of the scalars are all set to missing (.). Programmers intending to access results after `misstable summarize` should specify the all option.

`misstable patterns` stores the following in `r()`:

### Scalars

<code>r(N_complete)</code>	number of complete observations
<code>r(N_incomplete)</code>	number of incomplete observations
<code>r(K)</code>	number of patterns

### Macros

<code>r(vars)</code>	variables used in order presented
----------------------	-----------------------------------

`r(N_complete)` and `r(N_incomplete)` are defined with respect to the variables specified if variables were specified and otherwise, defined with respect to all the numeric variables in the dataset. `r(N_complete)` is the number of observations that contain no missing values.

`misstable tree` stores the following in `r()`:

### Macros

<code>r(vars)</code>	variables used in order presented
----------------------	-----------------------------------

`misstable nested` stores the following in `r()`:

### Scalars

<code>r(K)</code>	number of statements
-------------------	----------------------

### Macros

<code>r(stmt1)</code>	first statement
<code>r(stmt2)</code>	second statement
.	.
.	.
<code>r(stmt'r(K)')</code>	last statement
<code>r(stmtlwc)</code>	<code>r(stmt1)</code> with missing-value counts
<code>r(vars)</code>	variables considered

A statement is encoded “*varname*”, “*varname op varname*”, or “*varname op varname op varname*”, and so on; *op* is either “->” or “<->”.

## Description

`ml model` defines the current problem.

`ml clear` clears the current problem definition. This command is rarely used because when you type `ml model`, any previous problem is automatically cleared.

`ml query` displays a description of the current problem.

`ml check` verifies that the log-likelihood evaluator you have written works. We strongly recommend using this command.

`ml search` searches for (better) initial values. We recommend using this command.

`ml plot` provides a graphical way of searching for (better) initial values.

`ml init` provides a way to specify initial values.

`ml report` reports  $\ln L$ 's values, gradient, and Hessian at the initial values or current parameter estimates,  $\mathbf{b}_0$ .

`ml trace` traces the execution of the user-defined log-likelihood evaluation program.

`ml count` counts the number of times the user-defined log-likelihood evaluation program is called; this command is seldom used. `ml count clear` clears the counter. `ml count on` turns on the counter. `ml count` without arguments reports the current values of the counter. `ml count off` stops counting calls.

`ml maximize` maximizes the likelihood function and reports results. Once `ml maximize` has successfully completed, the previously mentioned `ml` commands may no longer be used unless `noclear` is specified. `ml graph` and `ml display` may be used whether or not `noclear` is specified.

`ml graph` graphs the log-likelihood values against the iteration number.

`ml display` redisplay results.

`ml footnote` displays a warning message when the model did not converge within the specified number of iterations.

`ml score` creates new variables containing the equation-level scores. The variables generated by `ml score` are equivalent to those generated by specifying the `score()` option of `ml maximize` (and `ml model ... , ... maximize`).

*progname* is the name of a Stata program you write to evaluate the log-likelihood function.

*funcname()* is the name of a Mata function you write to evaluate the log-likelihood function.

In this documentation, *progname* and *funcname()* are referred to as the user-written evaluator, the likelihood evaluator, or sometimes simply as the evaluator. The program you write is written in the style required by the method you choose. The methods are `lf`, `d0`, `d1`, `d2`, `lf0`, `lf1`, `lf2`, and `gf0`. Thus, if you choose to use method `lf`, your program is called a method-`lf` evaluator.

Method-`lf` evaluators are required to evaluate the observation-by-observation log likelihood  $\ln \ell_j$ ,  $j = 1, \dots, N$ .

Method-d0 evaluators are required to evaluate the overall log likelihood  $\ln L$ . Method-d1 evaluators are required to evaluate the overall log likelihood and its gradient vector  $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$ . Method-d2 evaluators are required to evaluate the overall log likelihood, its gradient, and its Hessian matrix  $H = \partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$ .

Method-lf0 evaluators are required to evaluate the observation-by-observation log likelihood  $\ln \ell_j$ ,  $j = 1, \dots, N$ . Method-lf1 evaluators are required to evaluate the observation-by-observation log likelihood and its equation-level scores  $g_{ji} = \partial \ln \ell / \partial \mathbf{x}_{ji} \mathbf{b}_i$ . Method-lf2 evaluators are required to evaluate the observation-by-observation log likelihood, its equation-level scores, and its Hessian matrix  $H = \partial^2 \ln \ell / \partial \mathbf{b} \partial \mathbf{b}'$ .

Method-gf0 evaluators are required to evaluate the summable pieces of the log likelihood  $\ln \ell_k$ ,  $k = 1, \dots, K$ .

`ml eval` is a subroutine used by evaluators of methods d0, d1, d2, lf0, lf1, lf2, and gf0 to evaluate the coefficient vector,  $\mathbf{b}$ , that they are passed.

`ml sum` is a subroutine used by evaluators of methods d0, d1, and d2 to define the value,  $\ln L$ , that is to be returned.

`ml vecsum` is a subroutine used by evaluators of methods d1 and d2 to define the gradient vector,  $\mathbf{g}$ , that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

`ml matsum` is a subroutine used by evaluators of methods d2 and lf2 to define the Hessian matrix,  $\mathbf{H}$ , that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

`ml matbysum` is a subroutine used by evaluator of method d2 to help define the Hessian matrix,  $\mathbf{H}$ , that is to be returned. It is suitable for use when the likelihood function contains terms made up of grouped sums, such as in panel-data models. For such models, use `ml matsum` to compute the observation-level outer products and `ml matbysum` to compute the group-level outer products. `ml matbysum` requires that the data be sorted by the variable identified in the `by()` option.

## Syntax

*ml model in interactive mode*

```
ml model    method progname eq [eq ...] [if] [in] [weight]
              [, model_options svy diparm_options]
```

```
ml model    method funcname() eq [eq ...] [if] [in] [weight]
              [, model_options svy diparm_options]
```

*ml model in noninteractive mode*

```
ml model    method progname eq [eq ...] [if] [in] [weight], maximize
              [model_options svy diparm_options noninteractive_options]
```

```
ml model    method funcname() eq [eq ...] [if] [in] [weight], maximize
              [model_options svy diparm_options noninteractive_options]
```

Noninteractive mode is invoked by specifying the `maximize` option. Use `maximize` when `ml` will be used as a subroutine of another ado-file or program and you want to carry forth the problem, from definition to posting of results, in one command.

```
ml clear

ml query

ml check

ml search    [ [ / ] eqname [ : ] #lb #ub ] [ ... ] [ , search_options ]

ml display   [ , display_options eform_option ]

ml footnote

ml score newvar [ if ] [ in ] [ , equation(eqname) missing ]

ml score newvarlist [ if ] [ in ] [ , missing ]

ml score [ type ] stub* [ if ] [ in ] [ , missing ]
```

where *method* is one of

lf	d0	lf0	gf0
	d1	lf1	
	d1debug	lf1debug	
	d2	lf2	
	d2debug	lf2debug	

or *method* can be specified using one of the longer, more descriptive names

<i>method</i>	Longer name
lf	linearform
d0	derivative0
d1	derivative1
d1debug	derivative1debug
d2	derivative2
d2debug	derivative2debug
lf0	linearform0
lf1	linearform1
lf1debug	linearform1debug
lf2	linearform2
lf2debug	linearform2debug
gf0	generalform0

*eq* is the equation to be estimated, enclosed in parentheses, and optionally with a name to be given to the equation, preceded by a colon,

( [*eqname*: ] [*varlist*<sub>*y*</sub> = ] [*varlist*<sub>*x*</sub> ] [ , *eq\_options* ] )

or *eq* is the name of a parameter, such as sigma, with a slash in front

*/eqname* which is equivalent to (*eqname*: , *freeparm*)

and *diparm\_options* is one or more *diparm*(*diparm\_args*) options where *diparm\_args* is either `__sep__` or anything accepted by the “undocumented” `_diparm` command; see help `_diparm`.

<i>eq_options</i>	Description
<code>noconstant</code>	do not include an intercept in the equation
<code>offset(<i>varname</i><sub><i>o</i></sub>)</code>	include <i>varname</i> <sub><i>o</i></sub> in model with coefficient constrained to 1
<code>exposure(<i>varname</i><sub><i>e</i></sub>)</code>	include ln( <i>varname</i> <sub><i>e</i></sub> ) in model with coefficient constrained to 1
<code>freeparm</code>	<i>eqname</i> is a free parameter

<i>model_options</i>	Description
<code>group(varname)</code>	use <i>varname</i> to identify groups
<code>vce(vcetype)</code>	<i>vcetype</i> may be <code>robust</code> , <code>cluster clustvar</code> , <code>oim</code> , or <code>opg</code>
<code>constraints(numlist)</code>	constraints by number to be applied
<code>constraints(matname)</code>	matrix that contains the constraints to be applied
<code>nocnsnotes</code>	do not display notes when constraints are dropped
<code>title(string)</code>	place a title on the estimation output
<code>nopreserve</code>	do not preserve the estimation subsample in memory
<code>collinear</code>	keep collinear variables within equations
<code>missing</code>	keep observations containing variables with missing values
<code>lf0(#<sub>k</sub> #<sub>ll</sub>)</code>	number of parameters and log-likelihood value of the constant-only model
<code>continue</code>	specifies that a model has been fit and sets the initial values $\mathbf{b}_0$ for the model to be fit based on those results
<code>waldtest(#)</code>	perform a Wald test; see <i>Options for use with ml model in interactive or noninteractive mode</i> below
<code>obs(#)</code>	number of observations
<code>crittype(string)</code>	describe the criterion optimized by <code>ml</code>
<code>subpop(varname)</code>	compute estimates for the single subpopulation
<code>nosvyadjust</code>	carry out Wald test as $W/k \sim F(k, d)$
<code>technique(nr)</code>	Stata's modified Newton–Raphson (NR) algorithm
<code>technique(bhhh)</code>	Berndt–Hall–Hall–Hausman (BHHH) algorithm
<code>technique(dfpr)</code>	Davidon–Fletcher–Powell (DFP) algorithm
<code>technique(bfgs)</code>	Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm
<code>deriv(min_spec)</code>	specify the minimum step size for computing numerical derivatives
<i>noninteractive_options</i>	Description
<code>init(ml_init_args)</code>	set the initial values $\mathbf{b}_0$
<code>search(on)</code>	equivalent to <code>ml search, repeat(0)</code> ; the default
<code>search(norescale)</code>	equivalent to <code>ml search, repeat(0) norescale</code>
<code>search(quietly)</code>	same as <code>search(on)</code> , except that output is suppressed
<code>search(off)</code>	prevents calling <code>ml search</code>
<code>repeat(#)</code>	<code>ml search</code> 's <code>repeat()</code> option; see below
<code>bounds(ml_search_bounds)</code>	specify bounds for <code>ml search</code>
<code>nowarning</code>	suppress “convergence not achieved” message of <code>iterate(0)</code>
<code>novce</code>	substitute the zero matrix for the variance matrix
<code>negh</code>	indicates that the evaluator returns the negative Hessian matrix
<code>score(newvars)</code>	new variables containing the contribution to the score
<code>maximize_options</code>	control the maximization process; seldom used

<i>search_options</i>	Description
<u>repeat</u> (#)	number of random attempts to find better initial-value vector; default is <code>repeat(10)</code> in interactive mode and <code>repeat(0)</code> in noninteractive mode
<u>restart</u>	use random actions to find starting values; not recommended
<u>norescale</u>	do not rescale to improve parameter vector; not recommended
<i>maximize_options</i>	control the maximization process; seldom used
<i>ml_maximize_options</i>	Description
<u>nowarning</u>	suppress “convergence not achieved” message of <code>iterate(0)</code>
<u>novce</u>	substitute the zero matrix for the variance matrix
<u>negh</u>	indicates that the evaluator returns the negative Hessian matrix
<u>score</u> ( <i>newvars</i>   <i>stub</i> *)	new variables containing the contribution to the score
<u>nooutput</u>	suppress display of final results
<u>noskipline</u>	suppress display of blank line before iteration log
<u>noclear</u>	do not clear ml problem definition after model has converged
<i>maximize_options</i>	control the maximization process; seldom used
<i>display_options</i>	Description
<u>noheader</u>	suppress header display above the coefficient table
<u>nofootnote</u>	suppress footnote display below the coefficient table
<u>level</u> (#)	set confidence level; default is <code>level(95)</code>
<u>first</u>	display coefficient table reporting results for first equation only
<u>neq</u> (#)	display coefficient table reporting first # equations
<u>showeqns</u>	display equation names in the coefficient table
<u>plus</u>	display coefficient table ending in dashes–plus–sign–dashes
<u>nocnsreport</u>	suppress constraints display above the coefficient table
<u>noomitted</u>	suppress display of omitted variables
<u>vsquish</u>	suppress blank space separating factor-variable terms or time-series–operated variables from other variables
<u>noemptycells</u>	suppress empty cells for interactions of factor variables
<u>baselevels</u>	report base levels of factor variables and interactions
<u>allbaselevels</u>	display all base levels of factor variables and interactions
<u>cformat</u> (% <i>fmt</i> )	format the coefficients, standard errors, and confidence limits in the coefficient table
<u>pformat</u> (% <i>fmt</i> )	format the <i>p</i> -values in the coefficient table
<u>sformat</u> (% <i>fmt</i> )	format the test statistics in the coefficient table
<u>no1stretch</u>	do not automatically widen the coefficient table to accommodate longer variable names
<u>coeflegend</u>	display legend instead of statistics

<i>eform_option</i>	Description
<u>e</u> form( <i>string</i> )	display exponentiated coefficients; column title is “ <i>string</i> ”
<u>e</u> form	display exponentiated coefficients; column title is “exp(b)”
hr	report hazard ratios
shr	report subhazard ratios
<u>i</u> rr	report incidence-rate ratios
or	report odds ratios
<u>r</u> rr	report relative-risk ratios

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 **weight**. With all but method lf, you must write your likelihood-evaluation program carefully if pweights are to be specified, and pweights may not be specified with method d0, d1, d1debug, d2, or d2debug. See Pitblado, Poi, and Gould (2024, chap. 7) for details.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

To redisplay results, type ml display.

## Syntax of subroutines for use by evaluator programs

```

mleval      newvar = vecname [ , eq(#) ]
mleval      scalarname = vecname , scalar [ eq(#) ]
mlsum       scalarnamelnf = exp [ if ] [ , noweight ]
mlvecsum    scalarnamelnf rowvecname = exp [ if ] [ , eq(#) ]
mlmatsum    scalarnamelnf matrixname = exp [ if ] [ , eq(#[,#]) ]
mlmatbysum  scalarnamelnf matrixname varnamea varnameb [ varnamec ] [ if ] ,
            by(varname) [ eq(#[,#]) ]

```

## Syntax of user-written evaluator

### Summary of notation

The log-likelihood function is  $\ln L(\theta_{1j}, \theta_{2j}, \dots, \theta_{Ej})$ , where  $\theta_{ij} = \mathbf{x}_{ij} \mathbf{b}_i$ ,  $j = 1, \dots, N$  indexes observations, and  $i = 1, \dots, E$  indexes the linear equations defined by ml model. If the likelihood satisfies the linear-form restrictions, it can be decomposed as  $\ln L = \sum_{j=1}^N \ln \ell(\theta_{1j}, \theta_{2j}, \dots, \theta_{Ej})$ .

### Method-lf evaluators

```

program progname
  version 18.0
  args lnfj theta1 theta2 ...
  // if you need to create any intermediate results:
  tempvar tmp1 tmp2 ...
  quietly generate double 'tmp1' = ...
  ...
  quietly replace 'lnfj' = ...
end

```

where

'lnfj' variable to be filled in with observation-by-observation values of  $\ln \ell_j$   
 'theta1' variable containing evaluation of first equation  $\theta_{1j} = \mathbf{x}_{1j} \mathbf{b}_1$   
 'theta2' variable containing evaluation of second equation  $\theta_{2j} = \mathbf{x}_{2j} \mathbf{b}_2$   
 ...

## Method-d0 evaluators

```
program programe
  version 18.0
  args todo b lnf
  tempvar theta1 theta2 ...
  mlevel 'theta1' = 'b', eq(1)
  mlevel 'theta2' = 'b', eq(2) // if there is a  $\theta_2$ 
  ...
  // if you need to create any intermediate results:
  tempvar tmp1 tmp2 ...
  generate double 'tmp1' = ...
  ...
  mlsum 'lnf' = ...
end
```

where

'todo' always contains 0 (may be ignored)  
 'b' full parameter row vector  $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$   
 'lnf' scalar to be filled in with overall  $\ln L$

## Method-d1 evaluators

```
program programe
  version 18.0
  args todo b lnf g
  tempvar theta1 theta2 ...
  mlevel 'theta1' = 'b', eq(1)
  mlevel 'theta2' = 'b', eq(2) // if there is a  $\theta_2$ 
  ...
  // if you need to create any intermediate results:
  tempvar tmp1 tmp2 ...
  generate double 'tmp1' = ...
  ...
  mlsum 'lnf' = ...
  if ('todo'==0 | 'lnf'>=.) exit
  tempname d1 d2 ...
  mlvecsum 'lnf' 'd1' = formula for  $\partial \ln \ell_j / \partial \theta_{1j}$ , eq(1)
  mlvecsum 'lnf' 'd2' = formula for  $\partial \ln \ell_j / \partial \theta_{2j}$ , eq(2)
  ...
  matrix 'g' = ('d1', 'd2', ...)
end
```

where

'todo' contains 0 or 1  
     0  $\Rightarrow$  'lnf' to be filled in;  
     1  $\Rightarrow$  'lnf' and 'g' to be filled in  
 'b' full parameter row vector  $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$   
 'lnf' scalar to be filled in with overall  $\ln L$   
 'g' row vector to be filled in with overall  $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$

## Method-d2 evaluators

```

program progname
  version 18.0
  args todo b lnf g H
  tempvar theta1 theta2 ...
  mlevel 'theta1' = 'b', eq(1)
  mlevel 'theta2' = 'b', eq(2) // if there is a  $\theta_2$

end

where
'todo'      always contains 0 (may be ignored)
'b'         full parameter row vector  $\mathbf{b}=(b_1, b_2, \dots, b_E)$ 
'lnfj'      variable to be filled in with the values of the log-likelihood  $\ln \ell_j$ 

```

## Global macros for use by all evaluators

```

$ML_y1      name of first dependent variable
$ML_y2      name of second dependent variable, if any
...
$ML_samp    variable containing 1 if observation to be used; 0 otherwise
$ML_w       variable containing weight associated with observation or 1 if no weights specified

```

Method-lf evaluators can ignore `$ML_samp`, but restricting calculations to the `$ML_samp==1` subsample will speed execution. Method-lf evaluators must ignore `$ML_w`; application of weights is handled by the method itself.

Methods d0, d1, d2, lf0, lf1, lf2, and gf0 can ignore `$ML_samp` as long as `ml model's nopreserve` option is not specified. These methods will run more quickly if `nopreserve` is specified. These evaluators can ignore `$ML_w` only if they use `mlsum`, `mlvecsum`, `mlmatsum`, and `mlmatbysum` to produce all final results.

## Options

Options are presented under the following headings:

- Options for use with ml model in interactive or noninteractive mode*
- Options for use with ml model in noninteractive mode*
- Options for use when specifying equations*
- Options for use with ml search*
- Option for use with ml plot*
- Options for use with ml init*
- Options for use with ml maximize*
- Option for use with ml graph*
- Options for use with ml display*
- Options for use with mleval*
- Option for use with mlsum*
- Option for use with mlvecsum*
- Option for use with mlmatsum*
- Options for use with mlmatbysum*
- Options for use with ml score*

### Options for use with ml model in interactive or noninteractive mode

`group(varname)` specifies the numeric variable that identifies groups. This option is typically used to identify panels for panel-data models.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that are derived from asymptotic theory (`oim`, `opg`); see [R] [vce\\_option](#).

`vce(robust)`, `vce(cluster clustvar)`, `pweight`, and `svy` will work with evaluators of methods `lf`, `lf0`, `lf1`, `lf2`, and `gf0`; all you need to do is specify them.

These options will not work with evaluators of methods `d0`, `d1`, or `d2`, and specifying these options will produce an error message.

`constraints(numlist | matname)` specifies the linear constraints to be applied during estimation. `constraints(numlist)` specifies the constraints by number. Constraints are defined by using the `constraint` command; see [R] [constraint](#). `constraint(matname)` specifies a matrix that contains the constraints.

`nocnsnotes` prevents notes from being displayed when constraints are dropped. A constraint will be dropped if it is inconsistent, contradicts other constraints, or causes some other error when the constraint matrix is being built. Constraints are checked in the order in which they are specified.

`title(string)` specifies the title for the estimation output when results are complete.

`nopreserve` specifies that `ml` need not ensure that only the estimation subsample is in memory when the user-written likelihood evaluator is called. `nopreserve` is irrelevant when you use method `lf`.

For the other methods, if `nopreserve` is not specified, `ml` saves the data in a file (preserves the original dataset) and drops the irrelevant observations before calling the user-written evaluator. This way, even if the evaluator does not restrict its attentions to the `$ML_samp==1` subsample, results will still be correct. Later, `ml` automatically restores the original dataset.

`ml` need not go through these machinations for method `lf` because the user-written evaluator calculates observation-by-observation values, and `ml` itself sums the components.

`ml` goes through these machinations if and only if the estimation sample is a subsample of the data in memory. If the estimation sample includes every observation in memory, `ml` does not preserve the original dataset. Thus, programmers must not alter the original dataset unless they `preserve` the data themselves.

We recommend that interactive users of `ml` not specify `nopreserve`; the speed gain is not worth the possibility of getting incorrect results.

We recommend that programmers specify `nopreserve`, but only after verifying that their evaluator really does restrict its attentions solely to the `$ML_samp==1` subsample.

`collinear` specifies that `ml` not remove the collinear variables within equations. There is no reason to leave collinear variables in place, but this option is of interest to programmers who, in their code, have already removed collinear variables and do not want `ml` to waste computer time checking again.

`missing` specifies that observations containing variables with missing values not be eliminated from the estimation sample. There are two reasons you might want to specify `missing`:

Programmers may wish to specify `missing` because, in other parts of their code, they have already eliminated observations with missing values and do not want `ml` to waste computer time looking again.

You may wish to specify `missing` if your model explicitly deals with missing values. Stata's `heckman` command is a good example of this. In such cases, there will be observations where missing values are allowed and other observations where they are not—where their presence should cause the observation to be eliminated. If you specify `missing`, it is your responsibility to specify an `if exp` that eliminates the irrelevant observations.

`lfo(#k #ll)` is typically used by programmers. It specifies the number of parameters and log-likelihood value of the constant-only model so that `ml` can report a likelihood-ratio test rather than a Wald test. These values may have been analytically determined, or they may have been determined by a previous fitting of the constant-only model on the estimation sample.

Also see the `continue` option directly below.

If you specify `lfo()`, it must be safe for you to specify the `missing` option, too, else how did you calculate the log likelihood for the constant-only model on the same sample? You must have identified the estimation sample, and done so correctly, so there is no reason for `ml` to waste time rechecking your results. All of which is to say, do not specify `lfo()` unless you are certain your code identifies the estimation sample correctly.

`lfo()`, even if specified, is ignored if `vce(robust)`, `vce(cluster clustvar)`, `pweight`, or `svy` is specified because, in that case, a likelihood-ratio test would be inappropriate.

`continue` is typically specified by programmers and does two things:

First, it specifies that a model has just been fit by either `ml` or some other estimation command, such as `logit`, and that the likelihood value stored in `e(l1)` and the number of parameters stored in `e(b)` as of that instant are the relevant values of the constant-only model. The current value of the log likelihood is used to present a likelihood-ratio test unless `vce(robust)`, `vce(cluster clustvar)`, `pweight`, `svy`, or `constraints()` is specified. A likelihood-ratio test is inappropriate when `vce(robust)`, `vce(cluster clustvar)`, `pweight`, or `svy` is specified. We suggest using `lrtest` when `constraints()` is specified; see [R] [lrtest](#).

Second, `continue` sets the initial values,  $b_0$ , for the model about to be fit according to the `e(b)` currently stored.

The comments made about specifying `missing` with `lfo()` apply equally well here.

`waldtest(#)` is typically specified by programmers. By default, `ml` presents a Wald test, but that is overridden if the `lfo()` or `continue` option is specified. A Wald test is performed if `vce(robust)`, `vce(cluster clustvar)`, or `pweight` is specified.

`waldtest(0)` prevents even the Wald test from being reported.

`waldtest(-1)` is the default. It specifies that a Wald test be performed by constraining all coefficients except the intercept to 0 in the first equation. Remaining equations are to be unconstrained. A Wald test is performed if neither `lfo()` nor `continue` was specified, and a Wald test is forced if `vce(robust)`, `vce(cluster clustvar)`, or `pweight` was specified.

`waldtest(k)` for  $k \leq -1$  specifies that a Wald test be performed by constraining all coefficients except intercepts to 0 in the first  $|k|$  equations; remaining equations are to be unconstrained. A Wald test is performed if neither `lfo()` nor `continue` was specified, and a Wald test is forced if `vce(robust)`, `vce(cluster clustvar)`, or `pweight` was specified.

`waldtest(k)` for  $k \geq 1$  works like the options above, except that it forces a Wald test to be reported even if the information to perform the likelihood-ratio test is available and even if none of `vce(robust)`, `vce(cluster clustvar)`, or `pweight` was specified. `waldtest(k)`,  $k \geq 1$ , may not be specified with `lfo()`.

`obs(#)` is used mostly by programmers. It specifies that the number of observations reported and ultimately stored in `e(N)` be `#`. Ordinarily, `ml` works that out for itself. Programmers may want to specify this option when, for the likelihood evaluator to work for  $N$  observations, they first had to modify the dataset so that it contained a different number of observations.

`crittype(string)` is used mostly by programmers. It allows programmers to supply a string (up to 32 characters long) that describes the criterion that is being optimized by `ml`. The default is "Log likelihood" for nonrobust and "Log pseudolikelihood" for robust estimation.

`svy` indicates that `ml` is to pick up the `svy` settings set by `svyset` and use the robust variance estimator. This option requires the data to be `svyset`; see [SVY] [svyset](#). `svy` may not be specified with `vce()` or `weights`.

`subpop(varname)` specifies that estimates be computed for the single subpopulation defined by the observations for which `varname`  $\neq$  0. Typically, `varname = 1` defines the subpopulation, and `varname = 0` indicates observations not belonging to the subpopulation. For observations whose subpopulation status is uncertain, `varname` should be set to missing (`.'`). This option requires the `svy` option.

`nosvyadjust` specifies that the model Wald test be carried out as  $W/k \sim F(k, d)$ , where  $W$  is the Wald test statistic,  $k$  is the number of terms in the model excluding the constant term,  $d$  is the total number of sampled PSUs minus the total number of strata, and  $F(k, d)$  is an  $F$  distribution with  $k$  numerator degrees of freedom and  $d$  denominator degrees of freedom. By default, an adjusted Wald test is conducted:  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ . See [Korn and Graubard \(1990\)](#) for a discussion of the Wald test and the adjustments thereof. This option requires the `svy` option.

`technique(algorithm_spec)` specifies how the likelihood function is to be maximized. The following algorithms are currently implemented in `ml`. For details, see [Pitblado, Poi, and Gould \(2024\)](#).

`technique(nr)` specifies Stata's modified Newton–Raphson (NR) algorithm.

`technique(bhhh)` specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.

`technique(dfpr)` specifies the Davidon–Fletcher–Powell (DFP) algorithm.

`technique(bfgs)` specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is `technique(nr)`.

You can switch between algorithms by specifying more than one in the `technique()` option. By default, `ml` will use an algorithm for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the technique in the option. For example, `technique(bhhh 10 nr 1000)` requests that `ml` perform 10 iterations using the BHHH algorithm, followed by 1,000 iterations using the NR algorithm, and then switch back to BHHH for

10 iterations, and so on. The process continues until convergence or until reaching the maximum number of iterations.

`deriv(min_spec)` specifies whether to use minimum values of step sizes for computing numerical derivatives and optionally specifies the minimum values.

`deriv(nomin)`, the default, suppresses the use of minimum values.

`deriv(min)` sets the minimum step size to  $1e-6$  for computing first-order derivatives and  $1e-4$  for computing second-order derivatives.

`deriv(min(#1, #2))` sets the minimum step size to #<sub>1</sub> for computing the first-order derivatives and #<sub>2</sub> for computing the second-order derivatives. Specifying `deriv(min(1e-6, 1e-4))` is equivalent to specifying `deriv(min)`.

`deriv(min(matname))` sets the minimum step size to the values in the  $1 \times 2$  matrix *matname*. The value in the first column of the row vector will set the minimum step size for the first-order derivatives, and the value in the second column will set the minimum step size for the second-order derivatives.

## Options for use with ml model in noninteractive mode

The following extra options are for use with `ml model` in noninteractive mode. Noninteractive mode is for programmers who use `ml` as a subroutine and want to issue one command that will carry forth the estimation from start to finish.

`maximize` is required. It specifies noninteractive mode.

`init(ml_init_args)` sets the initial values,  $b_0$ . *ml\_init\_args* are whatever you would type after the `ml init` command.

`search(on | norescale | quietly | off)` specifies whether `ml search` is to be used to improve the initial values. `search(on)` is the default and is equivalent to separately running `ml search, repeat(0)`. `search(norescale)` is equivalent to separately running `ml search, repeat(0) norescale`. `search(quietly)` is equivalent to `search(on)`, except that it suppresses `ml search`'s output. `search(off)` prevents calling `ml search`.

`repeat(#)` is `ml search`'s `repeat()` option. `repeat(0)` is the default.

`bounds(ml_search_bounds)` specifies the search bounds. *ml\_search\_bounds* is specified as

`[eqn_name] lower_bound upper_bound ... [eqn_name] lower_bound upper_bound`

for instance, `bounds(100 100 lnsigma 0 10)`. The `ml model` command issues `ml search ml_search_bounds, repeat(#)`. Specifying search bounds is optional.

`nowarning`, `novce`, `negh`, and `score()` are `ml maximize`'s equivalent options.

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

## Options for use when specifying equations

`noconstant` specifies that the equation not include an intercept.

`offset(varnameo)` specifies that the equation be  $\mathbf{x}\mathbf{b} + \text{varname}_o$ —that it include *varname<sub>o</sub>* with coefficient constrained to be 1.

`exposure(varnamee)` is an alternative to `offset(varnameo)`; it specifies that the equation be  $\mathbf{x}\mathbf{b} + \ln(\text{varname}_e)$ . The equation is to include  $\ln(\text{varname}_e)$  with coefficient constrained to be 1. `freeparm` specifies that the associated `eqname` is a free parameter. The corresponding full column name on `e(b)` will be `/eqname` instead of `eqname:_cons`. This option is not allowed with `varlistx`.

## Options for use with ml search

`repeat(#)` specifies the number of random attempts that are to be made to find a better initial-value vector. The default is `repeat(10)`.

`repeat(0)` specifies that no random attempts be made. More precisely, `repeat(0)` specifies that no random attempts be made if the first initial-value vector is a feasible starting point. If it is not, `ml search` will make random attempts, even if you specify `repeat(0)`, because it has no alternative. The `repeat()` option refers to the number of random attempts to be made to improve the initial values. When the initial starting value vector is not feasible, `ml search` will make up to 1,000 random attempts to find starting values. It stops when it finds one set of values that works and then moves into its improve-initial-values logic.

`repeat(k)`,  $k > 0$ , specifies the number of random attempts to be made to improve the initial values.

`restart` specifies that random actions be taken to obtain starting values and that the resulting starting values not be a deterministic function of the current values. Generally, you should not specify this option because, with `restart`, `ml search` intentionally does not produce as good a set of starting values as it could. `restart` is included for use by the optimizer when it gets into serious trouble. The random actions ensure that the optimizer and `ml search`, working together, do not cause an endless loop.

`restart` implies `norescale`, which is why we recommend that you do not specify `restart`. In testing, sometimes `rescale` worked so well that, even after randomization, the rescaler would bring the starting values right back to where they had been the first time and thus defeat the intended randomization.

`norescale` specifies that `ml search` not engage in its rescaling actions to improve the parameter vector. We do not recommend specifying this option because rescaling tends to work so well.

`maximize_options`: `[no]log` and `trace`; see [R] [Maximize](#). These options are seldom used.

## Option for use with ml plot

`saving(filename[, replace])` specifies that the graph be saved in `filename.gph`. See [G-3] [saving\\_option](#).

## Options for use with ml init

`copy` specifies that the list of numbers or the initialization vector be copied into the initial-value vector by position rather than by name.

`skip` specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

## Options for use with ml maximize

`nowarning` is allowed only with `iterate(0)`. `nowarning` suppresses the “convergence not achieved” message. Programmers might specify `iterate(0) nowarning` when they have a vector `b` already containing the final estimates and want `ml` to calculate the variance matrix and postestimation results. Then, specify `init(b) search(off) iterate(0) nowarning nolog`.

`novce` is allowed only with `iterate(0)`. `novce` substitutes the zero matrix for the variance matrix, which in effect posts estimation results as fixed constants.

`negh` indicates that the evaluator returns the negative Hessian matrix. By default, `ml` assumes `d2` and `lf2` evaluators return the Hessian matrix.

`score(newvars | stub*)` creates new variables containing the contributions to the score for each equation and ancillary parameter in the model; see [U] 20.23 **Obtaining scores**.

If `score(newvars)` is specified, the `newvars` must contain  $k$  new variables. For evaluators of methods `lf`, `lf0`, `lf1`, and `lf2`,  $k$  is the number of equations. For evaluators of method `gf0`,  $k$  is the number of parameters. If `score(stub*)` is specified, variables named `stub1`, `stub2`, . . . , `stubk` are created.

For evaluators of methods `lf`, `lf0`, `lf1`, and `lf2`, the first variable contains  $\partial \ln \ell_j / \partial (\mathbf{x}_{1j} \mathbf{b}_1)$ , the second variable contains  $\partial \ln \ell_j / \partial (\mathbf{x}_{2j} \mathbf{b}_2)$ , and so on.

For evaluators of method `gf0`, the first variable contains  $\partial \ln \ell_j / \partial \mathbf{b}_1$ , the second variable contains  $\partial \ln \ell_j / \partial \mathbf{b}_2$ , and so on.

`nooutput` suppresses display of results. This option is different from prefixing `ml maximize` with `quietly` in that the iteration log is still displayed (assuming that `nolog` is not specified).

`noskipline` suppresses display of a blank line before the iteration log. This is useful in programs when there is a header preceding the iteration log and a blank line is not wanted after the header.

`noclear` specifies that the `ml` problem definition not be cleared after the model has converged. Perhaps you are having convergence problems and intend to run the model to convergence. If so, use `ml search` to see if those values can be improved, and then restart the estimation.

*maximize\_options*: `difficult`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, and `nonrtolerance`; see [R] **Maximize**. These options are seldom used.

*display\_options*; see *Options for use with ml display* below.

*eform\_option*; see *Options for use with ml display* below.

## Option for use with ml graph

`saving(filename[, replace])` specifies that the graph be saved in `filename.gph`. See [G-3] *saving\_option*.

## Options for use with ml display

`noheader` suppresses the header display above the coefficient table that displays the final log-likelihood value, the number of observations, and the model significance test.

`nofootnote` suppresses the footnote display below the coefficient table, which displays a warning if the model fit did not converge within the specified number of iterations. Use `ml footnote` to display the warning if 1) you add to the coefficient table using the `plus` option or 2) you have your own footnotes and want the warning to be last.

`level(#)` is the standard confidence-level option. It specifies the confidence level, as a percentage, for confidence intervals of the coefficients. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals.

`first` displays a coefficient table reporting results for the first equation only, and the report makes it appear that the first equation is the only equation. This option is used by programmers who estimate ancillary parameters in the second and subsequent equations and who wish to report the values of such parameters themselves.

`neq(#)` is an alternative to `first`. `neq(#)` displays a coefficient table reporting results for the first # equations. This option is used by programmers who estimate ancillary parameters in the # + 1 and subsequent equations and who wish to report the values of such parameters themselves.

`showeqns` is a seldom-used option that displays the equation names in the coefficient table. `ml display` uses the numbers stored in `e(k_eq)` and `e(k_aux)` to determine how to display the coefficient table. `e(k_eq)` identifies the number of equations, and `e(k_aux)` identifies how many of these are for ancillary parameters. The `first` option is implied when `showeqns` is not specified and all but the first equation are for ancillary parameters.

`plus` displays the coefficient table, but rather than ending the table in a line of dashes, ends it in dashes-plus-sign-dashes. This is so that programmers can write additional display code to add more results to the table and make it appear as if the combined result is one table. Programmers typically specify `plus` with the `first` or `neq()` options. This option implies `nofootnote`.

`nocnsreport` suppresses the display of constraints above the coefficient table. This option is ignored if constraints were not used to fit the model.

`noomitted` specifies that variables that were omitted because of collinearity not be displayed. The default is to include in the table any variables omitted because of collinearity and to label them as “(omitted)”.

`vsquish` specifies that the blank space separating factor-variable terms or time-series-operated variables from other variables in the model be suppressed.

`noemptycells` specifies that empty cells for interactions of factor variables not be displayed. The default is to include in the table interaction cells that do not occur in the estimation sample and to label them as “(empty)”.

`baselevels` and `allbaselevels` control whether the base levels of factor variables and interactions are displayed. The default is to exclude from the table all base categories.

`baselevels` specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables.

`allbaselevels` specifies that all base levels of factor variables and interactions be reported.

`cformat(%fmt)` specifies how to format coefficients, standard errors, and confidence limits in the coefficient table.

`pformat(%fmt)` specifies how to format *p*-values in the coefficient table.

`sformat(%fmt)` specifies how to format test statistics in the coefficient table.

`nostretch` specifies that the width of the coefficient table not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the coefficient table up to the width of the Results window. Specifying `lstretch` or `nostretch` overrides the setting given by `set lstretch`. If `set lstretch` has not been set, the default is `lstretch`.

`coeflegend` specifies that the legend of the coefficients and how to specify them in an expression be displayed rather than displaying the statistics for the coefficients.

*eform\_option*: `eform(string)`, `eform`, `hr`, `shr`, `irr`, `or`, and `rrr` display the coefficient table in exponentiated form: for each coefficient,  $\exp(b)$  rather than  $b$  is displayed, and standard errors and confidence intervals are transformed. *string* is the table header that will be displayed above the transformed coefficients and must be 11 characters or shorter in length—for example, `eform("Odds ratio")`. The options `eform`, `hr`, `shr`, `irr`, `or`, and `rrr` provide a default *string* equivalent to “`exp(b)`”, “`Haz. ratio`”, “`SHR`”, “`IRR`”, “`Odds ratio`”, and “`RRR`”, respectively. These options may not be combined.

`ml display` looks at `e(k_eform)` to determine how many equations are affected by an *eform\_option*; by default, only the first equation is affected. Type `ereturn list`, `all` to view `e(k_eform)`; see [P] [ereturn](#).

## Options for use with `mlevel`

`eq(#)` specifies the equation number,  $i$ , for which  $\theta_{ij} = \mathbf{x}_{ij}\mathbf{b}_i$  is to be evaluated. `eq(1)` is assumed if `eq()` is not specified.

`scalar` asserts that the  $i$ th equation is known to evaluate to a constant, meaning that the equation was specified as `()`, `(name:)`, or `/name` on the `ml model` statement. If you specify this option, the new variable created is created as a scalar. If the  $i$ th equation does not evaluate to a scalar, an error message is issued.

## Option for use with `mlsum`

`noweight` specifies that weights (`$ML_w`) be ignored when summing the likelihood function.

## Option for use with `mlvecsum`

`eq(#)` specifies the equation for which a gradient vector  $\partial \ln L / \partial \mathbf{b}_i$  is to be constructed. The default is `eq(1)`.

## Option for use with `mlmatsum`

`eq(#[,#])` specifies the equations for which the Hessian matrix is to be constructed. The default is `eq(1)`, which is the same as `eq(1,1)`, which means  $\partial^2 \ln L / \partial \mathbf{b}_1 \partial \mathbf{b}'_1$ . Specifying `eq(i,j)` results in  $\partial^2 \ln L / \partial \mathbf{b}_i \partial \mathbf{b}'_j$ .

## Options for use with `mlmatbysum`

`by(varname)` is required and specifies the group variable.

`eq(#[,#])` specifies the equations for which the Hessian matrix is to be constructed. The default is `eq(1)`, which is the same as `eq(1,1)`, which means  $\partial^2 \ln L / \partial \mathbf{b}_1 \partial \mathbf{b}'_1$ . Specifying `eq(i,j)` results in  $\partial^2 \ln L / \partial \mathbf{b}_i \partial \mathbf{b}'_j$ .

## Options for use with `ml score`

`equation(eqname)` identifies from which equation the observation scores are to come. This option may be used only when generating one variable.

`missing` specifies that observations containing variables with missing values not be eliminated from the estimation sample.

## Remarks and examples

For a thorough discussion of `ml`, see the fifth edition of *Maximum Likelihood Estimation with Stata* (Pitblado, Poi, and Gould 2024). The book provides a tutorial introduction to `ml`, notes on advanced programming issues, and a discourse on maximum likelihood estimation from both theoretical and practical standpoints. See *Survey options and ml* at the end of *Remarks and examples* for examples of the new `svy` options. For more information about survey estimation, see [\[SVY\] Survey](#), [\[SVY\] svy estimation](#), and [\[SVY\] Variance estimation](#).

`ml` requires that you write a program that evaluates the log-likelihood function and, possibly, its first and second derivatives. The style of the program you write depends upon the method you choose. Methods `lf`, `lf0`, `d0`, and `gf0` require that your program evaluate the log likelihood only. Methods `d1` and `lf1` require that your program evaluate the log likelihood and its first derivatives. Methods `d2` and `lf2` requires that your program evaluate the log likelihood and its first and second derivatives. Methods `lf`, `lf0`, `d0`, and `gf0` differ from each other in that, with methods `lf` and `lf0`, your program is required to produce observation-by-observation log-likelihood values  $\ln \ell_j$  and it is assumed that  $\ln L = \sum_j \ln \ell_j$ ; with method `d0`, your program is required to produce only the overall value  $\ln L$ ; and with method `gf0`, your program is required to produce the summable pieces of the log likelihood, such as those in panel-data models.

Once you have written the program—called an evaluator—you define a model to be fit using `ml model` and obtain estimates using `ml maximize`. You might type

```
. ml model ...
. ml maximize
```

but we recommend that you type

```
. ml model ...
. ml check
. ml search
. ml maximize
```

`ml check` verifies your evaluator has no obvious errors, and `ml search` finds better initial values.

You fill in the `ml model` statement with 1) the method you are using, 2) the name of your program, and 3) the “equations”. You write your evaluator in terms of  $\theta_1, \theta_2, \dots$ , each of which has a linear equation associated with it. That linear equation might be as simple as  $\theta_i = b_0$ , it might be  $\theta_i = b_1\text{mpg} + b_2\text{weight} + b_3$ , or it might omit the intercept  $b_3$ . The equations are specified in parentheses on the `ml model` line.

Suppose that you are using method `lf` and the name of your evaluator program is `myprog`. The statement

```
. ml model lf myprog (mpg weight)
```

would specify one equation with  $\theta_i = b_1\text{mpg} + b_2\text{weight} + b_3$ . If you wanted to omit  $b_3$ , you would type

```
. ml model lf myprog (mpg weight, nocons)
```

and if all you wanted was  $\theta_i = b_0$ , you would type

```
. ml model lf myprog ()
```

With multiple equations, you list the equations one after the other; so, if you typed

```
. ml model lf myprog (mpg weight) ()
```

you would be specifying  $\theta_1 = b_1\text{mpg} + b_2\text{weight} + b_3$  and  $\theta_2 = b_4$ . You would write your likelihood in terms of  $\theta_1$  and  $\theta_2$ . If the model was linear regression,  $\theta_1$  might be the  $\mathbf{x}\mathbf{b}$  part and  $\theta_2$  the variance of the residuals.

When you specify the equations, you also specify any dependent variables. If you typed

```
. ml model lf myprog (price = mpg weight) ()
```

`price` would be the one and only dependent variable, and that would be passed to your program in `$ML_y1`. If your model had two dependent variables, you could type

```
. ml model lf myprog (price displ = mpg weight) ()
```

Then, `$ML_y1` would be `price` and `$ML_y2` would be `displ`. You can specify however many dependent variables are necessary and specify them on any equation. It does not matter on which equation you specify them; the first one specified is placed in `$ML_y1`, the second in `$ML_y2`, and so on.

### ▷ Example 1: Method lf

Using method `lf`, we want to produce observation-by-observation values of the log likelihood. The probit log-likelihood function is

$$\ln \ell_j = \begin{cases} \ln \Phi(\theta_{1j}) & \text{if } y_j = 1 \\ \ln \Phi(-\theta_{1j}) & \text{if } y_j = 0 \end{cases}$$

$$\theta_{1j} = \mathbf{x}_j \mathbf{b}_1$$

The following is the method-`lf` evaluator for this likelihood function:

```
program myprobit
  version 18.0
  args lnf theta1
  quietly replace `lnf' = ln(normal(`theta1')) if $ML_y1==1
  quietly replace `lnf' = ln(normal(-`theta1')) if $ML_y1==0
end
```

If we wanted to fit a model of `foreign` on `mpg` and `weight`, we would type the following commands. The `'foreign ='` part specifies that  $y$  is `foreign`. The `'mpg weight'` part specifies that  $\theta_{1j} = b_1\text{mpg}_j + b_2\text{weight}_j + b_3$ .

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. ml model lf myprobit (foreign = mpg weight)
. ml maximize
Initial:      Log likelihood = -51.292891
Alternative:  Log likelihood = -45.055272
Rescale:     Log likelihood = -45.055272
Iteration 0:  Log likelihood = -45.055272
Iteration 1:  Log likelihood = -27.904125
Iteration 2:  Log likelihood = -26.858643
Iteration 3:  Log likelihood = -26.844199
Iteration 4:  Log likelihood = -26.844189
Iteration 5:  Log likelihood = -26.844189
```

```
Log likelihood = -26.844189
Number of obs = 74
Wald chi2(2) = 20.75
Prob > chi2 = 0.0000
```

foreign	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
mpg	-.1039503	.0515689	-2.02	0.044	-.2050235	-.0028772

◀

## ▶ Example 2: Method lf for two-equation, two-dependent-variable model

A two-equation, two-dependent-variable model is a little different. Rather than receiving one  $\theta$ , our program will receive two. Rather than there being one dependent variable in `$ML_y1`, there will be dependent variables in `$ML_y1` and `$ML_y2`. For instance, the Weibull regression log-likelihood function is

$$\ln \ell_j = -(t_j e^{-\theta_{1j}})^{\exp(\theta_{2j})} + d_j \{ \theta_{2j} - \theta_{1j} + (e^{\theta_{2j}} - 1)(\ln t_j - \theta_{1j}) \}$$

$$\theta_{1j} = \mathbf{x}_j \mathbf{b}_1$$

$$\theta_{2j} = s$$

where  $t_j$  is the time of failure or censoring and  $d_j = 1$  if failure and 0 if censored. We can make the log likelihood a little easier to program by introducing some extra variables:

$$p_j = \exp(\theta_{2j})$$

$$M_j = \{t_j \exp(-\theta_{1j})\}^{p_j}$$

$$R_j = \ln t_j - \theta_{1j}$$

$$\ln \ell_j = -M_j + d_j \{ \theta_{2j} - \theta_{1j} + (p_j - 1)R_j \}$$

The method-lf evaluator for this is

```
program myweib
  version 18.0
  args lnf theta1 theta2
  tempvar p M R
  quietly generate double `p' = exp(`theta2')
  quietly generate double `M' = ($ML_y1*exp(-`theta1'))^`p'
  quietly generate double `R' = ln($ML_y1)-`theta1'
  quietly replace `lnf' = -`M' + $ML_y2*(`theta2'-`theta1' + (`p'-1)*`R')
end
```

We can fit a model by typing

```
. ml model lf myweib (studytime died = i.drug age) ()
. ml maximize
```

Note that we specified ‘()’ for the second equation. The second equation corresponds to the Weibull shape parameter  $s$ , and the linear combination we want for  $s$  contains just an intercept. Alternatively, we could type

```
. ml model lf myweib (studytime died = i.drug age) /s
```

Typing `/s` means the same thing as typing `(s:, freeparm)`. The `s`, either after a slash or in parentheses before a colon, labels the equation. The leading slash, `/`, is a shortcut for specifying that “`s`” is a free parameter. Free parameters are labeled using this shortcut notation, `/s`, in the column names of `e(b)` and in the estimation results. If we instead specified `(s:)`, then `s` would be the equation label for a constant linear equation and would be labeled as `s:_cons` in the column names of `e(b)` and in the estimation results.

```
. use https://www.stata-press.com/data/r18/cancer, clear
(Patient survival in drug trial)
. ml model lf myweib (studytime died = i.drug age) /s
. ml maximize
```

```
Initial:      Log likelihood =      -744
Alternative:  Log likelihood = -356.14276
Rescale:     Log likelihood = -200.80201
Rescale eq:  Log likelihood = -136.69232
Iteration 0:  Log likelihood = -136.69232 (not concave)

### ► Example 3: Method d0

Method-d0 evaluators receive  $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$ , the coefficient vector, rather than the already evaluated  $\theta_1, \theta_2, \dots, \theta_E$ , and they are required to evaluate the overall log-likelihood  $\ln L$  rather than  $\ln \ell_j$ ,  $j = 1, \dots, N$ .

Use `mlevel` to produce the thetas from the coefficient vector.

Use `mlsum` to sum the components that enter into  $\ln L$ .

In the case of Weibull,  $\ln L = \sum \ln \ell_j$ , and our method-d0 evaluator is

```

program weib0
  version 18.0
  args todo b lnf
  tempvar theta1 theta2
  mlevel 'theta1' = 'b', eq(1)
  mlevel 'theta2' = 'b', eq(2)
  local t "$ML_y1"          // this is just for readability
  local d "$ML_y2"
  tempvar p M R
  quietly generate double 'p' = exp('theta2')
  quietly generate double 'M' = ('t'*exp(-'theta1'))^'p'
  quietly generate double 'R' = ln('t')-'theta1'
  mlsum 'lnf' = -'M' + 'd'*('theta2'-'theta1' + ('p'-1)*'R')
end

```

To fit our model using this evaluator, we would type

```

. ml model d0 weib0 (studytime died = i.drug age) /s
. ml maximize

```

◀

## □ Technical note

Method d0 does not require  $\ln L = \sum_j \ln \ell_j$ ,  $j = 1, \dots, N$ , as method lf does. Your likelihood function might have independent components only for groups of observations. Panel-data estimators have a log-likelihood value  $\ln L = \sum_i \ln L_i$ , where  $i$  indexes the panels, each of which contains multiple observations. Conditional logistic regression has  $\ln L = \sum_k \ln L_k$ , where  $k$  indexes the risk pools. Cox regression has  $\ln L = \sum_{(t)} \ln L_{(t)}$ , where  $(t)$  denotes the ordered failure times.

To evaluate such likelihood functions, first calculate the within-group log-likelihood contributions. This usually involves `generate` and `replace` statements prefixed with `by`, as in

```

tempvar sumd
by group: generate double 'sumd' = sum($ML_y1)

```

Structure your code so that the log-likelihood contributions are recorded in the last observation of each group. Say that a variable is named `'cont'`. To sum the contributions, code

```

tempvar last
quietly by group: generate byte 'last' = (_n==_N)
mlsum 'lnf' = 'cont' if 'last'

```

You must inform `mlsum` which observations contain log-likelihood values to be summed. First, you do not want to include intermediate results in the sum. Second, `mlsum` does not skip missing values. Rather, if `mlsum` sees a missing value among the contributions, it sets the overall result, `'lnf'`, to missing. That is how `ml maximize` is informed that the likelihood function could not be evaluated at the particular value of `b`. `ml maximize` will then take action to escape from what it thinks is an infeasible area of the likelihood function.

When the likelihood function violates the linear-form restriction  $\ln L = \sum_j \ln \ell_j$ ,  $j = 1, \dots, N$ , with  $\ln \ell_j$  being a function solely of values within the  $j$ th observation, use method d0. In the following examples, we will demonstrate methods d1 and d2 with likelihood functions that meet this linear-form restriction. The d1 and d2 methods themselves do not require the linear-form restriction, but the utility routines `mlvecsum` and `mlmatsum` do. Using method d1 or d2 when the restriction is violated is difficult; however, `mlmatbysum` may be of some help for method-d2 evaluators. □

### ► Example 4: Method d1

Method-d1 evaluators are required to produce the gradient vector  $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$ , as well as the overall log-likelihood value. Using `mlvecsum`, we can obtain  $\partial \ln L / \partial \mathbf{b}$  from  $\partial \ln L / \partial \theta_i$ ,  $i = 1, \dots, E$ . The derivatives of the Weibull log-likelihood function are

$$\frac{\partial \ln \ell_j}{\partial \theta_{1j}} = p_j(M_j - d_j)$$

$$\frac{\partial \ln \ell_j}{\partial \theta_{2j}} = d_j - R_j p_j(M_j - d_j)$$

The method-d1 evaluator for this is

```

program weib1
  version 18.0
  args todo b lnf g                                // g is new
  tempvar t1 t2
  mlevel 't1' = 'b', eq(1)
  mlevel 't2' = 'b', eq(2)

  local t "$ML_y1"
  local d "$ML_y2"

  tempvar p M R
  quietly generate double 'p' = exp('t2')
  quietly generate double 'M' = ('t'*exp(-'t1'))^'p'
  quietly generate double 'R' = ln('t')-'t1'

  mlsum 'lnf' = -'M' + 'd'*('t2'-'t1' + ('p'-1)*'R')
  if ('todo'==0 | 'lnf'>=.) exit                    /* <-- new */

  tempname d1 d2                                   /* <-- new */
  mlvecsum 'lnf' 'd1' = 'p'*('M'-'d'), eq(1)        /* <-- new */
  mlvecsum 'lnf' 'd2' = 'd' - 'R'*'p'*('M'-'d'), eq(2) /* <-- new */
  matrix 'g' = ('d1','d2')                         /* <-- new */
end

```

We obtained this code by starting with our method-d0 evaluator and then adding the extra lines that method d1 requires. To fit our model using this evaluator, we could type

```

. ml model d1 weib1 (studytime died = drug2 drug3 age) /s
. ml maximize

```

but we recommend substituting `method d1debug` for `method d1` and typing

```

. ml model d1debug weib1 (studytime died = drug2 drug3 age) /s
. ml maximize

```

Method `d1debug` will compare the derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from method `d1debug` to method `d1`.

◀

### ► Example 5: Method d2

Method-d2 evaluators are required to produce  $\mathbf{H} = \partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$ , the Hessian matrix, as well as the gradient and log-likelihood value. `mlmatsum` will help calculate  $\partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$  from the second derivatives with respect to  $\theta$ . For the Weibull model, these second derivatives are

$$\begin{aligned}\frac{\partial^2 \ln \ell_j}{\partial \theta_{1j}^2} &= -p_j^2 M_j \\ \frac{\partial^2 \ln \ell_j}{\partial \theta_{1j} \partial \theta_{2j}} &= p_j (M_j - d_j + R_j p_j M_j) \\ \frac{\partial^2 \ln \ell_j}{\partial \theta_{2j}^2} &= -p_j R_j (R_j p_j M_j + M_j - d_j)\end{aligned}$$

The method-d2 evaluator is

```

program weib2
  version 18.0
  args todo b lnf g H // H added
  tempvar t1 t2
  mlevel 't1' = 'b', eq(1)
  mlevel 't2' = 'b', eq(2)
  local t "$ML_y1"
  local d "$ML_y2"
  tempvar p M R
  quietly generate double 'p' = exp('t2')
  quietly generate double 'M' = ('t'*exp(-'t1'))^'p'
  quietly generate double 'R' = ln('t')-'t1'
  mlsum 'lnf' = -'M' + 'd'*('t2'-'t1' + ('p'-1)*'R')
  if ('todo'==0 | 'lnf'>=.) exit
  tempname d1 d2
  mlvecsum 'lnf' 'd1' = 'p'*('M'-'d'), eq(1)
  mlvecsum 'lnf' 'd2' = 'd' - 'R'*'p'*('M'-'d'), eq(2)
  matrix 'g' = ('d1','d2')
  if ('todo'==1 | 'lnf'>=.) exit // new from here down
  tempname d11 d12 d22
  mlmatsum 'lnf' 'd11' = -'p'^2 * 'M', eq(1)
  mlmatsum 'lnf' 'd12' = 'p'*('M'-'d' + 'R'*'p'*'M'), eq(1,2)
  mlmatsum 'lnf' 'd22' = -'p'*'R'*('R'*'p'*'M' + 'M' - 'd'), eq(2)
  matrix 'H' = ('d11','d12' \ 'd12','d22')
end

```

We started with our previous method-d1 evaluator and added the lines that method d2 requires. We could now fit a model by typing

```

. ml model d2 weib2 (studytime died = drug2 drug3 age) /s
. ml maximize

```

but we would recommend substituting method d2debug for method d2 and typing

```

. ml model d2debug weib2 (studytime died = drug2 drug3 age) /s
. ml maximize

```

Method d2debug will compare the first and second derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from method d2debug to method d2.

◀

As we stated earlier, to produce the robust variance estimator with method lf, there is nothing to do except specify `vce(robust)`, `vce(cluster clustvar)`, or `pweight`. For methods d0, d1, and d2, these options do not work. If your likelihood function meets the linear-form restrictions, you can use methods lf0, lf1, and lf2, then these options will work. The equation scores are defined as

$$\frac{\partial \ln \ell_j}{\partial \theta_{1j}}, \frac{\partial \ln \ell_j}{\partial \theta_{2j}}, \dots$$

Your evaluator will be passed variables, one for each equation, which you fill in with the equation scores. For *both* method lf1 and lf2, these variables are passed in the fourth and subsequent positions of the argument list. That is, you must process the arguments as

```
args todo b lnf g1 g2 ... H
```

Note that for method lf1, the 'H' argument is not used and can be ignored.

### ▷ Example 6: Robust variance estimates

If you have used `mlvecsum` in your evaluator of method d1 or d2, it is easy to turn it into an evaluator of method lf1 or lf2 that allows the computation of the robust variance estimator. The expression that you specified on the right-hand side of `mlvecsum` is the equation score.

Here we turn the program that we gave earlier in the method-d1 example into a method-lf1 evaluator that allows `vce(robust)`, `vce(cluster clustvar)`, or `pweight`.

```
program weib1
  version 18.0
  args todo b lnfj g1 g2          // g1 and g2 are new
  tempvar t1 t2
  mlevel 't1' = 'b', eq(1)
  mlevel 't2' = 'b', eq(2)
  local t "$ML_y1"
  local d "$ML_y2"
  tempvar p M R
  quietly generate double 'p' = exp('t2')
  quietly generate double 'M' = ('t'*exp(-'t1'))^'p'
  quietly generate double 'R' = ln('t')-'t1'
  quietly replace 'lnfj' = -'M' + 'd'*('t2'-'t1' + ('p'-1)*'R')
  if ('todo'==0) exit
  quietly replace 'g1' = 'p'*('M'-'d')          /* <-- new */
  quietly replace 'g2' = 'd' - 'R'*'p'*('M'-'d') /* <-- new */
end
```

To fit our model and get the robust variance estimates, we type

```
. ml model lf1 weib1 (studytime died = drug2 drug3 age) /s, vce(robust)
. ml maximize
```

◀

## Survey options and ml

`ml` can handle stratification, poststratification, multiple stages of clustering, and finite population corrections. Specifying the `svy` option implies that the data come from a survey design and also implies that the survey linearized variance estimator is to be used; see [\[SVY\] Variance estimation](#).

### ▷ Example 7

Suppose that we are interested in a probit analysis of data from a survey in which `q1` is the answer to a yes/no question and `x1`, `x2`, `x3` are demographic responses. The following is a lf2 evaluator for the probit model that meets the requirements for `vce(robust)` (linear form and computes the scores).

```

program mylf2probit
  version 18.0
  args todo b lnfj g1 H
  tempvar z Fz lnf
  mlevel 'z' = 'b'
  quietly generate double 'Fz' = normal('z') if $ML_y1 == 1
  quietly replace 'Fz' = normal(-'z') if $ML_y1 == 0
  quietly replace 'lnfj' = log('Fz')
  if ('todo'==0) exit
  quietly replace 'g1' = normalden('z')/'Fz' if $ML_y1 == 1
  quietly replace 'g1' = -normalden('z')/'Fz' if $ML_y1 == 0
  if ('todo'==1) exit
  mlmatsum 'lnf' 'H' = -'g1'*('g1'+ 'z'), eq(1,1)
end

```

To fit a model, we `svyset` the data, then use `svy` with `ml`.

```

. svyset psuid [pw=w], strata(strid)
. ml model lf2 mylf2probit (q1 = x1 x2 x3), svy
. ml maximize

```

We could also use the `subpop()` option to make inferences about the subpopulation identified by the variable `sub`:

```

. svyset psuid [pw=w], strata(strid)
. ml model lf2 mylf2probit (q1 = x1 x2 x3), svy subpop(sub)
. ml maximize

```

◀

## Stored results

For results stored by `ml` without the `svy` option, see [\[R\] Maximize](#).

For results stored by `ml` with the `svy` option, see [\[SVY\] svy](#).

## Methods and formulas

`ml` is implemented using `moptimize()`; see [\[M-5\] moptimize\(\)](#).

# Title

**mlexp** — Maximum likelihood estimation of user-specified expressions

<a href="#">Description</a>	<a href="#">Quick start</a>	<a href="#">Menu</a>	<a href="#">Syntax</a>
<a href="#">Options</a>	<a href="#">Remarks and examples</a>	<a href="#">Stored results</a>	<a href="#">Methods and formulas</a>

## Description

`mlexp` performs maximum likelihood estimation of models that satisfy the linear-form restrictions, that is, models for which you can write the log likelihood for an individual observation and for which the overall log likelihood is the sum of the individual observations' log likelihoods.

You express the observation-level log-likelihood function by using a substitutable expression. Unlike models fit using `m1`, you do not need to do any programming. However, `m1` can fit classes of models that cannot be fit by `mlexp`.

## Quick start

Linear regression of  $y$  on  $x_1$  and  $x_2$

```
mlexp (ln(normalden(y, {xb: x1 x2 _cons}, {sigma})))
```

Same as above

```
mlexp (ln(normalden(y, {b0} + {b1}*x1 + {b2}*x2, {sigma})))
```

Same as above, and set initial values for  $b_2$  and  $\sigma$

```
mlexp (ln(normalden(y, {b0} + {b1}*x1 + {b2=0.5}*x2, {sigma=3})))
```

Constrain  $\sigma$  and the coefficient on  $x_1$  to be positive

```
mlexp (ln(normalden(y, {b0} + exp({lnb1})*x1 + {b2}*x2, exp({lnsigma})))  
nlcom (b1: exp(_b[lnb1:_cons])) (sigma: exp(_b[lnsigma:_cons]))
```

Omit observations with missing values for  $y$ ,  $x_1$ , or  $x_2$

```
mlexp (ln(normalden(y, {xb: x1 x2 _cons}, {sigma}))), variables(y x1 x2)
```

## Menu

Statistics > Other > Maximum likelihood estimation of expression

## Syntax

```
mlexp (lexp) [if] [in] [weight] [, options]
```

where *lexp* is a substitutable expression representing the log-likelihood function.

<i>options</i>	Description
<b>Model</b>	
<code>variables(<i>varlist</i>)</code>	specify variables in model
<code>from(<i>initial_values</i>)</code>	specify initial values for parameters
<code>constraints(<i>numlist</i>)</code>	apply specified linear constraints
<b>Derivatives</b>	
<code>derivative(/<i>name</i> = <i>dexp</i>)</code>	specify derivative of <i>lexp</i> with respect to parameter <i>name</i> ; can be specified more than once
<b>SE/Robust</b>	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>opg</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>bootstrap</code> , or <code>jackknife</code>
<b>Reporting</b>	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>title(<i>string</i>)</code>	display <i>string</i> as title above the table of parameter estimates
<code>title2(<i>string</i>)</code>	display <i>string</i> as subtitle
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>Maximization</b>	
<code>maximize_options</code>	control the maximization process; seldom used
<code>debug</code>	display debug output
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics

*lexp* and *dexp* may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.

`bootstrap`, `by`, `collect`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`aweights` are not allowed with the `jackknife` prefix; see [R] `jackknife`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`aweights`, `fweights`, `iwweights`, and `pweights` are allowed; see [U] 11.1.6 `weight`.

`debug`, `collinear`, and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

*lexp* and *dexp* are substitutable expressions, Stata expressions that also contain parameters to be estimated. The parameters are enclosed in curly braces and must satisfy the naming requirements for variables; `{beta}` is an example of a parameter. The notation `{lc:varlist}` is allowed for linear combinations of multiple covariates and their parameters. For example, `{xb: mpg price turn _cons}` defines a linear combination of the variables `mpg`, `price`, `turn`, and `_cons` (the constant term). See *Substitutable expressions* under *Remarks and examples* below.

## Options

### Model

`variables(varlist)` specifies the variables in the model. `mlexp` excludes observations for which any of these variables has missing values. If you do not specify `variables()`, then `mlexp` assumes all observations are valid. `mlexp` will exit with an error message if the log likelihood cannot be calculated at the initial values for any observation.

`from(initial_values)` specifies the initial values to begin the estimation. You can specify parameter names and values, or you can specify a  $1 \times k$  matrix, where  $k$  is the number of parameters in the model. For example, to initialize `alpha` to 1.23 and `delta` to 4.57, you would type

```
mlexp ..., from(alpha=1.23 delta=4.57) ...
```

or equivalently

```
matrix define initval = (1.23, 4.57)
mlexp ..., from(initval) ...
```

Initial values declared in the `from()` option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, `mlexp` exits with an error. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model.

`constraints(numlist)`; see [\[R\] Estimation options](#).

### Derivatives

`derivative(/name = dexp)` specifies the derivative of the observation-level log-likelihood function with respect to parameter *name*. If you wish to specify analytic derivatives, you must specify `derivative()` for each parameter in your model.

*dexp* uses the same substitutable expression syntax as is used to specify the log-likelihood function. If you declare a linear combination in the log-likelihood function, you provide the derivative for the linear combination; `mlexp` then applies the chain rule for you. See [Specifying derivatives](#) under *Remarks and examples* for examples.

If you do not specify the `derivative()` option, `mlexp` calculates derivatives numerically.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [\[R\] vce\\_option](#).

### Reporting

`level(#)`; see [\[R\] Estimation options](#).

`title(string)` specifies an optional title that will be displayed just above the table of parameter estimates.

`title2(string)` specifies an optional subtitle that will be displayed between the title specified in `title()` and the table of parameter estimates. If `title2()` is specified but `title()` is not, then `title2()` has the same effect as `title()`.

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [\[R\] Estimation options](#).

*maximize\_options*: [difficult](#), [technique\(\*algorithm\\_spec\*\)](#), [iterate\(#\)](#), [\[no\]log](#), [trace](#), [gradient](#), [showstep](#), [hessian](#), [showtolerance](#), [tolerance\(#\)](#), [ltolerance\(#\)](#), [nrtolerance\(#\)](#), and [nonrtolerance](#); see [\[R\] Maximize](#). These options are seldom used.

The following options are available with `mlexp` but are not shown in the dialog box:

`debug` specifies that differences between the numerically computed gradient and the gradient computed from your derivative expression are reported at each iteration. This option is only allowed with the `derivative()` option.

`collinear`, `coeflegend`; see [\[R\] Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Substitutable expressions](#)

[Parameter interpretation using margins](#)

[Parameter constraints](#)

[Specifying derivatives](#)

## Introduction

`mlexp` performs maximum likelihood estimation of models that satisfy the linear-form restrictions, that is, models for which you can write the log likelihood for a single observation and for which the overall log likelihood is the sum of the individual observations' log likelihoods. Models designed for use with cross-sectional data usually meet the linear-form restrictions, including linear regression, many discrete choice models, limited-dependent-variable models, and selection models. Examples of models that do not satisfy the linear-form restrictions are random-effects panel-data models (because the likelihood function is defined at the panel level) and Cox proportional hazards models (because the likelihood function is defined for risk sets).

Because of its straightforward syntax and accessibility from the menu system, `mlexp` is particularly suited to users who are new to Stata and to those using Stata for pedagogical purposes. You specify the log-likelihood function that `mlexp` is to maximize by using [substitutable expressions](#) that are similar to those used by `nl`, `nlSUR`, and `gmm`. `mlexp` allows you to avoid the programming requirements of `ml`. However, `ml` can fit classes of models that cannot be fit by `mlexp`, including those that do not meet the linear-form restrictions. See [Pitblado, Poi, and Gould \(2024, chap. 2\)](#) for examples using `mlexp` and for further discussion of the advantages of both `mlexp` and `ml`.

## Substitutable expressions

Substitutable expressions allow you to distinguish between variables and parameters. There are three rules to follow when defining substitutable expressions:

1. Parameters of the model are bound in curly braces: `{b0}`, `{param}`, etc. Parameter names must follow the same conventions as variable names; see [\[U\] 11.3 Naming conventions](#).
2. Initial values for parameters are given by including an equal sign and the initial value inside the curly braces: `{b0=1}`, `{param=3.571}`, etc.

3. Linear combinations of variables can be included using the notation `{lc:varlist}`: `{xb: mpg price weight _cons}`, `{score: w x z}`, etc. Parameters of linear combinations are initialized to zero.

Substitutable expressions can include any mathematical expression involving scalars and variables. See [U] **13.2 Operators** and [U] **13.3 Functions** for more information on expressions.

### ► Example 1: The gamma density function

In an extract of the March 2014 Current Population Survey downloaded from Integrated Public Use Microdata Series (IPUMS), `wage` contains the wage and salary income earned in tens of thousands of dollars per year for working individuals; see King et al. (2010). We want to model `wage` using the two-parameter gamma distribution with shape parameter  $\alpha$  and rate parameter  $\beta$ . The density function for  $y > 0$  is

$$f(y) = \frac{\beta^\alpha}{\Gamma(\alpha)} y^{\alpha-1} \exp(-\beta y) \quad \beta > 0, \alpha > 0$$

so that the log likelihood for the  $i$ th observation is

$$\ln(\ell_i) = \alpha \ln(\beta) - \ln\{\Gamma(\alpha)\} + (\alpha - 1) \ln(y_i) - \beta y_i$$

To fit `wage` to the two-parameter gamma distribution, we let `a` be the parameter name that conforms to Stata naming conventions for  $\alpha$  and `b` be the parameter name for  $\beta$ . We enclose both in `{}` in our substitutable expression for the log-likelihood function:

```
. use https://www.stata-press.com/data/r18/cpswage
. mlexp ({a}*ln({b}) - lngamma({a}) + ({a}-1)*ln(wage) - {b}*wage)
Initial:      Log likelihood =      -<inf>   (could not be evaluated)
Feasible:    Log likelihood = -239367.36
Rescale:     Log likelihood = -228037.02
Rescale eq:  Log likelihood = -163560.64
Iteration 0: Log likelihood = -163560.64
Iteration 1: Log likelihood = -162820.41
Iteration 2: Log likelihood = -162808.55
Iteration 3: Log likelihood = -162808.55
Maximum likelihood estimation
Log likelihood = -162808.55                                Number of obs = 64,748
```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
/a	1.097287	.0054134	202.70	0.000	1.086677	1.107897
/b	.2406718	.0014917	161.34	0.000	.2377482	.2435954

Because we did not specify initial values, `mlexp` initialized  $\alpha$  and  $\beta$  to be 0. When both parameters are 0, the log-likelihood function cannot be evaluated, because  $\ln(0)$  is undefined. Therefore, in the iteration log above the coefficient table, we see that `mlexp` reported the initial log likelihood to be `-<inf>` (could not be evaluated). When this occurs, `mlexp` uses a search routine to find alternative initial values that do allow the log-likelihood function to be calculated.

We now initialize `a` to 1 and `b` to 0.1 the first time that we type them within the substitutable expression:

```
. mlexp ({a=1}*ln({b=.1}) - lngamma({a}) + ({a}-1)*ln(wage) - {b}*wage)
Initial:      Log likelihood = -178608.12
Rescale:     Log likelihood = -178608.12
Rescale eq:  Log likelihood = -173389.94
Iteration 0: Log likelihood = -173389.94
Iteration 1: Log likelihood = -163081.69
Iteration 2: Log likelihood = -162813.54
Iteration 3: Log likelihood = -162808.55
Iteration 4: Log likelihood = -162808.55
Maximum likelihood estimation
Log likelihood = -162808.55                                Number of obs = 64,748
```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
/a	1.097287	.0054134	202.70	0.000	1.086677	1.107897
/b	.2406719	.0014917	161.34	0.000	.2377483	.2435955

Even when `mlexp` can find alternative initial values, specifying your own values facilitates optimization. ◀

By default, initial values of parameters are set to zero, and `mlexp` performs an iterative search for optimum starting values before beginning maximization. If `mlexp` cannot find initial parameter values for which it can calculate the log-likelihood function, it will exit with an error message. Restricting the sample or specifying starting values solves this problem.

Use the `variables()` option, an *if* qualifier, or an *in* qualifier to restrict the sample. You can also specify initial values by using the `from()` option or within the substitutable expression by including an equal sign and the initial value after the parameter. If you specify initial values by using `from()`, they override whatever initial values are given within the substitutable expression. Regardless of whether you specify initial values, `mlexp` performs a search procedure for better starting values before commencing the first iteration of the maximization routine.

## ▶ Example 2: Linear combinations of covariates

We frequently want to model the parameters as linear combinations of variables. Continuing [example 1](#), we see that the mean of the two-parameter gamma distribution is  $\mathbf{E}(y) = \alpha/\beta$ . By letting  $\alpha = a_1 \text{age} + a_0$ , we model the mean of `wage` conditional on `age` as  $\mathbf{E}(\text{wage}|\text{age}) = (a_1 \text{age} + a_0)/\beta$ . Below, we specify `{a: age _cons}` to model `a` as a linear combination of `age` and a constant term.

```

. mlexp ({a:age _cons}*ln({b=.1})-lngamma({a:})+({a:}-1)*ln(wage)-{b}*wage)
Initial:      Log likelihood =      -<inf> (could not be evaluated)
Feasible:    Log likelihood = -239367.36
Rescale:     Log likelihood = -228037.02
Rescale eq:  Log likelihood = -163560.64
Iteration 0: Log likelihood = -163560.64
Iteration 1: Log likelihood = -160123.65
Iteration 2: Log likelihood = -159838.42
Iteration 3: Log likelihood = -159838.38
Iteration 4: Log likelihood = -159838.38
Maximum likelihood estimation
Log likelihood = -159838.38                                Number of obs = 64,748

```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
<b>a</b>						
age	.0194396	.0002689	72.31	0.000	.0189126	.0199665
_cons	.4108355	.0096791	42.45	0.000	.3918647	.4298062
<b>/b</b>						
	.2667954	.0016423	162.45	0.000	.2635765	.2700142

The notation `{a: age _cons}` indicates to `mlexp` that you want a linear combination of the variable `age` and a constant term. We named the linear combination `a`, so `mlexp` names the parameters `a:age` and `a:_cons`, respectively.

Once you have declared a linear combination, you can subsequently refer to the linear combination by specifying its name and a colon inside curly braces, as we did in this example. You cannot use the same name for both an individual parameter and a linear combination. However, after a linear combination has been declared, you can refer to the parameter of an individual variable within that linear combination by using the notation `{lc:z}`, where `lc` is the name of the linear combination, and `z` is the variable whose parameter you want to reference.

◀

### ► Example 3: Linear combinations of factor variables

Factor variables and time-series operated variables can be included in a *varlist* defining a linear combination. Continuing [example 2](#), we want to allow different intercepts for males and females in  $\alpha$ , and we want different  $\beta$  parameters for males and females. We implement this model below by including `ibn.female` in each linear combination using [factor-variable](#) notation.

```
. mlexp ({a:age ibn.female}*ln({b:ibn.female}) - lngamma({a:}) +
> ({a:}-1)*ln(wage) - {b:}*wage)
Initial:      Log likelihood =      -<inf>   (could not be evaluated)
Feasible:    Log likelihood = -239367.36
Rescale:     Log likelihood = -228037.02
Rescale eq:  Log likelihood = -163560.64
Iteration 0: Log likelihood = -163560.64
Iteration 1: Log likelihood = -158999.51
Iteration 2: Log likelihood = -158135.16
Iteration 3: Log likelihood = -158130.94
Iteration 4: Log likelihood = -158130.93
Maximum likelihood estimation
Log likelihood = -158130.93                                Number of obs = 64,748
```

		Coefficient	Std. err.	z	P> z	[95% conf. interval]	
a	age	.020543	.0002781	73.88	0.000	.019998	.0210881
	female						
	Male	.3917619	.0111697	35.07	0.000	.3698696	.4136542
	Female	.4475977	.0116285	38.49	0.000	.4248063	.4703892
b	female						
	Male	.2279862	.0018677	122.07	0.000	.2243256	.2316468
	Female	.3600628	.0030156	119.40	0.000	.3541523	.3659733

◀

## Parameter interpretation using margins

The `margins` command can be used after `mlexp` to estimate the effect of a covariate from a set of parameter estimates. The estimated covariate effects can be conditional on the other covariates or population-averaged effects that average out the other covariates.

### ▶ Example 4

Continuing [example 3](#), we use `margins` to estimate the average wage if everyone in the sample were male and if everyone in the sample were female. The `expression()` option is used to specify the formula for the mean. Wages, measured in tens of thousands of dollars, have a gamma distribution, so the mean is a ratio of the  $\alpha$  and  $\beta$  parameters. The linear prediction is specified in the expression with `xb()`.

```
. margins i.female, expression(xb(a)/xb(b))
Predictive margins                                Number of obs = 64,748
Model VCE: OIM
Expression: xb(a)/xb(b)
```

		Margin	Delta-method std. err.	z	P> z	[95% conf. interval]	
female	Male	5.452281	.0267573	203.77	0.000	5.399838	5.504724
	Female	3.607372	.0178778	201.78	0.000	3.572332	3.642412

When everyone is male, the estimated average wage is 5.45; when everyone is female, the estimated average wage is 3.61.

## Parameter constraints

### ► Example 5

In examples 1, 2, and 3, we were lucky. The two-parameter gamma density function is defined only when both  $\alpha$  and  $\beta$  are positive. However, `mlexp` does not know this; when maximizing the log-likelihood function, it will consider all real values for the parameters. Also recall from above, `mlexp` will exit with an error message if it cannot find parameter values that produce nonmissing values for the likelihood for each sample observation.

We could reparameterize our model so that we avoid having to directly estimate parameters that are restricted. For example, consider the parameter  $\alpha > 0$ , and suppose we define the new parameter  $\theta = \ln(\alpha)$  so that  $\alpha = \exp(\theta)$ . With this parameterization, for any real value of  $\theta$  that `mlexp` might try to use when evaluating the log-likelihood function,  $\alpha$  is guaranteed to be positive. Below we apply this parameterization to the model in example 1.

```
. mlexp (exp({lna})*{lnb} - lngamma(exp({lna}))
> + (exp({lna})-1)*ln(wage) - exp({lnb})*wage)

Initial:      Log likelihood = -295203.41
Alternative:  Log likelihood = -249215.67
Rescale:     Log likelihood = -230376.58
Rescale eq:  Log likelihood = -166588.81
Iteration 0:  Log likelihood = -166588.81
Iteration 1:  Log likelihood = -162845.95
Iteration 2:  Log likelihood = -162808.56
Iteration 3:  Log likelihood = -162808.55
Iteration 4:  Log likelihood = -162808.55

Maximum likelihood estimation
Log likelihood = -162808.55                                Number of obs = 64,748
```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
/lna	.0928409	.0049334	18.82	0.000	.0831716	.1025103
/lnb	-1.424321	.0061979	-229.81	0.000	-1.436469	-1.412173

We can use `nlcom` to obtain the back-transformed parameter estimates, but first we need to know how to refer to the parameters estimated by `mlexp`. We can replay the results and request the coefficient legend.

```
. mlexp, coeflegend

Maximum likelihood estimation
Log likelihood = -162808.55                                Number of obs = 64,748
```

	Coefficient	Legend
/lna	.0928409	_b[lna:_cons]
/lnb	-1.424321	_b[lnb:_cons]

Now, we see that we can refer to `_b[lna:_cons]` and `_b[lnb:_cons]` in `nlcom`.

```
. nlcom (a: exp(_b[lna:_cons])) (b: exp(_b[lnb:_cons]))
      a: exp(_b[lna:_cons])
      b: exp(_b[lnb:_cons])
```

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
a	1.097287	.0054134	202.70	0.000	1.086677	1.107897
b	.2406718	.0014917	161.34	0.000	.2377482	.2435954

The optimal value of the log-likelihood function and the back-transformed parameter estimates match those reported in [example 1](#).

However, when you impose nonlinear constraints on linear combinations of covariates, you change the model. These nonlinear constraints change the model because they are not invertible functions of the original parameters. For example, we can use the exponential function to ensure  $\alpha > 0$  and  $\beta > 0$  in the model from [example 3](#).

```
. mlexp (exp({a:age ibn.female})*{b:ibn.female} - lngamma(exp({a:}))
> + (exp({a:})-1)*ln(wage) - exp({b:})*wage)
```

```
Initial:      Log likelihood = -295203.41
Alternative:  Log likelihood = -249215.67
Rescale:     Log likelihood = -230376.58
Rescale eq:  Log likelihood = -166588.81
Iteration 0:  Log likelihood = -166588.81
Iteration 1:  Log likelihood = -160273.12
Iteration 2:  Log likelihood = -158868.39
Iteration 3:  Log likelihood = -158864.02
Iteration 4:  Log likelihood = -158864.02
```

Maximum likelihood estimation

Log likelihood = -158864.02 Number of obs = 64,748

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
a						
age	.0126713	.0001785	70.98	0.000	.0123214	.0130212
female						
Male	-.3470203	.009978	-34.78	0.000	-.3665769	-.3274638
Female	-.3177398	.0103376	-30.74	0.000	-.338001	-.2974786
b						
female						
Male	-1.502222	.0085431	-175.84	0.000	-1.518966	-1.485478
Female	-1.059358	.0087602	-120.93	0.000	-1.076528	-1.042189

The value of the log-likelihood function is now  $-158,864.02$ , which is less than the value  $-158,130.93$ , which was reported in [example 3](#). The constrained parameterization that keeps  $\alpha > 0$  and  $\beta > 0$  has changed the model, and the optimal value of the log-likelihood function in the constrained model is less than the optimal value in the unconstrained model.

Because neither the unconstrained nor the constrained parameterization generates missing predicted values for  $\alpha$  or  $\beta$ , we can choose between them. However, if any of the predicted values for  $\alpha$  or  $\beta$  produce missing values for the log-likelihood function using the unconstrained parameterization, we could not compute the log-likelihood function for the unconstrained parameterization, and we would have to use a constrained parameterization.

## Specifying derivatives

By default, `mlexp` calculates derivatives of the log-likelihood function numerically using an algorithm that produces accurate results. However, `mlexp` will fit your model more quickly (and even more accurately) if you specify analytic derivatives.

You specify derivatives by using substitutable expressions in much the same way as you specify the log-likelihood function. If you specify a linear combination in your log-likelihood function, then you supply a derivative with respect to that linear combination; `mlexp` then uses the chain rule to obtain the derivatives with respect to the individual parameters.

We will illustrate how to specify derivatives using the probit model for dichotomous outcomes. The log-likelihood function for the probit model is often written as

$$\ln l_i = \begin{cases} \ln \Phi(\mathbf{x}'_i \boldsymbol{\beta}) & y_i = 1 \\ \ln \Phi(-\mathbf{x}'_i \boldsymbol{\beta}) & y_i = 0 \end{cases}$$

using the fact that  $1 - \Phi(\mathbf{x}'_i \boldsymbol{\beta}) = \Phi(-\mathbf{x}'_i \boldsymbol{\beta})$ , where  $\Phi(\cdot)$  is the cumulative standard normal distribution function. If we use the trick suggested by [Greene \(2018, 742, fn. 16\)](#), we can simplify the log-likelihood function, making the derivative calculation easier. Let  $q_i = 2y_i - 1$ . Then, we can write the log-likelihood function as

$$\ln l_i = \ln \Phi(q_i \mathbf{x}'_i \boldsymbol{\beta})$$

and the first derivative as

$$\frac{\partial \ln l_i}{\partial \boldsymbol{\beta}} = \frac{q_i \phi(q_i \mathbf{x}'_i \boldsymbol{\beta})}{\Phi(q_i \mathbf{x}'_i \boldsymbol{\beta})} \mathbf{x}_i$$

### ► Example 6: Probit with a linear combination

Now, let's fit a probit model of the indicator for whether an individual is below the official poverty level `offpov` on `age`, `female`, and a constant. We could specify the parameters and independent variables individually, but we will use a linear combination instead. First, note that

$$\frac{\partial \ln l_i}{\partial \mathbf{x}'_i \boldsymbol{\beta}} = \frac{q_i \phi(q_i \mathbf{x}'_i \boldsymbol{\beta})}{\Phi(q_i \mathbf{x}'_i \boldsymbol{\beta})}$$

When you specify a linear combination of variables, you specify the derivative with respect to the linear combination. That way, if you change the variables in the linear combination, you do not need to change the derivative. To see why this is the case, consider the function  $f(\mathbf{x}'_i \boldsymbol{\beta})$ , where  $\mathbf{x}'_i \boldsymbol{\beta}$  is a linear combination. Then, using the chain rule, we see that

$$\frac{\partial f(\mathbf{x}'_i \boldsymbol{\beta})}{\partial \beta_j} = \frac{\partial f(\mathbf{x}'_i \boldsymbol{\beta})}{\partial \mathbf{x}'_i \boldsymbol{\beta}} \times \frac{\partial \mathbf{x}'_i \boldsymbol{\beta}}{\partial \beta_j} = \frac{\partial f(\mathbf{x}'_i \boldsymbol{\beta})}{\partial \mathbf{x}'_i \boldsymbol{\beta}} \times x_{ij}$$

Once the derivative with respect to the linear combination is known, `mlexp` can then multiply it by each of the variables in the linear combination to get the full set of derivatives with respect to the parameters needed to maximize the likelihood function. Moreover, the derivative with respect to the linear combination does not depend on the variables within the linear combination, so even if you change the variables in it, you will not need to modify the specification of the corresponding `derivative()` option.

We type

```
. generate int q = 2*offpov - 1
. mlexp (ln(normal(q*({xb:age i.female _cons}))))
> deriv(/xb = q*normalden(q*{xb:})/normal(q*{xb:}))
```

```
Initial:      Log likelihood = -44879.894
Alternative:  Log likelihood = -27407.718
Rescale:     Log likelihood = -17888.147
Iteration 0:  Log likelihood = -17888.147
Iteration 1:  Log likelihood = -15805.22
Iteration 2:  Log likelihood = -15427.598
Iteration 3:  Log likelihood = -15427.04
Iteration 4:  Log likelihood = -15427.04
```

Maximum likelihood estimation

Log likelihood = -15427.04

Number of obs = 64,748

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
xb						
age	-.0179139	.0005852	-30.61	0.000	-.0190608	-.016767
female						
Female	.1514014	.0154565	9.80	0.000	.1211072	.1816955
_cons	-.8773462	.0244956	-35.82	0.000	-.9253567	-.8293357

After defining  $q$ , we specified the log-likelihood function using  $q$  and the linear combination  $xb$ . We also use  $xb$  in specifying the derivative.

## Stored results

`mlexp` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_aux)</code>	number of ancillary parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(N_clust)</code>	number of clusters
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>mlexp</code>
<code>e(cmdline)</code>	command as typed
<code>e(lexp)</code>	likelihood expression
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(usrtitle)</code>	user-specified title
<code>e(usrtitle2)</code>	user-specified secondary title
<code>e(clustvar)</code>	name of cluster variable
<code>e(vce)</code>	<i>vce</i> type specified in <code>vce()</code>
<code>e(vctype)</code>	title used to label Std. err.
<code>e(params)</code>	names of parameters
<code>e(hasderiv)</code>	yes, if <code>derivative()</code> is specified
<code>e(d_j)</code>	derivative expression for parameter <i>j</i>
<code>e(rhs)</code>	contents of <code>variables()</code>
<code>e(opt)</code>	type of optimization
<code>e(ml_method)</code>	type of ml method
<code>e(technique)</code>	maximization technique
<code>e(singularHmethod)</code>	m-marquardt or hybrid; method used when Hessian is singular <sup>1</sup>
<code>e(crittype)</code>	optimization criterion <sup>1</sup>
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(marginsnotok)</code>	predictions disallowed by <code>margins</code>
<code>e(marginsprop)</code>	signals to the <code>margins</code> command
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(init)</code>	initial values
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

---

1. Type `ereturn list, all` to view these results; see [\[P\] return](#).

In addition to the above, the following is stored in `r()`:

Matrices	
<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

Optimization is carried out using `moptimize()`; see [M-5] [moptimize\(\)](#).

## Postestimation commands

The following postestimation commands are available after `mlexp`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICC, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	linear predictions and scores
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`lrtest` is not appropriate with `svy` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as linear predictions and equation-level scores.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, xb equation(#eqno | eqname) ]
```

```
predict [type] stub* [if] [in], scores
```

Scores are only available for observations within the estimation sample.

## Options for predict

`xb` calculates the linear prediction.

`equation(#eqno | eqname)` specifies the equation for which the linear prediction is desired. Specifying `equation(#1)` indicates that the calculation be made for the first equation. Specifying `equation(demand)` indicates that the calculation be made for the equation named `demand`, assuming there is an equation named `demand` in the model.

If you specify one new variable name and omit `equation()`, results are the same as if you had specified `equation(#1)`.

For more information on using `predict` after multiple-equation estimation commands, see [\[R\] predict](#).

`scores` calculates the equation-level score variables. The *j*th new variable will contain the scores for the *j*th equation of the model.

# margins

## Description for margins

`margins` estimates margins of response for linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
------------------	-------------

---

<code>xb</code>	linear prediction
-----------------	-------------------

---

`xb` defaults to the first equation.

# Title

**mlogit** — Multinomial (polytomous) logistic regression

<a href="#">Description</a>	<a href="#">Quick start</a>	<a href="#">Menu</a>	<a href="#">Syntax</a>
<a href="#">Options</a>	<a href="#">Remarks and examples</a>	<a href="#">Stored results</a>	<a href="#">Methods and formulas</a>
<a href="#">References</a>	<a href="#">Also see</a>		

## Description

`mlogit` fits a multinomial logit (MNL) model for a categorical dependent variable with outcomes that have no natural ordering. The actual values taken by the dependent variable are irrelevant. The MNL model is also known as the polytomous logistic regression model. Some people refer to conditional logistic regression as multinomial logistic regression. If you are one of them, see [\[R\] clogit](#).

## Quick start

MNL model of `y` on `x1`, `x2`, and categorical variable `a`

```
mlogit y x1 x2 i.a
```

Same as above, but use `y = 1` as the base outcome even if 1 is not the most frequent

```
mlogit y x1 x2 i.a, baseoutcome(1)
```

Report results as relative-risk ratios

```
mlogit y x1 x2 i.a, rrr
```

Constrain coefficient of `x1` to be equal for second and third outcomes

```
constraint 1 [#2=#3]:x1  
mlogit y x1 x2 i.a, constraints(1)
```

## Menu

Statistics > Categorical outcomes > Multinomial logistic regression

## Syntax

```
mlogit depvar [indepvars] [if] [in] [weight] [, options]
```

<i>options</i>	Description
<b>Model</b>	
<code>noconstant</code>	suppress constant term
<code>baseoutcome(#)</code>	value of <i>depvar</i> that will be the base outcome
<code>constraints(<i>constraints</i>)</code>	apply specified linear constraints
<b>SE/Robust</b>	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>opg</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>bootstrap</code> , or <code>jackknife</code>
<b>Reporting</b>	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>rrr</code>	report relative-risk ratios
<code>nocnsreport</code>	do not display constraints
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>Maximization</b>	
<code>maximize_options</code>	control the maximization process; seldom used
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

*indepvars* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

`bayes`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] `bayes: mlogit` and [FMM] `fmm: mlogit`.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] `mi estimate`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

Model

`noconstant`; see [R] **Estimation options**.

`baseoutcome(#)` specifies the value of *depvar* to be treated as the base outcome. The default is to choose the most frequent outcome.

`constraints(constraints)`; see [R] **Estimation options**.

## SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `baseoutcome()`.

## Reporting

`level(#)`; see [R] [Estimation options](#).

`rrr` reports the estimated coefficients transformed to relative-risk ratios, that is,  $e^b$  rather than  $b$ ; see [Description of the model](#) below for an explanation of this concept. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `rrr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

*display\_options*: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `mlogit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Description of the model*  
*Fitting unconstrained models*  
*Fitting constrained models*

`mlogit` fits maximum likelihood models with discrete dependent (left-hand-side) variables when the dependent variable takes on more than two outcomes and the outcomes have no natural ordering. If the dependent variable takes on only two outcomes, estimates are identical to those produced by `logistic` or `logit`; see [R] [logistic](#) or [R] [logit](#). If the outcomes are ordered, see [R] [ologit](#). See [R] [logistic](#) for a list of related estimation commands.

## Description of the model

For an introduction to MNL models, see [Greene \(2018, 829–833\)](#), [Hosmer, Lemeshow, and Sturdivant \(2013, 269–289\)](#), [Long \(1997, chap. 6\)](#), [Long and Freese \(2014, chap. 8\)](#), and [Treiman \(2009, 336–341\)](#). For a description emphasizing the difference in assumptions and data requirements for conditional and multinomial logit, see [Davidson and MacKinnon \(1993\)](#).

Consider the outcomes 1, 2, 3, . . . ,  $m$  recorded in  $y$ , and the explanatory variables  $X$ . Assume that there are  $m = 3$  outcomes: “buy an American car”, “buy a Japanese car”, and “buy a European car”. The values of  $y$  are then said to be “unordered”. Even though the outcomes are coded 1, 2, and 3, the numerical values are arbitrary because  $1 < 2 < 3$  does not imply that outcome 1 (buy American) is less than outcome 2 (buy Japanese) is less than outcome 3 (buy European). This unordered categorical property of  $y$  distinguishes the use of **mlogit** from **regress** (which is appropriate for a continuous dependent variable), from **ologit** (which is appropriate for ordered categorical data), and from **logit** (which is appropriate for two outcomes, which can be thought of as ordered).

In the MNL model, you estimate a set of coefficients,  $\beta^{(1)}$ ,  $\beta^{(2)}$ , and  $\beta^{(3)}$ , corresponding to each outcome:

$$\begin{aligned}\Pr(y = 1) &= \frac{e^{X\beta^{(1)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}} \\ \Pr(y = 2) &= \frac{e^{X\beta^{(2)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}} \\ \Pr(y = 3) &= \frac{e^{X\beta^{(3)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}\end{aligned}$$

The model, however, is unidentified in the sense that there is more than one solution to  $\beta^{(1)}$ ,  $\beta^{(2)}$ , and  $\beta^{(3)}$  that leads to the same probabilities for  $y = 1$ ,  $y = 2$ , and  $y = 3$ . To identify the model, you arbitrarily set one of  $\beta^{(1)}$ ,  $\beta^{(2)}$ , or  $\beta^{(3)}$  to 0—it does not matter which. That is, if you arbitrarily set  $\beta^{(1)} = 0$ , the remaining coefficients  $\beta^{(2)}$  and  $\beta^{(3)}$  will measure the change relative to the  $y = 1$  group. If you instead set  $\beta^{(2)} = 0$ , the remaining coefficients  $\beta^{(1)}$  and  $\beta^{(3)}$  will measure the change relative to the  $y = 2$  group. The coefficients will differ because they have different interpretations, but the predicted probabilities for  $y = 1, 2$ , and 3 will still be the same. Thus, either parameterization will be a solution to the same underlying model.

Setting  $\beta^{(1)} = 0$ , the equations become

$$\begin{aligned}\Pr(y = 1) &= \frac{1}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}} \\ \Pr(y = 2) &= \frac{e^{X\beta^{(2)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}} \\ \Pr(y = 3) &= \frac{e^{X\beta^{(3)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}\end{aligned}$$

The relative probability of  $y = 2$  to the base outcome is

$$\frac{\Pr(y = 2)}{\Pr(y = 1)} = e^{X\beta^{(2)}}$$

Let’s call this ratio the relative risk, and let’s further assume that  $X$  and  $\beta_k^{(2)}$  are vectors equal to  $(x_1, x_2, \dots, x_k)$  and  $(\beta_1^{(2)}, \beta_2^{(2)}, \dots, \beta_k^{(2)})'$ , respectively. The ratio of the relative risk for a one-unit change in  $x_i$  is then

$$\frac{e^{\beta_1^{(2)} x_1 + \dots + \beta_i^{(2)} (x_i + 1) + \dots + \beta_k^{(2)} x_k}}{e^{\beta_1^{(2)} x_1 + \dots + \beta_i^{(2)} x_i + \dots + \beta_k^{(2)} x_k}} = e^{\beta_i^{(2)}}$$

Thus, the exponentiated value of a coefficient is the relative-risk ratio for a one-unit change in the corresponding variable (risk is measured as the risk of the outcome relative to the base outcome).

## Fitting unconstrained models

### ▷ Example 1: A first example

We have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). The insurance is categorized as either an indemnity plan (that is, regular fee-for-service insurance, which may have a deductible or coinsurance rate) or a prepaid plan (a fixed up-front payment allowing subsequent unlimited use as provided, for instance, by an HMO). The third possibility is that the subject has no insurance whatsoever. We wish to explore the demographic factors associated with each subject's insurance choice. One of the demographic factors in our data is the race of the participant, coded as white or nonwhite:

```
. use https://www.stata-press.com/data/r18/sysdsn1
(Health insurance data)
. tabulate insure nonwhite, chi2 col
```

Key			
	<i>frequency</i>		
	<i>column percentage</i>		
Type of insurance	Nonwhite		Total
	0	1	
Indemnity	251	43	294
	50.71	35.54	47.73
Prepaid	208	69	277
	42.02	57.02	44.97
Uninsure	36	9	45
	7.27	7.44	7.31
Total	495	121	616
	100.00	100.00	100.00

Pearson chi2(2) = 9.5599 Pr = 0.008

Although `insure` appears to take on the values `Indemnity`, `Prepaid`, and `Uninsure`, it actually takes on the values 1, 2, and 3. The words appear because we have associated a value label with the numeric variable `insure`; see [U] 12.6.3 Value labels.

When we fit an MNL model, we can tell `mlogit` which outcome to use as the base outcome, or we can let `mlogit` choose. To fit a model of `insure` on `nonwhite`, letting `mlogit` choose the base outcome, we type

```
. mlogit insure nonwhite
Iteration 0:  Log likelihood = -556.59502
Iteration 1:  Log likelihood = -551.78935
Iteration 2:  Log likelihood = -551.78348
Iteration 3:  Log likelihood = -551.78348
Multinomial logistic regression
Log likelihood = -551.78348
Number of obs = 616
LR chi2(2) = 9.62
Prob > chi2 = 0.0081
Pseudo R2 = 0.0086
```

insure	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
Indemnity	(base outcome)					
Prepaid						
nonwhite	.6608212	.2157321	3.06	0.002	.2379942	1.083648
_cons	-.1879149	.0937644	-2.00	0.045	-.3716896	-.0041401
Uninsure						
nonwhite	.3779586	.407589	0.93	0.354	-.4209011	1.176818
_cons	-1.941934	.1782185	-10.90	0.000	-2.291236	-1.592632

`mlogit` chose the indemnity outcome as the base outcome and presented coefficients for the outcomes prepaid and uninsured. According to the model, the probability of prepaid for whites (`nonwhite = 0`) is

$$\Pr(\text{insure} = \text{Prepaid}) = \frac{e^{-.188}}{1 + e^{-.188} + e^{-1.942}} = 0.420$$

Similarly, for nonwhites, the probability of prepaid is

$$\Pr(\text{insure} = \text{Prepaid}) = \frac{e^{-.188+.661}}{1 + e^{-.188+.661} + e^{-1.942+.378}} = 0.570$$

These results agree with the column percentages presented by `tabulate` because the `mlogit` model is fully saturated. That is, there are enough terms in the model to fully explain the column percentage in each cell. The model  $\chi^2$  and the `tabulate`  $\chi^2$  are in almost perfect agreement; both test that the column percentages of `insure` are the same for both values of `nonwhite`.

◀

## ► Example 2: Specifying the base outcome

By specifying the `baseoutcome()` option, we can control which outcome of the dependent variable is treated as the base. Left to its own, `mlogit` chose to make outcome 1, indemnity, the base outcome. To make outcome 2, prepaid, the base, we would type

```
. mlogit insure nonwhite, base(2)
Iteration 0:  Log likelihood = -556.59502
Iteration 1:  Log likelihood = -551.78935
Iteration 2:  Log likelihood = -551.78348
Iteration 3:  Log likelihood = -551.78348
Multinomial logistic regression
Log likelihood = -551.78348
Number of obs = 616
LR chi2(2) = 9.62
Prob > chi2 = 0.0081
Pseudo R2 = 0.0086
```

insure	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
Indemnity						
nonwhite	-.6608212	.2157321	-3.06	0.002	-1.083648	-.2379942
_cons	.1879149	.0937644	2.00	0.045	.0041401	.3716896
Prepaid	(base outcome)					
Uninsure						
nonwhite	-.2828627	.3977302	-0.71	0.477	-1.0624	.4966742
_cons	-1.754019	.1805145	-9.72	0.000	-2.107821	-1.400217

The `baseoutcome()` option requires that we specify the numeric value of the outcome, so we could not type `base(Prepaid)`.

Although the coefficients now appear to be different, the summary statistics reported at the top are identical. With this parameterization, the probability of prepaid insurance for whites is

$$\Pr(\text{insure} = \text{Prepaid}) = \frac{1}{1 + e^{.188} + e^{-1.754}} = 0.420$$

This is the same answer we obtained previously.

### ► Example 3: Displaying relative-risk ratios

By specifying `rrr`, which we can do at estimation time or when we redisplay results, we see the model in terms of relative-risk ratios:

```
. mlogit, rrr
Multinomial logistic regression
Log likelihood = -551.78348
Number of obs = 616
LR chi2(2) = 9.62
Prob > chi2 = 0.0081
Pseudo R2 = 0.0086
```

insure	RRR	Std. err.	z	P> z	[95% conf. interval]	
Indemnity						
nonwhite	.516427	.1114099	-3.06	0.002	.3383588	.7882073
_cons	1.206731	.1131483	2.00	0.045	1.004149	1.450183
Prepaid	(base outcome)					
Uninsure						
nonwhite	.7536233	.2997387	-0.71	0.477	.3456255	1.643247
_cons	.1730769	.0312429	-9.72	0.000	.1215024	.2465434

Note: `_cons` estimates baseline relative risk for each outcome.

Looked at this way, the relative risk of choosing an indemnity over a prepaid plan is 0.516 for nonwhites relative to whites.

To illustrate, from the output and discussions of examples 1 and 2 we find that

$$\Pr(\text{insure} = \text{Indemnity} \mid \text{white}) = \frac{1}{1 + e^{-.188} + e^{-1.942}} = 0.507$$

and thus the relative risk of choosing indemnity over prepaid (for whites) is

$$\frac{\Pr(\text{insure} = \text{Indemnity} \mid \text{white})}{\Pr(\text{insure} = \text{Prepaid} \mid \text{white})} = \frac{0.507}{0.420} = 1.207$$

For nonwhites,

$$\Pr(\text{insure} = \text{Indemnity} \mid \text{not white}) = \frac{1}{1 + e^{-.188+.661} + e^{-1.942+.378}} = 0.355$$

and thus the relative risk of choosing indemnity over prepaid (for nonwhites) is

$$\frac{\Pr(\text{insure} = \text{Indemnity} \mid \text{not white})}{\Pr(\text{insure} = \text{Prepaid} \mid \text{not white})} = \frac{0.355}{0.570} = 0.623$$

The ratio of these two relative risks, hence the name “relative-risk ratio”, is  $0.623/1.207 = 0.516$ , as given in the output under the heading “RRR”. ◀

#### □ Technical note

In models where only two categories are considered, the `mlogit` model reduces to standard `logit`. Consequently, the exponentiated regression coefficients, labeled as RRR within `mlogit`, are equal to the odds ratios as given when the `or` option is specified under `logit`; see [R] [logit](#).

As such, always referring to `mlogit`’s exponentiated coefficients as odds ratios may be tempting. However, the discussion in [example 3](#) demonstrates that doing so would be incorrect. In general `mlogit` models, the exponentiated coefficients are ratios of relative risks, not ratios of odds. □

#### ▷ Example 4: Model with continuous and multiple categorical variables

One of the advantages of `mlogit` over `tabulate` is that we can include continuous variables and multiple categorical variables in the model. In examining the data on insurance choice, we decide that we want to control for age, gender, and site of study (the study was conducted in three sites):

```
. mlogit insure age male nonwhite i.site
Iteration 0: Log likelihood = -555.85446
Iteration 1: Log likelihood = -534.67443
Iteration 2: Log likelihood = -534.36284
Iteration 3: Log likelihood = -534.36165
Iteration 4: Log likelihood = -534.36165

Multinomial logistic regression
Number of obs = 615
LR chi2(10) = 42.99
Prob > chi2 = 0.0000
Pseudo R2 = 0.0387

Log likelihood = -534.36165
```

insure	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
Indemnity						
(base outcome)						
Prepaid						
age	-.011745	.0061946	-1.90	0.058	-.0238862	.0003962
male	.5616934	.2027465	2.77	0.006	.1643175	.9590693
nonwhite	.9747768	.2363213	4.12	0.000	.5115955	1.437958
site						
2	.1130359	.2101903	0.54	0.591	-.2989296	.5250013
3	-.5879879	.2279351	-2.58	0.010	-1.034733	-.1412433
_cons	.2697127	.3284422	0.82	0.412	-.3740222	.9134476
Uninsure						
age	-.0077961	.0114418	-0.68	0.496	-.0302217	.0146294
male	.4518496	.3674867	1.23	0.219	-.268411	1.17211
nonwhite	.2170589	.4256361	0.51	0.610	-.6171725	1.05129
site						
2	-1.211563	.4705127	-2.57	0.010	-2.133751	-.2893747
3	-.2078123	.3662926	-0.57	0.570	-.9257327	.510108
_cons	-1.286943	.5923219	-2.17	0.030	-2.447872	-.1260134

These results suggest that the inclination of nonwhites to choose prepaid care is even stronger than it was without controlling. We also see that subjects in site 2 are less likely to be uninsured.

## Fitting constrained models

mlogit can fit models with subsets of coefficients constrained to be zero, with subsets of coefficients constrained to be equal both within and across equations, and with subsets of coefficients arbitrarily constrained to equal linear combinations of other estimated coefficients.

Before fitting a constrained model, you define the constraints with the `constraint` command; see [R] [constraint](#). Once the constraints are defined, you estimate using `mlogit`, specifying the `constraint()` option. Typing `constraint(4)` would use the constraint you previously saved as 4. Typing `constraint(1,4,6)` would use the previously stored constraints 1, 4, and 6. Typing `constraint(1-4,6)` would use the previously stored constraints 1, 2, 3, 4, and 6.

Sometimes, you will not be able to specify the constraints without knowing the omitted outcome. In such cases, assume that the omitted outcome is whatever outcome is convenient for you, and include the `baseoutcome()` option when you specify the `mlogit` command.

## ▷ Example 5: Specifying constraints to test hypotheses

We can use constraints to test hypotheses, among other things. In our insurance-choice model, let's test the hypothesis that there is no distinction between having indemnity insurance and being uninsured. Indemnity-style insurance was the omitted outcome, so we type

```
. test [Uninsure]
( 1) [Uninsure]age = 0
( 2) [Uninsure]male = 0
( 3) [Uninsure]nonwhite = 0
( 4) [Uninsure]1b.site = 0
( 5) [Uninsure]2.site = 0
( 6) [Uninsure]3.site = 0
    Constraint 4 dropped
           chi2( 5) =    9.31
           Prob > chi2 =   0.0973
```

If indemnity had not been the omitted outcome, we would have typed `test [Uninsure=Indemnity]`.

The results produced by `test` are an approximation based on the estimated covariance matrix of the coefficients. Because the probability of being uninsured is low, the log likelihood may be nonlinear for the uninsured. Conventional statistical wisdom is not to trust the asymptotic answer under these circumstances but to perform a likelihood-ratio test instead.

To use Stata's `lrtest` (likelihood-ratio test) command, we must fit both the unconstrained and constrained models. The unconstrained model is the one we have previously fit. Following the instruction in [R] [lrtest](#), we first store the unconstrained model results:

```
. estimates store unconstrained
```

To fit the constrained model, we must refit our model with all the coefficients except the constant set to 0 in the `Uninsure` equation. We define the constraint and then refit:

```

. constraint 1 [Uninsure]
. logit insure age male nonwhite i.site, constraints(1)
Iteration 0:  Log likelihood = -555.85446
Iteration 1:  Log likelihood = -539.80523
Iteration 2:  Log likelihood = -539.75644
Iteration 3:  Log likelihood = -539.75643
Multinomial logistic regression
Log likelihood = -539.75643
Number of obs = 615
Wald chi2(5) = 29.70
Prob > chi2 = 0.0000
( 1) [Uninsure]o.age = 0
( 2) [Uninsure]o.male = 0
( 3) [Uninsure]o.nonwhite = 0
( 4) [Uninsure]2o.site = 0
( 5) [Uninsure]3o.site = 0

```

insure	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
Indemnity (base outcome)						
Prepaid						
age	-.0107025	.0060039	-1.78	0.075	-.0224699	.0010649
male	.4963616	.1939683	2.56	0.010	.1161907	.8765324
nonwhite	.9421369	.2252094	4.18	0.000	.5007346	1.383539
site						
2	.2530912	.2029465	1.25	0.212	-.1446767	.6508591
3	-.5521773	.2187237	-2.52	0.012	-.9808678	-.1234869
_cons	.1792752	.3171372	0.57	0.572	-.4423023	.8008527
Uninsure						
age	0 (omitted)					
male	0 (omitted)					
nonwhite	0 (omitted)					
site						
2	0 (omitted)					
3	0 (omitted)					
_cons	-1.87351	.1601099	-11.70	0.000	-2.18732	-1.5597

We can now perform the likelihood-ratio test:

```

. lrtest unconstrained .
Likelihood-ratio test
Assumption: . nested within unconstrained
LR chi2(5) = 10.79
Prob > chi2 = 0.0557

```

The likelihood-ratio  $\chi^2$  is 10.79 with 5 degrees of freedom—just slightly greater than the magic  $p = 0.05$  level—so we should not call this difference significant.

## □ Technical note

In certain circumstances, you should fit an MNL model with conditional logit; see [R] **clogit**. With substantial data manipulation, **clogit** can handle the same class of models with some interesting additions. For example, if we had available the price and deductible of the most competitive insurance plan of each type, **mlogit** could not use this information, but **clogit** could. □

**Stored results**

**mlogit** stores the following in `e()`:

## Scalars

<code>e(N)</code>	number of observations
<code>e(N_cd)</code>	number of completely determined observations
<code>e(k_out)</code>	number of outcomes
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(r2_p)</code>	pseudo- $R^2$
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(p)</code>	$p$ -value for model test
<code>e(k_eq_base)</code>	equation number of the base outcome
<code>e(baseout)</code>	the value of <i>devar</i> to be treated as the base outcome
<code>e(ibaseout)</code>	index of the base outcome
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

## Macros

<code>e(cmd)</code>	<b>mlogit</b>
<code>e(cmdline)</code>	command as typed
<code>e(devar)</code>	name of dependent variable
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(chi2type)</code>	Wald or LR; type of model $\chi^2$ test

Matrices	
e(b)	coefficient vector
e(out)	outcome values
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance
Functions	
e(sample)	marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices	
r(table)	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

## Methods and formulas

The MNL model is described in [Greene \(2018, 829–833\)](#).

Suppose that there are  $k$  categorical outcomes and—without loss of generality—let the base outcome be 1. The probability that the response for the  $j$ th observation is equal to the  $i$ th outcome is

$$p_{ij} = \Pr(y_j = i) = \begin{cases} \frac{1}{1 + \sum_{m=2}^k \exp(\mathbf{x}_j \boldsymbol{\beta}_m)}, & \text{if } i = 1 \\ \frac{\exp(\mathbf{x}_j \boldsymbol{\beta}_i)}{1 + \sum_{m=2}^k \exp(\mathbf{x}_j \boldsymbol{\beta}_m)}, & \text{if } i > 1 \end{cases}$$

where  $\mathbf{x}_j$  is the row vector of observed values of the independent variables for the  $j$ th observation and  $\boldsymbol{\beta}_m$  is the coefficient vector for outcome  $m$ . The log pseudolikelihood is

$$\ln L = \sum_j w_j \sum_{i=1}^k I_i(y_j) \ln p_{ik}$$

where  $w_j$  is an optional weight and

$$I_i(y_j) = \begin{cases} 1, & \text{if } y_j = i \\ 0, & \text{otherwise} \end{cases}$$

Newton–Raphson maximum likelihood is used; see [\[R\] Maximize](#).

For constrained equations, the set of constraints is orthogonalized, and a subset of maximizable parameters is selected. For example, a parameter that is constrained to zero is not a maximizable parameter. If two parameters are constrained to be equal to each other, only one is a maximizable parameter.

Let  $\mathbf{r}$  be the vector of maximizable parameters.  $\mathbf{r}$  is physically a subset of the solution parameters,  $\mathbf{b}$ . A matrix,  $\mathbf{T}$ , and a vector,  $\mathbf{m}$ , are defined as

$$\mathbf{b} = \mathbf{T}\mathbf{r} + \mathbf{m}$$

so that

$$\frac{\partial f}{\partial \mathbf{b}} = \frac{\partial f}{\partial \mathbf{r}} \mathbf{T}'$$

$$\frac{\partial^2 f}{\partial \mathbf{b}^2} = \mathbf{T} \frac{\partial^2 f}{\partial \mathbf{r}^2} \mathbf{T}'$$

$\mathbf{T}$  consists of a block form in which one part is a permutation of the identity matrix and the other part describes how to calculate the constrained parameters from the maximizable parameters.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`mlogit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

Remarks and examples

## Postestimation commands

The following postestimation commands are available after `mlogit`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	probabilities, linear predictions and their SEs, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic outcome(outcome)]
```

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>pr</code>	predicted probabilities; the default
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the linear prediction
<code>stddp</code>	standard error of the difference in two linear predictions

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb`, `stdp`, and `stddp`. If you do not specify `outcome()`, then `outcome(#1)` is assumed. You must specify `outcome()` with the `stddp` option.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction. You must also specify the `outcome(outcome)` option.

`stdp` calculates the standard error of the linear prediction. You must also specify the `outcome(outcome)` option.

`stddp` calculates the standard error of the difference in two linear predictions. You must specify the `outcome(outcome)` option, and here you specify the two particular outcomes of interest inside the parentheses, for example, `predict sed, stddp outcome(1,3)`.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is not allowed with `scores`.

`scores` calculates equation-level score variables. The number of score variables created will be one less than the number of outcomes in the model. If the number of outcomes in the model were  $k$ , then

the first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta_1)$ ;

the second new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta_2)$ ;

...

the  $(k - 1)$ th new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta_{k-1})$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
default	probabilities for each outcome
<code>pr</code>	probability for a specified outcome
<code>xb</code>	linear prediction for a specified outcome
<code>stdp</code>	not allowed with <code>margins</code>
<code>stddp</code>	not allowed with <code>margins</code>

`pr` and `xb` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $\mathbf{e}(\mathbf{b})$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

Remarks are presented under the following headings:

*Obtaining predicted values*  
*Calculating marginal effects*  
*Testing hypotheses about coefficients*

### Obtaining predicted values

#### ► Example 1: Obtaining predicted probabilities

After estimation, we can use `predict` to obtain predicted probabilities, index values, and standard errors of the index, or differences in the index. For instance, in [example 4](#) of [R] `mlogit`, we fit a model of insurance choice on various characteristics. We can obtain the predicted probabilities for outcome 1 by typing

```
. use https://www.stata-press.com/data/r18/sysdsn1
(Health insurance data)
. mlogit insure age i.male i.nonwhite i.site
(output omitted)
. predict p1 if e(sample), outcome(1)
(option pr assumed; predicted probability)
(29 missing values generated)
. summarize p1
```

Variable	Obs	Mean	Std. dev.	Min	Max
p1	615	.4764228	.1032279	.1698142	.71939

We added the `i.` prefix to the `male`, `nonwhite`, and `site` variables to explicitly identify them as factor variables. That makes no difference in the estimated results, but we will take advantage of it in later examples. We also included `if e(sample)` to restrict the calculation to the estimation sample. In [example 4](#) of [R] `mlogit`, the multinomial logit model was fit on 615 observations, so there must be missing values in our dataset.

Although we typed `outcome(1)`, specifying 1 for the indemnity outcome, we could have typed `outcome(Indemnity)`. For instance, to obtain the probabilities for prepaid, we could type

```
. predict p2 if e(sample), outcome(Prepaid)
(option pr assumed; predicted probability)
(29 missing values generated)
. summarize p2
```

Variable	Obs	Mean	Std. dev.	Min	Max
p2	615	.4504065	.1125962	.1964103	.7885724

We must specify the label exactly as it appears in the underlying value label (or how it appears in the `mlogit` output), including capitalization.

Here we have used `predict` to obtain probabilities for the same sample on which we estimated. That is not necessary. We could use another dataset that had the independent variables defined (in our example, `age`, `male`, `nonwhite`, and `site`) and use `predict` to obtain predicted probabilities; here, we would not specify `if e(sample)`.

## ▷ Example 2: Obtaining index values

`predict` can also be used to obtain the index values—the  $\sum x_i \widehat{\beta}_i^{(k)}$ —as well as the probabilities:

```
. predict idx1, outcome(Indemnity) xb
(1 missing value generated)
. summarize idx1
```

Variable	Obs	Mean	Std. dev.	Min	Max
idx1	643	0	0	0	0

The indemnity outcome was our base outcome—the outcome for which all the coefficients were set to 0—so the index is always 0. For the prepaid and uninsured outcomes, we type

```
. predict idx2, outcome(Prepaid) xb
(1 missing value generated)
. predict idx3, outcome(Uninsure) xb
(1 missing value generated)
. summarize idx2 idx3
```

Variable	Obs	Mean	Std. dev.	Min	Max
idx2	643	-.0566113	.4962973	-1.298198	1.700719
idx3	643	-1.980747	.6018139	-3.112741	-.8258458

We can obtain the standard error of the index by specifying the `stdp` option:

```
. predict se2, outcome(Prepaid) stdp
(1 missing value generated)
. list p2 idx2 se2 in 1/5
```

	p2	idx2	se2
1.	.3709022	-.4831167	.2437772
2.	.4977667	.055111	.1694686
3.	.4113073	-.1712106	.1793498
4.	.5424927	.3788345	.2513701
5.	.	-.0925817	.1452616

We obtained the probability, `p2`, in the [previous example](#).

Finally, `predict` can calculate the standard error of the difference in the index values between two outcomes with the `stdpp` option:

```
. predict se_2_3, outcome(Prepaid,Uninsure) stdpp
(1 missing value generated)
. list idx2 idx3 se_2_3 in 1/5
```

	idx2	idx3	se_2_3
1.	-.4831167	-3.073253	.5469354
2.	.055111	-2.715986	.4331918
3.	-.1712106	-1.579621	.3053815
4.	.3788345	-1.462007	.4492552
5.	-.0925817	-2.814022	.4024784

In the first observation, the difference in the indexes is  $-0.483 - (-3.073) = 2.59$ . The standard error of that difference is 0.547.

◀

### ► Example 3: Interpreting results using predictive margins

It is more difficult to interpret the results from `mlogit` than those from `clogit` or `logit` because there are multiple equations. For example, suppose that one of the independent variables in our model takes on the values 0 and 1, and we are attempting to understand the effect of this variable. Assume that the coefficient on this variable for the second outcome,  $\beta^{(2)}$ , is positive. We might then be tempted to reason that the probability of the second outcome is higher if the variable is 1 rather than 0. Most of the time, that will be true, but occasionally we will be surprised. The probability of some other outcome could increase even more (say,  $\beta^{(3)} > \beta^{(2)}$ ), and thus the probability of outcome 2 would actually fall relative to that outcome. We can use `predict` to help interpret such results.

Continuing with our previously fit insurance-choice model, we wish to describe the model's predictions by race. For this purpose, we can use the method of predictive margins (also known as recycled predictions), in which we vary characteristics of interest across the whole dataset and average the predictions. That is, we have data on both whites and nonwhites, and our individuals have other characteristics as well. We will first pretend that all the people in our data are white but hold their other characteristics constant. We then calculate the probabilities of each outcome. Next we will pretend that all the people in our data are nonwhite, still holding their other characteristics constant. Again, we calculate the probabilities of each outcome. The difference in those two sets of calculated probabilities, then, is the difference due to race, holding other characteristics constant.

```
. gen byte nonwhold=nonwhite // save real race
. replace nonwhite=0 // make everyone white
(126 real changes made)
. predict wpp, outcome(Indemnity) // predict probabilities
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wpp, outcome(Prepaid)
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wppoi, outcome(Uninsure)
(option pr assumed; predicted probability)
(1 missing value generated)
. replace nonwhite=1 // make everyone nonwhite
(644 real changes made)
```

```

. predict nwpind, outcome(Indemnity)
(option pr assumed; predicted probability)
(1 missing value generated)

. predict nwpp, outcome(Prepaid)
(option pr assumed; predicted probability)
(1 missing value generated)

. predict nwpnoi, outcome(Uninsure)
(option pr assumed; predicted probability)
(1 missing value generated)

. replace nonwhite=nonwhold           // restore real race
(518 real changes made)

. summarize wp* nwp*, sep(3)

```

Variable	Obs	Mean	Std. dev.	Min	Max
wpind	643	.5141673	.0872679	.3092903	.71939
wpp	643	.4082052	.0993286	.1964103	.6502247
wpnoi	643	.0776275	.0360283	.0273596	.1302816
nwpind	643	.3112809	.0817693	.1511329	.535021
nwpp	643	.630078	.0979976	.3871782	.8278881
nwpnoi	643	.0586411	.0287185	.0209648	.0933874

In [example 1](#) of [\[R\] mlogit](#), we presented a cross-tabulation of insurance type and race. Those values were unadjusted. The means reported above are the values adjusted for age, sex, and site. Combining the results gives

	Unadjusted		Adjusted	
	white	nonwhite	white	nonwhite
Indemnity	0.51	0.36	0.51	0.31
Prepaid	0.42	0.57	0.41	0.63
Uninsured	0.07	0.07	0.08	0.06

We find, for instance, after adjusting for age, sex, and site, that although 57% of nonwhites in our data had prepaid plans, 63% of nonwhites chose prepaid plans.

Computing predictive margins by hand was instructive, but we can compute these values more easily using the `margins` command (see [\[R\] margins](#)). The two margins for the indemnity outcome can be estimated by typing

```

. margins nonwhite, predict(outcome(Indemnity)) noesample
Predictive margins                               Number of obs = 643
Model VCE: OIM
Expression: Pr(insure==Indemnity), predict(outcome(Indemnity))

```

	Delta-method				
	Margin	std. err.	z	P> z	[95% conf. interval]
nonwhite					
0	.5141673	.0223485	23.01	0.000	.470365 .5579695
1	.3112809	.0418049	7.45	0.000	.2293448 .393217

`margins` also estimates the standard errors and confidence intervals of the margins. By default, `margins` uses only the estimation sample. We added the `noesample` option so that `margins` would use the entire sample and produce results comparable with our earlier analysis.

We can use `marginsplot` to graph the results from `margins`:

```
. marginsplot
```

Variables that uniquely identify margins: **nonwhite**

The margins for the other two outcomes can be computed by typing

```
. margins nonwhite, predict(outcome(Prepaid)) noesample
(output omitted)
```

```
. margins nonwhite, predict(outcome(Uninsure)) noesample
(output omitted)
```

The margins for each outcome is computed when no outcome is specified. For example,

```
. margins nonwhite, noesample
(output omitted)
```

◀

## □ Technical note

You can use `predict` to classify predicted values and compare them with the observed outcomes to interpret a multinomial logit model. This is a variation on the notions of sensitivity and specificity for logistic regression. Here we will classify indemnity and prepaid as definitely predicting indemnity, definitely predicting prepaid, and ambiguous.

```
. predict indem, outcome(Indemnity) index // obtain indexes
(1 missing value generated)
. predict prepaid, outcome(Prepaid) index
(1 missing value generated)
. gen diff = prepaid-indem // obtain difference
(1 missing value generated)
. predict sediff, outcome(Indemnity,Prepaid) stddp // & its standard error
(1 missing value generated)
. gen type = 1 if diff/sediff < -1.96 // definitely indemnity
(504 missing values generated)
. replace type = 3 if diff/sediff > 1.96 // definitely prepaid
(100 real changes made)
```

```
. replace type = 2 if type>=. & diff/sediff < . // ambiguous
(404 real changes made)
. label def type 1 "Def Ind" 2 "Ambiguous" 3 "Def Prep"
. label values type type // label results
. tabulate insure type
```

Type of insurance	type			Total
	Def Ind	Ambiguous	Def Prep	
Indemnity	78	183	33	294
Prepaid	44	177	56	277
Uninsure	12	28	5	45
Total	134	388	94	616

We can see that the predictive power of this model is modest. There are many misclassifications in both directions, though there are more correctly classified observations than misclassified observations.

Also, the uninsured look overwhelmingly as though they might have come from the indemnity system rather than from the prepaid system.

□

## Calculating marginal effects

### ▷ Example 4

We have already noted that the coefficients from multinomial logit can be difficult to interpret because they are relative to the base outcome. Another way to evaluate the effect of covariates is to examine the marginal effect of changing their values on the probability of observing an outcome.

The `margins` command can be used for this too. We can estimate the marginal effect of each covariate on the probability of observing the first outcome—indemnity insurance—by typing

```
. margins, dydx(*) predict(outcome(Indemnity))
Average marginal effects                               Number of obs = 615
Model VCE: OIM
Expression: Pr(insure==Indemnity), predict(outcome(Indemnity))
dy/dx wrt: age 1.male 1.nonwhite 2.site 3.site
```

	Delta-method				[95% conf. interval]	
	dy/dx	std. err.	z	P> z		
age	.0026655	.001399	1.91	0.057	-.0000765	.0054074
1.male	-.1295734	.0450945	-2.87	0.004	-.2179571	-.0411898
1.nonwhite	-.2032404	.0482554	-4.21	0.000	-.2978192	-.1086616
site						
2	.0070995	.0479993	0.15	0.882	-.0869775	.1011765
3	.1216165	.0505833	2.40	0.016	.022475	.220758

Note: dy/dx for factor levels is the discrete change from the base level.

By default, `margins` estimates the average marginal effect over the estimation sample, and that is what we see above. Being male decreases the average probability of having indemnity insurance by 0.130. We also see, from the note at the bottom of the table, that the marginal effect was computed as a discrete change in the probability of being male rather than female. That is why we made `male` a factor variable when fitting the model.

The `dydx(*)` option requested that `margins` estimate the marginal effect for each regressor, `dydx(age)` would have produced estimates only for the effect of `age`. `margins` has many options for controlling how the marginal effect is computed, including the ability to average over subgroups or to compute estimates for specified values of the regressors; see [R] [margins](#).

`margins` will compute the marginal effects on each outcome when no outcome is specified.

```
. margins, dydx(*)
      (output omitted)
```

◀

## Testing hypotheses about coefficients

### ▷ Example 5

`test` tests hypotheses about the coefficients just as after any estimation command; see [R] [test](#). Note, however, `test`'s syntax for dealing with multiple-equation models. Because `test` bases its results on the estimated covariance matrix, we might prefer a likelihood-ratio test; see [example 5](#) in [R] [mlogit](#) for an example of `lrtest`.

If we simply list variables after the `test` command, we are testing that the corresponding coefficients are zero across all equations:

```
. test 2.site 3.site
      ( 1) [Indemnity]2o.site = 0
      ( 2) [Prepaid]2.site = 0
      ( 3) [Uninsure]2.site = 0
      ( 4) [Indemnity]3o.site = 0
      ( 5) [Prepaid]3.site = 0
      ( 6) [Uninsure]3.site = 0
      Constraint 1 dropped
      Constraint 4 dropped
           chi2( 4) =   19.74
           Prob > chi2 =   0.0006
```

We can test that all the coefficients (except the constant) in an equation are zero by simply typing the outcome in square brackets:

```
. test [Uninsure]
      ( 1) [Uninsure]age = 0
      ( 2) [Uninsure]0b.male = 0
      ( 3) [Uninsure]1.male = 0
      ( 4) [Uninsure]0b.nonwhite = 0
      ( 5) [Uninsure]1.nonwhite = 0
      ( 6) [Uninsure]1b.site = 0
      ( 7) [Uninsure]2.site = 0
      ( 8) [Uninsure]3.site = 0
      Constraint 2 dropped
      Constraint 4 dropped
      Constraint 6 dropped
           chi2( 5) =    9.31
           Prob > chi2 =   0.0973
```

We specify the outcome just as we do with `predict`; we can specify the label if the outcome variable is labeled, or we can specify the numeric value of the outcome. We would have obtained the same test as above if we had typed `test [3]` because 3 is the value of `insure` for the outcome `uninsured`.

We can combine the two syntaxes. To test that the coefficients on the `site` variables are 0 in the equation corresponding to the outcome `prepaid`, we can type

```
. test [Prepaid]: 2.site 3.site
( 1) [Prepaid]2.site = 0
( 2) [Prepaid]3.site = 0
      chi2( 2) =    10.78
      Prob > chi2 =    0.0046
```

We specified the outcome and then followed that with a colon and the variables we wanted to test.

We can also test that coefficients are equal across equations. To test that all coefficients except the constant are equal for the prepaid and uninsured outcomes, we can type

```
. test [Prepaid=Uninsure]
( 1) [Prepaid]age - [Uninsure]age = 0
( 2) [Prepaid]0b.male - [Uninsure]0b.male = 0
( 3) [Prepaid]1.male - [Uninsure]1.male = 0
( 4) [Prepaid]0b.nonwhite - [Uninsure]0b.nonwhite = 0
( 5) [Prepaid]1.nonwhite - [Uninsure]1.nonwhite = 0
( 6) [Prepaid]1b.site - [Uninsure]1b.site = 0
( 7) [Prepaid]2.site - [Uninsure]2.site = 0
( 8) [Prepaid]3.site - [Uninsure]3.site = 0
      Constraint 2 dropped
      Constraint 4 dropped
      Constraint 6 dropped
      chi2( 5) =    13.80
      Prob > chi2 =    0.0169
```

To test that only the site variables are equal, we can type

```
. test [Prepaid=Uninsure]: 2.site 3.site
( 1) [Prepaid]2.site - [Uninsure]2.site = 0
( 2) [Prepaid]3.site - [Uninsure]3.site = 0
      chi2( 2) =    12.68
      Prob > chi2 =    0.0018
```

Finally, we can test any arbitrary constraint by simply entering the equation and specifying the coefficients as described in [\[U\] 13.5 Accessing coefficients and standard errors](#). The following hypothesis is senseless but illustrates the point:

```
. test ([Prepaid]age+[Uninsure]2.site)/2 = 2-[Uninsure]1.nonwhite
( 1) .5*[Prepaid]age + [Uninsure]1.nonwhite + .5*[Uninsure]2.site = 2
      chi2( 1) =    22.45
      Prob > chi2 =    0.0000
```

See [\[R\] test](#) for more information about `test`. The [information](#) there about combining hypotheses across `test` commands (the `accumulate` option) also applies after `mlogit`.

# Title

**more** — The —more— message

[Description](#)

[Syntax](#)

[Option](#)

[Remarks and examples](#)

[Also see](#)

## Description

`set more off`, which is the default, tells Stata not to pause or display a —more— message. `set more on` tells Stata to wait until you press a key before continuing when a —more— message is displayed.

`set pagesize #` sets the number of lines between —more— messages.

## Syntax

*Tell Stata to pause or not pause for —more— messages*

```
set more { on|off } [ , permanently ]
```

*Set number of lines between —more— messages*

```
set pagesize #
```

## Option

`permanently` specifies that, in addition to making the change right now, the `more` setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

When you see —more— at the bottom of the screen,

<u>Press ...</u>	<u>and Stata ...</u>
letter <i>l</i> or <i>Enter</i>	displays the next line
letter <i>q</i>	acts as if you pressed <i>Break</i>
Spacebar or any other key	displays the next screen

You can also click on the **More** button or click on —more— to display the next screen.

—more— is Stata's way of telling you that it has something more to show you but that showing it to you will cause the information on the screen to scroll off.

If you type `set more off`, —more— conditions will never arise, and Stata's output will scroll by at full speed.

If you type `set more on`, —more— conditions will be restored at the appropriate places.

If `set more` is used within a do-file or program, Stata automatically restores the previous `set more` setting when the do-file or program concludes.

Programmers should see [\[P\] more](#) for information on the `more` programming command.

# Title

**mprobit** — Multinomial probit regression

<a href="#">Description</a>	<a href="#">Quick start</a>	<a href="#">Menu</a>	<a href="#">Syntax</a>
<a href="#">Options</a>	<a href="#">Remarks and examples</a>	<a href="#">Stored results</a>	<a href="#">Methods and formulas</a>
<a href="#">References</a>	<a href="#">Also see</a>		

## Description

`mprobit` fits a multinomial probit (MNP) model for a categorical dependent variable with outcomes that have no natural ordering. The actual values taken by the dependent variable are irrelevant. The error terms are assumed to be independent, standard normal, random variables. `cmmprobit` relaxes the independence of irrelevant alternatives assumption by specifying correlated latent-variable errors. `cmmprobit` also allows heteroskedastic latent-variable errors and alternative-specific independent variables.

## Quick start

Multinomial probit model of  $y$  on  $x_1$ ,  $x_2$ , and categorical  $a$

```
mprobit y x1 x2 i.a
```

Same as above, but use  $a$  as the base outcome  $y = 3$

```
mprobit y x1 x2 i.a, baseoutcome(3)
```

Probit variance parameterization of differenced latent errors

```
mprobit y x1 x2 i.a, probitparam
```

Multiple-imputation estimates with Monte Carlo errors from `mi set data`

```
mi estimate, merror: mprobit y x1 x2 i.a
```

## Menu

Statistics > Categorical outcomes > Multinomial probit regression

## Syntax

```
mprobit devar [indepvars] [if] [in] [weight] [, options]
```

<i>options</i>	Description
<b>Model</b>	
<code>noconstant</code>	suppress constant terms
<code>baseoutcome(#   <i>lbl</i>)</code>	outcome used to normalize location
<code>probitparam</code>	use the probit variance parameterization
<code>constraints(<i>constraints</i>)</code>	apply specified linear constraints
<b>SE/Robust</b>	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>opg</code> , <code>bootstrap</code> , or <code>jackknife</code>
<b>Reporting</b>	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>nocnsreport</code>	do not display constraints
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<b>Integration</b>	
<code>intpoints(#)</code>	number of quadrature points
<b>Maximization</b>	
<code>maximize_options</code>	control the maximization process; seldom used
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics

*indepvars* may contain factor variables; see [U] 11.4.3 **Factor variables**.

`bayes`, `bootstrap`, `by`, `collect`, `fp`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 **Prefix commands**. For more details, see [BAYES] `bayes: mprobit`.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] `mi estimate`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()` and `weights` are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

## Options

### Model

`noconstant` suppresses the  $J - 1$  constant terms.

`baseoutcome(# | lbl)` specifies the outcome used to normalize the location of the latent variable. The base outcome may be specified as a number or a label. The default is to use the most frequent outcome. The coefficients associated with the base outcome are zero.

`probitparam` specifies to use the probit variance parameterization by fixing the variance of the differenced latent errors between the scale and the base alternatives to be one. The default is to

make the variance of the base and scale latent errors one, thereby making the variance of the difference to be two.

`constraints(constraints)`; see [R] [Estimation options](#).

#### SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `baseoutcome()`.

#### Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

#### Integration

`intpoints(#)` specifies the number of Gaussian quadrature points to use in approximating the likelihood. The default is `intpoints(15)`.

#### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vctype` to `vce(opg)`.

The following options are available with `mprobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

The MNP model is used with discrete dependent variables that take on more than two outcomes that do not have a natural ordering. The stochastic error terms for this implementation of the model are assumed to have independent, standard normal distributions. To use `mprobit`, you must have one observation for each decision maker in the sample. See [CM] [cmmprobit](#) for another implementation of the MNP model that permits correlated and heteroskedastic errors and is suitable when you have data for each alternative that a decision maker faced.

The MNP model is frequently motivated using a latent-variable framework. The latent variable for the  $j$ th alternative,  $j = 1, \dots, J$ , is

$$\eta_{ij} = \mathbf{z}_i \boldsymbol{\alpha}_j + \xi_{ij}$$

where the  $1 \times q$  row vector  $\mathbf{z}_i$  contains the observed independent variables for the  $i$ th decision maker. Associated with  $\mathbf{z}_i$  are the  $J$  vectors of regression coefficients  $\boldsymbol{\alpha}_j$ . The  $\xi_{i,1}, \dots, \xi_{i,J}$  are distributed independently and identically standard normal. The decision maker chooses the alternative  $k$  such that  $\eta_{ik} \geq \eta_{im}$  for  $m \neq k$ .

Suppose that case  $i$  chooses alternative  $k$ , and take the difference between latent variable  $\eta_{ik}$  and the  $J - 1$  others:

$$\begin{aligned} v_{ijk} &= \eta_{ij} - \eta_{ik} \\ &= \mathbf{z}_i(\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \mathbf{z}_i\boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \end{aligned} \tag{1}$$

where  $j' = j$  if  $j < k$  and  $j' = j - 1$  if  $j > k$  so that  $j' = 1, \dots, J - 1$ .  $\text{Var}(\epsilon_{ij'}) = \text{Var}(\xi_{ij} - \xi_{ik}) = 2$  and  $\text{Cov}(\epsilon_{ij'}, \epsilon_{il'}) = 1$  for  $j' \neq l'$ . The probability that alternative  $k$  is chosen is

$$\begin{aligned} \Pr(i \text{ chooses } k) &= \Pr(v_{i1k} \leq 0, \dots, v_{i,J-1,k} \leq 0) \\ &= \Pr(\epsilon_{i1} \leq -\mathbf{z}_i\boldsymbol{\gamma}_1, \dots, \epsilon_{i,J-1} \leq -\mathbf{z}_i\boldsymbol{\gamma}_{J-1}) \end{aligned}$$

Hence, evaluating the likelihood function involves computing probabilities from the multivariate normal distribution. That all the covariances are equal simplifies the problem somewhat; see [Methods and formulas](#) for details.

In (1), not all  $J$  of the  $\boldsymbol{\alpha}_j$  are identifiable. To remove the indeterminacy,  $\boldsymbol{\alpha}_l$  is set to the zero vector, where  $l$  is the base outcome as specified in the `baseoutcome()` option. That fixes the  $l$ th latent variable to zero so that the remaining variables measure the attractiveness of the other alternatives relative to the base.

## ► Example 1

As discussed in [example 1](#) of [\[R\] mlogit](#), we have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). Patients may have either an indemnity (fee-for-service) plan or a prepaid plan such as an HMO, or the patient may be uninsured. Demographic variables include age, gender, race, and site. Indemnity insurance is the most popular alternative, so `mprobit` will choose it as the base outcome by default.

```
. use https://www.stata-press.com/data/r18/sydsdn1
(Health insurance data)
```

```
. mprobit insure age male nonwhite i.site
```

```
Iteration 0: Log likelihood = -535.89424
Iteration 1: Log likelihood = -534.56173
Iteration 2: Log likelihood = -534.52835
Iteration 3: Log likelihood = -534.52833
```

```
Multinomial probit regression
```

```
Number of obs = 615
Wald chi2(10) = 40.18
Prob > chi2 = 0.0000
```

```
Log likelihood = -534.52833
```

The likelihood function for `mprobit` is derived under the assumption that all decision-making units face the same choice set, which is the union of all outcomes observed in the dataset. If that is not true for your model, then an alternative is to use the `cmmprobit` command, which does not require this assumption. To do that, you will need to expand the dataset so that each decision maker has  $k_i$  observations, where  $k_i$  is the number of alternatives in the choice set faced by decision maker  $i$ . You will also need to create a binary variable to indicate the choice made by each decision maker. Moreover, you will need to use the `correlation(independent)` and `stddev(homoskedastic)` options with `cmmprobit` unless you have alternative-specific variables.

## Stored results

`mprobit` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(k_out)</code>	number of outcomes
<code>e(k_points)</code>	number of quadrature points
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_indvars)</code>	number of independent variables
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(p)</code>	<i>p</i> -value for model test
<code>e(k_eq_base)</code>	equation number of the base outcome
<code>e(baseout)</code>	the value of <code>depvar</code> to be treated as the base outcome
<code>e(ibaseout)</code>	index of the base outcome
<code>e(const)</code>	0 if <code>noconstant</code> is specified, 1 otherwise
<code>e(probitparam)</code>	1 if <code>probitparam</code> is specified, 0 otherwise
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>mprobit</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(indvars)</code>	independent variables
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(chi2type)</code>	Wald, type of model $\chi^2$ test
<code>e(vce)</code>	<i>vce</i> type specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(outeqs)</code>	outcome equations
<code>e(out#)</code>	outcome labels, <code>#=1,...,e(k_out)</code>
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(marginsnotok)</code>	predictions disallowed by <code>margins</code>
<code>e(marginsdefault)</code>	default <code>predict()</code> specification for <code>margins</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(outcomes)</code>	outcome values
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance-covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices

`r(table)` matrix containing the coefficients with their standard errors, test statistics, *p*-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

See Cameron and Trivedi (2005, chap. 15) for a discussion of multinomial models, including multinomial probit. Long and Freese (2014, chap. 8) discuss the multinomial logistic, multinomial probit, and stereotype logistic regression models, with examples using Stata.

As discussed in *Remarks and examples*, the latent variables for a *J*-alternative model are  $\eta_{ij} = \mathbf{z}_i \boldsymbol{\alpha}_j + \xi_{ij}$ , for  $j = 1, \dots, J$ ,  $i = 1, \dots, n$ , and  $\{\xi_{i,1}, \dots, \xi_{i,J}\} \sim \text{i.i.d. } N(0, 1)$ . The experimenter observes alternative *k* for the *i*th observation if  $\eta_{ik} > \eta_{il}$  for  $l \neq k$ . For  $j \neq k$ , let

$$\begin{aligned} v_{ij'} &= \eta_{ij} - \eta_{ik} \\ &= \mathbf{z}_i(\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \mathbf{z}_i \boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \end{aligned}$$

where  $j' = j$  if  $j < k$  and  $j' = j - 1$  if  $j > k$  so that  $j' = 1, \dots, J - 1$ .  $\boldsymbol{\epsilon}_i = (\epsilon_{i1}, \dots, \epsilon_{i,J-1}) \sim MVN(\mathbf{0}, \boldsymbol{\Sigma})$ , where

$$\boldsymbol{\Sigma} = \begin{pmatrix} 2 & 1 & 1 & \dots & 1 \\ 1 & 2 & 1 & \dots & 1 \\ 1 & 1 & 2 & \dots & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & 1 & \dots & 2 \end{pmatrix}$$

Denote the deterministic part of the model as  $\lambda_{ij'} = \mathbf{z}_i \boldsymbol{\gamma}_{j'}$ ; the probability that subject *i* chooses outcome *k* is

$$\begin{aligned} \Pr(y_i = k) &= \Pr(v_{i1} \leq 0, \dots, v_{i,J-1} \leq 0) \\ &= \Pr(\epsilon_{i1} \leq -\lambda_{i1}, \dots, \epsilon_{i,J-1} \leq -\lambda_{i,J-1}) \\ &= \frac{1}{(2\pi)^{(J-1)/2} |\boldsymbol{\Sigma}|^{1/2}} \int_{-\infty}^{-\lambda_{i1}} \dots \int_{-\infty}^{-\lambda_{i,J-1}} \exp\left(-\frac{1}{2} \mathbf{z}' \boldsymbol{\Sigma}^{-1} \mathbf{z}\right) dz \end{aligned}$$

Because of the exchangeable correlation structure of  $\boldsymbol{\Sigma}$  ( $\rho_{ij} = 1/2$  for all  $i \neq j$ ), we can use Dunnett's (1989) result to reduce the multidimensional integral to one dimension:

$$\Pr(y_i = k) = \frac{1}{\sqrt{\pi}} \int_0^\infty \left\{ \prod_{j=1}^{J-1} \Phi\left(-z\sqrt{2} - \lambda_{ij}\right) + \prod_{j=1}^{J-1} \Phi\left(z\sqrt{2} - \lambda_{ij}\right) \right\} e^{-z^2} dz$$

Gaussian quadrature is used to approximate this integral, resulting in the  $K$ -point quadrature formula

$$\Pr(y_i = k) \approx \frac{1}{2} \sum_{k=1}^K w_k \left\{ \prod_{j=1}^{J-1} \Phi(-\sqrt{2x_k} - \lambda_{ij}) + \prod_{j=1}^{J-1} \Phi(\sqrt{2x_k} - \lambda_{ij}) \right\}$$

where  $w_k$  and  $x_k$  are the weights and roots of the Laguerre polynomial of order  $K$ . In **mprobit**,  $K$  is specified by the `intpoints()` option.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

**mprobit** also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

Remarks and examples

## Postestimation commands

The following postestimation commands are available after `mprobit`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	probabilities, linear predictions and their SEs, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

------------------	-------------

Main

<code>pr</code>	predicted probabilities; the default
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the linear prediction

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb` and `stdp`. If you do not specify `outcome()`, then `outcome(#1)` is assumed. These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction,  $\mathbf{x}_i\alpha_j$ , for alternative  $j$  and individual  $i$ . The index,  $j$ , corresponds to the outcome specified in `outcome()`.

`stdp` calculates the standard error of the linear prediction.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is not allowed with `scores`.

`scores` calculates equation-level score variables. The  $j$ th new variable will contain the scores for the  $j$ th fitted equation.

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
default	probabilities for each outcome
pr	probability for a specified outcome
xb	linear prediction for a specified outcome
stdp	not allowed with <code>margins</code>

`pr` and `xb` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than  $e(b)$ .

For the full syntax, see [R] [margins](#).

## Remarks and examples

Once you have fit a multinomial probit model, you can use `predict` to obtain probabilities that an individual will choose each of the alternatives for the estimation sample, as well as other samples; see [U] [20 Estimation and postestimation commands](#) and [R] [predict](#).

### ► Example 1

In [example 1](#) of [R] [mprobit](#), we fit the multinomial probit model to a dataset containing the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). We can obtain the predicted probabilities by typing

```
. use https://www.stata-press.com/data/r18/sysdsn1
(Health insurance data)
. mprobit insure age male nonwhite i.site
(output omitted)
. predict p1-p3
(option pr assumed; predicted probabilities)
. list p1-p3 insure in 1/10
```

	p1	p2	p3	insure
1.	.5961306	.3741824	.029687	Indemnity
2.	.4719296	.4972289	.0308415	Prepaid
3.	.4896086	.4121961	.0981953	Indemnity
4.	.3730529	.5416623	.0852848	Prepaid
5.	.5063069	.4629773	.0307158	.
6.	.4768125	.4923548	.0308327	Prepaid
7.	.5035672	.4657016	.0307312	Prepaid
8.	.3326361	.5580404	.1093235	.
9.	.4758165	.4384811	.0857024	Uninsure
10.	.5734057	.3316601	.0949342	Prepaid

`insure` contains a missing value for observations 5 and 8. Because of that, those two observations were not used in the estimation. However, because none of the independent variables is missing, `predict` can still calculate the probabilities. Had we typed

```
. predict p1-p3 if e(sample)
```

`predict` would have filled in missing values for `p1`, `p2`, and `p3` for those observations because they were not used in the estimation.

## Description

`nbreg` fits a negative binomial regression model for a nonnegative count dependent variable. In this model, the count variable is believed to be generated by a Poisson-like process, except that the variation is allowed to be greater than that of a true Poisson. This extra variation is referred to as overdispersion.

`gnbreg` fits a generalization of the negative binomial mean-dispersion model; the shape parameter  $\alpha$  may also be parameterized.

## Quick start

Negative binomial model of `y` on `x1` and categorical variable `a`

```
nbreg y x1 i.a
```

Same as above, but report results as incidence-rate ratios

```
nbreg y x1 i.a, irr
```

Same as above, and specify exposure variable `evar`

```
nbreg y x1 i.a, irr exposure(evar)
```

Generalized negative binomial model with shape parameter  $\alpha$  a function of `x2` and `x3`

```
gnbreg y x1 i.a, lnalpha(x2 x3)
```

Add log of exposure, `lnevar`, as an offset

```
gnbreg y x1 i.a, lnalpha(x2 x3) offset(lnevar)
```

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *indepvars*, *varname<sub>e</sub>*, and *varname<sub>o</sub>* may contain time-series operators (nbreg only); see [U] 11.4.4 Time-series varlists.

`bayes`, `bootstrap`, `by` (nbreg only), `collect`, `fmm` (nbreg only), `fp` (nbreg only), `jackknife`, `mfp` (nbreg only), `mi estimate`, `nestreg` (nbreg only), `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] `bayes: gnbreg`, [BAYES] `bayes: nbreg`, and [FMM] `fmm: nbreg`.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] `mi estimate`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iwweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options for nbreg

### Model

`noconstant`; see [R] Estimation options.

`dispersion(mean | constant)` specifies the parameterization of the model. `dispersion(mean)`, the default, yields a model with dispersion equal to  $1 + \alpha \exp(\mathbf{x}_j\beta + \text{offset}_j)$ ; that is, the dispersion is a function of the expected mean:  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$ . `dispersion(constant)` has dispersion equal to  $1 + \delta$ ; that is, it is a constant for all observations.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] Estimation options.

## SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`nolrtest` suppresses fitting the Poisson model. Without this option, a comparison Poisson model is fit, and the likelihood is used in a likelihood-ratio test of the null hypothesis that the dispersion parameter is zero.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrntolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vctype` to `vce(opg)`.

The following options are available with `nbreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Options for `gnbreg`

## Model

`noconstant`; see [R] [Estimation options](#).

`lnalpha(varlist)` allows you to specify a linear equation for  $\ln\alpha$ . Specifying `lnalpha(male old)` means that  $\ln\alpha = \gamma_0 + \gamma_1\text{male} + \gamma_2\text{old}$ , where  $\gamma_0$ ,  $\gamma_1$ , and  $\gamma_2$  are parameters to be estimated along with the other model coefficients. If this option is not specified, `gnbreg` and `nbreg` will produce the same results because the shape parameter will be parameterized as a constant.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] [Estimation options](#).

SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vctype` to `vce(opg)`.

The following options are available with `gnbreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[Introduction to negative binomial regression](#)  
[nbreg](#)  
[gnbreg](#)

## Introduction to negative binomial regression

Negative binomial regression models the number of occurrences (counts) of an event when the event has extra-Poisson variation, that is, when it has overdispersion. The Poisson regression model is

$$y_j \sim \text{Poisson}(\mu_j)$$

where

$$\mu_j = \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$$

for observed counts  $y_j$  with covariates  $\mathbf{x}_j$  for the  $j$ th observation. One derivation of the negative binomial mean-dispersion model is that individual units follow a Poisson regression model, but there is an omitted variable  $\zeta_j$ , such that  $e^{\zeta_j}$  follows a gamma distribution with mean 1 and variance  $\alpha$ :

$$y_j \sim \text{Poisson}(\mu_j^*)$$

where

$$\mu_j^* = \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j + \zeta_j)$$

and

$$e^{\zeta_j} \sim \text{Gamma}(1/\alpha, \alpha)$$

With this parameterization, a  $\text{Gamma}(a, b)$  distribution will have expectation  $ab$  and variance  $ab^2$ .

We refer to  $\alpha$  as the overdispersion parameter. The larger  $\alpha$  is, the greater the overdispersion. The Poisson model corresponds to  $\alpha = 0$ . `nbreg` parameterizes  $\alpha$  as  $\text{In}\alpha$ . `gnbreg` allows  $\text{In}\alpha$  to be modeled as  $\text{In}\alpha_j = \mathbf{z}_j\boldsymbol{\gamma}$ , a linear combination of covariates  $\mathbf{z}_j$ .

`nbreg` will fit two different parameterizations of the negative binomial model. The default, described above and also given by the `dispersion(mean)` option, has dispersion for the  $j$ th observation equal to  $1 + \alpha \exp(\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j)$ . This is seen by noting that the above implies that

$$\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha\mu_j)$$

and thus

$$\begin{aligned} \text{Var}(y_j) &= E \{ \text{Var}(y_j | \mu_j^*) \} + \text{Var} \{ E(y_j | \mu_j^*) \} \\ &= E(\mu_j^*) + \text{Var}(\mu_j^*) \\ &= \mu_j(1 + \alpha\mu_j) \end{aligned}$$

The alternative parameterization, given by the `dispersion(constant)` option, has dispersion equal to  $1 + \delta$ ; that is, it is constant for all observations. This is so because the constant-dispersion model assumes instead that

$$\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$$

and thus  $\text{Var}(y_j) = \mu_j(1 + \delta)$ . The Poisson model corresponds to  $\delta = 0$ .

For detailed derivations of both models, see [Cameron and Trivedi \(2013, 80–89\)](#). In particular, note that the mean-dispersion model is known as the NB2 model in their terminology, whereas the constant-dispersion model is referred to as the NB1 model.

See [Long and Freese \(2014\)](#) and [Cameron and Trivedi \(2022, chap. 20\)](#) for a discussion of the negative binomial regression model with Stata examples and for a discussion of other regression models for count data.

[Hilbe \(2011\)](#) provides an extensive review of the negative binomial model and its variations, using Stata examples.

nbreg

It is not uncommon to posit a Poisson regression model and observe a lack of model fit. The following data appeared in Rodríguez (1993):

```
. use https://www.stata-press.com/data/r18/rod93
. list, sepby(cohort)
```

	cohort	age_mos	deaths	exposure
1.	1941-1949	0.5	168	278.4
2.	1941-1949	2.0	48	538.8
3.	1941-1949	4.5	63	794.4

```
LR test of alpha=0: chibar2(01) = 4056.27      Prob >= chibar2 = 0.000
```

Our original Poisson model is a special case of the negative binomial—it corresponds to  $\alpha = 0$ . `nbreg`, however, estimates  $\alpha$  indirectly, estimating instead  $\ln\alpha$ . In our model,  $\ln\alpha = 0.594$ , meaning that  $\alpha = 1.81$  (`nbreg` undoes the transformation for us at the bottom of the output).

To test  $\alpha = 0$  (equivalent to  $\ln\alpha = -\infty$ ), `nbreg` performs a likelihood-ratio test. The staggering  $\chi^2$  value of 4,056 asserts that the probability that we would observe these data conditional on  $\alpha = 0$  is virtually zero, that is, conditional on the process being Poisson. The data are not Poisson. It is not accidental that this  $\chi^2$  value is close to the goodness-of-fit statistic from the Poisson regression itself.

## □ Technical note

The usual Gaussian test of  $\alpha = 0$  is omitted because this test occurs on the boundary, invalidating the usual theory associated with such tests. However, the likelihood-ratio test of  $\alpha = 0$  has been modified to be valid on the boundary. In particular, the null distribution of the likelihood-ratio test statistic is not the usual  $\chi^2_1$ , but rather a 50:50 mixture of a  $\chi^2_0$  (point mass at zero) and a  $\chi^2_1$ , denoted as  $\bar{\chi}^2_{01}$ . See [Gutierrez, Carter, and Drukker \(2001\)](#) for more details. □

## □ Technical note

The negative binomial model deals with cases in which there is more variation than would be expected if the process were Poisson. The negative binomial model is not helpful if there is less than Poisson variation—if the variance of the count variable is less than its mean. However, underdispersion is uncommon. Poisson models arise because of independently generated events. Overdispersion comes about if some of the parameters (causes) of the Poisson processes are unknown. To obtain underdispersion, the sequence of events somehow would have to be regulated; that is, events would not be independent but controlled based on past occurrences. □

## gnbreg

gnbreg is a generalization of nbreg, dispersion(mean). Whereas in nbreg, one  $\ln\alpha$  is estimated, gnbreg allows  $\ln\alpha$  to vary, observation by observation, as a linear combination of another set of covariates:  $\ln\alpha_j = \mathbf{z}_j\boldsymbol{\gamma}$ .

We will assume that the number of deaths is a function of age, whereas the  $\ln\alpha$  parameter is a function of cohort. To fit the model, we type

```
. gnbreg deaths age_mos, lnalpha(i.cohort) offset(logexp)
Fitting constant-only model:
Iteration 0: Log likelihood = -187.067 (not concave)
Iteration 1: Log likelihood = -138.13047
Iteration 2: Log likelihood = -133.83164
Iteration 3: Log likelihood = -131.59551
Iteration 4: Log likelihood = -131.5795
Iteration 5: Log likelihood = -131.57948
Iteration 6: Log likelihood = -131.57948
Fitting full model:
Iteration 0: Log likelihood = -124.34327
Iteration 1: Log likelihood = -117.76701
Iteration 2: Log likelihood = -117.56403
Iteration 3: Log likelihood = -117.56164
Iteration 4: Log likelihood = -117.56164
Generalized negative binomial regression
Log likelihood = -117.56164
Number of obs = 21
LR chi2(1) = 28.04
Prob > chi2 = 0.0000
Pseudo R2 = 0.1065
```

	deaths	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
<b>deaths</b>							
	age_mos	-.0516657	.0051747	-9.98	0.000	-.061808	-.0415233
	_cons	-1.867225	.2227944	-8.38	0.000	-2.303894	-1.430556
	logexp	1	(offset)				
<b>lnalpha</b>							
	cohort						
	1960-1967	.0939546	.7187747	0.13	0.896	-1.314818	1.502727
	1968-1976	.0815279	.7365476	0.11	0.912	-1.362079	1.525135
	_cons	-.4759581	.5156502	-0.92	0.356	-1.486614	.5346978

We find that age is a significant determinant of the number of deaths. The standard errors for the variables in the  $\ln\alpha$  equation suggest that the overdispersion parameter does not vary across cohorts. We can test this assertion by typing

```
. test 2.cohort 3.cohort
( 1) [lnalpha]2.cohort = 0
( 2) [lnalpha]3.cohort = 0
      chi2( 2) = 0.02
      Prob > chi2 = 0.9904
```

There is no evidence of variation by cohort in these data.

## □ Technical note

Note the intentional absence of a likelihood-ratio test for  $\alpha = 0$  in `gnbreg`. The test is affected by the same boundary condition that affects the comparison test in `nbreg`; however, when  $\alpha$  is parameterized by more than a constant term, the null distribution becomes intractable. For this reason, we recommend using `nbreg` to test for overdispersion and, if you have reason to believe that overdispersion exists, only then modeling the overdispersion using `gnbreg`. □

## Stored results

`nbreg` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(r2_p)</code>	pseudo- $R^2$
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(ll_c)</code>	log likelihood, comparison model
<code>e(alpha)</code>	value of alpha
<code>e(delta)</code>	value of delta
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(chi2_c)</code>	$\chi^2$ for comparison test
<code>e(p)</code>	$p$ -value for model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(rank0)</code>	rank of <code>e(V)</code> for constant-only model
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>nbreg</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output

In addition to the above, the following is stored in `r()`:

Matrices	
r(table)	matrix containing the coefficients with their standard errors, test statistics, $p$ -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

## Methods and formulas

See [R] [poisson](#) and [Johnson, Kemp, and Kotz \(2005, chap. 4\)](#) for an introduction to the Poisson distribution.

Methods and formulas are presented under the following headings:

*Mean-dispersion model*  
*Constant-dispersion model*

## Mean-dispersion model

A negative binomial distribution can be regarded as a gamma mixture of Poisson random variables. The number of times something occurs,  $y_j$ , is distributed as  $\text{Poisson}(\nu_j \mu_j)$ . That is, its conditional likelihood is

$$f(y_j | \nu_j) = \frac{(\nu_j \mu_j)^{y_j} e^{-\nu_j \mu_j}}{\Gamma(y_j + 1)}$$

where  $\mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$  and  $\nu_j$  is an unobserved parameter with a  $\text{Gamma}(1/\alpha, \alpha)$  density:

$$g(\nu) = \frac{\nu^{(1-\alpha)/\alpha} e^{-\nu/\alpha}}{\alpha^{1/\alpha} \Gamma(1/\alpha)}$$

This gamma distribution has mean 1 and variance  $\alpha$ , where  $\alpha$  is our ancillary parameter.

The unconditional likelihood for the  $j$ th observation is therefore

$$f(y_j) = \int_0^\infty f(y_j | \nu) g(\nu) d\nu = \frac{\Gamma(m + y_j)}{\Gamma(y_j + 1) \Gamma(m)} p_j^m (1 - p_j)^{y_j}$$

where  $p_j = 1/(1 + \alpha \mu_j)$  and  $m = 1/\alpha$ . Solutions for  $\alpha$  are handled by searching for  $\ln \alpha$  because  $\alpha$  must be greater than zero.

The log likelihood (with weights  $w_j$  and offsets) is given by

$$m = 1/\alpha \quad p_j = 1/(1 + \alpha \mu_j) \quad \mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$$

$$\ln L = \sum_{j=1}^n w_j \left[ \ln\{\Gamma(m + y_j)\} - \ln\{\Gamma(y_j + 1)\} \right. \\ \left. - \ln\{\Gamma(m)\} + m \ln(p_j) + y_j \ln(1 - p_j) \right]$$

For `gnbreg`,  $\alpha$  can vary across the observations according to the parameterization  $\ln \alpha_j = \mathbf{z}_j \boldsymbol{\gamma}$ .

## Constant-dispersion model

The constant-dispersion model assumes that  $y_j$  is conditionally distributed as  $\text{Poisson}(\mu_j^*)$ , where  $\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$  for some dispersion parameter  $\delta$  (by contrast, the mean-dispersion model assumes that  $\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha\mu_j)$ ). The log likelihood is given by

$$m_j = \mu_j/\delta \quad p = 1/(1 + \delta)$$

$$\ln L = \sum_{j=1}^n w_j \left[ \ln\{\Gamma(m_j + y_j)\} - \ln\{\Gamma(y_j + 1)\} \right. \\ \left. - \ln\{\Gamma(m_j)\} + m_j \ln(p) + y_j \ln(1 - p) \right]$$

with everything else defined as before in the calculations for the mean-dispersion model.

`nbgreg` and `gnbgreg` support the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

These commands also support estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `nbreg` and `gnbreg`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICC, and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>linktest</code>	link test for model specification
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	number of events, incidence rates, probabilities, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

\*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

# predict

## Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, standard errors, and predicted values.

## Menu for predict

Statistics > Postestimation

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] stub* [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

<i>statistic</i>	Description
Main	
<code>n</code>	number of events; the default
<code>ir</code>	incidence rate (equivalent to <code>predict ... , n nooffset</code> )
<code>pr(<i>n</i>)</code>	probability $\Pr(y_j = n)$
<code>pr(<i>a</i>,<i>b</i>)</code>	probability $\Pr(a \leq y_j \leq b)$
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the linear prediction

In addition, relevant only after `gnbreg` are the following:

<i>statistic</i>	Description
------------------	-------------

<i>statistic</i>	Description
Main	
<code><u>alpha</u></code>	predicted values of $\alpha_j$
<code><u>lnalpha</u></code>	predicted values of $\ln\alpha_j$
<code><u>stdplna</u></code>	standard error of predicted $\ln\alpha_j$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Options for predict

Main

`n`, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta)$  if neither `offset(varnameo)` nor `exposure(varnamee)` was specified when the model was fit;  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$  if `offset()` was specified; or  $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$  if `exposure()` was specified.

`ir` calculates the incidence rate  $\exp(\mathbf{x}_j\beta)$ , which is the predicted number of events when exposure is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where  $n$  is a nonnegative integer that may be specified as a number or a variable.

`pr(a,b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where  $a$  and  $b$  are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20,.)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20,b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(.,b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a,b)`.

`xb` calculates the linear prediction, which is  $\mathbf{x}_j\beta$  if neither `offset()` nor `exposure()` was specified;  $\mathbf{x}_j\beta + \text{offset}_j$  if `offset()` was specified; or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$  if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`alpha`, `lnalpha`, and `stdplna` are relevant after `gnbreg` estimation only; they produce the predicted values of  $\alpha_j$ ,  $\ln\alpha_j$ , and the standard error of the predicted  $\ln\alpha_j$ , respectively.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j$  or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ . Specifying `predict ... , nooffset` is equivalent to specifying `predict ... , ir`.

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial (\ln\alpha_j)$  for `dispersion(mean)` and `gnbreg`.

The second new variable will contain  $\partial \ln L / \partial (\ln\delta)$  for `dispersion(constant)`.

## margins

### Description for margins

`margins` estimates margins of response for numbers of events, incidence rates, probabilities, linear predictions, and predicted values.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>n</code>	number of events; the default
<code>ir</code>	incidence rate (equivalent to <code>predict ... , n nooffset</code> )
<code>pr(<i>n</i>)</code>	probability $\Pr(y_j = n)$
<code>pr(<i>a,b</i>)</code>	probability $\Pr(a \leq y_j \leq b)$
<code>xb</code>	linear prediction
<code>stdp</code>	not allowed with <code>margins</code>

In addition, relevant only after `gnbreg` are the following:

<i>statistic</i>	Description
<code><u>alpha</u></code>	predicted values of $\alpha_j$
<code><u>lnalpha</u></code>	predicted values of $\ln\alpha_j$
<code><u>stdplna</u></code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

## Remarks and examples

After `nbreg` and `gnbreg`, `predict` returns the expected number of deaths per cohort and the probability of observing the number of deaths recorded or fewer.

```
. use https://www.stata-press.com/data/r18/rod93
. nbreg deaths i.cohort, nolog
Negative binomial regression                Number of obs =    21
                                           LR chi2(2)      =    0.14
Dispersion: mean                          Prob > chi2     = 0.9307
Log likelihood = -108.48841                Pseudo R2      = 0.0007
```

deaths	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
cohort						
1960-1967	.0591305	.2978419	0.20	0.843	-.5246289	.64289
1968-1976	-.0538792	.2981621	-0.18	0.857	-.6382662	.5305077
_cons	4.435906	.2107213	21.05	0.000	4.0229	4.848912
/lnalpha	-1.207379	.3108622			-1.816657	-.5980999
alpha	.29898	.0929416			.1625683	.5498555

```
LR test of alpha=0: chibar2(01) = 434.62                Prob >= chibar2 = 0.000
```

```
. predict count
(option n assumed; predicted number of events)
. predict p, pr(0, deaths)
. summarize deaths count p
```

Variable	Obs	Mean	Std. dev.	Min	Max
deaths	21	84.66667	48.84192	10	197
count	21	84.66667	4.00773	80	89.57143
p	21	.4991542	.2743702	.0070255	.9801285

The expected number of deaths ranges from 80 to 90. The probability  $\Pr(y_i \leq \text{deaths})$  ranges from 0.007 to 0.98.

The estimated expected and observed mean number of deaths, 84.67, happen to be the same in our example because our model included only a categorical predictor. In general, in the presence of other continuous predictors, the two estimates may not always be the same.

## Methods and formulas

In the following, we use the same notation as in [\[R\] nbreg](#).

Methods and formulas are presented under the following headings:

*Mean-dispersion model*  
*Constant-dispersion model*

## Mean-dispersion model

The equation-level scores are given by

$$\begin{aligned}\text{score}(\mathbf{x}\boldsymbol{\beta})_j &= p_j(y_j - \mu_j) \\ \text{score}(\tau)_j &= -m \left\{ \frac{\alpha_j(\mu_j - y_j)}{1 + \alpha_j\mu_j} - \ln(1 + \alpha_j\mu_j) + \psi(y_j + m) - \psi(m) \right\}\end{aligned}$$

where  $\tau_j = \ln\alpha_j$  and  $\psi(z)$  is the digamma function.

## Constant-dispersion model

The equation-level scores are given by

$$\begin{aligned}\text{score}(\mathbf{x}\boldsymbol{\beta})_j &= m_j \{ \psi(y_j + m_j) - \psi(m_j) + \ln(p) \} \\ \text{score}(\tau)_j &= y_j - (y_j + m_j)(1 - p) - \text{score}(\mathbf{x}\boldsymbol{\beta})_j\end{aligned}$$

where  $\tau_j = \ln\delta_j$ .

## Description

`nestreg` fits nested models by sequentially adding blocks of variables and then reports comparison tests between the nested models.

## Quick start

Fit nested (hierarchical) models sequentially, including covariates `x1` and `x2` first and then adding `x3` and `x4`

```
nestreg: regress y (x1 x2) (x3 x4)
```

Also fit third model including indicators for categorical variable `a`

```
nestreg: regress y (x1 x2) (x3 x4) (i.a)
```

Report table of likelihood-ratio tests instead of Wald tests comparing models

```
nestreg, lrtable: regress y (x1 x2) (x3 x4) (i.a)
```

Fit nested models and adjust for complex survey design using `svyset` data

```
nestreg: svy: regress y (x1 x2) (x3 x4) (i.a)
```

Note: In the above examples, `regress` could be replaced with any estimation command allowing the `nestreg` prefix.

## Menu

Statistics > Other > Nested model statistics

## Syntax

Standard estimation command syntax

```
nestreg [ , options ]: command_name depvar (varlist) [(varlist) ... ]
      [if] [in] [weight] [ , command_options ]
```

Survey estimation command syntax

```
nestreg [ , options ]: svy [vcetype] [ , svy_options ]: command_name depvar
      (varlist) [(varlist) ... ] [if] [in] [ , command_options ]
```

<i>options</i>	Description
----------------	-------------

Reporting

<code>waldtable</code>	report Wald test results; the default
<code>lrtable</code>	report likelihood-ratio test results
<code>quietly</code>	suppress any output from <i>command_name</i>
<code>store(<i>stub</i>)</code>	store nested estimation results in <code>_est_</code> <i>stub</i> #

`by` is allowed; see [U] 11.1.10 Prefix commands.

Weights are allowed if *command\_name* allows them; see [U] 11.1.6 weight.

A *varlist* in parentheses indicates that this list of variables is to be considered as a block. Each variable in a *varlist* not bound in parentheses will be treated as its own block.

All postestimation commands behave as they would after *command\_name* without the `nestreg` prefix; see the postestimation manual entry for *command\_name*.

## Options

Reporting

`waldtable` specifies that the table of Wald test results be reported. `waldtable` is the default.

`lrtable` specifies that the table of likelihood-ratio tests be reported. This option is not allowed if `pweights`, the `vce(robust)` option, or the `vce(cluster clustvar)` option is specified. `lrtable` is also not allowed with the `svy` prefix.

`quietly` suppresses the display of any output from *command\_name*.

`store(stub)` specifies that each model fit by `nestreg` be stored under the name `_est_`*stub*#, where # is the nesting order from first to last.

## Remarks and examples

Remarks are presented under the following headings:

- [Estimation commands](#)
- [Wald tests](#)
- [Likelihood-ratio tests](#)
- [Programming for nestreg](#)

## Estimation commands

nestreg removes collinear predictors and observations with missing values from the estimation sample before calling *command\_name*.

The following Stata commands are supported by nestreg:

betareg, clogit, cloglog, glm, intreg, logistic, logit, nbreg, ologit, oprobit, poisson, probit, qreg, regress, scobit, stcox, stcrreg, stintreg, streg, and tobit

You do not supply a *depvar* for stcox, stintreg, stcrreg, or streg; otherwise, *depvar* is required. You must supply two *depvars* for intreg.

## Wald tests

Use nestreg to test the significance of blocks of predictors, building the regression model one block at a time. Using the data from [example 1](#) of [\[R\] test](#), we wish to test the significance of the following predictors of birthrate: median age (*medage*), median age squared (*c.medage#c.medage*), and indicators of the census region (*i.region*).

```
. use https://www.stata-press.com/data/r18/census4
(Census data on birthrate, median age)
. nestreg: regress brate (medage) (c.medage#c.medage) (i.region)
note: 1.region omitted because of estimability.
```

nestreg collected the  $F$  statistic for the corresponding block of predictors and the model  $R^2$  statistic from each model fit.

The  $F$  statistic for the first block, 164.72, is for a test of the joint significance of the first block of variables; it is simply the  $F$  statistic from the regression of `brate` on `medage`. The  $F$  statistic for the second block, 35.25, is for a test of the joint significance of the second block of variables in a regression of both the first and second blocks of variables. In our example, it is an  $F$  test of `c.medage#c.medage` in the regression of `brate` on `medage` and `c.medage#c.medage`. Similarly, the third block's  $F$  statistic of 8.85 corresponds to a joint test of the indicators for the `N Cntrl`, `South`, and `West` regions in the final regression.

## Likelihood-ratio tests

The `nestreg` command provides a simple syntax for performing likelihood-ratio tests for nested model specifications; also see `lrtest`. Using the data from [example 1](#) of [\[R\] lrtest](#), we wish to jointly test the significance of the following predictors of low birthweight: `age`, `lwt`, `ptl`, and `ht`.

```
. use https://www.stata-press.com/data/r18/lbw
(Hosmer & Lemeshow data)
. nestreg, lr: logistic low (i.race smoke ui) (age lwt ptl ht)
note: 1.race omitted because of estimability.
Block 1: 2.race 3.race smoke ui
Logistic regression
Log likelihood = -107.93404
```

	Number of obs =	189
	LR chi2(4) =	18.80
	Prob > chi2 =	0.0009
	Pseudo R2 =	0.0801

	low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
	race						
	Black	3.052746	1.498087	2.27	0.023	1.166747	7.987382
	Other	2.922593	1.189229	2.64	0.008	1.316457	6.488285
	smoke	2.945742	1.101838	2.89	0.004	1.415167	6.131715
	ui	2.419131	1.047359	2.04	0.041	1.035459	5.651788
	_cons	.1402209	.0512295	-5.38	0.000	.0685216	.2869447

Note: `_cons` estimates baseline odds.

Block 2: `age` `lwt` `ptl` `ht`

```
Logistic regression
Log likelihood = -100.724
```

	Number of obs =	189
	LR chi2(8) =	33.22
	Prob > chi2 =	0.0001
	Pseudo R2 =	0.1416

	low	Odds ratio	Std. err.	z	P> z	[95% conf. interval]	
	race						
	Black	3.534767	1.860737	2.40	0.016	1.259736	9.918406
	Other	2.368079	1.039949	1.96	0.050	1.001356	5.600207
	smoke	2.517698	1.00916	2.30	0.021	1.147676	5.523162
	ui	2.1351	.9808153	1.65	0.099	.8677528	5.2534
	age	.9732636	.0354759	-0.74	0.457	.9061578	1.045339
	lwt	.9849634	.0068217	-2.19	0.029	.9716834	.9984249
	ptl	1.719161	.5952579	1.56	0.118	.8721455	3.388787
	ht	6.249602	4.322408	2.65	0.008	1.611152	24.24199
	_cons	1.586014	1.910496	0.38	0.702	.1496092	16.8134

Note: `_cons` estimates baseline odds.

Block	LL	LR	df	Pr > LR	AIC	BIC
1	-107.934	18.80	4	0.0009	225.8681	242.0768
2	-100.724	14.42	4	0.0061	219.448	248.6237

The estimation results from the full model are left in `e()`, so we can later use `estat` and other postestimation commands.

```
. estat gof
Goodness-of-fit test after logistic model
Variable: low
      Number of observations =    189
      Number of covariate patterns =   182
      Pearson chi2(173) = 179.24
      Prob > chi2 = 0.3567
```

## Programming for nestreg

If you want your community-contributed command (*command\_name*) to work with `nestreg`, it must follow standard Stata syntax and allow the `if` qualifier. Furthermore, *command\_name* must have `sw` or `swml` as a program property; see [P] [program properties](#). If *command\_name* has `swml` as a property, *command\_name* must store the log-likelihood value in `e(l1)` and the model degrees of freedom in `e(df_m)`.

## Stored results

`nestreg` stores the following in `r()`:

```
Matrices
  r(wald)      matrix corresponding to the Wald table
  r(1r)       matrix corresponding to the likelihood-ratio table
```

## Acknowledgment

We thank Paul H. Bern of Syracuse University for developing the hierarchical regression command that inspired `nestreg`.

# Title

**net** — Install and manage community-contributed additions from the Internet

[Description](#)   [Syntax](#)   [Options](#)   [Remarks and examples](#)  
[Also see](#)

## Description

`net` downloads and installs additions to Stata. The additions can be obtained from the Internet or from physical media. The additions can be ado-files (new commands), help files, or even datasets. Collections of files that may be installed as a group are bound together into a *package*.

`ado` manages the packages you have installed by using `net`. The `ado` command lets you list and uninstall previously installed packages.

You can also access the `net` and `ado` features by selecting **Help > SJ and community-contributed features**; this is the recommended method to find and install additions to Stata.

## Syntax

*Set current location for net*

```
net from directory_or_url
```

*Change to a different net directory*

```
net cd path_or_url
```

*Change to a different net site*

```
net link linkname
```

*Search for installed packages*

```
net search                    (see [R] net search)
```

*Report current net location*

```
net
```

*Describe a package*

```
net describe pkgname [ , from(directory_or_url) ]
```

*Set location where packages will be installed*

```
net set ado dirname
```

Set location where ancillary files will be installed

```
net set other dirname
```

Report net ‘from’, ‘ado’, and ‘other’ settings

```
net query
```

Install ado-files and help files from a package

```
net install pkgname [, all replace force from(directory_or_url) ]
```

Install ancillary files from a package

```
net get pkgname [, all replace force from(directory_or_url) ]
```

Shortcut to access Stata Journal (SJ) net site

```
net sj vol-issue [insert ]
```

List installed packages

```
ado [, find(string) from(dirname) ]
```

```
ado dir [pkgid] [, find(string) from(dirname) ]
```

Describe installed packages

```
ado describe [pkgid] [, find(string) from(dirname) ]
```

Update installed packages

```
ado update (see [R] ado update)
```

Uninstall an installed package

```
ado uninstall pkgid [, from(dirname) ]
```

where

```
pkgname is name of a package
pkgid is name of a package
        or a number in square brackets: [#]
dirname is a directory name
        or PLUS (default)
        or PERSONAL
        or SITE
```

## Options

**all** is used with `net install` and `net get`. Typing it with either one makes the command equivalent to typing `net install` followed by `net get`.

**replace** is for use with `net install` and `net get`. It specifies that the downloaded files replace existing files if any of the files already exists.

**force** specifies that the downloaded files replace existing files if any of the files already exists, even if Stata thinks all the files are the same. **force** implies **replace**.

**find**(*string*) is for use with `ado`, `ado dir`, and `ado describe`. It specifies that the descriptions of the packages installed on your computer be searched, and that the package descriptions containing *string* be listed.

**from**(*dirname*), when used with `ado`, specifies where the packages are installed. The default is **from**(PLUS). PLUS is a code word that Stata understands to correspond to a particular directory on your computer that was set at installation time. On Windows computers, PLUS probably means the directory `c:\ado\plus`, but it might mean something else. You can find out what it means by typing `sysdir`, but doing so is irrelevant if you use the defaults.

**from**(*directory\_or\_url*), when used with `net`, specifies the directory or URL where installable packages may be found. The directory or URL is the same as the one that would have been specified with `net from`.

## Remarks and examples

For an introduction to using `net` and `ado`, see [\[U\] 29 Using the Internet to keep up to date](#). The purpose of this documentation is

- to briefly, but accurately, describe `net` and `ado` and all their features and
- to provide documentation to those who wish to set up their own sites to distribute additions to Stata.

Remarks are presented under the following headings:

*Definition of a package*

*The purpose of the net and ado commands*

*Content pages*

*Package-description pages*

*Where packages are installed*

*A summary of the net command*

*A summary of the ado command*

*Relationship of net and ado to the point-and-click interface*

*Creating your own site*

*Format of content and package-description files*

*Example 1*

*Example 2*

*Additional package directives*

*SMCL in content and package-description files*

*Error-free file delivery*

## Definition of a package

A *package* is a collection of files—typically, `.ado` and `.sthlp` files—that together provide a new feature in Stata. Packages contain additions that you wish had been part of Stata at the outset. For instance, the package named `zz49` might add the `xyz` command to Stata. At a minimum, such a package would contain `xyz.ado`, the code to implement the new command, and `xyz.sthlp`, the system help to describe it. We write such additions, and so do other users.

One source of these additions is the *Stata Journal*, a printed and electronic journal with corresponding software. If you want the journal, you must subscribe, but the software is available for free from our website.

## The purpose of the `net` and `ado` commands

The `net` command makes it easy to distribute and install packages. The goal is to get you quickly to a package-description page that summarizes the addition, for example,

---

```
. net describe rte_stat, from(http://www.wemakeitupaswego.edu/faculty/sgazer/)
```

---

```
package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer/
```

---

### TITLE

`rte_stat`. The robust-to-everything statistic; update.

### DESCRIPTION/AUTHOR(S)

S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ. Aleph-0 100% confidence intervals proved too conservative for some applications; Aleph-1 confidence intervals have been substituted. The new robust-to-everything supplants the previous robust-to-everything-conceivable statistic. See "Inference in the absence of data" (forthcoming). After installation, see help `rte`.

### INSTALLATION FILES

(type `net install rte_stat`)

```
rte.ado
rte.sthlp
nullset.ado
random.ado
```

---

If you decide that the addition might prove useful, `net` makes the installation easy:

```
. net install rte_stat
checking rte_stat consistency and verifying not already installed...
installing into c:\ado\plus\ ...
installation complete.
```

The `ado` command helps you manage packages installed with `net`. Perhaps you remember that you installed a package that calculates the robust-to-everything statistic, but you cannot remember the command's name. You could use `ado` to search what you have previously installed for the `rte` command,

```
. ado
[1] package tomata from https://fmwww.bc.edu/RePEc/bocode/t
    'TONATA': module to make vectors in Mata of variables in Stata
    (output omitted)
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
    rte_stat. The robust-to-everything statistic; update.
    (output omitted)
[21] package st0119 from https://www.stata-journal.com/software/sj7-1
    SJ7-1 st0119. Rasch analysis
```

or you might type

```
. ado, find("robust-to-everything")
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
      rte_stat. The robust-to-everything statistic; update.
```

Perhaps you decide that `rte`, despite the author's claims, is not worth the disk space it occupies. You can use `ado` to erase it:

```
. ado uninstall rte_stat
package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
      rte_stat. The robust-to-everything statistic; update.
(package uninstalled)
```

`ado uninstall` is easier than erasing the files by hand because `ado uninstall` erases every file associated with the package, and, moreover, `ado` knows where on your computer `rte_stat` is installed; you would have to hunt for these files.

## Content pages

There are two types of pages displayed by `net`: content pages and package-description pages. When you type `net` from, `net cd`, `net link`, or `net` without arguments, Stata goes to the specified place and displays the content page:

```
. net from https://www.stata.com
```

---

```
https://www.stata.com/
StataCorp
```

---

Welcome to StataCorp.

Below we provide links to sites providing additions to Stata, including the Stata Journal and Statalist. These are NOT THE OFFICIAL UPDATES; you fetch and install the official updates by typing **-update-**.

PLACES you could **-net link-** to:

sj	The Stata Journal
----	-------------------

DIRECTORIES you could **-net cd-** to:

users	materials written by various people, including StataCorp employees
meetings	software packages from Stata Users Group meetings
links	links to other locations providing additions to Stata

---

A content page tells you about other content pages and package-description pages. The example above lists other content pages only. Below, we follow one of the links for the *Stata Journal*:

```
. net link sj
```

---

```
https://www.stata-journal.com/
```

```
The Stata Journal
```

---

The Stata Journal is a refereed, quarterly journal containing articles of interest to Stata users. For more details and subscription information, visit the Stata Journal website at <https://www.stata-journal.com>.

PLACES you could **-net link-** to:

```
stata          StataCorp website
```

DIRECTORIES you could **-net cd-** to:

```
production    Files for authors of the Stata Journal
software      Software associated with Stata Journal articles
```

---

```
. net cd software
```

---

```
https://www.stata-journal.com/software/
```

```
The Stata Journal
```

---

PLACES you could **-net link-** to:

```
stata          StataCorp website
stb            Historical materials published in the Stata Technical
               Bulletin
```

DIRECTORIES you could **-net cd-** to:

```
(output omitted)
sj7-1          volume 7, issue 1
(output omitted)
sj1-1          volume 1, issue 1
```

---

```
. net cd sj7-1
```

---

```
https://www.stata-journal.com/software/sj7-1/
```

```
Stata Journal volume 7, issue 1
```

---

DIRECTORIES you could **-net cd-** to:

```
..            Other Stata Journals
```

PACKAGES you could **-net describe-**:

```
dm0027        File filtering in Stata: handling complex data
               formats and navigating log files efficiently
st0119        Rasch analysis
st0120        Multivariable regression spline models
st0121        mhbounds - Sensitivity Analysis for Average
               Treatment Effects
```

---

dm0027, st0119, ..., st0121 are links to package-description pages.

1. When you type `net from`, you follow that with a location to display the location's content page.
  - a. The location could be a URL, such as <https://www.stata.com>. The content page at that location would then be listed.
  - b. The location could be `e:` on a Windows computer or a mounted volume on a Mac computer. The content page on that source would be listed. That would work if you had special media obtained from StataCorp or special media prepared by another user.
  - c. The location could even be a directory on your computer, but that would work only if that directory contained the right kind of files.

2. Once you have specified a location, typing `net cd` will take you into subdirectories of that location, if there are any. Typing

```
. net from https://www.stata-journal.com
. net cd software
```

is equivalent to typing

```
. net from https://www.stata-journal.com/software
```

Typing `net cd` displays the content page from that location.

3. Typing `net` without arguments redisplayes the current content page, which is the content page last displayed.
4. `net link` is similar to `net cd` in that the result is to change the location, but rather than changing to subdirectories of the current location, `net link` jumps to another location:

```
. net from https://www.stata-journal.com
```

---

```
https://www.stata-journal.com/
```

```
The Stata Journal
```

---

```
The Stata Journal is a refereed, quarterly journal containing articles
of interest to Stata users. For more details and subscription information,
visit the Stata Journal website at
https://www.stata-journal.com.
```

```
PLACES you could -net link- to:
```

```
  stata          StataCorp website
```

```
DIRECTORIES you could -net cd- to:
```

```
  production     Files for authors of the Stata Journal
  software       Software associated with Stata Journal articles
```

---

Typing `net link stata` would jump to <https://www.stata.com>:

```
. net link stata
```

---

```
https://www.stata.com/
```

```
StataCorp
```

---

```
Welcome to StataCorp.
```

```
(output omitted)
```

---

## Package-description pages

Package-description pages describe what could be installed:

```
. net from https://www.stata-journal.com/software/sj7-1
```

---

```
https://www.stata-journal.com/software/sj7-1/
(output omitted)
```

```
. net describe st0119
```

---

```
package st0119 from https://www.stata-journal.com/software/sj7-1
```

---

### TITLE

SJ7-1 st0119. Rasch analysis

### DESCRIPTION/AUTHOR(S)

Rasch analysis

by Jean-Benoit Hardouin, University of Nantes, France

Support: jean-benoit.hardouin@univ-nantes.fr

After installation, type help **gammasym**, **gausshermite**,  
**geekel2d**, **raschtest**, and **raschtestv7**

### INSTALLATION FILES

(type **net install st0119**)

```
st0119/raschtest.ado
st0119/raschtest.hlp
st0119/raschtestv7.ado
st0119/raschtestv7.hlp
st0119/gammasym.ado
st0119/gammasym.hlp
st0119/gausshermite.ado
st0119/gausshermite.hlp
st0119/geekel2d.ado
st0119/geekel2d.hlp
```

### ANCILLARY FILES

(type **net get st0119**)

```
st0119/data.dta
st0119/outrasch.do
```

---

A package-description page describes the package and tells you how to install the component files. Package-description pages potentially describe two types of files:

1. Installation files: files that you type **net install** to install and that are required to make the addition work.
2. Ancillary files: additional files that you might want to install—you type **net get** to install them—but that you can ignore. Ancillary files are typically datasets that are useful for demonstration purposes. Ancillary files are not really installed in the sense of being copied to an official place for use by Stata itself. They are merely copied into the current directory so that you may use them if you wish.

You install the official files by typing **net install** followed by the package name. For example, to install **st0119**, you would type

```
. net install st0119
checking st0119 consistency and verifying not already installed...
installing into c:\ado\plus\ ...
installation complete.
```

You get the ancillary files—if there are any and if you want them—by typing **net get** followed by the package name:

```
. net get st0119
checking st0119 consistency and verifying not already installed...
copying into current directory...
  copying data.dta
  copying outrasch.do
ancillary files successfully copied.
```

Most users ignore the ancillary files.

Once you have installed a package—by typing `net install`—use `ado` to redisplay the package-description page whenever you wish:

```
. ado describe st0119
```

---

```
[1] package st0119 from https://www.stata-journal.com/software/sj7-1
```

---

**TITLE**

```
SJ7-1 st0119. Rasch analysis
```

**DESCRIPTION/AUTHOR(S)**

```
Rasch analysis
by Jean-Benoit Hardouin, University of Nantes, France
Support: jean-benoit.hardouin@univ-nantes.fr
After installation, type help gammasym, gausshermite,
geekel2d, raschtest, and raschtestv7
```

**INSTALLATION FILES**

```
r/raschtest.ado
r/raschtest.hlp
r/raschtestv7.ado
r/raschtestv7.hlp
g/gammasym.ado
g/gammasym.hlp
g/gausshermite.ado
g/gausshermite.hlp
g/geekel2d.ado
g/geekel2d.hlp
```

**INSTALLED ON**

```
24 Feb 2023
```

---

The package-description page shown by `ado` includes the location from which we got the package and when we installed it. It does not mention the ancillary files that were originally part of this package because they are not tracked by `ado`.

## Where packages are installed

Packages should be installed in `PLUS` or `SITE`, which are code words that Stata understands and that correspond to some real directories on your computer. Typing `sysdir` will tell you where these are, if you care.

```
. sysdir
STATA: C:\Program Files\Stata18\
BASE: C:\Program Files\Stata18\ado\base\
SITE: C:\Program Files\Stata18\ado\site\
PLUS: c:\ado\plus\
PERSONAL: c:\ado\personal\
OLDPLACE: c:\ado\
```

If you type `sysdir`, you may obtain different results.

By default, `net` installs in the PLUS directory, and `ado` tells you about what is installed there. If you are on a multiple-user system, you may wish to install some packages in the SITE directory. This way, they will be available to other Stata users. To do that, before using `net install`, type

```
. net set ado SITE
```

and when reviewing what is installed or removing packages, redirect `ado` to that directory:

```
. ado ..., from(SITE)
```

In both cases, you type `SITE` because Stata will understand that `SITE` means the site `ado`-directory as defined by `sysdir`. To install into `SITE`, you must have write access to that directory.

If you reset where `net` installs and then, in the same session, wish to install into your private `ado`-directory, type

```
. net set ado PLUS
```

That is how things were originally. If you are confused as to where you are, type `net query`.

## A summary of the net command

The `net` command displays content pages and package-description pages. Such pages are provided over the Internet, and most users get them there. We recommend that you start at <https://www.stata.com> and work out from there. We also recommend using `net search` to find packages of interest to you; see [R] [net search](#).

`net from` moves you to a location and displays the content page.

`net cd` and `net link` change from your current location to other locations. `net cd` enters subdirectories of the original location. `net link` jumps from one location to another, depending on the code on the content page.

`net describe` lists a package-description page. Packages are named, and you type `net describe pkgname`.

`net install` installs a package into your copy of Stata. `net get` copies any additional files (ancillary files) to your current directory.

`net sj` simplify loading files from the *Stata Journal*.

```
net sj vol-issue
```

is a synonym for typing

```
net from https://www.stata-journal.com/software/sjvol-issue
```

whereas

```
net sj vol-issue insert
```

is a synonym for typing

```
net from https://www.stata-journal.com/software/sjvol-issue
net describe insert
```

`net set` controls where `net` installs files. By default, `net` installs in the PLUS directory; see [P] [sysdir](#). `net set ado SITE` would cause subsequent `net` commands to install in the SITE directory. `net set other` sets where ancillary files, such as `.dta` files, are installed. The default is the current directory.

`net query` displays the current `net from`, `net set ado`, and `net set other` settings.

## A summary of the ado command

The `ado` command lists the package descriptions of previously installed packages.

Typing `ado` without arguments is the same as typing `ado dir`. Both list the names and titles of the packages you have installed.

`ado describe` lists full package-description pages.

`ado uninstall` removes packages from your computer.

Because you can install packages from a variety of sources, the package names may not always be unique. Thus the packages installed on your computer are numbered sequentially, and you may refer to them by name or by number. For instance, say that you wanted to get rid of the `robust-to-everything` statistic command you installed. Type

```
. ado, find("robust-to-everything")
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
rte_stat. The robust-to-everything statistic; update.
```

You could then type

```
. ado uninstall rte_stat
```

or

```
. ado uninstall [15]
```

Typing `ado uninstall rte_stat` would work only if the name `rte_stat` were unique; otherwise, `ado` would refuse, and you would have to type the number.

The `find()` option is allowed with `ado dir` and `ado describe`. It searches the package description for the word or phrase you specify, ignoring case (`alpha` matches `Alpha`). The complete package description is searched, including the author's name and the name of the files. Thus if `rte` was the name of a command that you wanted to eliminate, but you could not remember the name of the package, you could type

```
. ado, find(rte)
[15] package rte_stat from http://www.wemakeitupaswego.edu/faculty/sgazer
rte_stat. The robust-to-everything statistic; update.
```

## Relationship of net and ado to the point-and-click interface

Users may instead select **Help > SJ and community-contributed features**. There are advantages and disadvantages:

1. Flipping through content and package-description pages is easier; it is much like a browser. See [GS] **19 Updating and extending Stata—Internet functionality** (*GSM*, *GSU*, or *GSW*).
2. When browsing a product-description page, note that the `.sthlp` files are highlighted. You may click on `.sthlp` files to review them before installing the package.
3. You may not redirect from where `ado` searches for files.

## Creating your own site

Users who wish to share content with the Stata community often do so via the Statistical Software Components (SSC) Archive. See [R] `ssc` and also see <http://repec.org/bocode/s/sscsubmit.html>.

The rest of this entry concerns how to create your own site to distribute additions to Stata. The idea is that you have written additions for use with Stata—say, `xyz.ado` and `xyz.sthlp`—and you wish to put them out so that coworkers or researchers at other institutions can easily install them. Or, perhaps you just have a dataset that you and others want to share.

In any case, all you need is a webpage. You place the files that you want to distribute on your webpage (or in a subdirectory), and you add two more files—a content file and a package-description file—and you are done.

## Format of content and package-description files

The content file describes the content page. It must be named `stata.toc`:

---

```

begin stata.toc
OFF                                     (to make site unavailable temporarily)
* lines starting with * are comments; they are ignored
* blank lines are ignored, too
* v indicates version—specify v 3, which is the current version of .toc files
v 3
* d lines display description text
* the first d line is the title, and the remaining ones are text
* blank d lines display a blank line
d title
d text
d text
d
...
* l lines display links
l word-to-show path-or-url [description]
l word-to-show path-or-url [description]
...
* t lines display other directories within the site
t path [description]
t path [description]
...
* p lines display packages
p pkgname [description]
p pkgname [description]
...
end stata.toc

```

---

Package files describe packages and are named `pkgname.pkg`:

```

* lines starting with * are comments; they are ignored
* blank lines are ignored, too
* v indicates version—specify v 3, which is the current version of .toc files
v 3
* d lines display package description text
* the first d line is the title, and the remaining ones are text
* blank d lines display a blank line
d title
d text
d Distribution-Date: date
d text
d
...
* f identifies the component files
f [path/]filename [description]
f [path/]filename [description]
...
* e line is optional; it means stop reading
e

```

Note the Distribution-Date description line. This line is optional but recommended. Stata can look for updates to community-contributed programs with the `ado update` command if the package files from which those programs were installed contain a Distribution-Date description line.

## Example 1

Say that we want the user to see the following:

```

. net from http://www.university.edu/~me

```

---

```

http://www.university.edu/~me
Chris Farrar, Uni University

```

---

```

PACKAGES you could -net describe-:
  xyz          interval-truncated survival
. net describe xyz

```

---

```

package xyz from http://www.university.edu/~me

```

---

```

TITLE
  xyz. interval-truncated survival.
DESCRIPTION/AUTHOR(S)
  C. Farrar, Uni University.
INSTALLATION FILES
  xyz.ado
  xyz.sthlp
ANCILLARY FILES
  sample.dta

```

The files needed to do this would be

```

v 3
d Chris Farrar, Uni University
p xyz interval-truncated survival

```

---

```

v 3
d xyz. interval-truncated survival.
d C. Farrar, Uni University.
f xyz.ado
f xyz.sthlp
f sample.dta

```

---

```

end xyz.pkg

```

---

On his homepage, Chris would place the following files:

stata.toc	(shown above)
xyz.pkg	(shown above)
xyz.ado	file to be delivered (for use by <code>net install</code> )
xyz.sthlp	file to be delivered (for use by <code>net install</code> )
sample.dta	file to be delivered (for use by <code>net get</code> )

Chris does nothing to distinguish ancillary files from installation files.

## Example 2

S. Gazer wants to create a more complex site:

```
. net from http://www.wemakeitupaswego.edu/faculty/sgazer
```

---

```
http://www.wemakeitupaswego.edu/faculty/sgazer
```

```
Data-free inference materials
```

---

S. Gazer, Department of Applied Theoretical Mathematics

Also see my homepage for the preprint of "Irrefutable inference".

PLACES you could **-net link-** to:

```
stata          StataCorp website
```

DIRECTORIES you could **-net cd-** to:

```
ir             irrefutable inference programs (work in progress)
```

PACKAGES you could **-net describe-**:

```
rtec          Robust-to-everything-conceivable statistic
```

```
rte           Robust-to-everything statistic
```

```
. net describe rte
```

---

```
package rte from http://www.wemakeitupaswego.edu/faculty/sgazer/
```

---

**TITLE**

```
rte. The robust-to-everything statistic; update.
```

**DESCRIPTION/AUTHOR(S)**

```
S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.  
Aleph-0 100% confidence intervals proved too conservative for some  
applications; Aleph-1 confidence intervals have been substituted.  
The new robust-to-everything supplants the previous robust-to-  
everything-conceivable statistic. See "Inference in the absence  
of data" (forthcoming). After installation, see help rte.
```

```
Distribution-Date: 20190320
```

```
Support: email sgazer@wemakeitupaswego.edu
```

**INSTALLATION FILES**

```
(type net install rte_stat)
```

```
rte.ado  
rte.sthlp  
nullset.ado  
random.ado
```

**ANCILLARY FILES**

```
(type net get rte_stat)
```

```
empty.dta
```

---

The files needed to do this would be

---

```
-----begin stata.toc-----
```

```
v 3  
d Data-free inference materials  
d S. Gazer, Department of Applied Theoretical Mathematics  
d  
d Also see my homepage for the preprint of "Irrefutable inference".  
l stata https://www.stata.com  
t ir irrefutable inference programs (work in progress)  
p rtec Robust-to-everything-conceivable statistic  
p rte Robust-to-everything statistic
```

```
-----end stata.toc-----
```

---

```
-----begin rte.pkg-----
```

```
v 3  
d rte. The robust-to-everything statistic; update.  
d {bf:S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.}  
d Aleph-0 100% confidence intervals proved too conservative for some  
d applications; Aleph-1 confidence intervals have been substituted.  
d The new robust-to-everything supplants the previous robust-to-  
d everything-conceivable statistic. See "Inference in the absence  
d of data" (forthcoming). After installation, see help {bf:rte}.  
d  
d Distribution-Date: 20190320  
d  
d Support: email sgazer@wemakeitupaswego.edu  
f rte.ado  
f rte.sthlp  
f nullset.ado  
f random.ado  
f empty.dta
```

```
-----end rte.pkg-----
```

On his homepage, Mr. Gazer would place the following files:

```

stata.toc      (shown above)
rte.pkg       (shown above)
rte.ado       (file to be delivered)
rte.sthlp     (file to be delivered)
nullset.ado   (file to be delivered)
random.ado    (file to be delivered)
empty.dta     (file to be delivered)

rtec.pkg      the other package referred to in stata.toc
rtec.ado      the corresponding files to be delivered
rtec.sthlp

ir/stata.toc  the contents file for when the user types net cd ir
ir/...       whatever other .pkg files are referred to
ir/...       whatever other files are to be delivered

```

If Mr. Gazer later updated the `rte` package, he could change the Distribution-Date description line in his package. Then, if someone who had previously installed the `rte` packaged wanted to obtain the latest version, that person could use the `ado update` command; see [R] [ado update](#).

For complex sites, a different structure may prove more convenient:

```

stata.toc      (shown above)
rte.pkg       (shown above)
rtec.pkg      the other package referred to in stata.toc

rte/          directory containing rte files to be delivered:
rte/rte.ado   (file to be delivered)
rte/rte.sthlp (file to be delivered)
rte/nullset.ado (file to be delivered)
rte/random.ado (file to be delivered)
rte/empty.dta (file to be delivered)

rtec/         directory containing rtec files to be delivered:
rtec/...     (files to be delivered)

ir/stata.toc  the contents file for when the user types net cd ir
ir/*.*.pkg   whatever other package files are referred to
ir/*/*.*     whatever other files are to be delivered

```

If you prefer this structure, it is simply a matter of changing the bottom of the `rte.pkg` from

```

f rte.ado
f rte.sthlp
f nullset.ado
f random.ado
f empty.dta

```

to

```

f rte/rte.ado
f rte/rte.sthlp
f rte/nullset.ado
f rte/random.ado
f rte/empty.dta

```

In writing paths and files, the directory separator forward slash (/) is used, regardless of operating system, because this is what the Internet uses.

It does not matter whether the files you put out are in Windows, Mac, or Unix format (how lines end is recorded differently). When Stata reads the files over the Internet, it will figure out the file format on its own and will automatically translate the files to what is appropriate for the receiver.

## Additional package directives

**F** *filename* is similar to **f** *filename*, except that, when the file is installed, it will always be copied to the system directories (and not the current directory).

With **f** *filename*, the file is installed into a directory according to the file's suffix. For instance, `xyz.ado` would be installed in the system directories, whereas `xyz.dta` would be installed in the current directory.

Coding **F** `xyz.ado` would have the same result as coding **f** `xyz.ado`.

Coding **F** `xyz.dta`, however, would state that `xyz.dta` is to be installed in the system directories.

**g** *platformname filename* is also a variation on **f** *filename*. It specifies that the file be installed only if the user's operating system is of type *platformname*; otherwise, the file is ignored. The platform names are **WIN64** (64-bit x86-64) for Windows; **MACARM64** (Apple Silicon, GUI) and **OSX.ARM64** (Apple Silicon, console), **MACINTEL64** (64-bit Intel, GUI) and **OSX.X8664** (64-bit Intel, console) for Mac; and **LINUX64** (64-bit x86-64) and **LINUX64P** (64-bit x86-64, libpng v1.6) for Linux. For **LINUX64P**, the **LINUX64**-specific version of a file will be installed if no **LINUX64P**-specific one exists. **LINUX64** will not install a **LINUX64P**-specific version of a file because of possible changes in system libraries.

**G** *platformname filename* is a variation on **F** *filename*. The file, if not ignored, is to be installed in the system directories.

**g** *platformname filename1 filename2* is a more detailed version of **g** *platformname filename*. In this case, *filename1* is the name of the file on the server (the file to be copied), and *filename2* is to be the name of the file on the user's system; for example, you might code

```
g WIN64 mydll.forwin mydll.plugin
g LINUX64 mydll.forlinux mydll.plugin
```

When you specify one *filename*, the result is the same as specifying two identical *filenames*.

**G** *platformname filename1 filename2* is the install-in-system-directories version of **g** *platformname filename1 filename2*.

**h** *filename* asserts that *filename* must be loaded, or this package is not to be installed; for example, you might code

```
g WIN64 mydll.forwin mydll.plugin
g LINUX64 mydll.forlinux mydll.plugin
h mydll.plugin
```

if you were offering the plugin `mydll.plugin` for Windows and Linux only.

## SMCL in content and package-description files

The text listed on the second and subsequent **d** lines in both `stata.toc` and `pkgname.pkg` may contain SMCL as long as you include **v** 3; see [P] [smcl](#).

Thus, in `rte.pkg`, S. Gazer coded the third line as

```
d {bf:S. Gazer, Dept. of Applied Theoretical Mathematics, WMIUAWG Univ.}
```

## Error-free file delivery

Most people transport files over the Internet and never worry about the file being corrupted in the process because corruption rarely occurs. If, however, the files must be delivered perfectly or not at all, you can include checksum files in the directory.

For instance, say that `big.dta` is included in your package and that it must be sent perfectly. First, use Stata to make the checksum file for `big.dta`

```
. checksum big.dta, save
```

That command creates a small file called `big.sum`; see [D] [checksum](#). Then, copy both `big.dta` and `big.sum` to your homepage.

If you do this, be cautious. If you put `big.dta` and `big.sum` on your homepage and then later change `big.dta` without changing `big.sum`, people will think that there are transmission errors when they try to download `big.dta`.

# Title

**net search** — Search the Internet for installable packages

[Description](#)      [Quick start](#)      [Syntax](#)      [Options](#)  
[Remarks and examples](#)      [Also see](#)

## Description

`net search` searches the Internet for community-contributed additions to Stata, including, but not limited to, community-contributed additions published in the *Stata Journal* (SJ). `net search` lists the available additions that contain the specified keywords.

The community-contributed materials found are available for immediate download by using the `net` command or by clicking on the link.

In addition to typing `net search`, you may select **Help > Search...** and choose **Search net resources**. This is the recommended way to search for community-contributed additions to Stata.

## Quick start

Search community-contributed commands for all terms `word1`, `word2`, and `word3`

```
net search word1 word2 word3
```

Same as above, but search for any term

```
net search word1 word2 word3, or
```

Search Internet sources other than the *Stata Journal*

```
net search word1 word2 word3, nosj
```

## Syntax

```
net search word [word ...] [, options]
```

<i>options</i>	Description
<code>or</code>	list packages that contain any of the keywords; default is all
<code>nosj</code>	search non-SJ sources
<code>tocpkg</code>	search both tables of contents and packages; the default
<code>toc</code>	search tables of contents only
<code>pkg</code>	search packages only
<code>everywhere</code>	search packages for match
<code>filenames</code>	search filenames associated with package for match
<code>errnone</code>	make return code 111 instead of 0 when no matches found

## Options

`or` is relevant only when multiple keywords are specified. By default, `net search` lists only packages that include all the keywords. `or` changes the command to list packages that contain any of the keywords.

`nosj` specifies that `net search` not list matches that were published in the SJ.

`tocpkg`, `toc`, and `pkg` determine what is searched. `tocpkg` is the default, meaning that both tables of contents (tocs) and packages (pkgs) are searched. `toc` restricts the search to tables of contents. `pkg` restricts the search to packages.

`everywhere` and `filenames` determine where in packages `net search` looks for *keywords*. The default is `everywhere`. `filenames` restricts `net search` to search for matches only in the filenames associated with a package. Specifying `everywhere` implies `pkg`.

`errnone` is a programmer's option that causes the return code to be 111 instead of 0 when no matches are found.

## Remarks and examples

`net search` searches the Internet for community-contributed additions to Stata. If you want to search the Stata documentation for a particular topic, command, or author, see [R] [search](#). `net search word [word ...]` (without options) is equivalent to typing `search word [word ...]`, `net`.

Remarks are presented under the following headings:

*Topic searches*  
*Author searches*  
*Command searches*  
*Where does net search look?*  
*How does net search work?*

## Topic searches

### Example: Find what is available about random effects

```
. net search random effect
```

Comments:

- It is best to search using the singular form of a word. `net search random effect` will find both “random effect” and “random effects”.
- `net search random effect` will also find “random-effect” because `net search` performs a string search and not a word search.
- `net search random effect` lists all packages containing the words “random” and “effect”, not necessarily used together.
- If you wanted all packages containing the word “random” or the word “effect”, you would type `net search random effect, or`.

## Author searches

### Example: Find what is available by author Jeroen Weesie

```
. net search weesie
```

Comments:

- You could type `net search jeroen weesie`, but that might list fewer results because sometimes the last name is used without the first.
- You could type `net search Weesie`, but it would not matter. Capitalization is ignored in the search.

### Example: Find what is available by Jeroen Weesie, excluding SJ materials

```
. net search weesie, nosj
```

- The SJ tends to dominate search results because so much has been published in it. If you know that what you are looking for is not in the SJ, specifying the `nosj` option will narrow the search.
