matexpsym( ) — Exponentiation and logarithms of symmetric matrices

Description Syntax Remarks and examples Conformability
Diagnostics Also see

Description

`matexpsym(`*A*`)` returns the matrix exponential of the symmetric (Hermitian) matrix *A*.

`matlogsym(`*A*`)` returns the matrix natural logarithm of the symmetric (Hermitian) matrix *A*.

`_matexpsym(`*A*`)` and `_matlogsym(`*A*`)` do the same thing as `matexpsym()` and `matlogsym()`, but instead of returning the result, they store the result in *A*.

Syntax

numeric matrix	`matexpsym(`*numeric matrix A*`)`
numeric matrix	`matlogsym(`*numeric matrix A*`)`
void	`_matexpsym(`*numeric matrix A*`)`
void	`_matlogsym(`*numeric matrix A*`)`

Remarks and examples

stata.com

Do not confuse `matexpsym(`*A*`)` with `exp(`*A*`)`, nor `matlogsym(`*A*`)` with `log(`*A*`)`.

`matexpsym(2*matlogsym(`*A*`))` produces the same result as *A***A*. `exp()` and `log()` return elementwise results.

Exponentiated results and logarithms are obtained by extracting the eigenvectors and eigenvalues of *A*, performing the operation on the eigenvalues, and then rebuilding the matrix. That is, first *X* and *L* are found such that

$$AX = X * \text{diag}(L) \tag{1}$$

For symmetric (Hermitian) matrix *A*, *X* is orthogonal, meaning $X'X = XX' = I$. Thus

$$A = X * \text{diag}(L) * X' \tag{2}$$

`matexpsym(`*A*`)` is then defined

$$A = X * \text{diag}(\exp(L)) * X' \tag{3}$$

and `matlogsym(`*A*`)` is defined

$$A = X * \text{diag}(\log(L)) * X' \tag{4}$$

(1) is obtained via `symeigensystem()`; see [M-5] **eigensystem( )**.

Conformability

`matexpsym(`*A*`)`, `matlogsym(`*A*`)`:

A:	$n \times n$
result:	$n \times n$

`_matexpsym(`*A*`)`, `_matlogsym(`*A*`)`:

input:	
A:	$n \times n$
output:	
A:	$n \times n$

Diagnostics

`matexpsym(`*A*`)`, `matlogsym(`*A*`)`, `_matexpsym(`*A*`)`, and `_matlogsym(`*A*`)` return missing results if *A* contains missing values.

Also:

1. These functions do not check that *A* is symmetric or Hermitian. If *A* is a real matrix, only the lower triangle, including the diagonal, is used. If *A* is a complex matrix, only the lower triangle and the real parts of the diagonal elements are used.

2. These functions return a matrix of the same storage type as *A*.

   For `symatlog(`*A*`)`, this means that if *A* is real and the result cannot be expressed as a real, a matrix of missing values is returned. If you want the generalized solution, code `matlogsym(C(`*A*`))`. This is the same rule as with scalars: `log(-1)` evaluates to missing, but `log(C(-1))` is `3.14159265i`.

3. These functions are guaranteed to return a matrix that is numerically symmetric, Hermitian, or symmetriconly if theory states that the matrix should be symmetric, Hermitian, or symmetriconly. See [M-5] **matpowersym( )** for a discussion of this issue.

   For the functions here, real function `exp(`*x*`)` is defined for all real values of *x* (ignoring overflow), and thus the matrix returned by `matexpsym()` will be symmetric (Hermitian).

   The same is not true for `matlogsym()`. `log(`*x*`)` is not defined for $x = 0$, so if any of the eigenvalues of *A* are 0 or very small, a matrix of missing values will result. Also, `log(`*x*`)` is complex for $x < 0$, and thus if any of the eigenvalues are negative, the resulting matrix will be (1) missing if *A* is real stored as real, (2) symmetriconly if *A* contains reals stored as complex, and (3) general if *A* is complex.
