## Description

`fracreg` fits a fractional response model for a dependent variable that is greater than or equal to 0 and less than or equal to 1. It uses a probit, logit, or heteroskedastic probit model for the conditional mean. These models are often used for outcomes such as rates, proportions, and fractional data.

## Quick start

Fractional probit model for  $y$  with values between 0 and 1 on continuous variable  $x_1$

```
fracreg probit y x1
```

As above, but use logit distribution

```
fracreg logit y x1
```

Fractional probit model for  $y$  on  $x_1$  and use  $x_2$  to model the variance of  $y$

```
fracreg probit y x1, het(x2)
```

## Menu

Statistics > Fractional outcomes > Fractional regression

## Syntax

Syntax for fractional probit regression

```
fracreg probit depvar [indepvars] [if] [in] [weight] [, options]
```

Syntax for fractional logistic regression

```
fracreg logit depvar [indepvars] [if] [in] [weight] [, options]
```

Syntax for fractional heteroskedastic probit regression

```
fracreg probit depvar [indepvars] [if] [in] [weight],  
het(varlist [, offset(varnameo)) [options]
```

*options*

Description

Model

noconstant

suppress constant term

offset(*varname*)

include *varname* in model with coefficient constrained to 1

constraints(*constraints*)

apply specified linear constraints

collinear

keep collinear variables

\*het(*varlist* [, offset(*varname<sub>o</sub>*) ])

independent variables to model the variance and possible  
offset variable with fracreg probit

SE/Robust

vce(*vcetype*)

*vcetype* may be robust, cluster *clustvar*, bootstrap, or  
jackknife

Reporting

level(#)

set confidence level; default is level(95)

or

report odds ratios; only valid with fracreg logit

nocnsreport

do not display constraints

display\_options

control columns and column formats, row spacing, line width,  
display of omitted variables and base and empty cells, and  
factor-variable labeling

Maximization

maximize\_options

control the maximization process; seldom used

nocoef

do not display the coefficient table; seldom used

coeflegend

display legend instead of statistics

\* `het()` may be used only with `fracreg probit` to compute fractional heteroskedastic probit regression.

`indepvars` may contain factor variables; see [U] 11.4.3 [Factor variables](#).

`devar` and `indepvars` may contain time-series operators; see [U] 11.4.4 [Time-series varlists](#).

`bayes`, `bootstrap`, `by`, `fp`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 [Prefix commands](#). For more details, see [BAYES] [bayes: fracreg](#).

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] [mi estimate](#).

Weights are not allowed with the `bootstrap` prefix; see [R] [bootstrap](#).

`vce()`, `nocoef`, and `weights` are not allowed with the `svy` prefix; see [SVY] [svy](#).

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 [weight](#).

`nocoef` and `coeflegend` do not appear in the dialog box.

See [U] 20 [Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

### Model

`noconstant`, `offset(varname)`, `constraints(constraints)`, `collinear`; see [R] [estimation options](#).

`het(varlist [offset(varnameo)])` specifies the independent variables and the offset variable, if there is one, in the variance function. `het()` may only be used with `fracreg probit` to compute fractional heteroskedastic probit regression.

`offset(varnameo)` specifies that selection offset *varname*<sub>o</sub> be included in the model with the coefficient constrained to be 1.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`; see [R] [estimation options](#).

`or` reports the estimated coefficients transformed to odds ratios, that is,  $e^b$  rather than  $b$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `or` may be specified at estimation or when replaying previously estimated results. This option may only be used with `fracreg logit`.

`nocnsreport`; see [R] [estimation options](#).

*display\_options*: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [estimation options](#).

### Maximization

*maximize\_options*: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [maximize](#). These options are seldom used.

The following options are available with `fracreg` but are not shown in the dialog box:

`nocoef` specifies that the coefficient table not be displayed. This option is sometimes used by programmers but is of no use interactively.

`coeflegend`; see [R] [estimation options](#).

## Remarks and examples

[stata.com](http://www.stata.com)

Fractional response data may occur when the outcome of interest is measured as a fraction, for example, a patient's oxygen saturation or Gini coefficient values. These data are also often observed when proportions are generated from aggregated binary outcomes. For example, rather than having data on whether individual students passed an exam, we might simply have data on the proportion of students in each school that passed.

These models are appropriate when you have a dependent variable that takes values between 0 and 1 and may also be equal to 0 or 1, denoted for conciseness with the notation  $[0, 1]$ . If the dependent variable takes only values between 0 and 1, `betareg` might be a valid alternative. `betareg` provides more flexibility in the distribution of the mean of the dependent variable but is misspecified if the dependent variable is equal to 0 or 1. See [R] [betareg](#) for more information.

These models have been applied to various topics. For example, [Papke and Wooldridge \(1996\)](#) studied the participation rates of employees in firms' 401(k) retirement plans. [Papke and Wooldridge \(2008\)](#) also evaluated an education policy by studying the pass rates for an exam administered to fourth grade Michigan students over time.

The models fit by `fracreg` are quasilielihood estimators like the generalized linear models described in [R] [glm](#). Fractional regression is a model of the mean of the dependent variable  $y$  conditional on covariates  $\mathbf{x}$ , which we denote by  $\mu_{\mathbf{x}}$ . Because  $y$  is in  $[0, 1]$ , we must ensure that  $\mu_{\mathbf{x}}$  is also in  $[0, 1]$ . We do this by using a probit, logit, or heteroskedastic probit model for  $\mu_{\mathbf{x}}$ .

The key insight from quasilielihood estimation is that you do not need to know the true distribution of the entire model to obtain consistent parameter estimates. In fact, the only information that you need is the correct specification of the conditional mean.

This means that the true model does not need to be, for example, a probit. If the true model is a probit, then fitting a probit regression via maximum likelihood gives you consistent parameter estimates and asymptotically efficient standard errors.

By contrast, if the conditional mean of the model is the same as the conditional mean of a probit but the model is not a probit, the point estimates are consistent, but the standard errors are not asymptotically efficient. The standard errors are not efficient, because no assumptions about the distribution of the unobserved components in the model are made. Thus `fracreg` uses robust standard errors by default.

For further discussion on quasilielihood estimation in the context of fractional regression, please see [Papke and Wooldridge \(1996\)](#) and [Wooldridge \(2010\)](#).

## ► Example 1: Fractional probit model of rates

In this example, we look at the expected participation rate in 401(k) plans for a cross-section of firms. Participation rate (`prate`) is defined as the fraction of eligible employees in a firm that participate in a 401(k) plan. We use `summarize` to see the range of the participation rate.

```
. use http://www.stata-press.com/data/r15/401k
(Firm-level data on 401k participation)
```

```
. summarize prate
```

Variable	Obs	Mean	Std. Dev.	Min	Max
prate	4,075	.840607	.1874841	.0036364	1

The variable has values between 0 and 1 but also has at least 1 firm for which the participation rate is exactly 1.

As in [Papke and Wooldridge \(1996\)](#), we surmise that the expected participation rate depends on the matching rate of employee 401(k) contributions (`mrate`), the natural log of the total number of employees (`ltotemp`), the age of the plan (`age`), and whether the 401(k) plan is the only retirement plan offered by the employer (`sole`). We include `ltotemp` and `age`, along with their squares, using factor-variable notation; see [\[U\] 11.4.3 Factor variables](#).

If we believe that the functional form of the expected participation rate is a cumulative normal density, we may use `fracreg probit`.

```
. fracreg probit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole
```

```
Iteration 0: log pseudolikelihood = -1769.6832
Iteration 1: log pseudolikelihood = -1675.2763
Iteration 2: log pseudolikelihood = -1674.6234
Iteration 3: log pseudolikelihood = -1674.6232
Iteration 4: log pseudolikelihood = -1674.6232
```

```
Fractional probit regression           Number of obs   =    4,075
                                       Wald chi2(6)     =    815.88
                                       Prob > chi2      =    0.0000
                                       Pseudo R2       =    0.0632
Log pseudolikelihood = -1674.6232
```

prate	Coef.	Robust Std. Err.	z	P> z	[95% Conf. Interval]	
mrate	.5859715	.0387616	15.12	0.000	.5100002	.6619429
ltotemp	-.6102767	.0615052	-9.92	0.000	-.7308246	-.4897288
c.ltotemp# c.ltotemp	.0313576	.003975	7.89	0.000	.0235667	.0391484
age	.0273266	.0031926	8.56	0.000	.0210691	.033584

sole						
only plan	.0683196	.0272091	2.51	0.012	.0149908	.1216484
_cons	3.25991	.2323929	14.03	0.000	2.804429	3.715392

Like those obtained from `probit`, the parameters provide the sign of the marginal effect of the covariates on the outcome, but the magnitude is difficult to interpret. We can use `margins` to estimate conditional or population-averaged effects; see [example 2](#). The standard errors are robust by default because the true data-generating process need not be a probit, even though we use the probit likelihood to obtain our parameter estimates.

### ► Example 2: Changing the distribution of the conditional mean

Continuing with [example 1](#), we may instead believe that the expected participation rate follows a fractional logistic response. In this case, we should use fractional logistic regression instead of fractional probit regression to obtain consistent estimates of the parameters of the conditional mean.

```
. fracreg logit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole
Iteration 0:  log pseudolikelihood = -1983.8372
Iteration 1:  log pseudolikelihood = -1682.4496
Iteration 2:  log pseudolikelihood = -1673.6458
Iteration 3:  log pseudolikelihood = -1673.5566
Iteration 4:  log pseudolikelihood = -1673.5566

Fractional logistic regression                Number of obs    =      4,075
                                              Wald chi2(6)     =      817.73
                                              Prob > chi2      =      0.0000
Log pseudolikelihood = -1673.5566          Pseudo R2       =      0.0638
```

prate	Coef.	Robust Std. Err.	z	P> z	[95% Conf. Interval]	
mrate	1.143516	.074748	15.30	0.000	.9970125	1.290019
ltotemp	-1.103275	.1130667	-9.76	0.000	-1.324882	-.8816687
c.ltotemp# c.ltotemp	.0565782	.0072883	7.76	0.000	.0422934	.070863
age	.0512643	.0059399	8.63	0.000	.0396223	.0629064
c.age#c.age	-.0005891	.0001645	-3.58	0.000	-.0009114	-.0002667
sole						
only plan	.1137479	.0507762	2.24	0.025	.0142284	.2132674
_cons	5.747761	.4294386	13.38	0.000	4.906077	6.589445

Like those obtained from [logit](#), the parameters provide the sign of the marginal effect of the covariates on the outcome, but the magnitude is again difficult to interpret. As with [fracreg probit](#) in [example 1](#), we would use [margins](#) to obtain the marginal effects or other predictions of interest.

◀

### ► Example 3: Odds ratios from a fractional logit model

When the conditional mean of our outcome is interpretable as a probability, it is possible to adopt an odds-ratio interpretation of the results of a fractional logit model. In [example 2](#), this is plausible because expected participation rates can be viewed as estimates of the probability of participation. We obtain the odds ratios by specifying the option `or`.

```

. fracreg logit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole, or
Iteration 0: log pseudolikelihood = -1983.8372
Iteration 1: log pseudolikelihood = -1682.4496
Iteration 2: log pseudolikelihood = -1673.6458
Iteration 3: log pseudolikelihood = -1673.5566
Iteration 4: log pseudolikelihood = -1673.5566
Fractional logistic regression      Number of obs      =      4,075
                                   Wald chi2(6)        =      817.73
                                   Prob > chi2          =      0.0000
Log pseudolikelihood = -1673.5566  Pseudo R2         =      0.0638

```

prate	Odds Ratio	Robust Std. Err.	z	P> z	[95% Conf. Interval]	
mrate	3.137781	.2345429	15.30	0.000	2.710173	3.632857
ltotemp	.3317826	.0375136	-9.76	0.000	.2658343	.4140913
c.ltotemp# c.ltotemp	1.058209	.0077125	7.76	0.000	1.043201	1.073434
age	1.052601	.0062524	8.63	0.000	1.040418	1.064927
c.age#c.age	.9994111	.0001644	-3.58	0.000	.999089	.9997333
sole only plan	1.12047	.0568932	2.24	0.025	1.01433	1.237716
_cons	313.4879	134.6238	13.38	0.000	135.1083	727.3771

Note: \_cons estimates baseline odds.

Among other things, we see that if the 401(k) is the only plan offered by the employer, then the odds of an employee participating increase by a factor of 1.12. We can also see that if the matching rate goes from 0 to 1:1 (exactly matching employee contributions) or from 1:1 to 2:1 (doubling employee contributions), then the odds of participating increase by 3.1.

The use of an odds-ratio interpretation is not appropriate if the conditional mean cannot be viewed as a probability. For example, if the fractional outcome were a Gini coefficient, we could not interpret the expected values of our outcomes as probabilities. The Gini coefficient is a measure of inequality between zero and one and cannot be interpreted as a probability. In this case, using the odds-ratio option would not be sensible.

## Stored results

`fracreg` stores the following in `e()`:

### Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(r2_p)</code>	pseudo- <i>R</i> -squared
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	$\chi^2$
<code>e(p)</code>	significance
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

### Macros

<code>e(cmd)</code>	<code>fracreg</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset)</code>	offset
<code>e(chi2type)</code>	Wald; type of model $\chi^2$ test
<code>e(vce)</code>	<i>vce</i> type specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. Err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

### Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance-covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

### Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

## Methods and formulas

The log-likelihood function for fractional models is of the form

$$\ln L = \sum_{j=1}^N w_j y_j \ln \left\{ G(\mathbf{x}'_j \boldsymbol{\beta}) \right\} + w_j (1 - y_j) \ln \left\{ 1 - G(\mathbf{x}'_j \boldsymbol{\beta}) \right\}$$

where  $N$  is the sample size,  $y_j$  is the dependent variable,  $w_j$  denotes the optional weights,  $\ln L$  is maximized, as described in [R] [maximize](#), and  $G(\cdot)$  can be

Model	Functional form for $G(\mathbf{x}'_j \boldsymbol{\beta})$
probit	$\Phi(\mathbf{x}'_j \boldsymbol{\beta})$
logit	$\exp(\mathbf{x}'_j \boldsymbol{\beta}) / \{1 + \exp(\mathbf{x}'_j \boldsymbol{\beta})\}$
hetprobit	$\Phi \{ \mathbf{x}'_j \boldsymbol{\beta} / \exp(\mathbf{z}'_j \boldsymbol{\gamma}) \}$

where  $\mathbf{x}_j$  are the covariates for individual  $j$ ,  $\mathbf{z}_j$  are the covariates used to model the variance of the outcome for the heteroskedastic probit model, and  $\Phi$  is the standard normal cumulative density function.
