

fracreg postestimation — Postestimation tools for fracreg

[Postestimation commands](#) [predict](#) [margins](#)
[Remarks and examples](#) [Also see](#)

Postestimation commands

The following standard postestimation commands are available after `fracreg`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code>	Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combination
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	predictions, residuals, influence statistics, and other diagnostic measures
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

* `forecast` and `hausman` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

predict

Description for predict

`predict` creates a new variable containing predictions such as conditional means, linear predictions, standard errors, and equation-level scores.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

```
predict [type] { stub* | newvar | newvarlist } [if] [in] , scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>cm</code>	conditional mean; the default
<code>xb</code>	linear prediction
<code>sigma</code>	standard deviation of the error term (for <code>het()</code>)
<code>stdp</code>	standard error of the linear prediction
<code>scores</code>	equation-level score variables

Options for predict

Main

`cm`, the default, calculates the conditional mean of the outcome.

`xb` calculates the linear prediction.

`sigma` calculates the standard deviation of the error term. It is available only when `het()` is specified.

`stdp` calculates the standard error of the linear prediction.

`scores` calculates the equation-level score, $\partial \ln L / \partial (\mathbf{x}_j \boldsymbol{\beta})$, in the case of `fracreg probit` and `fracreg logit`, and can also calculate $\partial \ln L / \partial (\mathbf{z}_j \boldsymbol{\gamma})$ if the option `het()` is specified.

`nooffset` is relevant only if you specified `offset(varname)`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j \mathbf{b}$ rather than as $\mathbf{x}_j \mathbf{b} + \text{offset}_j$.

margins

Description for margins

`margins` estimates margins of response for conditional means and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [, options]
```

```
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>cm</code>	conditional mean; the default
<code>xb</code>	linear prediction
<code>sigma</code>	standard deviation of the error term (for <code>het()</code>)
<code>stdp</code>	not allowed with <code>margins</code>
<code>scores</code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] [margins](#).

Remarks and examples

[stata.com](http://www.stata.com)

Remarks are presented under the following headings:

Obtaining predicted values
Performing hypothesis tests

Obtaining predicted values

Once you have fit a model using `fracreg`, you can obtain the conditional mean of the fractional response by using the `predict` command for both the estimation sample and other samples; see [U] [20 Estimation and postestimation commands](#) and [R] [predict](#).

When you use the fractional probit estimator, `fracreg probit`, with the option `het()`, there is an additional statistic available, `sigma`. With the `sigma` option, `predict` calculates the predicted standard deviation, $\sigma_j = \exp(\mathbf{z}_j\gamma)$.

Performing hypothesis tests

▷ Example 1: Conditional means

In [example 1](#) of [\[R\] fracreg](#), we fit a fractional probit model to see how participation rate (`prate`) in 401(k) plans is affected by the matching rate of employer contributions (`mrate`). To obtain the predicted conditional means, we use `predict` and do not specify the default `cm` option.

```
. use http://www.stata-press.com/data/r15/401k
(Firm-level data on 401k participation)
. fracreg probit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole
Iteration 0:  log pseudolikelihood = -1769.6832
Iteration 1:  log pseudolikelihood = -1675.2763
Iteration 2:  log pseudolikelihood = -1674.6234
Iteration 3:  log pseudolikelihood = -1674.6232
Iteration 4:  log pseudolikelihood = -1674.6232

Fractional probit regression              Number of obs   =       4,075
                                          Wald chi2(6)    =       815.88
                                          Prob > chi2     =       0.0000
                                          Pseudo R2      =       0.0632

Log pseudolikelihood = -1674.6232
```

prate	Coef.	Robust Std. Err.	z	P> z	[95% Conf. Interval]	
mrate	.5859715	.0387616	15.12	0.000	.5100002	.6619429
ltotemp	-.6102767	.0615052	-9.92	0.000	-.7308246	-.4897288
c.ltotemp# c.ltotemp	.0313576	.003975	7.89	0.000	.0235667	.0391484
age	.0273266	.0031926	8.56	0.000	.0210691	.033584
c.age#c.age	-.0003159	.0000875	-3.61	0.000	-.0004874	-.0001443
sole						
only plan	.0683196	.0272091	2.51	0.012	.0149908	.1216484
_cons	3.25991	.2323929	14.03	0.000	2.804429	3.715392

```
. predict mpart
(option cm assumed)
```

We can then summarize these conditional mean estimates (`cmean`) over the population to get the population average conditional mean participation rate in our sample.

```
. summarize mpart
```

Variable	Obs	Mean	Std. Dev.	Min	Max
mpart	4,075	.8405767	.0828094	.6251739	.9964518

The average of the conditional mean of participation rate in our sample is 84% with a range between 62.5% and 99.6%.

▷ Example 2: Average marginal effects

In [example 2](#) of [R] [fracreg](#), we used the outcome variable and covariates of [example 1](#) but instead of fitting a fractional probit regression, we fit a fractional logit. Using margins, we explore the average marginal effect of `mrate` on `prate` for both specifications.

Below we use `margins` after `fracreg logit` with the option `post` to post the average marginal effects as estimates. We then store our results with the name `logit`. We do the same with our probit estimates.

```
. use http://www.stata-press.com/data/r15/401k, clear
(Firm-level data on 401k participation)
. fracreg logit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole, or
Iteration 0:  log pseudolikelihood = -1983.8372

Note: `_cons` estimates baseline odds.

```
. margins, dydx(mrate) post
Average marginal effects          Number of obs      =      4,075
Model VCE      : Robust
Expression    : Conditional mean of prate, predict()
dy/dx w.r.t.  : mrate
```

	Delta-method		z	P> z	[95% Conf. Interval]	
	dy/dx	Std. Err.				
mrate	.1450106	.0094558	15.34	0.000	.1264776	.1635436

```
. estimates store logit
```

The marginal effects from `fracreg logit` suggest that a small change in the matching rate of employers can increase participation by more than 14%.

```
. quietly fracreg probit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole
. margins, dydx(mrate) post
Average marginal effects          Number of obs    =      4,075
Model VCE      : Robust
Expression    : Conditional mean of prate, predict()
dy/dx w.r.t.  : mrate
```

	Delta-method		z	P> z	[95% Conf. Interval]	
	dy/dx	Std. Err.				
mrate	.1335505	.0087385	15.28	0.000	.1164233	.1506776

```
. estimates store probit
```

For the probit model, a change in the matching rate increases participation by more than 13%.

Because we stored our margins results as estimates, we can now produce a table showing both the logit and probit results.

```
. estimates table logit probit, se
```

Variable	logit	probit
mrate	.14501059 .00945578	.13355046 .00873852

legend: b/se

As indicated by the standard errors in the table, both average marginal effects are significant. The difference between the two estimates is approximately one percentage point. This relatively small difference is consistent with the intuition that marginal effects obtained from probit and logit conditional means give us analogous results.

► Example 3: Average marginal effects for different levels of participation

We can also use `margins` to find the expected participation rate for various levels of employer matching. Using our probit model, we obtain the following by typing

```
. quietly fracreg probit prate mrate c.ltotemp##c.ltotemp c.age##c.age i.sole
. margins, at(mrate=(0(.2)2))
Predictive margins                                Number of obs    =    4,075
Model VCE      : Robust
Expression     : Conditional mean of prate, predict()
1._at         : mrate          =          0
2._at         : mrate          =          .2
3._at         : mrate          =          .4
4._at         : mrate          =          .6
5._at         : mrate          =          .8
6._at         : mrate          =          1
7._at         : mrate          =         1.2
8._at         : mrate          =         1.4
9._at         : mrate          =         1.6
10._at        : mrate          =         1.8
11._at        : mrate          =          2
```

	Delta-method				[95% Conf. Interval]	
	Margin	Std. Err.	z	P> z		
_at						
1	.780858	.0052738	148.06	0.000	.7705216	.7911944
2	.8128364	.003441	236.22	0.000	.8060923	.8195806
3	.8417642	.002672	315.03	0.000	.8365271	.8470013
4	.8675979	.0029882	290.34	0.000	.8617412	.8734547
5	.8903734	.0036591	243.33	0.000	.8832018	.8975451
6	.9101957	.0042293	215.21	0.000	.9019065	.9184849
7	.9272265	.0045767	202.60	0.000	.9182563	.9361966
8	.9416712	.004694	200.61	0.000	.9324711	.9508712
9	.9537652	.0046115	206.82	0.000	.9447268	.9628035
10	.9637608	.004372	220.44	0.000	.9551919	.9723298
11	.9719159	.0040207	241.73	0.000	.9640355	.9797964

Going from no matching to equal matching changes the participation rate from 78% to 91%, and double matching moves participation all the way to 97.2%.

We can also see these results in a graph by using `marginsplot`.

```
. marginsplot
```
