### xtpoisson — Fixed-effects, random-effects, and population-averaged Poisson models

Description Syntax Options for PA model Methods and formulas Quick start Options for RE model Remarks and examples References Menu Options for FE model Stored results Also see

# Description

xtpoisson fits random-effects, conditional fixed-effects, and population-averaged Poisson models. These models are typically used for a nonnegative count dependent variable.

# **Quick start**

Random-effects Poisson regression of y on x and indicators for levels of categorical variable a using xtset data

xtpoisson y x i.a

Conditional fixed-effects model with exposure variable evar

xtpoisson y x i.a, fe exposure(evar)

Population-averaged model with robust standard errors

xtpoisson y x i.a, pa vce(robust)

Same as above, but report incidence-rate ratios

xtpoisson y x i.a, pa vce(robust) irr

### Menu

Statistics > Longitudinal/panel data > Count outcomes > Poisson regression (FE, RE, PA)

# **Syntax**

Random-effects (RE) model
<pre>xtpoisson depvar [indepvars] [if] [in] [weight] [, re RE_options]</pre>
Conditional fixed-effects (FE) model

```
xtpoisson depvar [indepvars] [if] [in] [weight], fe [FE_options]
```

### Population-averaged (PA) model

xtpoisson depvar [indepvars] [if] [in] [weight], pa [PA\_options]

RE_options	Description
Model	
<u>nocons</u> tant	suppress constant term
re	use random-effects estimator; the default
exposure( <i>varname</i> )	include ln(varname) in model with coefficient constrained to 1
<u>off</u> set( <i>varname</i> )	include varname in model with coefficient constrained to 1
normal	use a normal distribution for random effects instead of gamma
<pre><u>const</u>raints(constraints)</pre>	apply specified linear constraints
SE/Robust	
vce( <i>vcetype</i> )	<i>vcetype</i> may be oim, <u>r</u> obust, <u>cl</u> uster <i>clustvar</i> , <u>boot</u> strap, or <u>jackknife</u>
Reporting	
<u>l</u> evel(#)	set confidence level; default is level(95)
<u>ir</u> r	report incidence-rate ratios
lrmodel	perform the likelihood-ratio model test instead of the default Wald test
<u>nocnsr</u> eport	do not display constraints
display_options	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Integration	
<u>intm</u> ethod( <i>intmethod</i> )	integration method; <i>intmethod</i> may be <u>mv</u> aghermite (the default) or ghermite
<pre>intpoints(#)</pre>	use $\overline{\#}$ quadrature points; default is intpoints (12)
Maximization	
maximize_options	control the maximization process; seldom used
<u>col</u> linear	keep collinear variables
<u>coefl</u> egend	display legend instead of statistics

### xtpoisson — Fixed-effects, random-effects, and population-averaged Poisson models 3

FE_options	Description
Model	
fe <u>exp</u> osure(varname) <u>off</u> set(varname) <u>const</u> raints(constraints)	use fixed-effects estimator include ln( <i>varname</i> ) in model with coefficient constrained to 1 include <i>varname</i> in model with coefficient constrained to 1 apply specified linear constraints
SE/Robust	
vce( <i>vcetype</i> )	<i>vcetype</i> may be oim, <u>r</u> obust, <u>boot</u> strap, or <u>jack</u> knife
Reporting	
<u>l</u> evel(#)	set confidence level; default is level(95)
<u>ir</u> r	report incidence-rate ratios
<u>nocnsr</u> eport	do not display constraints
display_options	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
maximize_options	control the maximization process; seldom used

#### xtpoisson — Fixed-effects, random-effects, and population-averaged Poisson models 4

PA_options	Description
Model	
<u>nocons</u> tant	suppress constant term
pa	use population-averaged estimator
exposure(varname)	include ln(varname) in model with coefficient constrained to 1
<u>off</u> set( <i>varname</i> )	include varname in model with coefficient constrained to 1
Correlation	
<u>c</u> orr( <i>correlation</i> )	within-panel correlation structure
force	estimate even if observations unequally spaced in time
SE/Robust	
vce( <i>vcetype</i> )	<i>vcetype</i> may be conventional, <u>r</u> obust, <u>boot</u> strap, or jackknife
nmp	use divisor $N - P$ instead of the default $N$
<pre>scale(parm)</pre>	overrides the default scale parameter; parm may be x2, dev, phi, or #
Reporting	
<u>l</u> evel(#)	set confidence level; default is level(95)
<u>ir</u> r	report incidence-rate ratios
display_options	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Optimization	
optimize_options	control the optimization process; seldom used
<u>coefl</u> egend	display legend instead of statistics
correlation	Description
	•
<u>exc</u> hangeable <u>ind</u> ependent	exchangeable independent
unstructured	unstructured
fixed matname	user-specified
ar#	autoregressive of order #
<u>sta</u> tionary #	stationary of order #
<u>sta</u> tionary # <u>non</u> stationary #	nonstationary of order #
$\underline{\mathrm{non}}$ stationary $\pi$	nonsumonary of order $\pi$

A panel variable must be specified. For xtpoisson, pa, correlation structures other than exchangeable and independent require that a time variable also be specified. Use xtset; see [XT] xtset.

indepvars may contain factor variables; see [U] 11.4.3 Factor variables.

depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.

by, collect, mi estimate, and statsby are allowed; see [U] 11.1.10 Prefix commands. bayes is allowed for the randomeffects model. For more details, see [BAYES] bayes: xtpoisson. fp is allowed for the random-effects and fixed-effects models.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.

iweights, fweights, and pweights are allowed for the population-averaged model, and iweights are allowed for the random-effects and fixed-effects models; see [U] 11.1.6 weight. Weights must be constant within panel.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

# **Options for RE model**

Model

noconstant; see [R] Estimation options.

re, the default, requests the random-effects estimator.

exposure(varname), offset(varname); see [R] Estimation options.

normal specifies that the random effects follow a normal distribution instead of a gamma distribution.

constraints(constraints); see [R] Estimation options.

SE/Robust

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster *clustvar*), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce\_options.

Specifying vce(robust) is equivalent to specifying vce(cluster *panelvar*); see *xtpoisson*, *re and the robust VCE estimator* in *Methods and formulas*.

Reporting

level(#); see [R] Estimation options.

irr reports exponentiated coefficients  $e^b$  rather than coefficients b. For the Poisson model, exponentiated coefficients are interpreted as incidence-rate ratios.

lrmodel, nocnsreport; see [R] Estimation options.

```
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels,
allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt),
sformat(%fmt), and nolstretch; see [R] Estimation options.
```

Integration

intmethod(intmethod), intpoints(#); see [R] Estimation options. normal must also be specified.

Maximization

maximize\_options: difficult, technique(algorithm\_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init\_specs); see [R] Maximize. These options are seldom used.

The following options are available with xtpoisson but are not shown in the dialog box:

collinear, coeflegend; see [R] Estimation options.

## **Options for FE model**

[ Model ]

fe requests the fixed-effects estimator.

exposure(varname), offset(varname), constraints(constraints); see [R] Estimation options.

SE/Robust

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim), that are robust to some kinds of misspecification (robust), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce\_options.

vce(robust) invokes a cluster-robust estimate of the VCE in which the ID variable specifies the clusters.

Reporting

level(#); see [R] Estimation options.

irr reports exponentiated coefficients  $e^b$  rather than coefficients b. For the Poisson model, exponentiated coefficients are interpreted as incidence-rate ratios.

nocnsreport; see [R] Estimation options.

```
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels,
allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt),
sformat(%fmt), and nolstretch; see [R] Estimation options.
```

Maximization

maximize\_options: difficult, technique(algorithm\_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init\_specs); see [R] Maximize. These options are seldom used.

The following options are available with xtpoisson but are not shown in the dialog box:

collinear, coeflegend; see [R] Estimation options.

## **Options for PA model**

Model

noconstant; see [R] Estimation options.

pa requests the population-averaged estimator.

exposure(varname), offset(varname); see [R] Estimation options.

Correlation

corr(*correlation*) specifies the within-panel correlation structure; the default corresponds to the equalcorrelation model, corr(exchangeable).

When you specify a correlation structure that requires a lag, you indicate the lag after the structure's name with or without a blank; for example, corr(ar 1) or corr(ar1).

If you specify the fixed correlation structure, you specify the name of the matrix containing the assumed correlations following the word fixed, for example, corr(fixed myr).

force specifies that estimation be forced even though the time variable is not equally spaced. This is relevant only for correlation structures that require knowledge of the time variable. These correlation structures require that observations be equally spaced so that calculations based on lags correspond to a constant time change. If you specify a time variable indicating that observations are not equally spaced, the (time dependent) model will not be fit. If you also specify force, the model will be fit, and it will be assumed that the lags based on the data ordered by the time variable are appropriate.

SE/Robust

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional), that are robust to some kinds of misspecification (robust), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce\_options.

vce(conventional), the default, uses the conventionally derived variance estimator for generalized least-squares regression.

nmp, scale(x2 | dev | phi | #); see [XT] vce\_options.

Reporting

level(#); see [R] Estimation options.

- irr reports exponentiated coefficients  $e^b$  rather than coefficients b. For the Poisson model, exponentiated coefficients are interpreted as incidence-rate ratios.
- display\_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

Optimization

optimize\_options control the iterative optimization process. These options are seldom used.

<u>iter</u>ate(#) specifies the maximum number of iterations. When the number of iterations equals #, the optimization stops and presents the current results, even if convergence has not been reached. The default is iterate(100).

<u>tol</u>erance(#) specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to #, the optimization process is stopped. tolerance(1e-6) is the default.

log and nolog specify whether to display the iteration log. The iteration log is displayed by default unless you used set iterlog off to suppress it; see set iterlog in [R] set iter.

 $\underline{tr}$  ace specifies that the current estimates be printed at each iteration.

The following option is available with xtpoisson but is not shown in the dialog box:

coeflegend; see [R] Estimation options.

## **Remarks and examples**

xtpoisson fits random-effects, conditional fixed-effects, and population-averaged Poisson models. Whenever we refer to a fixed-effects model, we mean the conditional fixed-effects model. These models are typically used for a nonnegative count dependent variable but may be used for any dependent variable in natural logs. For more information about the assumptions of the Poisson model, see [R] poisson.

By default, the population-averaged model is an equal-correlation model; xtpoisson, pa assumes corr(exchangeable). Thus, xtpoisson is a convenience command for fitting the population-averaged model using xtgee; see [XT] xtgee. Typing

. xtpoisson ..., ... pa exposure(time)

is equivalent to typing

. xtgee ..., ... family(poisson) link(log) corr(exchangeable) exposure(time)

Also see [XT] xtgee for information about xtpoisson.

By default or when re is specified, xtpoisson fits via maximum likelihood the random-effects model

$$\Pr(Y_{it} = y_{it} | \mathbf{x}_{it}) = F(y_{it}, \mathbf{x}_{it} \boldsymbol{\beta} + \nu_i)$$

for i = 1, ..., n panels, where  $t = 1, ..., n_i$ , and F(x, z) = Pr(X = x), where X is Poisson distributed with mean  $\exp(z)$ . In the standard random-effects model,  $\nu_i$  is assumed to be i.i.d. such that  $\exp(\nu_i)$  is gamma with mean one and variance  $\alpha$ , which is estimated from the data. If normal is specified,  $\nu_i$  is assumed to be i.i.d.  $N(0, \sigma_{\nu}^2)$ .

### Example 1

We have data on the number of ship accidents for five different types of ships (McCullagh and Nelder 1989, 205). We wish to analyze whether the "incident" rate is affected by the period in which the ship was constructed and operated. Our measure of exposure is months of service for the ship, and in this model, we assume that the exponentiated random effects are distributed as gamma with mean one and variance  $\alpha$ .

. use https:/,	/www.stata-pr	ess.com/data	/r19/ship	S		
. xtpoisson accident op_75_79 co_65_69 co_70_74 co_75_79, exp(service) irr						
Fitting Poiss	on model:

alpha	.0936298	.0793475			.0177851	.4929165
Note: Estimates are transformed only in the first equation to incidence-rate ratios.						
		line inciden	ce rate (	condit	ional on zero r	andom
LR test of alpha=0: $chibar2(01) = 10.61$ Prob >= $chibar2 = 0.001$						

The output also includes a likelihood-ratio test of  $\alpha = 0$ , which compares the panel estimator with the pooled (Poisson) estimator.

We find that the incidence rate for accidents is significantly different for the periods of construction and operation of the ships and that the random-effects model is significantly different from the pooled model. We may alternatively fit a fixed-effects specification instead of a random-effects specification:

. xtpoisson a	ccident op_75	_79 co_65_69	co_70_74	co_75_7	9, exp(servic	e) irr fe
Iteration 0:	Log likeliho	od = -80.7389	973			
Iteration 1:	Log likeliho					
Iteration 2:	Log likeliho					
Iteration 3: Iteration 4:	Log likeliho Log likeliho					
	U					
Conditional f:		Poisson regre	ession		mber of obs	
Group variable	e: ship			Nu	mber of group	s = 5
				Ob	s per group:	
						n = 6
						g = 6.8
						x = 7
					ld chi2(4)	
Log likelihood	1 = -54.64185	9		Pr	ob > chi2	= 0.0000
accident	IRR	Std. err.	Z	P> z	[95% conf.	interval]
op_75_79	1.468831	.1737218	3.25	0.001	1.164926	1.852019
co_65_69	2.008002	.3004803	4.66	0.000	1.497577	2.692398
co_70_74	2.26693		4.82		1.625274	
co_75_79	1.573695		1.94	0.052	.9964273	2.485397
ln(service)	1	(exposure)				

Both of these models fit the same thing but will differ in efficiency, depending on whether the assumptions of the random-effects model are true.

We could have assumed that the random effects followed a normal distribution,  $N(0, \sigma_{\nu}^2)$ , instead of a "log-gamma" distribution, and obtained

. xtpoisson accident op_7 > normal nolog	5_79 co_65_69	) co_70_74	ł co_75	_79, exp(servic	e) irr

sigma_u .3085306	.1324562			.1330045	.7156988
Note: Estimates are transformed only in the first equation to incidence-rate ratios.					
Note: <b>_cons</b> estimates baseline incidence rate (conditional on zero random effects).					
LR test of sigma_u=0: chi	bar2(01) = 10	0.67		Prob >= chiba	r2 = 0.001

The output includes the additional panel-level variance component. This is parameterized as the log of the variance  $\ln(\sigma_{\nu}^2)$  (labeled lnsig2u in the output). The standard deviation  $\sigma_{\nu}$  is also included in the output labeled sigma\_u.

When sigma\_u is zero, the panel-level variance component is unimportant and the panel estimator is no different from the pooled estimator. A likelihood-ratio test of this is included at the bottom of the output. This test formally compares the pooled estimator (poisson) with the panel estimator. Here  $\sigma_{\nu}$  is significantly greater than zero, so a panel estimator is indicated.

### Example 2

This time we fit a robust equal-correlation population-averaged model:

<pre>. xtpoisson a &gt; vce(robust)</pre>	ccident op_75_79 co_6 eform	5_69 c	o_70_74	co_75_7	9, exp(	service	) p	a
Iteration 2: Iteration 3: Iteration 4: Iteration 5:	Tolerance = .0408319 Tolerance = .0027018 Tolerance = .0003066 Tolerance = .0000346 Tolerance = 3.891e-0 Tolerance = 4.359e-0							
GEE population	n-averaged model			Nu	nber of	obs	=	34
Group variable	e: ship			Nu	nber of	groups	=	5
Family: Poiss	on			Ob	s per g	roup:		
Link: Log						min	=	6

### Technical note

The random-effects model is calculated using quadrature, which is an approximation whose accuracy depends partially on the number of integration points used. We can use the quadchk command to see if changing the number of integration points affects the results. If the results change, the quadrature approximation is not accurate given the number of integration points. Try increasing the number of integration points using the intpoints() option and run quadchk again. Do not attempt to interpret the results of estimates when the coefficients reported by quadchk differ substantially. See [XT] quadchk for details and [XT] xtprobit for an example.

Because the xtpoisson, re normal likelihood function is calculated by Gauss-Hermite quadrature, on large problems the computations can be slow. Computation time is roughly proportional to the number of points used for the quadrature.

### Stored results

xtpoisson, re stores the following in e():

```
Scalars

### Methods and formulas

xtpoisson, pa reports the population-averaged results obtained by using xtgee, family(poisson) link(log) to obtain estimates. See [XT] **xtgee** for details about the methods and formulas.

xtpoisson, fe with robust standard errors implements the formula presented in Wooldridge (1999). The formula is a cluster-robust estimate of the VCE in which the ID variable specifies the clusters.

Although Hausman, Hall, and Griliches (1984) wrote the seminal article on the random-effects and fixed-effects models, Cameron and Trivedi (2013) provide a good textbook treatment. Allison (2009, chap. 4) succinctly discusses these models and illustrates the differences between them using Stata.

For a random-effects specification, we know that

$$\Pr(y_{i1}, \dots, y_{in_i} | \alpha_i, \mathbf{x}_{i1}, \dots, \mathbf{x}_{in_i}) = \left(\prod_{t=1}^{n_i} \frac{\lambda_{it}^{y_{it}}}{y_{it}!}\right) \exp\left\{-\exp(\alpha_i) \sum_{t=1}^{n_i} \lambda_{it}\right\} \exp\left(\alpha_i \sum_{t=1}^{n_i} y_{it}\right)$$

where  $\lambda_{it} = \exp(\mathbf{x}_{it}\boldsymbol{\beta})$ . We may rewrite the above as [defining  $\epsilon_i = \exp(\alpha_i)$ ]

$$\begin{split} \Pr(y_{i1}, \dots, y_{in_i} | \epsilon_i, \mathbf{x}_{i1}, \dots, \mathbf{x}_{in_i}) &= \left\{ \prod_{t=1}^{n_i} \frac{(\lambda_{it} \epsilon_i)^{y_{it}}}{y_{it}!} \right\} \, \exp\left( -\sum_{t=1}^{n_i} \lambda_{it} \epsilon_i \right) \\ &= \left( \prod_{t=1}^{n_i} \frac{\lambda_{it}^{y_{it}}}{y_{it}!} \right) \, \exp\left( -\epsilon_i \sum_{t=1}^{n_i} \lambda_{it} \right) \, \epsilon_i^{\sum_{t=1}^{n_i} y_{it}} \end{split}$$

We now assume that  $\epsilon_i$  follows a gamma distribution with mean one and variance  $1/\theta$  so that unconditional on  $\epsilon_i$ 

$$\begin{split} \Pr(y_{i1}, \dots, y_{in_i} | \mathbf{X}_i) &= \frac{\theta^{\theta}}{\Gamma(\theta)} \left( \prod_{t=1}^{n_i} \frac{\lambda_{it}^{y_{it}}}{y_{it}!} \right) \int_0^{\infty} \exp\left( -\epsilon_i \sum_{t=1}^{n_i} \lambda_{it} \right) \epsilon_i^{\sum_{t=1}^{n_i} y_{it}} \epsilon_i^{\theta-1} \exp(-\theta \epsilon_i) d\epsilon_i \\ &= \frac{\theta^{\theta}}{\Gamma(\theta)} \left( \prod_{t=1}^{n_i} \frac{\lambda_{it}^{y_{it}}}{y_{it}!} \right) \int_0^{\infty} \exp\left\{ -\epsilon_i \left( \theta + \sum_{t=1}^{n_i} \lambda_{it} \right) \right\} \epsilon_i^{\theta + \sum_{t=1}^{n_i} y_{it} - 1} d\epsilon_i \\ &= \left( \prod_{t=1}^{n_i} \frac{\lambda_{it}^{y_{it}}}{y_{it}!} \right) \frac{\Gamma\left( \theta + \sum_{t=1}^{n_i} y_{it} \right)}{\Gamma(\theta)} \left( \frac{\theta}{\theta + \sum_{t=1}^{n_i} \lambda_{it}} \right)^{\theta} \left( \frac{1}{\theta + \sum_{t=1}^{n_i} \lambda_{it}} \right)^{\sum_{t=1}^{n_i} y_{it}} \end{split}$$

for  $X_i = (x_{i1}, ..., x_{in_i})$ .

The log likelihood (assuming gamma heterogeneity) is then derived using

$$u_i = \frac{\theta}{\theta + \sum_{t=1}^{n_i} \lambda_{it}} \qquad \lambda_{it} = \exp(\mathbf{x}_{it} \boldsymbol{\beta})$$

$$\Pr(Y_{i1} = y_{i1}, \dots, Y_{in_i} = y_{in_i} | \mathbf{X}_i) = \frac{\prod_{t=1}^{n_i} \lambda_{it}^{y_{it}} \Gamma\left(\theta + \sum_{t=1}^{n_i} y_{it}\right)}{\prod_{t=1}^{n_i} y_{it}! \Gamma(\theta) \left(\sum_{t=1}^{n_i} \lambda_{it}\right)^{\sum_{t=1}^{n_i} y_{it}}} u_i^{\theta} (1 - u_i)^{\sum_{t=1}^{n_i} y_{it}}$$

such that the log likelihood may be written as

$$\begin{split} L &= \sum_{i=1}^{n} w_i \Bigg\{ \log \Gamma \left( \theta + \sum_{t=1}^{n_i} y_{it} \right) - \sum_{t=1}^{n_i} \log \Gamma \left( 1 + y_{it} \right) - \log \Gamma(\theta) + \theta \log u_i \\ &+ \log (1 - u_i) \sum_{t=1}^{n_i} y_{it} + \sum_{t=1}^{n_i} y_{it} (\mathbf{x}_{it} \boldsymbol{\beta}) - \left( \sum_{t=1}^{n_i} y_{it} \right) \log \left( \sum_{t=1}^{n_i} \lambda_{it} \right) \Bigg\} \end{split}$$

where  $w_i$  is the user-specified weight for panel *i*; if no weights are specified,  $w_i = 1$ .

Alternatively, if we assume a normal distribution,  $N(0, \sigma_{\nu}^2)$ , for the random effects  $\nu_i$ 

$$\begin{split} &\Pr(y_{i1},\ldots,y_{in_i}|\mathbf{X}_i) = \int_{-\infty}^{\infty} \frac{e^{-\nu_i^2/2\sigma_\nu^2}}{\sqrt{2\pi}\sigma_\nu} \left\{ \prod_{t=1}^{n_i} F(y_{it},\mathbf{x}_{it}\boldsymbol{\beta}+\nu_i) \right\} d\nu_i \\ & F(y,z) = \, \exp\Bigl\{ -\exp(z) + yz - \log(y!) \Bigr\}. \end{split}$$

where

The panel-level likelihood  $l_i$  is given by

$$\begin{split} l_i &= \int_{-\infty}^{\infty} \frac{e^{-\nu_i^2/2\sigma_{\nu}^2}}{\sqrt{2\pi}\sigma_{\nu}} \left\{ \prod_{t=1}^{n_i} F(y_{it}, \mathbf{x}_{it} \boldsymbol{\beta} + \nu_i) \right\} d\nu_i \\ &\equiv \int_{-\infty}^{\infty} g(y_{it}, x_{it}, \nu_i) d\nu_i \end{split}$$

This integral can be approximated with M-point Gauss-Hermite quadrature

$$\int_{-\infty}^{\infty} e^{-x^2} h(x) dx \approx \sum_{m=1}^{M} w_m^* h(a_m^*)$$

This is equivalent to

$$\int_{-\infty}^{\infty} f(x) dx \approx \sum_{m=1}^{M} w_m^* \exp\left\{(a_m^*)^2\right\} f(a_m^*)$$

where the  $w_m^*$  denote the quadrature weights and the  $a_m^*$  denote the quadrature abscissas. The log likelihood, L, is the sum of the logs of the panel-level likelihoods  $l_i$ .

The default approximation of the log likelihood is by adaptive Gauss-Hermite quadrature, which approximates the panel-level likelihood with

$$l_i\approx \sqrt{2}\hat{\sigma}_i\sum_{m=1}^M w_m^*\exp\left\{(a_m^*)^2\right\}g(y_{it},x_{it},\sqrt{2}\hat{\sigma}_ia_m^*+\hat{\mu}_i)$$

where  $\hat{\sigma}_i$  and  $\hat{\mu}_i$  are the adaptive parameters for panel *i*. Therefore, with the definition of  $g(y_{it}, x_{it}, \nu_i)$ , the total log likelihood is approximated by

$$\begin{split} L \approx \sum_{i=1}^n w_i \log \biggl[ \sqrt{2} \hat{\sigma}_i \sum_{m=1}^M w_m^* \exp\{(a_m^*)^2\} \frac{\exp\{-(\sqrt{2} \hat{\sigma}_i a_m^* + \hat{\mu}_i)^2 / 2\sigma_\nu^2\}}{\sqrt{2\pi}\sigma_\nu} \\ \prod_{t=1}^{n_i} F(y_{it}, x_{it}\beta + \sqrt{2} \hat{\sigma}_i a_m^* + \hat{\mu}_i) \biggr] \end{split}$$

where  $w_i$  is the user-specified weight for panel *i*; if no weights are specified,  $w_i = 1$ .

The default method of adaptive Gauss–Hermite quadrature is to calculate the posterior mean and variance and use those parameters for  $\hat{\mu}_i$  and  $\hat{\sigma}_i$  by following the method of Naylor and Smith (1982), further discussed in Skrondal and Rabe-Hesketh (2004). We start with  $\hat{\sigma}_{i,0} = 1$  and  $\hat{\mu}_{i,0} = 0$ , and the posterior means and variances are updated in the *k*th iteration. That is, at the *k*th iteration of the optimization for  $l_i$ , we use

$$l_{i,k} \approx \sum_{m=1}^{M} \sqrt{2} \hat{\sigma}_{i,k-1} w_m^* \exp\{a_m^*)^2 \} g(y_{it}, x_{it}, \sqrt{2} \hat{\sigma}_{i,k-1} a_m^* + \hat{\mu}_{i,k-1})$$

Letting

$$\tau_{i,m,k-1} = \sqrt{2}\hat{\sigma}_{i,k-1}a_m^* + \hat{\mu}_{i,k-1}$$

$$\hat{\mu}_{i,k} = \sum_{m=1}^{M} (\tau_{i,m,k-1}) \frac{\sqrt{2} \hat{\sigma}_{i,k-1} w_m^* \exp\{(a_m^*)^2\} g(y_{it}, x_{it}, \tau_{i,m,k-1})}{l_{i,k}}$$

and

$$\hat{\sigma}_{i,k} = \sum_{m=1}^{M} (\tau_{i,m,k-1})^2 \frac{\sqrt{2} \hat{\sigma}_{i,k-1} w_m^* \exp\{(a_m^*)^2\} g(y_{it}, x_{it}, \tau_{i,m,k-1})}{l_{i,k}} - \left(\hat{\mu}_{i,k}\right)^2$$

and this is repeated until  $\hat{\mu}_{i,k}$  and  $\hat{\sigma}_{i,k}$  have converged for this iteration of the maximization algorithm. This adaptation is applied on every iteration until the log-likelihood change from the preceding iteration is less than a relative difference of 1e–6; after this, the quadrature parameters are fixed. The log likelihood can also be calculated by nonadaptive Gauss-Hermite quadrature, the intmethod(ghermite) option, where  $\rho = \sigma_{\nu}^2/(\sigma_{\nu}^2 + 1)$ :

$$\begin{split} L &= \sum_{i=1}^{n} w_i \log \Big\{ \Pr(y_{i1}, \dots, y_{in_i} | \mathbf{x}_{i1}, \dots, \mathbf{x}_{in_i}) \Big\} \\ &\approx \sum_{i=1}^{n} w_i \log \left[ \frac{1}{\sqrt{\pi}} \sum_{m=1}^{M} w_m^* \prod_{t=1}^{n_i} F\left\{ y_{it}, \mathbf{x}_{it} \boldsymbol{\beta} + a_m^* \left( \frac{2\rho}{1-\rho} \right)^{1/2} \right\} \right] \end{split}$$

Both quadrature formulas require that the integrated function be well approximated by a polynomial of degree equal to the number of quadrature points. The number of periods (panel size) can affect whether

$$\prod_{t=1}^{n_i} F(y_{it}, \mathbf{x}_{it} \boldsymbol{\beta} + \nu_i)$$

is well approximated by a polynomial. As panel size and  $\rho$  increase, the quadrature approximation can become less accurate. For large  $\rho$ , the random-effects model can also become unidentified. Adaptive quadrature gives better results for correlated data and large panels than nonadaptive quadrature; however, we recommend that you use the quadchk command (see [XT] quadchk) to verify the quadrature approximation used in this command, whichever approximation you choose.

For a fixed-effects specification, we know that

$$\begin{split} \Pr(Y_{it} = y_{it} | \mathbf{x}_{it}) &= \exp\{-\exp(\alpha_i + \mathbf{x}_{it}\boldsymbol{\beta})\}\exp(\alpha_i + \mathbf{x}_{it}\boldsymbol{\beta})^{y_{it}} / y_{it}! \\ &= \frac{1}{y_{it}!}\exp\{-\exp(\alpha_i)\exp(\mathbf{x}_{it}\boldsymbol{\beta}) + \alpha_i y_{it}\}\exp(\mathbf{x}_{it}\boldsymbol{\beta})^{y_{it}} \\ &\equiv F_{it} \end{split}$$

Because we know that the observations are independent, we may write the joint probability for the observations within a panel as

$$\begin{split} \Pr\left(Y_{i1} = y_{i1}, \dots, Y_{in_i} = y_{in_i} | \mathbf{X}_i\right) \\ &= \prod_{t=1}^{n_i} \frac{1}{y_{it}!} \exp\{-\exp(\alpha_i) \exp(\mathbf{x}_{it}\boldsymbol{\beta}) + \alpha_i y_{it}\} \exp(\mathbf{x}_{it}\boldsymbol{\beta})^{y_{it}} \\ &= \left(\prod_{t=1}^{n_i} \frac{\exp(\mathbf{x}_{it}\boldsymbol{\beta})^{y_{it}}}{y_{it}!}\right) \exp\left\{-\exp(\alpha_i) \sum_t \exp(\mathbf{x}_{it}\boldsymbol{\beta}) + \alpha_i \sum_t y_{it}\right\} \end{split}$$

and we also know that the sum of  $n_i$  Poisson independent random variables, each with parameter  $\lambda_{it}$  for  $t = 1, \ldots, n_i$ , is distributed as Poisson with parameter  $\sum_i \lambda_{it}$ . Thus

$$\begin{split} &\Pr\left(\sum_{t}Y_{it} = \sum_{t}y_{it}\Big|\mathbf{X}_{i}\right) = \\ & \frac{1}{\left(\sum_{t}y_{it}\right)!}\exp\left\{-\exp(\alpha_{i})\sum_{t}\exp(\mathbf{x}_{it}\boldsymbol{\beta}) + \alpha_{i}\sum_{t}y_{it}\right\}\left\{\sum_{t}\exp(\mathbf{x}_{it}\boldsymbol{\beta})\right\}^{\sum_{t}y_{it}} \end{split}$$

So the conditional likelihood is conditioned on the sum of the outcomes in the set (panel). The appropriate function is given by

$$\begin{split} \Pr\Bigl(Y_{i1} &= y_{i1}, \dots, Y_{in_i} = y_{in_i} \Big| \mathbf{X}_i, \sum_t Y_{it} = \sum_t y_{it} \Bigr) = \\ & \left[ \left( \prod_{t=1}^{n_i} \frac{\exp(\mathbf{x}_{it} \boldsymbol{\beta})^{y_{it}}}{y_{it}!} \right) \exp\left\{ - \exp(\alpha_i) \sum_t \exp(\mathbf{x}_{it} \boldsymbol{\beta}) + \alpha_i \sum_t y_{it} \right\} \right] \Big/ \\ & \left[ \frac{1}{\left(\sum_t y_{it}\right)!} \exp\left\{ - \exp(\alpha_i) \sum_t \exp(\mathbf{x}_{it} \boldsymbol{\beta}) + \alpha_i \sum_t y_{it} \right\} \left\{ \sum_t \exp(\mathbf{x}_{it} \boldsymbol{\beta}) \right\}^{\sum_t y_{it}} \right] \\ & = \left( \sum_t y_{it} \right)! \prod_{t=1}^{n_i} \frac{\exp(\mathbf{x}_{it} \boldsymbol{\beta})^{y_{it}}}{y_{it}! \left\{ \sum_k \exp(\mathbf{x}_{ik} \boldsymbol{\beta}) \right\}^{y_{it}}} \end{split}$$

which is free of  $\alpha_i$ .

The conditional log likelihood is given by

$$\begin{split} L &= \log \prod_{i=1}^{n} \left[ \left( \sum_{t=1}^{n_{i}} y_{it} \right)! \prod_{t=1}^{n_{i}} \frac{\exp(\mathbf{x}_{it}\beta)^{y_{it}}}{y_{it}! \left\{ \sum_{\ell=1}^{n_{\ell}} \exp(\mathbf{x}_{i\ell}\beta) \right\}^{y_{it}}} \right]^{w_{i}} \\ &= \log \prod_{i=1}^{n} \left\{ \frac{(\sum_{t} y_{it})!}{\prod_{t=1}^{n_{i}} y_{it}!} \prod_{t=1}^{n_{i}} p_{it}^{y_{it}} \right\}^{w_{i}} \\ &= \sum_{i=1}^{n} w_{i} \left\{ \log \Gamma\left( \sum_{t=1}^{n_{i}} y_{it} + 1 \right) - \sum_{t=1}^{n_{i}} \log \Gamma(y_{it} + 1) + \sum_{t=1}^{n_{i}} y_{it} \log p_{it} \right\} \end{split}$$

where

$$p_{it} = e^{\mathbf{x}_{it}} \boldsymbol{\beta} / \sum_{\ell} e^{\mathbf{x}_{i\ell}} \boldsymbol{\beta}$$

#### xtpoisson, re and the robust VCE estimator

Specifying vce(robust) or vce(cluster *clustvar*) causes the Huber/White/sandwich VCE estimator to be calculated for the coefficients estimated in this regression. See [P] **\_robust**, particularly *Introduction* and *Methods* and *formulas*. Wooldridge (2020) and Arellano (2003) discuss this application of the Huber/White/sandwich VCE estimator. As discussed by Wooldridge (2020), Stock and Watson (2008), and Arellano (2003), specifying vce(robust) is equivalent to specifying vce(cluster *panel-var*), where *panelvar* is the variable that identifies the panels.

Clustering on the panel variable produces a consistent VCE estimator when the disturbances are not identically distributed over the panels or there is serial correlation in  $\epsilon_{it}$ .

The cluster–robust VCE estimator requires that there are many clusters and the disturbances are uncorrelated across the clusters. The panel variable must be nested within the cluster variable because of the within-panel correlation that is generally induced by the random-effects transform when there is heteroskedasticity or within-panel serial correlation in the idiosyncratic errors.
