## Description

The following postestimation command is of special interest after `nlogit`:

Command	Description
<code>estat alternatives</code>	alternative summary statistics

The following standard postestimation commands are also available:

Command	Description
<code>estat ic</code>	Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>lrtest</code>	likelihood-ratio test
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	predictions, residuals, influence statistics, and other diagnostic measures
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

## Special-interest postestimation command

`estat alternatives` displays summary statistics about the alternatives in the estimation sample for each level of the tree structure.

## Syntax for predict

```
predict [type] newvar [if] [in] [, statistic hlevel(#) altwise]
```

```
predict [type] { stub* | newvarlist } [if] [in], scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<b>pr</b>	predicted probabilities of choosing the alternatives at all levels of the hierarchy or at level #, where # is specified by <code>hlevel(#)</code> ; the default
<b>xb</b>	linear predictors for all levels of the hierarchy or at level #, where # is specified by <code>hlevel(#)</code>
<b>condp</b>	predicted conditional probabilities at all levels of the hierarchy or at level #, where # is specified by <code>hlevel(#)</code>
<b>iv</b>	inclusive values for levels 2, ..., <code>e(levels)</code> or for <code>hlevel(#)</code>

The inclusive value for the first-level alternatives is not used in estimation; therefore, it is not calculated.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Menu for predict

Statistics > Postestimation > Predictions, residuals, etc.

## Options for predict

Main

**pr** calculates the probability of choosing each alternative at each level of the hierarchy. Use the `hlevel(#)` option to compute the alternative probabilities at level #. When `hlevel(#)` is not specified,  $j$  new variables must be given, where  $j$  is the number of levels, or use the `stub*` option to have `predict` generate  $j$  variables with the prefix `stub` and numbered from 1 to  $j$ . The `pr` option is the default and if one new variable is given, the probability of the bottom-level alternatives are computed. Otherwise, probabilities for all levels are computed and the `stub*` option is still valid.

**xb** calculates the linear prediction for each alternative at each level. Use the `hlevel(#)` option to compute the linear predictor at level #. When `hlevel(#)` is not specified,  $j$  new variables must be given, where  $j$  is the number of levels, or use the `stub*` option to have `predict` generate  $j$  variables with the prefix `stub` and numbered from 1 to  $j$ .

**condp** calculates the conditional probabilities for each alternative at each level. Use the `hlevel(#)` option to compute the conditional probabilities of the alternatives at level #. When `hlevel(#)` is not specified,  $j$  new variables must be given, where  $j$  is the number of levels, or use the `stub*` option to have `predict` generate  $j$  variables with the prefix `stub` and numbered from 1 to  $j$ .

**iv** calculates the inclusive value for each alternative at each level. Use the `hlevel(#)` option to compute the inclusive value at level #. There is no inclusive value at level 1. If `hlevel(#)` is not used,  $j - 1$  new variables are required, where  $j$  is the number of levels, or use `stub*` to have `predict` generate  $j - 1$  variables with the prefix `stub` and numbered from 2 to  $j$ . See [Methods and formulas](#) in [R] **nlogit** for a definition of the inclusive values.

**hlevel(#)** calculates the prediction only for hierarchy level #.

`altwise` specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion. The `xb` option always uses alternativewise deletion.

`scores` calculates the scores for each coefficient in  $e(b)$ . This option requires a new-variable list of length equal to the number of columns in  $e(b)$ . Otherwise, use the `stub*` option to have `predict` generate enumerated variables with prefix `stub`.

## Syntax for estat alternatives

```
estat alternatives
```

## Menu for estat

Statistics > Postestimation > Reports and statistics

## Remarks and examples

[stata.com](http://www.stata.com)

`predict` may be used after `nlogit` to obtain the predicted values of the probabilities, the conditional probabilities, the linear predictions, and the inclusive values for each level of the nested logit model. Predicted probabilities for `nlogit` must be interpreted carefully. Probabilities are estimated for each case as a whole and not for individual observations.

### ▶ Example 1

Continuing with our model in [example 3](#) of [\[R\] nlogit](#), we refit the model and then examine a summary of the alternatives and their frequencies in the estimation sample.

```
. use http://www.stata-press.com/data/r13/restaurant
. nlogitgen type = restaurant(fast: Freebirds | MamasPizza,
> family: CafeEccell | LosNortenos | WingsNmore, fancy: Christophers | MadCows)
  (output omitted)
. nlogit chosen cost rating distance || type: income kids, base(family) ||
> restaurant:, noconst case(family_id)
  (output omitted)
```

```
. estat alternatives
```

```
Alternatives summary for type
```

index	Alternative value	label	Cases present	Frequency selected	Percent selected
1	1	fast	600	27	9.00
2	2	family	900	222	74.00
3	3	fancy	600	51	17.00

```
Alternatives summary for restaurant
```

index	Alternative value	label	Cases present	Frequency selected	Percent selected
1	1	Freebirds	300	12	4.00
2	2	MamasPizza	300	15	5.00
3	3	CafeEccell	300	78	26.00
4	4	LosNortenos	300	75	25.00
5	5	WingsNmore	300	69	23.00
6	6	Christophers	300	27	9.00
7	7	MadCows	300	24	8.00

Next we predict  $p_2 = \Pr(\text{restaurant})$ ;  $p_1 = \Pr(\text{type})$ ;  $\text{condp} = \Pr(\text{restaurant} \mid \text{type})$ ;  $\text{xb}_2$ , the linear prediction for the bottom-level alternatives;  $\text{xb}_1$ , the linear prediction for the first-level alternatives; and  $\text{iv}$ , the inclusive values for the bottom-level alternatives.

```
. predict p*
(option pr assumed)
. predict condp, condp hlevel(2)
. sort family_id type restaurant
. list restaurant type chosen p2 p1 condp in 1/14, sepby(family_id) divider
```

	restaurant	type	chosen	p2	p1	condp
1.	Freebirds	fast	1	.0642332	.1189609	.5399519
