

example 29g — Two-parameter logistic IRT model

[Description](#)[Remarks and examples](#)[References](#)[Also see](#)

Description

We demonstrate a two-parameter logistic (2-PL) IRT model with the same data used in [\[SEM\] example 28g](#):

```
. use http://www.stata-press.com/data/r13/gsem_cfa
(Fictional math abilities data)
```

```
. summarize
```

```
. notes
```

```
_dta:
```

1. Fictional data on math ability and attitudes of 500 students from 20 schools.
2. Variables q1-q8 are incorrect/correct (0/1) on individual math questions.
3. Variables att1-att5 are items from a Likert scale measuring each student's attitude toward math.
4. Variables test1-test4 are test scores from tests of four different aspects of mathematical abilities. Range of scores: 0-100.

These data record results from a fictional instrument measuring mathematical ability. Variables q1 through q8 are the items from the instrument.

For discussions of IRT models and their extensions, see [Embretson and Reise \(2000\)](#), [van der Linden and Hambleton \(1997\)](#), [Skron dal and Rabe-Hesketh \(2004\)](#), and [Rabe-Hesketh, Skron dal, and Pickles \(2004\)](#).

See *Item-response theory (IRT) models* in [\[SEM\] intro 5](#) for background.

Remarks and examples

Remarks are presented under the following headings:

Fitting the 2-PL IRT model

Obtaining predicted difficulty and discrimination

Using `coeflegend` to obtain the symbolic names of the parameters

Graphing item-characteristic curves

Fitting the model with the Builder

Fitting the 2-PL IRT model

When we fit the 1-PL model, we commented that it was similar to the probit measure model we demonstrated in [SEM] [example 27g](#). The 1-PL model differed in that it used logit rather than probit, and it placed constraints on the loadings to judge the difficulty of the individual questions.

The 2-PL model is even more similar to [SEM] [example 27g](#). We still substitute logit for probit, but we only constrain the variance (the latent variable) to be 1—we leave the loadings unconstrained—and we constrain the variance to be 1 merely to aid interpretation. Compared with the 1-PL example, this time we will measure not just difficulty but discrimination as well.

The model we wish to fit is

The results are

```
. gsem (MathAb -> q1-q8), logit var(MathAb@1)
Fitting fixed-effects model:
Iteration 0:   log likelihood = -2750.3114
Iteration 1:   log likelihood = -2749.3709
Iteration 2:   log likelihood = -2749.3708
Refining starting values:
Grid node 0:   log likelihood = -2645.8536
Fitting full model:
Iteration 0:   log likelihood = -2645.8536
Iteration 1:   log likelihood = -2637.4315
Iteration 2:   log likelihood = -2637.3761
Iteration 3:   log likelihood = -2637.3759
Generalized structural equation model           Number of obs   =       500
Log likelihood = -2637.3759
( 1)  [var(MathAb)]_cons = 1
```

var(MathAb)	1	(constrained)				

Notes:

1. In the above model, we constrain the variance MathAb to be 1 by typing var(MathAb@1).
2. Had we not constrained var(MathAb@1), the path coefficient from MathAb to q1 would have automatically constrained to be 1 to set the latent variable's scale. When we applied

`var(MathAb@1)`, the automatic constraint was automatically released. Setting the variance of a latent variable is another way of setting its scale.

3. We set `var(MathAb@1)` to ease interpretation. Our latent variable, `MathAb`, is now $N(0, 1)$.
4. Factor loadings, which are the slopes, are estimated above for each question.
5. The slopes reveal how discriminating each question is in regard to mathematical ability. Question 1 is the most discriminating, and question 4 is the least discriminating.
6. In the 1-PL model, the negative of the intercept is a measure of difficulty if we constrain the slopes to be equal to each other. To measure difficulty in the 2-PL model, we divide the negative of the intercept by the unconstrained slope. If you do the math, you will discover that question 2 is the most difficult and question 3 is the least difficult. It will be easier, however, merely to continue reading; in the next section, we show an easy way to calculate the discrimination and difficulty for all the questions.

Obtaining predicted difficulty and discrimination

For each question, discrimination is defined as the question's slope coefficient.

For each question, difficulty is defined as the negative of the question's intercept divided by its slope.

Here is how we quickly obtain all the discrimination and difficulty values in a single, easy-to-read table:

```
. preserve
. drop _all
. set obs 8
obs was 0, now 8
. gen str question = "q" + strofreal(_n)
. gen diff = .
(8 missing values generated)
. gen disc = .
(8 missing values generated)
. forvalues i = 1/8 {
  2. replace diff = -_b[q'i':_cons] / _b[q'i':MathAb] in 'i'
  3. replace disc = _b[q'i':MathAb] in 'i'
  4. }

7.	q7	-0.0880	1.1973	2	6
8.	q8	0.0316	0.8462	4	4

```
. restore
```

Notes:

1. Our goal in the Stata code above is to create a dataset containing one observation for each question. The dataset will contain the following variables: `question` containing `q1`, `q2`, ...; `diff` and `disc` containing each question's difficulty and discrimination values; and `rank_disc` and `rank_diff` containing the ranks of those discrimination and difficulty values.
2. We first `preserved` the current data before tossing out the data in memory. Later, after making and displaying our table, we `restored` the original contents.
3. We then made an 8-observation, 0-variable dataset (`set obs 8`) and added variables to it. We created string variable `question` containing `q1`, `q2`, ...
4. We were ready to create variables `diff` and `disc`. They are defined in terms of estimated coefficients, and we had no idea what the names of those coefficients were. To find out, we typed `gsem, coeflegend` (output shown below). We quickly learned that the slope coefficients had names like `_b[q1:MathAb]`, `_b[q2:MathAb]`, ..., and the intercepts had names like `_b[q1:_cons]`, `_b[q2:_cons]`, ...
5. We created new variables `diff` and `disc` containing missing values and then created a `forvalues` loop to fill in the new variables. Notice the odd-looking 'i' inside the loop. 'i' is the way that you say "substitute the value of (local macro) i here".
6. We put a display format on new variables `diff` and `disc` so that when we listed them, they would be easier to read.
7. We created the rank of each variable by using the `egen` command.
8. We `listed` the results. So now you do not have to do the math to see that question 2 is the most difficult (it has `rank_diff = 8`) and question 3 is the least (it has `rank_diff = 1`).
9. We typed `restore`, bringing our original data back into memory and leaving ourselves in a position to continue with this example.

Using `coeflegend` to obtain the symbolic names of the parameters

In the section above, we did not retype coefficient values to obtain discrimination and difficulty. After estimation, coefficient values are stored in `_b[name]`. To find out what the names are, type `gsem, coeflegend`. Here are the results:

```
. gsem, coeflegend
Generalized structural equation model           Number of obs   =           500
Log likelihood = -2637.3759
( 1) [var(MathAb)]_cons = 1
```

	Coef.	Legend
q1 <- MathAb _cons	1.466636 .0373363	_b[q1:MathAb] _b[q1:_cons]
q2 <- MathAb _cons	.5597118 -.4613391	_b[q2:MathAb] _b[q2:_cons]
q3 <- MathAb _cons	.73241 .1533363	_b[q3:MathAb] _b[q3:_cons]
q4 <- MathAb _cons	.4839501 -.3230667	_b[q4:MathAb] _b[q4:_cons]
q5 <- MathAb _cons	1.232244 -.0494684	_b[q5:MathAb] _b[q5:_cons]
q6 <- MathAb _cons	.946535 -.3147231	_b[q6:MathAb] _b[q6:_cons]
q7 <- MathAb _cons	1.197317 .1053405	_b[q7:MathAb] _b[q7:_cons]
q8 <- MathAb _cons	.8461858 -.026705	_b[q8:MathAb] _b[q8:_cons]
var(MathAb)	1	_b[var(MathAb):_cons]

Graphing item–characteristic curves

We showed you the item–characteristic curves in [SEM] [example 28g](#), so we will show them to you again. Graphs of item–characteristic curves plot the probability of a correct answer against the latent trait, which in this case is math ability.

We obtain the probabilities of a correct answer (the values of the latent variable) just as we did previously,

```
. predict pr2pl*, pr
(using 7 quadrature points)
. predict ability2pl, latent(MathAb)
(using 7 quadrature points)
```

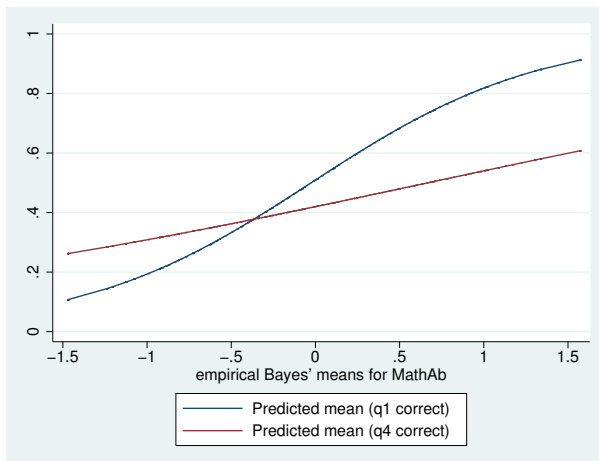

and we graph the curves just as we did previously, too. Here are all eight curves on one graph:

```
. twoway line pr2p1* ability2p1, sort xlabel(-1.5(.5)1.5)
```

In [SEM] example 28g, we showed a graph for the most and least difficult questions. This time we show a graph for the most and least discriminating questions:

```
. twoway line pr2p11 pr2p14 ability2p1, sort xlabel(-1.5(.5)1.5)
```

Here the curves are not parallel because the discrimination has not been constrained to be equal across the questions. Question 1 has a steeper slope, so it is more discriminating.

Fitting the model with the Builder

Use the diagram in *Fitting the 2-PL IRT model* above for reference.

1. Open the dataset.

In the Command window, type

```
. use http://www.stata-press.com/data/r13/gsem_cfa
```

2. Open a new Builder diagram.

Select menu item **Statistics > SEM (structural equation modeling) > Model building and estimation**.

3. Put the Builder in gsem mode by clicking on the  button.

4. Create the measurement component for MathAb.

Select the Add Measurement Component tool, , and then click in the diagram about one-third of the way down from the top and slightly left of the center.

In the resulting dialog box,

- change the *Latent variable name* to MathAb;
- select q1, q2, q3, q4, q5, q6, q7, and q8 by using the *Measurement variables* control;
- check *Make measurements generalized*;
- select Bernoulli, Logit in the *Family/Link* control;
- select Down in the *Measurement direction* control;
- click on **OK**.

If you wish, move the component by clicking on any variable and dragging it.

5. Constrain the variance of MathAb to 1.

- Choose the Select tool, .
- Click on the oval for MathAb. In the Contextual Toolbar, type 1 in the  box and press *Enter*.

6. Estimate.

Click on the **Estimate** button, , in the Standard Toolbar, and then click on **OK** in the resulting *GSEM estimation options* dialog box.

You can open a completed diagram in the Builder by typing

```
. webgetsem gsem_irt3
```
