Remarks and examples

## Description

The following postestimation commands are available after **xtcloglog**:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of estimates
<code>estat ic</code> <sup>1</sup>	Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>forecast</code> <sup>2</sup>	dynamic forecasts and simulations
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of coefficients
<code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients
<code>predict</code>	predictions, residuals, influence statistics, and other diagnostic measures
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of estimates
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

<sup>1</sup> `estat ic` is not appropriate after `xtcloglog`, pa.

<sup>2</sup> `forecast` is not appropriate with `mi` estimation results.

## Syntax for predict

*Random-effects (RE) model*

```
predict [type] newvar [if] [in] [, RE_statistic nooffset]
```

*Population-averaged (PA) model*

```
predict [type] newvar [if] [in] [, PA_statistic nooffset]
```

*RE\_statistic* Description

## Main

<b>xb</b>	linear prediction; the default
<b>pu0</b>	probability of a positive outcome
<b>stdp</b>	standard error of the linear prediction

*PA\_statistic* Description

## Main

<b>mu</b>	predicted probability of <i>depvar</i> ; considers the <code>offset()</code> ; the default
<b>rate</b>	predicted probability of <i>depvar</i>
<b>xb</b>	linear prediction
<b>stdp</b>	standard error of the linear prediction
<b>score</b>	first derivative of the log likelihood with respect to $\mathbf{x}_j\beta$

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

## Menu for predict

Statistics > Postestimation > Predictions, residuals, etc.

## Options for predict

## Main

**xb** calculates the linear prediction. This is the default for the random-effects model.

**pu0** calculates the probability of a positive outcome, assuming that the random effect for that observation's panel is zero ( $\nu = 0$ ). This may not be similar to the proportion of observed outcomes in the group.

**stdp** calculates the standard error of the linear prediction.

**mu** and **rate** both calculate the predicted probability of *depvar*. **mu** takes into account the `offset()`. **rate** ignores those adjustments. **mu** and **rate** are equivalent if you did not specify `offset()`. **mu** is the default for the population-averaged model.

**score** calculates the equation-level score,  $u_j = \partial \ln L_j(\mathbf{x}_j\beta) / \partial(\mathbf{x}_j\beta)$ .

**nooffset** is relevant only if you specified `offset(varname)` for **xtcloglog**. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_{it}\beta$  rather than  $\mathbf{x}_{it}\beta + \text{offset}_{it}$ .

## Remarks and examples

[stata.com](#)

### ▷ Example 1

In example 1 of [XT] **xtcloglog**, we fit the model

```
. use http://www.stata-press.com/data/r13/union
(NLS Women 14-24 in 1968)
. xtcloglog union age grade not_smsa south##c.year, pa
(output omitted)
```

Here we use **margins** to determine the average effect each regressor has on the probability of a positive response in the sample.

```
. margins, dydx(*)
Average marginal effects                                         Number of obs     =      26200
Model VCE       : Conventional
Expression     : Pr(union != 0), predict()
dy/dx w.r.t.  : age grade not_smsa 1.south year
```

	Delta-method					
	dy/dx	Std. Err.	z	P> z	[95% Conf. Interval]	
age	.0028297	.0014952	1.89	0.058	-.000101	.0057603
grade	.0101144	.0017498	5.78	0.000	.0066848	.013544
not_smsa	-.0192384	.0079304	-2.43	0.015	-.0347818	-.0036951
1.south	-.0913197	.0073101	-12.49	0.000	-.1056473	-.0769921
year	-.0012694	.001534	-0.83	0.408	-.004276	.0017371

Note: dy/dx for factor levels is the discrete change from the base level.

We see that an additional year of schooling (covariate **grade**) increases the probability that a woman belongs to a union by an average of about one percentage point.
