### *RE/FE\_options*

### Description

#### Model

|  |   |
|--|---|
| <b><u>noconstant</u></b>               | suppress constant term; not available with <b>fe</b>                  |
| <b>re</b>                              | use random-effects estimator; the default                             |
| <b>fe</b>                              | use fixed-effects estimator   |
| <b>exposure(<i>varname</i>)</b>        | include <i>ln(varname)</i> in model with coefficient constrained to 1 |
| <b>offset(<i>varname</i>)</b>          | include <i>varname</i> in model with coefficient constrained to 1     |
| <b>constraints(<i>constraints</i>)</b> | apply specified linear constraints                                    |
| <b><u>collinear</u></b>                | keep collinear variables  |

#### SE

|                     |   |
|---------------------|---|
| <b>vce(vcetype)</b> | <i>vcetype</i> may be <b>oim</b> , <b>bootstrap</b> , or <b>jackknife</b> |
|---------------------|---|

#### Reporting

|                        |  |
|------------------------|--|
| <b>level(#)</b>        | set confidence level; default is <b>level(95)</b>  |
| <b>irr</b>             | report incidence-rate ratios   |
| <b>noskip</b>          | perform overall model test as a likelihood-ratio test  |
| <b>nocnsreport</b>     | do not display constraints   |
| <b>display_options</b> | control column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |

#### Maximization

|                         |   |
|-------------------------|---|
| <b>maximize_options</b> | control the maximization process; seldom used |
| <b>coeflegend</b>       | display legend instead of statistics          |

| <i>PA_options</i>                  | Description  |
|------------------------------------|--|
| <b>Model</b>                       |  |
| <u>noconstant</u>                  | suppress constant term   |
| <u>pa</u>                          | use population-averaged estimator  |
| <u>exposure</u> ( <i>varname</i> ) | include <i>ln(varname)</i> in model with coefficient constrained to 1  |
| <u>offset</u> ( <i>varname</i> )   | include <i>varname</i> in model with coefficient constrained to 1  |
| <b>Correlation</b>                 |  |
| <u>corr</u> ( <i>correlation</i> ) | within-panel correlation structure   |
| <u>force</u>                       | estimate even if observations unequally spaced in time   |
| <b>SE/Robust</b>                   |  |
| <u>vce</u> ( <i>vcetype</i> )      | <i>vcetype</i> may be conventional, <u>robust</u> , <u>bootstrap</u> , or <u>jackknife</u>   |
| <u>nmp</u>                         | use divisor $N - P$ instead of the default $N$   |
| <u>scale</u> ( <i>parm</i> )       | overrides the default scale parameter; <i>parm</i> may be x2, dev, phi, or #   |
| <b>Reporting</b>                   |  |
| <u>level</u> (#)                   | set confidence level; default is <b>level(95)</b>  |
| <u>irr</u>                         | report incidence-rate ratios   |
| <i>display_options</i>             | control column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| <b>Optimization</b>                |  |
| <u>optimize_options</u>            | control the optimization process; seldom used  |
| <u>coeflegend</u>                  | display legend instead of statistics   |

| <i>correlation</i>          | Description               |
|-----------------------------|---------------------------|
| <u>exchangeable</u>         | exchangeable              |
| <u>independent</u>          | independent               |
| <u>unstructured</u>         | unstructured              |
| <u>fixed</u> <i>matname</i> | user-specified            |
| <u>ar</u> #                 | autoregressive of order # |
| <u>stationary</u> #         | stationary of order #     |
| <u>nonstationary</u> #      | nonstationary of order #  |

A panel variable must be specified. For **xtnbreg**, **pa**, correlation structures other than **exchangeable** and **independent** require that a time variable also be specified. Use **xtset**; see [XT] **xtset**.

*indepvars* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

*by*, *mi estimate*, and *statsby* are allowed; see [U] 11.1.10 Prefix commands. *fp* is allowed for the random-effects and fixed-effects models.

*vce(bootstrap)* and *vce(jackknife)* are not allowed with the *mi estimate* prefix; see [MI] **mi estimate**.

*iweights*, *fweights*, and *pweights* are allowed for the population-averaged model, and *iweights* are allowed in the random-effects and fixed-effects models; see [U] 11.1.6 weight. Weights must be constant within panel.

**coeflegend** does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Description

xtnbreg fits random-effects overdispersion models, conditional fixed-effects overdispersion models, and population-averaged negative binomial models. Here “random effects” and “fixed effects” apply to the distribution of the dispersion parameter, not to the  $x\beta$  term in the model. In the random-effects and fixed-effects overdispersion models, the dispersion is the same for all elements in the same group (that is, elements with the same value of the panel variable). In the random-effects model, the dispersion varies randomly from group to group, such that the inverse of one plus the dispersion follows a Beta( $r, s$ ) distribution. In the fixed-effects model, the dispersion parameter in a group can take on any value, because a conditional likelihood is used in which the dispersion parameter drops out of the estimation.

By default, the population-averaged model is an equal-correlation model; xtnbreg, pa assumes corr(exchangeable). See [XT] xtgee for information on how to fit other population-averaged models.

## Options for RE/FE models

### Model

`noconstant`; see [R] estimation options.

`re` requests the random-effects estimator, which is the default.

`fe` requests the conditional fixed-effects estimator.

`exposure(varname)`, `offset(varname)`, `constraints(constraints)`, `collinear`; see [R] estimation options.

### SE

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`) and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [XT] vce\_options.

### Reporting

`level(#)`; see [R] estimation options.

`irr` reports exponentiated coefficients  $e^b$  rather than coefficients  $b$ . For the negative binomial model, exponentiated coefficients have the interpretation of incidence-rate ratios.

`noskip`; see [R] estimation options.

`nocnsreport`; see [R] estimation options.

`display_options`: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] estimation options.

**Maximization**

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, [no] `log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **maximize**. These options are seldom used.

The following option is available with `xtnbreg` but is not shown in the dialog box:  
`coeflegend`; see [R] **estimation options**.

## Options for PA model

**Model**

`noconstant`; see [R] **estimation options**.

`pa` requests the population-averaged estimator.

`exposure(varname)`, `offset(varname)`; see [R] **estimation options**.

**Correlation**

`corr(correlation)` specifies the within-panel correlation structure; the default corresponds to the equal-correlation model, `corr(exchangeable)`.

When you specify a correlation structure that requires a lag, you indicate the lag after the structure's name with or without a blank; for example, `corr(ar 1)` or `corr(ar1)`.

If you specify the fixed correlation structure, you specify the name of the matrix containing the assumed correlations following the word `fixed`, for example, `corr(fixed myr)`.

`force` specifies that estimation be forced even though the time variable is not equally spaced. This is relevant only for correlation structures that require knowledge of the time variable. These correlation structures require that observations be equally spaced so that calculations based on lags correspond to a constant time change. If you specify a time variable indicating that observations are not equally spaced, the (time dependent) model will not be fit. If you also specify `force`, the model will be fit, and it will be assumed that the lags based on the data ordered by the time variable are appropriate.

**SE/Robust**

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`conventional`), that are robust to some kinds of misspecification (`robust`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [XT] **vce\_options**.

`vce(conventional)`, the default, uses the conventionally derived variance estimator for generalized least-squares regression.

`nmp`, `scale(x2 | dev | phi | #)`; see [XT] **vce\_options**.

**Reporting**

`level(#)`; see [R] **estimation options**.

`irr` reports exponentiated coefficients  $e^b$  rather than coefficients  $b$ . For the negative binomial model, exponentiated coefficients have the interpretation of incidence-rate ratios.

*display\_options*: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] estimation options.

### Optimization

*optimize\_options* control the iterative optimization process. These options are seldom used.

`iterate(#)` specifies the maximum number of iterations. When the number of iterations equals `#`, the optimization stops and presents the current results, even if convergence has not been reached. The default is `iterate(100)`.

`tolerance(#)` specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to `#`, the optimization process is stopped. `tolerance(1e-6)` is the default.

`nolog` suppresses display of the iteration log.

`trace` specifies that the current estimates be printed at each iteration.

The following option is available with `xtnbreg` but is not shown in the dialog box:

`coeflegend`; see [R] estimation options.

[stata.com](#)

## Remarks and examples

`xtnbreg` is a convenience command if you want the population-averaged model. Typing

```
. xtnbreg ..., ... pa exposure(time)
```

is equivalent to typing

```
. xtgee ..., ... family(nbinomial) link(log) corr(exchangeable) exposure(time)
```

See also [XT] `xtgee` for information about `xtnbreg`.

By default, or when `re` is specified, `xtnbreg` fits a maximum-likelihood random-effects overdispersion model.

### Example 1

You have (fictional) data on injury “incidents” incurred among 20 airlines in each of 4 years. (Incidents range from major injuries to exceedingly minor ones.) The government agency in charge of regulating airlines has run an experimental safety training program, and, in each of the years, some airlines have participated and some have not. You now wish to analyze whether the “incident” rate is affected by the program. You choose to estimate using random-effects negative binomial regression, as the dispersion might vary across the airlines for unidentified airline-specific reasons. Your measure of exposure is passenger miles for each airline in each year.

```
. use http://www.stata-press.com/data/r13/airacc
. xtnbreg i_cnt inprog, exposure(pmiles) irr
Fitting negative binomial (constant dispersion) model:
Iteration 0: log likelihood = -293.57997
Iteration 1: log likelihood = -293.57997
(output omitted)
Fitting full model:
Iteration 0: log likelihood = -295.72633
Iteration 1: log likelihood = -270.49929 (not concave)
(output omitted)

Random-effects negative binomial regression          Number of obs      =     80
Group variable: airline                            Number of groups   =      20
Random effects u_i ~ Beta                         Obs per group: min =       4
                                                    avg =     4.0
                                                    max =       4
Wald chi2(1)                               =     2.04
Log likelihood = -265.38202                    Prob > chi2        =    0.1532
```

| i_cnt      | IRR      | Std. Err.  | z     | P> z  | [95% Conf. Interval] |
|------------|----------|------------|-------|-------|----------------------|
| inprog     | .911673  | .0590277   | -1.43 | 0.153 | .8030206 1.035027    |
| _cons      | .0367524 | .0407032   | -2.98 | 0.003 | .0041936 .3220983    |
| ln(pmiles) | 1        | (exposure) |       |       |                      |
| /ln_r      | 4.794991 | .951781    |       |       | 2.929535 6.660448    |
| /ln_s      | 3.268052 | .4709033   |       |       | 2.345098 4.191005    |
| r          | 120.9033 | 115.0735   |       |       | 18.71892 780.9007    |
| s          | 26.26013 | 12.36598   |       |       | 10.4343 66.08918     |

Likelihood-ratio test vs. pooled: chibar2(01) = 19.03 Prob>=chibar2 = 0.000

In the output above, the /ln\_r and /ln\_s lines refer to  $\ln(r)$  and  $\ln(s)$ , where the inverse of one plus the dispersion is assumed to follow a Beta( $r, s$ ) distribution. The output also includes a likelihood-ratio test, which compares the panel estimator with the pooled estimator (that is, a negative binomial estimator with constant dispersion).

You find that the incidence rate for accidents is not significantly different for participation in the program and that the panel estimator is significantly different from the pooled estimator.

We may alternatively fit a fixed-effects overdispersion model:

```
. xtnbreg i_cnt inprog, exposure(pmiles) irr fe nolog
Conditional FE negative binomial regression      Number of obs      =      80
Group variable: airline                         Number of groups   =      20
                                                Obs per group: min =       4
                                                               avg =      4.0
                                                               max =       4
                                                Wald chi2(1)     =     2.11
Log likelihood = -174.25143                      Prob > chi2      = 0.1463
```

| i_cnt      | IRR      | Std. Err.  | z     | P> z  | [95% Conf. Interval] |
|------------|----------|------------|-------|-------|----------------------|
| inprog     | .9062669 | .0613917   | -1.45 | 0.146 | .793587 1.034946     |
| _cons      | .0329025 | .0331262   | -3.39 | 0.001 | .0045734 .2367111    |
| ln(pmiles) | 1        | (exposure) |       |       |                      |

## ▷ Example 2

We rerun our [previous example](#), but this time we fit a robust equal-correlation population-averaged model:

```
. xtnbreg i_cnt inprog, exposure(pmiles) irr vce(robust) pa
Iteration 1: tolerance = .02499392
Iteration 2: tolerance = .0000482
Iteration 3: tolerance = 2.929e-07
GEE population-averaged model
Group variable: airline                         Number of obs      =      80
Link: log                                         Number of groups   =      20
Family: negative binomial(k=1)                  Obs per group: min =       4
Correlation: exchangeable                      avg =      4.0
                                         max =       4
Scale parameter: 1                               Wald chi2(1)     =     1.28
                                                       Prob > chi2      = 0.2571
                                                       (Std. Err. adjusted for clustering on airline)
```

| i_cnt      | IRR      | Std. Err.  | z      | P> z  | [95% Conf. Interval] |
|------------|----------|------------|--------|-------|----------------------|
| inprog     | .927275  | .0617857   | -1.13  | 0.257 | .8137513 1.056636    |
| _cons      | .0080211 | .0004117   | -94.02 | 0.000 | .0072535 .00887      |
| ln(pmiles) | 1        | (exposure) |        |       |                      |

We compare this with a pooled estimator with clustered robust-variance estimates:

```
. nbreg i_cnt inprog, exposure(pmiles) irr vce(cluster airline)
```

Fitting Poisson model:

Iteration 0: log pseudolikelihood = -293.57997

Iteration 1: log pseudolikelihood = -293.57997

Fitting constant-only model:

Iteration 0: log pseudolikelihood = -335.13615

Iteration 1: log pseudolikelihood = -279.43327

Iteration 2: log pseudolikelihood = -276.09296

Iteration 3: log pseudolikelihood = -274.84036

Iteration 4: log pseudolikelihood = -274.81076

Iteration 5: log pseudolikelihood = -274.81075

Fitting full model:

Iteration 0: log pseudolikelihood = -274.56985

Iteration 1: log pseudolikelihood = -274.55077

Iteration 2: log pseudolikelihood = -274.55077

Negative binomial regression Number of obs = 80

Dispersion = mean Wald chi2(1) = 0.60

Log pseudolikelihood = -274.55077 Prob > chi2 = 0.4369

(Std. Err. adjusted for 20 clusters in airline)

## Methods and formulas

`xtnbreg`, `pa` reports the population-averaged results obtained by using `xtgee`, `family(nbinomial)` `link(log)` to obtain estimates. See [XT] `xtgee` for details on the methods and formulas.

For the random-effects and fixed-effects overdispersion models, let  $y_{it}$  be the count for the  $t$ th observation in the  $i$ th group. We begin with the model  $y_{it} | \gamma_{it} \sim \text{Poisson}(\gamma_{it})$ , where  $\gamma_{it} | \delta_i \sim \text{gamma}(\lambda_{it}, \delta_i)$  with  $\lambda_{it} = \exp(\mathbf{x}_{it}\beta + \text{offset}_{it})$  and  $\delta_i$  is the dispersion parameter. This yields the model

$$\Pr(Y_{it} = y_{it} | \mathbf{x}_{it}, \delta_i) = \frac{\Gamma(\lambda_{it} + y_{it})}{\Gamma(\lambda_{it})\Gamma(y_{it} + 1)} \left( \frac{1}{1 + \delta_i} \right)^{\lambda_{it}} \left( \frac{\delta_i}{1 + \delta_i} \right)^{y_{it}}$$

(See Hausman, Hall, and Griliches [1984, eq. 3.1, 922]; our  $\delta$  is the inverse of their  $\delta$ .) Looking at within-panel effects only, we find that this specification yields a negative binomial model for the  $i$ th group with dispersion (variance divided by the mean) equal to  $1 + \delta_i$ , that is, constant dispersion within group. This parameterization of the negative binomial model differs from the default parameterization of `nbreg`, which has dispersion equal to  $1 + \alpha \exp(\mathbf{x}\beta + \text{offset})$ ; see [R] `nbreg`.

For a random-effects overdispersion model, we allow  $\delta_i$  to vary randomly across groups; namely, we assume that  $1/(1 + \delta_i) \sim \text{Beta}(r, s)$ . The joint probability of the counts for the  $i$ th group is

$$\begin{aligned} \Pr(Y_{i1} = y_{i1}, \dots, Y_{in_i} = y_{in_i} | \mathbf{X}_i) &= \int_0^\infty \prod_{t=1}^{n_i} \Pr(Y_{it} = y_{it} | \mathbf{x}_{it}, \delta_i) f(\delta_i) d\delta_i \\ &= \frac{\Gamma(r+s)\Gamma(r + \sum_{t=1}^{n_i} \lambda_{it})\Gamma(s + \sum_{t=1}^{n_i} y_{it})}{\Gamma(r)\Gamma(s)\Gamma(r+s + \sum_{t=1}^{n_i} \lambda_{it} + \sum_{t=1}^{n_i} y_{it})} \prod_{t=1}^{n_i} \frac{\Gamma(\lambda_{it} + y_{it})}{\Gamma(\lambda_{it})\Gamma(y_{it} + 1)} \end{aligned}$$

for  $\mathbf{X}_i = (\mathbf{x}_{i1}, \dots, \mathbf{x}_{in_i})$  and where  $f$  is the probability density function for  $\delta_i$ . The resulting log likelihood is

$$\begin{aligned} \ln L &= \sum_{i=1}^n w_i \left[ \ln \Gamma(r+s) + \ln \Gamma\left(r + \sum_{k=1}^{n_i} \lambda_{ik}\right) + \ln \Gamma\left(s + \sum_{k=1}^{n_i} y_{ik}\right) - \ln \Gamma(r) - \ln \Gamma(s) \right. \\ &\quad \left. - \ln \Gamma\left(r+s + \sum_{k=1}^{n_i} \lambda_{ik} + \sum_{k=1}^{n_i} y_{ik}\right) + \sum_{t=1}^{n_i} \left\{ \ln \Gamma(\lambda_{it} + y_{it}) - \ln \Gamma(\lambda_{it}) - \ln \Gamma(y_{it} + 1) \right\} \right] \end{aligned}$$

where  $\lambda_{it} = \exp(\mathbf{x}_{it}\beta + \text{offset}_{it})$  and  $w_i$  is the weight for the  $i$ th group (Hausman, Hall, and Griliches 1984, eq. 3.5, 927).

For the fixed-effects overdispersion model, we condition the joint probability of the counts for each group on the sum of the counts for the group (that is, the observed  $\sum_{t=1}^{n_i} y_{it}$ ). This yields

$$\begin{aligned} \Pr(Y_{i1} = y_{i1}, \dots, Y_{in_i} = y_{in_i} | \mathbf{X}_i, \sum_{t=1}^{n_i} Y_{it} = \sum_{t=1}^{n_i} y_{it}) \\ = \frac{\Gamma(\sum_{t=1}^{n_i} \lambda_{it})\Gamma(\sum_{t=1}^{n_i} y_{it} + 1)}{\Gamma(\sum_{t=1}^{n_i} \lambda_{it} + \sum_{t=1}^{n_i} y_{it})} \prod_{t=1}^{n_i} \frac{\Gamma(\lambda_{it} + y_{it})}{\Gamma(\lambda_{it})\Gamma(y_{it} + 1)} \end{aligned}$$

The conditional log likelihood is

$$\ln L = \sum_{i=1}^n w_i \left[ \ln \Gamma \left( \sum_{t=1}^{n_i} \lambda_{it} \right) + \ln \Gamma \left( \sum_{t=1}^{n_i} y_{it} + 1 \right) - \ln \Gamma \left( \sum_{t=1}^{n_i} \lambda_{it} + \sum_{t=1}^{n_i} y_{it} \right) \right. \\ \left. + \sum_{t=1}^{n_i} \left\{ \ln \Gamma(\lambda_{it} + y_{it}) - \ln \Gamma(\lambda_{it}) - \ln \Gamma(y_{it} + 1) \right\} \right]$$

See [Hausman, Hall, and Griliches \(1984\)](#) for a more thorough development of the random-effects and fixed-effects models. Also see [Cameron and Trivedi \(2013\)](#) for a good textbook treatment of this model.
