Title

mi append — Append mi data

Description	Menu	Syntax	Options
Remarks and examples	Stored results	Also see	

Description

mi append is append for mi data; see [D] **append** for a description of appending datasets.

Menu

Statistics > Multiple imputation

Syntax

mi append using *filename* [, *options*]

options	Description
generate(*newvar*)	create *newvar*; 0 = master, 1 = using
nolabel	do not copy value labels from using
nonotes	do not copy notes from using
force	string $\leftrightarrow$ numeric not type mismatch error
noupdate	see [MI] **noupdate option**

Notes:

1. Jargon:
   master = data in memory
   using = data on disk (*filename*)

2. Master must be mi set; using may be mi set.

3. mi append is logically equivalent to append; see [D] **append**. The resulting data have $M = \max(M_{\text{master}}, M_{\text{using}})$, not their sum. See [MI] **mi add** to append imputations holding $m = 0$ constant.

4. mi append syntactically differs from append in that multiple using files may not be specified and the keep(*varlist*) option is not allowed.

5. *filename* must be enclosed in double quotes if *filename* contains blanks or other special characters.

Options

generate(*newvar*) specifies that new variable *newvar* be created containing 0 for observations from the master and 1 for observations from the using.

1

nolabel prevents copying the value-label definitions from the using data to the master. Even if you do not specify this option, label definitions from the using never replace those of the master.

nonotes prevents any notes in the using from being incorporated into the master; see [D] **notes**.

force allows string variables to be appended to numeric variables and vice versa. The results of such type mismatches are, of course, missing values. Default behavior is to issue an error message rather than append datasets with such violently differing types.

noupdate in some cases suppresses the automatic mi update this command might perform; see [MI] **noupdate option**.

Remarks and examples   stata.com

Use mi append when you would use append if the data were not mi.

Remarks are presented under the following headings:

> Adding new observations
> Adding new observations and imputations
> Adding new observations and imputations, M unequal
> Treatment of registered variables

Adding new observations

Assume that file mymi.dta contains data on three-quarters of the patients in the ICU. The data are mi set and $M = 5$. File remaining.dta arrives containing the remaining patients. The data are not mi set. To combine the datasets, you type

```
. use mymi, clear
. mi append using remaining
```

The original mi data had $M = 5$ imputations, and so do the resulting data. If the new data contain no missing values of the imputed variables, you are ready to go. Otherwise, you will need to impute values for the new data.

Adding new observations and imputations

Assume that file westwing.dta contains data on patients in the west wing of the ICU. File eastwing.dta contains data on patients in the east wing of the ICU. Both datasets are mi set with $M = 5$. You originally intended to analyze the datasets separately, but you now wish to combine them. You type

```
. use westwing, clear
. mi append using eastwing
```

The original data had $M = 5$ imputations, and so do the resulting data.

The data for $m = 0$ are the result of running an ordinary append on the two $m = 0$ datasets.

The data for $m = 1$ are also the result of running an ordinary append, this time on the two $m = 1$ datasets. Thus the result is a combination of observations of westwing.dta and eastwing.dta in the same way that $m = 0$ is. Imputations for observations that previously existed are obtained from westwing.dta, and imputations for the newly appended observations are obtained from eastwing.dta.

Adding new observations and imputations, M unequal

Consider the same situation as above, but this time assume $M = 5$ in westwing.dta and $M = 4$ in eastwing.dta. The combined result will still have $M = 5$. Imputed values in $m = 5$ will be missing for imputed variables from observations in westwing.dta.

Treatment of registered variables

It is possible that the two datasets will have variables registered inconsistently.

Variables registered as imputed in either dataset will be registered as imputed in the final result regardless of how they were registered (or unregistered) in the other dataset.

Barring that, variables registered as passive in either dataset will be registered as passive in the final result.

Barring that, variables registered as regular in either dataset will be registered as regular in the final result.

Stored results

mi append stores the following in r():

Scalars
    r(N_master)   number of observations in $m=0$ in master
    r(N_using)   number of observations in $m=0$ in using
    r(M_master)   number of imputations (M) in master
    r(M_using)   number of imputations (M) in using

Macros
    r(newvars)   new variables added

Thus values in the resulting data are

$$
\begin{aligned}
N &= \text{\# of observations in } m = 0 \\
&= \texttt{r(N\_master)} + \texttt{r(N\_using)}
\end{aligned}
$$

$$
\begin{aligned}
k &= \text{\# of variables} \\
&= k\_master + \text{'}:\texttt{word count 'r(newvars)''}
\end{aligned}
$$

$$
\begin{aligned}
M &= \text{\# of imputations} \\
&= \max(\texttt{r(M\_master)}, \texttt{r(M\_using)})
\end{aligned}
$$
