New meta-analysis features in Stata 18

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

Introduction

Meta-analysis for prevalence Multilevel meta-analysis Conclusion

Introduction

STATA 18

æ

New meta-analysis features in Stata 18

- Meta-analysis for prevalence
 - Stata's meta suite of commands now supports one-sample binary data, allowing you to estimate an overall proportion or prevalence of a symptom, disease, infection, or some other event
- Multilevel meta-analysis
 - You can now perform meta-analysis with effect sizes that are nested within higher-level groupings, such as regions or schools

Overview

- Meta-analysis for prevalence
 - Effect-size computation
 - Summarizing meta-analysis data
- Multilevel meta-analysis
 - Meta-regression
 - Exploring heterogeneity at different levels
 - Sensitivity analysis

What is meta-analysis?

- This is a statistical technique for combining the results from several similar studies.
- The goal is to provide a single estimate of the effect of interest.
- If results vary widely across studies, the goal is then to understand the inconsistencies in the results.

Introduction

Meta-analysis for prevalence Multilevel meta-analysis Conclusion

Chronic kidney disease

| | Number of | | | Proportion | Weight |
|----------|-----------|-------|---------------|--------------------|--------|
| Study | events | Total | | with 95% CI | (%) |
| Study 1 | 208 | 1,200 | | 0.17 [0.15, 0.20] | 6.70 |
| Study 2 | 277 | 1,125 | | 0.25 [0.22, 0.27] | 6.70 |
| Study 3 | 54 | 1,000 | - | 0.05 [0.04, 0.07] | 6.69 |

Meta-analysis goals

- The department of health needs to know the prevalence of chronic kidney disease (CKD) because it is a risk factor for cardiovascular disease
- Our goal is to report a single estimate of the prevalence of CKD
 We assume that the effect sizes are independent across studies.
- If we observe substantial variation across the studies, we instead focus on trying to explain this variation
- Perhaps the age of study participants or some other study-level covariates can explain the discrepancies

New meta-analysis features in Stata 18

Random effects meta-analysis model

K independent studies; each reports the number of events observed and the sample size of the study, allowing us to compute the following:

- an estimate, $\hat{\theta}_j$, of the true (unknown) effect size θ_j
- an estimate, $\hat{\sigma}_j$, of its standard error

$$\hat{\theta}_j = \theta + u_j + \epsilon_j$$

for j = 1, 2, ..., K, where $\epsilon_j \sim \mathcal{N}(0, \hat{\sigma}_j^2)$ and $u_j \sim \mathcal{N}(0, \tau^2)$. The ϵ_j s are the sampling errors and the u_j s are the random effects

• The estimate of the overall effect size is the mean of the distribution of effect sizes, $\theta_{pop} = \mathbb{E}(\theta_j)$.

イロト イポト イラト イラト

Random-effects meta-analysis

- For each study, we'll compute an estimate of the proportion, $\hat{\theta}_j$, and an estimate, $\hat{\sigma}_j$, of its standard error
- The overall estimate of the prevalence is a weighted average of the study-specific estimates

$$\hat{\theta}^* = \frac{\sum_{j=1}^{K} w_j \hat{\theta}_j}{\sum_{j=1}^{K} w_j}$$

where $w_j = rac{1}{\hat{\sigma}_j^2 + \hat{ au}^2}$ and $\hat{ au}^2$ is the variance of the random effects

Effect sizes for a proportion

| Effect size | Estimate | Variance |
|----------------|--|---|
| Raw proportion | $\hat{p} = \frac{e}{n}$ | $rac{\hat{p}(1-\hat{p})}{n}$ |
| Freeman–Tukey | $\hat{p}_{FT} = \arcsin(\sqrt{\frac{e}{n+1}}) + \arcsin(\sqrt{\frac{e+1}{n+1}})$ | $\frac{1}{n+0.5}$ |
| Logit | $logit(\hat{p}) = ln(rac{\hat{p}}{1-\hat{p}})$ | $\frac{1}{n\hat{p}} + \frac{1}{n-n\hat{p}}$ |

Summary

- We are now familiar with
 - the random-effects meta-analysis model
 - how the overall estimate is computed (weighted average of the study-specific estimates)
 - effect sizes for proportions
- We can now begin working with our data

Freeman–Tukey-transformed proportions

- Freeman–Tukey-transformed proportions have two advantages:
 - The back-transformed CIs are guaranteed to be in the [0,1] range
 - The variance does not depend on the number of events, which means it will not assign artificially large or small weights to studies with \hat{p} close to 0 or 1

Declare meta-analysis data

STATA 18

< 注 → < 注 → ...

Effect sizes for a proportion

Logit transformation

- Like the Freeman–Tukey transformation, guarantees that back-transformed confidence intervals will be in the [0, 1] range
- $\bullet\,$ However, it assigns small weights to studies with \hat{p} close to 0 or 1 for common-effect models
- Raw proportions
 - Can produce confidence limits outside the [0,1] range
 - $\bullet\,$ Tends to assign large weights to studies with \hat{p} close to 0 or 1 for common-effect models
- Freeman–Tukey-transformed proportions solve both of these problems; they are variance stabilizing and produce a reasonable CI range

- 4 同 ト 4 ヨ ト 4 ヨ ト

Cls for individual studies

- By default, meta summarize and meta forestplot compute Wald intervals for the proportion of each individual study
- However, it has been argued that the coverage probability of the Wald interval does not meet the nominal level for extreme values of the proportion and for small sample sizes

Alternative CIs for individual studies

- Alternative CI computations include the Clopper-Pearson, Wilson, Agresti-Coull, and Jeffreys and can be obtained with the citype() option
- Brown, Cai, and DasGupta (2001) recommend either the Wilson or Jeffreys interval for a sample size of 40 or less
- For sample sizes greater than 40, they found the Wilson, Jeffreys, and Agresti-Coull intervals to behave similarly

Forest plot with alternative CI

STATA 18

æ

Multilevel data

- In our previous example, we performed a standard random-effects meta-analysis in which we assumed that the effect sizes were independent across studies
- However, if your data have a multilevel (hierarchical) structure, you can perform multilevel meta-analysis to account for the correlation between effect sizes in the same group

Standard meta-analysis as a two-level model

- Consider a series of studies that examined whether students performed better under a modified school calendar, with frequent breaks, as opposed to the traditional schedule (Cooper et al. 2003).
- Each study was performed in a different school
- The effect size is the standardized mean difference in performance, with positive values indicating that students on the modified calendar performed better than students on the traditional calendar

Standard meta-analysis as a two-level model

• Here we see the effect size reported by each study

Three-level model

- Now suppose that multiple studies belong to the same district
- Schools belonging to the same district will be more similar in terms of demographics and socioeconomical factors, resulting in a correlation between results within a district

• Here we see how studies are grouped by district

Modified school calendar data

Multilevel meta-analysis model

By performing a multilevel meta-analysis, we can

- estimate the effect size more precisely by accounting for the dependence between observations within a group
- assess the heterogeneity between schools within a district and between districts
- estimate how each district varies from the overall mean
 - This will help us decide whether the modified calendar should be applied to some districts and not others

Multilevel meta-analysis model

We'll fit a three-level random-intercepts model

$$\hat{\theta}_{jk} = \theta + u_j^{(3)} + u_{jk}^{(2)} + \epsilon_{jk}$$

where $u_j^{(3)} \sim \mathcal{N}(0, \tau_3^2)$, $u_{jk}^{(2)} \sim \mathcal{N}(0, \tau_2^2)$, and $\epsilon_{jk} \sim \mathcal{N}(0, \hat{\sigma}_{jk}^2)$. Note that *j* represents the third level (district), *k* represents the second level (school within district), and ϵ_{jk} represents the sampling errors.

- . generate double ustan3 = u3/se_u3
- . qnorm ustan3 if tolist, mlabel(district)

New meta-analysis features in Stata 18

Models with random slopes

- meta multilevel allows us to fit random-intercepts meta-analysis models
 - . meta multilevel stdmdiff, relevels(district school) esse(se)
- We can also fit this model as follows:
 - . meta meregress stdmdiff || district: || school:, esse(se)
- If we wish to include random slopes, we can instead use meta meregress
 - . meta meregress stdmdiff x1 || district: x1 || school:, esse(se)
 - The me in meregress refers to mixed effects

Conclusion

STATA 18

æ

Summary

- Today, we learned how to do the following in Stata:
 - Compute different effect sizes for meta-analysis of prevalence.
 - Summarize meta-analysis data in both a table and a graph.
 - Perform meta-regression with effect sizes that have hierarchical structures.
 - Assess heterogeneity at different levels of the hierarchy.
