Postestimation commands

Title

The following postestimation commands are available after heckoprobit:

Command	Description				
contrast	contrasts and ANOVA-style joint tests of estimates				
estat ic	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian in formation criteria (AIC, CAIC, AICc, and BIC)				
estat summarize	summary statistics for the estimation sample				
estat vce	variance-covariance matrix of the estimators (VCE)				
estat (svy)	postestimation statistics for survey data				
estimates	cataloging estimation results				
etable	table of estimation results				
* hausman	Hausman's specification test				
lincom	point estimates, standard errors, testing, and inference for linear combinations of coefficients				
*lrtest	likelihood-ratio test				
margins	marginal means, predictive margins, marginal effects, and average marginal effects				
marginsplot	graph the results from margins (profile plots, interaction plots, etc.)				
nlcom	point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients				
predict	probabilities, linear predictions and their SEs, etc.				
predictnl	point estimates, standard errors, testing, and inference for generalized predictions				
pwcompare	pairwise comparisons of estimates				
suest	seemingly unrelated estimation				
test	Wald tests of simple and composite linear hypotheses				
testnl	Wald tests of nonlinear hypotheses				

*hausman and lrtest are not appropriate with svy estimation results.

predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
outcome(outcome) nooffset]
```

predict	type	stub*	[if		in	,	<u>sc</u> ores
---------	------	-------	------	--	----	---	----------------

statistic	Description				
Main					
pmargin	marginal probabilities; the default				
<u>p1</u>	bivariate probabilities of levels with selection				
p0	bivariate probabilities of levels with no selection				
pcond1	probabilities of levels conditional on selection				
pcond0	probabilities of levels conditional on no selection				
psel	selection probability				
xb	linear prediction				
stdp	standard error of the linear prediction				
xbsel	linear prediction for selection equation				
stdpsel	standard error of the linear prediction for selection equation				

If you do not specify outcome(), pmargin (with one new variable specified) assumes outcome(#1).

You specify one or k new variables with pmargin, where k is the number of outcomes.

You specify one new variable with psel, xb, stdp, xbsel, and stdpsel.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

Main)

pmargin, the default, calculates the predicted marginal probabilities.

You specify one or k new variables, where k is the number of categories of the outcome variable y_j . If you specify the outcome() option, you must specify one new variable. If you specify one new variable and do not specify outcome(), outcome(#1) is assumed.

When outcome() is specified, the marginal probability that y_j is equal to the level outcome() is calculated. When outcome() is not specified, the marginal probabilities for each outcome level are calculated.

p1 calculates the predicted bivariate probabilities of outcome levels with selection.

You specify one or k new variables, where k is the number of categories of the outcome variable y_j . If you specify the outcome() option, you must specify one new variable. If you specify one new variable and do not specify outcome(), outcome(#1) is assumed.

When outcome() is specified, the bivariate probability that y_j is equal to the level outcome() and that y_j is observed is calculated. When outcome() is not specified, the bivariate probabilities for each outcome level and selection are calculated.

p0 calculates the predicted bivariate probabilities of outcome levels with no selection.

You specify one or k new variables, where k is the number of categories of the outcome variable y_j . If you specify the outcome() option, you must specify one new variable. If you specify one new variable and do not specify outcome(), outcome(#1) is assumed.

When outcome() is specified, the bivariate probability that y_j is equal to the level outcome() and that y_j is not observed is calculated. When outcome() is not specified, the bivariate probabilities for each outcome level and no selection are calculated.

pcond1 calculates the predicted probabilities of outcome levels conditional on selection.

You specify one or k new variables, where k is the number of categories of the outcome variable y_j . If you specify the outcome() option, you must specify one new variable. If you specify one new variable and do not specify outcome(), outcome(#1) is assumed.

When outcome() is specified, the probability that y_j is equal to the level outcome() given that y_j is observed is calculated. When outcome() is not specified, the probabilities for each outcome level conditional on selection are calculated.

pcond0 calculates the predicted probabilities of outcome levels conditional on no selection.

You specify one or k new variables, where k is the number of categories of the outcome variable y_j . If you specify the outcome() option, you must specify one new variable. If you specify one new variable and do not specify outcome(), outcome(#1) is assumed.

When outcome() is specified, the probability that y_j is equal to the level outcome() given that y_j is not observed is calculated. When outcome() is not specified, the probabilities for each outcome level conditional on no selection are calculated.

- psel calculates the predicted univariate (marginal) probability of selection.
- xb calculates the linear prediction for the outcome variable, which is $\mathbf{x}_j \boldsymbol{\beta}$ if offset() was not specified and $\mathbf{x}_j \boldsymbol{\beta}$ + offset^{β} if offset() was specified.
- stdp calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.
- xbsel calculates the linear prediction for the selection equation, which is $\mathbf{z}_j \gamma$ if offset() was not specified in select() and $\mathbf{z}_j \gamma + \text{offset}_i^{\gamma}$ if offset() was specified in select().
- stdpsel calculates the standard error of the linear prediction for the selection equation.
- outcome(outcome) specifies for which outcome the predicted probabilities are to be calculated. outcome() should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc.

nooffset is relevant only if you specified offset(*varname*) for heckoprobit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as $x_j b$ rather than as $x_j b + offset_j$.

scores calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (\mathbf{x}_i \boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L / \partial (\mathbf{z}_i \boldsymbol{\gamma})$.

When the dependent variable takes k different values, new variables three through k + 1 will contain $\partial \ln L/\partial(\kappa_{j-2})$.

The last new variable will contain $\partial \ln L / \partial (\operatorname{atanh} \rho)$.

margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins	[marginlist] [, options]			
margins	[marginlist], predict(statistic) [predict(statistic)] [options]			
statistic	Description			
default	marginal probabilities for each outcome			
pmargin	marginal probabilities			
<u>p1</u>	bivariate probabilities of levels with selection			
p0	bivariate probabilities of levels with no selection			
pcond1	probabilities of levels conditional on selection			
pcond0	probabilities of levels conditional on no selection			
psel	selection probability			
xb	linear prediction			
<u>xbs</u> el	linear prediction for selection equation			
stdp	not allowed with margins			
stdpsel	not allowed with margins			

pmargin, p1, p0, pcond1, and pcond0 default to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than e(b). For the full syntax, see [R] margins.

Remarks and examples

stata.com

Example 1

In example 1 of [R] heckoprobit, we examined a simulated dataset of 5,000 women, 3,480 of whom work and can thus report job satisfaction. Using job satisfaction (satisfaction) as the outcome variable and employment (work) as the selection variable, we estimated the parameters of an ordered probit sample-selection model. Covariates age (age), years of education (education), number of children (children), and marital status (married) are expected to affect selection. The outcome, job satisfaction, is affected by age (age) and education (education).

We first reestimate the parameters of the regression, but this time we request a robust variance estimator:

```
. use https://www.stata-press.com/data/r18/womensat
(Job satisfaction, female)
. heckoprobit satisfaction education age,
> select(work=education age i.married##c.children) vce(robust)
(output omitted)
```

We then use margins (see [R] margins) to estimate the average marginal effect of education on the probability of having low job satisfaction.

```
. margins, dydx(education) vce(unconditional)
Average marginal effects Number of obs = 5,000
dy/dx wrt: education
1._predict: Pr(satisfaction=1), predict(pmargin outcome(1))
2._predict: Pr(satisfaction=2), predict(pmargin outcome(2))
3._predict: Pr(satisfaction=3), predict(pmargin outcome(3))
4._predict: Pr(satisfaction=4), predict(pmargin outcome(4))
```

	t dy/dx	Unconditiona std. err.	l z	P> z	[95% conf.	interval]
education						
_predict						
1	0234776	.0019176	-12.24	0.000	027236	0197192
2	0230858	.0015143	-15.24	0.000	0260538	0201178
3	0020603	.001142	-1.80	0.071	0042987	.000178
4	.0486238	.0018593	26.15	0.000	.0449795	.052268

The estimated average marginal effect of education on the probability of having low job satisfaction is approximately -0.023.

4

Methods and formulas

The ordinal outcome equation is

$$y_j = \sum_{h=1}^{H} v_h 1 \left(\kappa_{h-1} < \mathbf{x}_j \boldsymbol{\beta} + u_{1j} \le \kappa_h \right)$$

where \mathbf{x}_j is the outcome covariates, $\boldsymbol{\beta}$ is the coefficients, and u_{1j} is a random-error term. The observed outcome values v_1, \ldots, v_H are integers such that $v_i < v_m$ for i < m. $\kappa_1, \ldots, \kappa_{H-1}$ are real numbers such that $\kappa_i < \kappa_m$ for i < m. κ_0 is taken as $-\infty$ and κ_H is taken as $+\infty$.

The selection equation is

$$s_j = 1(\mathbf{z}_j \boldsymbol{\gamma} + u_{2j} > 0)$$

where $s_j = 1$ if we observed y_j and 0 otherwise, \mathbf{z}_j is the covariates used to model the selection process, $\boldsymbol{\gamma}$ is the coefficients for the selection process, and u_{2j} is a random-error term.

 (u_{1j}, u_{2j}) have bivariate normal distribution with mean zero and variance matrix

$$\begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix}$$

The probability of selection is

$$\Pr(s_j = 1) = \Phi(\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^{\boldsymbol{\gamma}})$$

 $\Phi(\cdot)$ is the standard cumulative normal distribution function.

The probability of selection and the outcome $y_j = v_h$ is

$$\Pr(y_j = v_h, s_j = 1) = \Phi_2 \left(\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^{\gamma}, \kappa_h - x_j \boldsymbol{\beta} - \text{offset}_j^{\beta}, -\rho \right) - \Phi_2 \left(\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^{\gamma}, \kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta} - \text{offset}_j^{\beta}, -\rho \right)$$

 $\Phi_2(\cdot)$ is the cumulative bivariate normal distribution function (with mean $\begin{bmatrix} 0 & 0 \end{bmatrix}'$).

The probability of y_j not being selected and the outcome $y_j = v_h$ is

$$\Pr(y_j = v_h, s_j = 0) = \Phi_2 \left(-\mathbf{z}_j \boldsymbol{\gamma} - \operatorname{offset}_j^{\gamma}, \kappa_h - x_j \boldsymbol{\beta} - \operatorname{offset}_j^{\beta}, \rho \right) - \Phi_2 \left(-\mathbf{z}_j \boldsymbol{\gamma} - \operatorname{offset}_j^{\gamma}, \kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta} - \operatorname{offset}_j^{\beta}, \rho \right)$$

The probability of outcome $y_j = v_h$ given selection is

$$\Pr(y_j = v_h | s_j = 1) = \frac{\Pr(y_j = v_h, s_j = 1)}{\Pr(s_j = 1)}$$

The probability of outcome $y_j = v_h$ given y_j is not selected is

$$\Pr(y_j = v_h | s_j = 0) = \frac{\Pr(y_j = v_h, s_j = 0)}{\Pr(s_j = 0)}$$

The marginal probabilities of the outcome y_i are

$$Pr(y_j = v_1) = \Phi(\kappa_1 - x_j\beta - \text{offset}_j^\beta)$$

$$Pr(y_j = v_H) = 1 - \Phi(\kappa_{H-1} - x_j\beta - \text{offset}_j^\beta)$$

$$Pr(y_j = v_h) = \Phi(\kappa_h - x_j\beta - \text{offset}_j^\beta) - \Phi(\kappa_{h-1} - x_j\beta - \text{offset}_j^\beta)$$
