tabulate oneway — One-way table of frequencies

Description Quick start Menu Syntax
Options Remarks and examples Stored results References

Also see

Description

tabulate produces a one-way table of frequency counts.

For information on a two-way table of frequency counts along with measures of association, including the common Pearson χ^2 , the likelihood-ratio χ^2 , Cramér's V, Fisher's exact test, Goodman and Kruskal's gamma, and Kendall's τ_b , see [R] **tabulate twoway**.

tab1 produces a one-way tabulation for each variable specified in varlist.

Also see [R] **table** and [R] **tabstat** if you want one-, two-, or n-way table of frequencies and a wide variety of statistics. See [R] **tabulate**, **summarize()** for a description of **tabulate** with the **summarize()** option; it produces a table (breakdowns) of means and standard deviations. **table** is better than **tabulate**, **summarize()**, but **tabulate**, **summarize()** is faster. See [R] **Epitab** for a 2×2 table with statistics of interest to epidemiologists.

Quick start

```
One-way table of frequencies for v1 tabulate v1
```

Sort table in descending order of frequency

tabulate v1, sort

Generate indicator variables v1_1, v1_2, ... representing the levels of v1 tabulate v1, generate(v1_)

Treat missing values like other values of v1 tabulate v1, missing

Display numeric values of v1 rather than value labels tabulate v1, nolabel

Create one-way tables for v1, v2, and v3 tab1 v1 v2 v3

Menu

tabulate oneway

Statistics > Summaries, tables, and tests > Frequency tables > One-way table

tabulate ..., generate()

Data > Create or change data > Other variable-creation commands > Create indicator variables

tab1

Statistics > Summaries, tables, and tests > Frequency tables > Multiple one-way tables

Syntax

```
One-way table
```

```
<u>tabulate</u> varname [if] [in] [weight] [, tabulate1_options]
```

One-way table for each variable—a convenience tool

```
tab1 varlist [if] [in] [weight] [, tab1_options]
```

$tabulate1_options$	Description
Main	
<pre>subpop(varname)</pre>	exclude observations for which $varname = 0$
<u>m</u> issing	treat missing values like other values
<u>nof</u> req	do not display frequencies
<u>nol</u> abel	display numeric codes rather than value labels
plot	produce a bar chart of the relative frequencies
sort	display the table in descending order of frequency
Advanced	
<pre>generate(stubname)</pre>	create indicator variables for stubname
_ matcell(<i>matname</i>)	save frequencies in matname; programmer's option
<pre>matrow(matname)</pre>	save unique values of varname in matname; programmer's option
tab1_options	Description

	1
Main	
<pre>subpop(varname)</pre>	exclude observations for which $varname = 0$
<u>m</u> issing	treat missing values like other values
<u>nof</u> req	do not display frequencies
<u>nol</u> abel	display numeric codes rather than value labels
plot	produce a bar chart of the relative frequencies
sort	display the table in descending order of frequency

by is allowed with tabulate and tab1, and collect is allowed with tabulate; see [U] 11.1.10 Prefix commands. fweights, aweights, and iweights are allowed; see [U] 11.1.6 weight.

Options

subpop(varname) excludes observations for which varname = 0 in tabulating frequencies. The mathematical results of tabulate ..., subpop(myvar) are the same as tabulate ... if myvar !=0, but the table may be presented differently. The identities of the rows and columns will be determined from all the data, including the myvar = 0 group, so there may be entries in the table with frequency 0.

Consider tabulating answer, a variable that takes on values 1, 2, and 3, but consider tabulating it just for the male==1 subpopulation. Assume that answer is never 2 in this group, tabulate answer if male==1 produces a table with two rows: one for answer 1 and one for answer 3. There will be no row for answer 2 because answer 2 was never observed tabulate answer, subpop(male) produces a table with three rows. The row for answer 2 will be shown as having 0 frequency.

missing requests that missing values be treated like other values in calculations of counts, percentages, and other statistics.

nofreq suppresses the printing of the frequencies.

nolabel causes the numeric codes to be displayed rather than the value labels.

plot produces a bar chart of the relative frequencies in a one-way table. (Also see [R] histogram.) sort puts the table in descending order of frequency (and ascending order of the variable within equal values of frequency).

Advanced

generate(stubname) creates a set of indicator variables (stubname1, stubname2, ...) reflecting the observed values of the tabulated variable. The generate() option may not be used with the by prefix.

matcell (matname) saves the reported frequencies in matname. This option is for use by programmers.

matrow(matname) saves the numeric values of the $r \times 1$ row stub in matname. This option is for use by programmers. matrow() may not be specified if the row variable is a string.

Limits

A one-way table may have a maximum of 12,000 rows (Stata/MP and Stata/SE) or 3,000 rows (Stata/BE).

Remarks and examples

stata.com

Remarks are presented under the following headings:

tabulate tah1 Video example

For each value of a specified variable, tabulate reports the number of observations with that value. The number of times a value occurs is called its frequency.

tabulate

Example 1

We have data summarizing the speed limit and the accident rate per million vehicle miles along various Minnesota highways in 1973. The variable containing the speed limit is called spdlimit. If we summarize the variable, we obtain its mean and standard deviation:

- . use https://www.stata-press.com/data/r18/hiway (Minnesota highway data, 1973)
- . summarize spdlimit

Variable	Obs	Mean	Std. dev.	Min	Max
spdlimit	39	55	5.848977	40	70

The average speed limit is 55 miles per hour. We can learn more about this variable by tabulating it:

. tabulate spdlimit

Speed limit	${\tt Freq.}$	Percent	Cum.
40	1	2.56	2.56
45	3	7.69	10.26
50	7	17.95	28.21
55	15	38.46	66.67
60	11	28.21	94.87
65	1	2.56	97.44
70	1	2.56	100.00
Total	39	100.00	

We see that one highway has a speed limit of 40 miles per hour, three have speed limits of 45, 7 of 50, and so on. The column labeled Percent shows the percentage of highways in the dataset that have the indicated speed limit. For instance, 38.46% of highways in our dataset have a speed limit of 55 miles per hour. The final column shows the cumulative percentage. We see that 66.67% of highways in our dataset have a speed limit of 55 miles per hour or less.

▶ Example 2

The plot option places a sideways histogram alongside the table:

. tabulate spdlimit, plot

Speed limit	Freq.	
40	1	*
45 50	3 7	***
55	15	*******
60	11	******
65	1	*
70	1	*
Total	39	

Of course, graph can produce better-looking histograms; see [R] histogram.

▶ Example 3

tabulate labels tables using *variable* and *value labels* if they exist. To demonstrate how this works, let's add a new variable to our dataset that categorizes spdlimit into three categories. We will call this new variable spdcat:

. generate spdcat=recode(spdlimit,50,60,70)

1

4

The recode() function divides spdlimit into 50 miles per hour or below, 51-60, and above 60; see [FN] **Programming functions**. We specified the breakpoints in the arguments (spdlimit, 50, 60, 70). The first argument is the variable to be recoded. The second argument is the first breakpoint, the third argument is the second breakpoint, and so on. We can specify as many breakpoints as we wish.

recode() used our arguments not only as the breakpoints but also to label the results. If spdlimit is less than or equal to 50, spdcat is set to 50; if spdlimit is between 51 and 60, spdcat is 60; otherwise, spdcat is arbitrarily set to 70. (See [U] 26 Working with categorical data and factor variables.)

Because we just created the variable spdcat, it is not yet labeled. When we make a table using this variable, tabulate uses the variable's name to label it:

. tabulate spdcat

spdcat	Freq.	Percent	Cum.
50	11	28.21	28.21
60	26	66.67	94.87
70	2	5.13	100.00
Total	39	100.00	

Even through the table is not well labeled, recode()'s coding scheme provides us with clues as to the table's meaning. The first line of the table corresponds to 50 miles per hour and below, the next to 51 through 60 miles per hour, and the last to above 60 miles per hour.

We can improve this table by labeling the values and variables:

- . label define scat 50 "40 to 50" 60 "55 to 60" 70 "Above 60"
- . label values spdcat scat
- . label variable spdcat "Speed Limit Category"

We define a value label called scat that attaches labels to the numbers 50, 60, and 70 using the label define command; see [U] 12.6.3 Value labels. We label the value 50 as "40 to 50", because we looked back at our original tabulation in the first example and saw that the speed limit was never less than 40. Similarly, we could have labeled the last category "65 to 70" because the speed limit is never greater than 70 miles per hour.

Next, we requested that Stata label the values of the new variable spdcat using the value label scat. Finally, we labeled our variable Speed Limit Category. We are now ready to tabulate the result:

. tabulate spdcat

Speed Limit Category	Freq.	Percent	Cum.
40 to 50 55 to 60	11 26	28.21 66.67	28.21 94.87
Above 60	20	5.13	100.00
Total	39	100.00	

Example 4

If we have missing values in our dataset, tabulate ignores them unless we explicitly indicate otherwise. We have no missing data in our example, so let's add some:

. replace spdcat=. in 39 (1 real change made, 1 to missing) 4

We changed the first observation on spdcat to missing. Let's now tabulate the result:

. tabulate spdcat

Speed Limit Category	Freq.	Percent	Cum.
40 to 50	11	28.95	28.95
55 to 60	26	68.42	97.37
Above 60	1	2.63	100.00
Total	38	100.00	

Comparing this output with that in the previous example, we see that the total frequency count is now one less than it was—38 rather than 39. Also, the 'Above 60' category now has only one observation where it used to have two, so we evidently changed a road with a high speed limit.

We want tabulate to treat missing values just as it treats numbers, so we specify the missing option:

. tabulate spdcat, missing

Speed Limit Category	Freq.	Percent	Cum.
40 to 50	11	28.21	28.21
55 to 60	26	66.67	94.87
Above 60	1	2.56	97.44
•	1	2.56	100.00
Total	39	100.00	

We now see our missing value—the last category, labeled '.', shows a frequency count of 1. The table sum is once again 39.

Let's put our dataset back as it was originally:

. replace spdcat=70 in 39
(1 real change made)

4

□ Technical note

tabulate also can automatically create indicator variables from categorical variables. We will briefly review that capability here, but see [U] **26 Working with categorical data and factor variables** for a complete description. Let's begin by describing our highway dataset:

. describe

Contains data from https://www.stata-press.com/data/r18/hiway.dta
Observations: 39 Minnesota highway data, 1973
Variables: 3 16 Nov 2022 12:39

Variable name	Storage type	Display format	Value label	Variable label
spdlimit rate	byte byte	%8.0g %9.0g	rcat	Speed limit Accident rate per million vehicle miles
spdcat	float	%9.0g	scat	Speed Limit Category

Sorted by:

Note: Dataset has changed since last saved.

Our dataset contains three variables. We will type tabulate spdcat, generate(spd), describe our data, and then explain what happened.

. tabulate spdcat, generate(spd)

Speed Limit Category	Freq.	Percent	Cum.
40 to 50 55 to 60 Above 60	11 26 2	28.21 66.67 5.13	28.21 94.87 100.00
Total	39	100.00	

Contains data from https://www.stata-press.com/data/r18/hiway.dta

Observations: Minnesota highway data, 1973 Variables: 6 16 Nov 2022 12:39

Variable Storage Display Value format label Variable label name type spdlimit byte %8.0g Speed limit byte %9.0g rate rcat Accident rate per million vehicle spdcat float %9.0g Speed Limit Category scat %8.0g byte spdcat==40 to 50 spd1 spd2 byte %8.0g spdcat==55 to 60 spd3 byte %8.0g spdcat == Above 60

Sorted by:

Note: Dataset has changed since last saved.

When we typed tabulate with the generate() option, Stata responded by producing a one-way frequency table, so it appeared that the option did nothing. Yet when we describe our dataset, we find that we now have six variables instead of the original three. The new variables are named spd1, spd2, and spd3.

When we specify the generate() option, we are telling Stata to not only produce the table but also create a set of indicator variables that correspond to that table. Stata adds a numeric suffix to the name we specify in the parentheses. spd1 refers to the first line of the table, spd2 to the second line, and so on. Also, Stata labels the variables so that we know what they mean. spd1 is an indicator variable that is true (takes on the value 1) when spdcat is between 40 and 50; otherwise, it is zero. (There is an exception: if spdcat is missing, so are the spd1, spd2, and spd3 variables. This did not happen in our dataset.)

We want to prove our claim. Because we have not yet introduced two-way tabulations, we will use the summarize statement:

. summarize spdlimit if spd1==1

Variable	Obs	Mean	Std. dev.	Min	Max
spdlimit	11	47.72727	3.437758	40	50
. summarize sp	odlimit if sp	od2==1			
Variable	Obs	Mean	Std. dev.	Min	Max
spdlimit	26	57.11538	2.519157	55	60

. summarize spdlimit if spd3==1

Variable	Obs	Mean	Std. dev.	Min	Max
spdlimit	2	67.5	3.535534	65	70

Notice the indicated minimum and maximum in each of the tables above. When we restrict the sample to spd1, spdlimit is between 40 and 50; when we restrict the sample to spd2, spdlimit is between 55 and 60; when we restrict the sample to spd3, spd1imit is between 65 and 70.

Thus tabulate provides an easy way to create indicator (sometimes called dummy) variables. For an overview of indicator and categorical variables, see [U] 26 Working with categorical data and factor variables.

tab1

tab1 is a convenience tool. Typing

. tab1 myvar thisvar thatvar, plot

is equivalent to typing

- . tabulate myvar, plot
- . tabulate thisvar, plot
- . tabulate thatvar, plot

Video example

Tables and cross-tabulations in Stata

Stored results

tabulate and tab1 store the following in r():

Scalars

number of observations r(N)

r(r)

number of rows
