Description

`cmroprobit` fits rank-ordered probit (ROP) models by using maximum simulated likelihood (MSL). The model allows you to relax the independence of irrelevant alternatives (IIA) property that is characteristic of the rank-ordered logistic model by estimating covariances between the error terms for the alternatives.

`cmroprobit` allows two types of independent variables: alternative-specific variables, in which the values of each variable vary with each alternative, and case-specific variables, which vary with each case.

The estimation technique of `cmroprobit` is nearly identical to that of `cmmprobit`, and the two routines share many of the same options; see [\[CM\] cmmprobit](#).

Quick start

Rank-ordered probit model of rankings `y` as a function of `x1` using `cmset` data

```
cmroprobit y x1
```

Same as above, but interpret the lowest value of `y` as the best

```
cmroprobit y x1, reverse
```

Same as above, and include case-specific covariate `x2`

```
cmroprobit y x1, casevars(x2) reverse
```

Same as above, but with factor covariance structure of dimension 1

```
cmroprobit y x1, casevars(x2) reverse factor(1)
```

With all correlations of utility errors constrained to 0

```
cmroprobit y x1, correlation(independent)
```

With a common correlation parameter for all pairs of alternatives

```
cmroprobit y x1, correlation(exchangeable)
```

Menu

Statistics > Choice models > Rank-ordered probit model

Syntax

```
cmprobit depvar [indepvars] [if] [in] [weight] [, options]
```

<i>options</i>	Description
Model	
<u>casevars</u> (<i>varlist</i>)	case-specific variables
<u>reverse</u>	interpret the lowest rank in <i>depvar</i> as the best; the default is the highest rank is the best
<u>basealternative</u> (# <i>lbl</i> <i>str</i>)	alternative used for normalizing location
<u>scalealternative</u> (# <i>lbl</i> <i>str</i>)	alternative used for normalizing scale
<u>noconstant</u>	suppress the alternative-specific constant terms
<u>altwise</u>	use alternatively deletion instead of casewise deletion
<u>constraints</u> (<i>constraints</i>)	apply specified linear constraints
Model 2	
<u>correlation</u> (<i>correlation</i>)	correlation structure of the utility errors
<u>stddev</u> (<i>stddev</i>)	variance structure of the utility errors
<u>factor</u> (#)	use the factor covariance structure with dimension #
<u>structural</u>	use the structural covariance parameterization; default is the differenced covariance parameterization
SE/Robust	
<u>vce</u> (<i>vcetype</i>)	<i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>opg</u> , <u>bootstrap</u> , or <u>jackknife</u>
Reporting	
<u>level</u> (#)	set confidence level; default is level(95)
<u>notransform</u>	do not transform variance–covariance estimates to the standard deviation and correlation metric
<u>nocnsreport</u>	do not display constraints
<u>display_options</u>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Integration	
<u>intmethod</u> (<i>seqtype</i>)	type of quasi–uniform or pseudo–uniform sequence
<u>intpoints</u> (#)	number of points in each sequence
<u>intburn</u> (#)	starting index in the Hammersley or Halton sequence
<u>intseed</u> (<i>code</i> #)	pseudo–uniform random-number seed
<u>antithetics</u>	use antithetic draws
<u>nopivot</u>	do not use integration interval pivoting
<u>initbhhh</u> (#)	use the BHHH optimization algorithm for the first # iterations
<u>favor</u> (<u>speed</u> <u>space</u>)	favor speed or space when generating integration points

Maximization	
<i>maximize_options</i>	control the maximization process; seldom used
<i>collinear</i>	keep collinear variables
<i>coeflegend</i>	display legend instead of statistics
<hr/>	
<i>correlation</i>	Description
<i>unstructured</i>	one correlation parameter for each pair of alternatives; correlations with the <code>basealternative()</code> are zero; the default
<i>exchangeable</i>	one correlation parameter common to all pairs of alternatives; correlations with the <code>basealternative()</code> are zero
<i>independent</i>	constrain all correlation parameters to zero
<i>pattern matname</i>	user-specified matrix identifying the correlation pattern
<i>fixed matname</i>	user-specified matrix identifying the fixed and free correlation parameters
<hr/>	
<i>stddev</i>	Description
<i>heteroskedastic</i>	estimate standard deviation for each alternative; standard deviations for <code>basealternative()</code> and <code>scalealternative()</code> set to one
<i>homoskedastic</i>	all standard deviations are one
<i>pattern matname</i>	user-specified matrix identifying the standard deviation pattern
<i>fixed matname</i>	user-specified matrix identifying the fixed and free standard deviations
<hr/>	
<i>seqtype</i>	Description
<i>hammersley</i>	Hammersley point set
<i>halton</i>	Halton point set
<i>random</i>	uniform pseudo-random point set

You must `cmset` your data before using `cmprobit`; see [CM] [cmset](#).
indepvars and *varlist* may contain factor variables; see [U] [11.4.3 Factor variables](#).
`bootstrap`, `by`, `collect`, `jackknife`, and `statsby` are allowed; see [U] [11.1.10 Prefix commands](#).
Weights are not allowed with the `bootstrap` prefix; see [R] [bootstrap](#).
`fweights`, `iweights`, and `pweights` are allowed; see [U] [11.1.6 weight](#).
`collinear` and `coeflegend` do not appear in the dialog box.
See [U] [20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

Options

Model
<code>casevars</code> (<i>varlist</i>) specifies the case-specific variables that are constant for each <code>case()</code> . If there are a maximum of J alternatives, there will be $J - 1$ sets of coefficients associated with <code>casevars()</code> .
<code>reverse</code> directs <code>cmprobit</code> to interpret the rank in <i>depvar</i> that is smallest in value as the most preferred alternative. By default, the rank that is largest in value is the most preferred alternative.

`basealternative(#|lbl|str)` specifies the alternative used to normalize the level of utility. The base alternative may be specified as a number when the alternatives variable is numeric, as a label when it is numeric and has a [value label](#), or as a string when it is a string variable. The standard deviation for the utility error associated with the base alternative is fixed to one, and its correlations with all other utility errors are set to zero. The default is the first alternative when sorted. If a fixed or pattern matrix is given in the `stddev()` and `correlation()` options, the `basealternative()` will be implied by the fixed standard deviations and correlations in the matrix specifications. `basealternative()` cannot be equal to `scalealternative()`.

`scalealternative(#|lbl|str)` specifies the alternative used to normalize the scale of the utility. The scale alternative may be specified as a number, label, or string. The default is to use the second alternative when sorted. If a fixed or pattern matrix is given in the `stddev()` option, the `scalealternative()` will be implied by the fixed standard deviations in the matrix specification. `scalealternative()` cannot be equal to `basealternative()`.

If a fixed or pattern matrix is given for the `stddev()` option, the base alternative and scale alternative are implied by the standard deviations and correlations in the matrix specifications, and they need not be specified in the `basealternative()` and `scalealternative()` options.

`noconstant` suppresses the $J - 1$ alternative-specific constant terms.

`altwise` specifies that alternativewise deletion be used when omitting observations because of missing values in your variables. The default is to use casewise deletion; that is, the entire group of observations making up a case is omitted if any missing values are encountered. This option does not apply to observations that are excluded by the `if` or `in` qualifier or the `by` prefix; these observations are always handled alternativewise regardless of whether `altwise` is specified.

`constraints(constraints)`; see [\[R\] Estimation options](#).

Model 2

`correlation(correlation)` specifies the correlation structure of the utility (latent-variable) errors.

`correlation(unstructured)` is the most general and has $J(J - 3)/2 + 1$ unique correlation parameters. This is the default unless `stddev()` or `structural` is specified.

`correlation(exchangeable)` provides for one correlation coefficient common to all utilities, except the utility associated with the `basealternative()` option.

`correlation(independent)` assumes that all correlations are zero.

`correlation(pattern matname)` and `correlation(fixed matname)` give you more flexibility in defining the correlation structure. See [Covariance structures](#) in [\[CM\] cmmprobit](#) for more information.

`stddev(stddev)` specifies the variance structure of the utility (latent-variable) errors.

`stddev(heteroskedastic)` is the most general and has $J - 2$ estimable parameters. The standard deviations of the utility errors for the alternatives specified in `basealternative()` and `scalealternative()` are fixed to one.

`stddev(homoskedastic)` constrains all the standard deviations to equal one.

`stddev(pattern matname)` and `stddev(fixed matname)` give you added flexibility in defining the standard deviation parameters. See [Covariance structures](#) in [\[CM\] cmmprobit](#) for more information.

`factor(#)` requests that the factor covariance structure of dimension `#` be used. The `factor()` option can be used with the `structural` option but cannot be used with `stddev()` or `correlation()`. A $\# \times J$ (or $\# \times J - 1$) matrix, `C`, is used to factor the covariance matrix as $I + C'C$, where I is the identity matrix of dimension J (or $J - 1$). The column dimension of `C`, `#`, must be less than or equal to $\text{floor}[\{J(J - 1)/2 - 1\}/(J - 2)]$, because there are only $J(J - 1)/2 - 1$ identifiable covariance parameters. This covariance parameterization may be useful for reducing the number of covariance parameters that need to be estimated.

If the covariance is structural, the column of `C` corresponding to the base alternative contains zeros. The column corresponding to the scale alternative has a one in the first row and zeros elsewhere. If the covariance is differenced, the column corresponding to the scale alternative (differenced with the base) has a one in the first row and zeros elsewhere.

`structural` requests the $J \times J$ structural covariance parameterization instead of the default $J - 1 \times J - 1$ differenced covariance parameterization (the covariance of the utility errors differenced with that of the base alternative). The differenced covariance parameterization will achieve the same MSL regardless of the choice of `basealternative()` and `scalealternative()`. On the other hand, the structural covariance parameterization imposes more normalizations that may bound the model away from its maximum likelihood and thus prevent convergence with some datasets or choices of `basealternative()` and `scalealternative()`.

SE/Robust

`vce(vctype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce_option](#).

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `basealternative()` and `scalealternative()`.

Reporting

`level(#)`; see [R] [Estimation options](#).

`notransform` prevents retransforming the Cholesky-factored covariance estimates to the correlation and standard deviation metric. `notransform` may not be specified on `replay`.

This option has no effect if `structural` is not specified because the default differenced covariance estimates have no interesting interpretation as correlations and standard deviations. `notransform` also has no effect if the `correlation()` and `stddev()` options are specified with anything other than their default values. Here it is generally not possible to factor the covariance matrix, so optimization is already performed using the standard deviation and correlation representations.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

Integration

`intmethod(hammersley | halton | random)` specifies the method of generating the point sets used in the quasi–Monte Carlo integration of the multivariate normal density. `intmethod(hammersley)`, the default, uses the Hammersley sequence; `intmethod(halton)` uses the Halton sequence; and `intmethod(random)` uses a sequence of uniform random numbers.

`intpoints(#)` specifies the number of points to use in the Monte Carlo integration. If option `intmethod(hammersley)` or `intmethod(halton)` is used, the default is $500 + \text{floor}[2.5\sqrt{N_c\{\ln(k+5) + v\}}]$, where N_c is the number of cases, k is the number of coefficients in the model, and v is the number of variance parameters. If `intmethod(random)` is used, the number of points is the above times 2. Larger values of `intpoints()` provide better approximations of the log likelihood at the cost of additional computation time.

`intburn(#)` specifies where in the Hammersley or Halton sequence to start, which helps reduce the correlation between the sequences of each dimension. The default is `intburn(0)`. This option may not be specified with `intmethod(random)`.

`intseed(code | #)` specifies the seed to use for generating the uniform pseudo–random sequence. This option may be specified only with `intmethod(random)`. `code` refers to a string that records the state of the random-number generator `runiform()`; see [R] [set seed](#). An integer value `#` may be used also. The default is to use the current seed value from Stata’s uniform random-number generator, which can be obtained from `c(rngstate)`.

`antithetics` specifies that antithetic draws be used. The antithetic draw for the $J - 1$ vector uniform-random variables, \mathbf{x} , is $1 - \mathbf{x}$.

`nopivot` turns off integration interval pivoting. By default, `cmprobit` will pivot the wider intervals of integration to the interior of the multivariate integration. This improves the accuracy of the quadrature estimate. However, discontinuities may result in the computation of numerical second-order derivatives using finite differencing (for the Newton–Raphson optimize technique, `tech(nr)`) when few simulation points are used, resulting in a non–positive-definite Hessian. `cmprobit` uses the Broyden–Fletcher–Goldfarb–Shanno optimization algorithm, by default, which does not require computing the Hessian numerically using finite differencing.

`initbhhh(#)` specifies that the Berndt–Hall–Hall–Hausman (BHHH) algorithm be used for the initial `#` optimization steps. This option is the only way to use the BHHH algorithm along with other optimization techniques. The algorithm switching feature of `ml`’s `technique()` option cannot include `bhhh`.

`favor(speed | space)` instructs `cmprobit` to favor either speed or space when generating the integration points. `favor(speed)` is the default. When favoring speed, the integration points are generated once and stored in memory, thus increasing the speed of evaluating the likelihood. This speed increase can be seen when there are many cases or when the user specifies many integration points, `intpoints(#)`. When favoring space, the integration points are generated repeatedly with each likelihood evaluation.

For unbalanced data, where the number of alternatives varies with each case, the estimates computed using `intmethod(random)` will vary slightly between `favor(speed)` and `favor(space)`. This is because the uniform sequences will not be identical, even when initiating the sequences using the same uniform seed, `intseed(code | #)`. For `favor(speed)`, `ncase` blocks of `intpoints(#)` \times $J - 2$ uniform points are generated, where J is the maximum number of alternatives. For `favor(space)`, the column dimension of the matrices of points varies with the number of alternatives that each case has.

Maximization

maximize_options: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#).

The following options may be particularly useful in obtaining convergence with `cmprobit`: `difficult`, `technique(algorithm_spec)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`.

If `technique()` contains more than one algorithm specification, `bhhh` cannot be one of them. To use the BHHH algorithm with another algorithm, use the `initbhhh()` option, and specify the other algorithm in `technique()`.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The default optimization technique is `technique(bfgs)`.

When you specify `from(matname [, copy])`, the values in *matname* associated with the utility error variances must be for the log-transformed standard deviations and inverse-hyperbolic tangent-transformed correlations. This option makes using the coefficient vector from a previously fitted `cmprobit` model convenient as a starting point.

The following options are available with `cmprobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

Remarks and examples

The mathematical description and numerical computations of the rank-ordered probit model are similar to that of the multinomial probit model. The only difference is that the dependent variable of the rank-ordered probit model is ordinal, showing preferences among alternatives, as opposed to the binary dependent variable of the multinomial probit model, indicating a chosen alternative.

Only the order in the ranks, not the magnitude of their differences, is assumed to be relevant. By default, the largest rank indicates the more desirable alternative. Use the `reverse` option if the lowest rank should be interpreted as the more desirable alternative.

Tied ranks are allowed, but they increase the computation time because all permutations of the tied ranks are used in computing the likelihood for each case.

We will describe how the likelihood of a ranking is computed using the utility (latent-variable) framework here, but for details of the utility parameterization of these models and the method of maximum simulated likelihood, see [CM] [cmmprobit](#).

Consider the utility of a J alternative rank-ordered probit model. Using the notation from `cmmprobit`, we have utilities (latent variables) η_{ij} , $j = 1, \dots, J$, such that

$$\eta_{ij} = \mathbf{x}_{ij}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\alpha}_j + \xi_{ij}$$

Here the \mathbf{x}_{ij} are the alternative-specific independent variables, the \mathbf{z}_i are the case-specific variables, and the ξ_{ij} are multivariate normal with mean zero and covariance $\boldsymbol{\Omega}$. Without loss of generality, assume that individual i ranks the alternatives in order of the alternative indices $j = 1, 2, \dots, J$, so the alternative J is the preferred alternative, and alternative 1 is the least preferred alternative. The probability of this ranking given $\boldsymbol{\beta}$ and $\boldsymbol{\alpha}_j$ is the probability that $\eta_{i,J-1} - \eta_{i,J} \leq 0$ and $\eta_{i,J-2} - \eta_{i,J-1} \leq 0, \dots$, and $\eta_{i,1} - \eta_{i,2} \leq 0$.

► Example 1

Long and Freese (2014, 477) provide an example of a rank-ordered logit model with alternative-specific variables. We use this dataset to demonstrate cmroprobit. The data come from the Wisconsin Longitudinal Study. This is a study of 1957 Wisconsin high school graduates who were asked to report their relative preferences of four job characteristics: esteem, a job other people regard highly; variety, a job that is not repetitive and allows you to do a variety of things; autonomy, a job where your supervisor does not check on you frequently; and security, a job with a low risk of being laid off.

The case-specific covariates are gender, female, an indicator variable for females, and score, a score on a general mental ability test measured in standard deviations. We also have alternative-specific variables high and low, which indicate whether the respondent's current job is high or low in esteem, variety, autonomy, or security. When taken together, high and low provide three states for a respondent's current job status for each alternative—high, low, or neither. From these variables, we create a new variable, currentjob, that we include as an alternative-specific variable in our model.

The alternatives are ranked such that 1 is the preferred alternative and 4 is the least preferred.

```
. use https://www.stata-press.com/data/r19/wlsrank
(1992 Wisconsin Longitudinal Study data on job values)

. generate currentjob = 1 if low==1
(10,264 missing values generated)

. replace currentjob = 2 if low==0 & high==0
(6,319 real changes made)

. replace currentjob = 3 if high==1
(3,945 real changes made)

. label define current 1 "Low" 2 "Neither" 3 "High"
. label values currentjob current
. list id jobchar rank female score currentjob in 1/12, sepby(id)
```

	id	jobchar	rank	female	score	curren~b
1.	1	Esteem	3	Female	.0492111	Neither
2.	1	Variety	1	Female	.0492111	Neither
3.	1	Autonomy	4	Female	.0492111	Neither
4.	1	Security	1	Female	.0492111	Neither
5.	5	Esteem	2	Female	2.115012	High
6.	5	Variety	2	Female	2.115012	High
7.	5	Autonomy	1	Female	2.115012	Neither
8.	5	Security	2	Female	2.115012	High
9.	7	Esteem	4	Male	1.701852	Neither
10.	7	Variety	1	Male	1.701852	Low
11.	7	Autonomy	1	Male	1.701852	High
12.	7	Security	1	Male	1.701852	Neither

The three cases listed have tied ranks. cmroprobit will allow ties but at the cost of increased computation time. To evaluate the likelihood of the first observation, cmroprobit must compute

$$\begin{aligned} & \Pr(\text{Esteem} = 3, \text{Variety} = 1, \text{Autonomy} = 4, \text{Security} = 2) + \\ & \Pr(\text{Esteem} = 3, \text{Variety} = 2, \text{Autonomy} = 4, \text{Security} = 1) \end{aligned}$$

and both of these probabilities are estimated using simulation. In fact, the full dataset contains 7,237 tied ranks, and cmroprobit takes a long time to estimate the parameters. For exposition, we fit the rank-ordered probit model by using the cases without ties. These cases are marked in the variable noties.

The model of job preference is

$$\eta_{ij} = \beta_1 \text{Neither}_{ij} + \beta_2 \text{High}_{ij} + \alpha_{1j} \text{female}_i + \alpha_{2j} \text{score}_i + \alpha_{0j} + \xi_{ij}$$

for $j = 1, 2, 3, 4$. The base alternative will be Esteem, so $\alpha_{01} = \alpha_{11} = \alpha_{21} = 0$.

Before we can fit our model, we must `cmset` our data. The first argument to `cmset` is the case ID variable. For these data, it is the variable `id`, which identifies respondents. The second argument is the alternatives variable, which identifies the alternatives that could have been chosen. In this instance, it is the variable `jobchar`, which gives the four job characteristics: esteem, variety, autonomy, and security.

```
. cmset id jobchar
      Case ID variable: id
      Alternatives variable: jobchar
```

We fit our model:

```
. cmprobit rank i.currentjob if noties, casevars(i.female score) reverse
note: variable 2.currentjob has 69 cases that are not alternative-specific;
      there is no within-case variability.
note: variable 3.currentjob has 107 cases that are not alternative-specific;
      there is no within-case variability.

(jobchar=Variety is the alternative normalizing scale)

```

We specified the reverse option because a rank of 1 is the highest preference. The variance–covariance estimates are for the Cholesky-factored variance–covariance for the utility errors differenced with that of alternative Esteem. We can view the estimated correlations by typing

```
. estat correlation
```

	Variety	Autonomy	Security
Variety	1.0000		
Autonomy	0.4512	1.0000	
Security	0.2642	0.2402	1.0000

Note: Correlations are for alternatives differenced with Esteem.

and typing

```
. estat covariance
```

	Variety	Autonomy	Security
Variety	2		
Autonomy	.8570563	1.804358	
Security	.6352061	.5485839	2.889653

Note: Covariances are for alternatives differenced with Esteem.

gives the variances and covariances. In [\[R\] mprobit](#), we explain that if the utility errors are independent, then the correlations in the differenced parameterization should be ~ 0.5 , and the variances should be ~ 2.0 , which seems to be the case here.

The coefficient estimates for the probit models can be difficult to interpret because of the normalization for location and scale. The regression estimates for the case-specific variables will be relative to the base alternative, and the regression estimates for both the case-specific and alternative-specific variables are affected by the scale normalization. The more pronounced the heteroskedasticity and correlations, the more pronounced the resulting estimate differences when choosing alternatives to normalize for location and scale. However, when using the differenced covariance structure, you will obtain the same model likelihood regardless of which alternatives you choose as the base and scale alternatives.

For model interpretation, you can obtain predicted probabilities using `predict`; see [\[CM\] cmprobit postestimation](#). You can also use `margins` to estimate expected probabilities, marginal effects, and more. See [\[CM\] Intro 1](#) and [\[CM\] margins](#) for more information and examples using `margins` for interpretation of the results of `cm` commands. Also, see [\[CM\] Intro 6](#) for an example after `cmprobit`.

After you have fit what you consider your final model, you should run the same model again, but this time setting `intpoints(#)`, the number of integration points in the simulated likelihood to a larger number. In this example, we see from the header that the default number of points was 642. We would run our model again using, say, 2000 points and see by how much the coefficient or covariance parameter estimates change. If changes are small compared with standard errors, we can have confidence in the numerical soundness of the simulation used to compute the likelihood. See [Setting the number of integration points](#) in [\[CM\] Intro 5](#) for more information.

Stored results

`cmprobit` stores the following in `e()`:

Scalars

<code>e(N)</code>	number of observations
<code>e(N_case)</code>	number of cases
<code>e(N_ties)</code>	number of ties
<code>e(N_ic)</code>	N for Bayesian information criterion (BIC)
<code>e(N_clust)</code>	number of clusters
<code>e(k)</code>	number of parameters
<code>e(k_alt)</code>	number of alternatives
<code>e(k_indvars)</code>	number of alternative-specific variables
<code>e(k_casevars)</code>	number of case-specific variables
<code>e(k_sigma)</code>	number of variance estimates
<code>e(k_rho)</code>	number of correlation estimates
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test

e(df_m)	model degrees of freedom
e(ll)	log simulated-likelihood
e(const)	constant indicator
e(i_base)	base alternative index
e(i_scale)	scale alternative index
e(mc_points)	number of Monte Carlo replications
e(mc_burn)	starting sequence index
e(mc_antithetics)	antithetics indicator
e(reverse)	1 if minimum rank is best, 0 if maximum rank is best
e(chi2)	χ^2
e(p)	p -value for model test
e(fullcov)	unstructured covariance indicator
e(structcov)	1 if structured covariance, 0 otherwise
e(cholesky)	Cholesky-factored covariance indicator
e(alt_min)	minimum number of alternatives
e(alt_avg)	average number of alternatives
e(alt_max)	maximum number of alternatives
e(rank)	rank of $e(V)$
e(ic)	number of iterations
e(rc)	return code
e(converged)	1 if converged, 0 otherwise

Macros

e(cmd)	cmroprobit
e(cmdline)	command as typed
e(depvar)	name of dependent variable
e(caseid)	name of case ID variable
e(altvar)	name of alternatives variable
e(alteqs)	alternative equation names
e(alt#)	alternative labels
e(wtype)	weight type
e(wexp)	weight expression
e(marktype)	casewise or altwise, type of markout
e(key_N_ic)	cases, key for N for Bayesian information criterion (BIC)
e(title)	title in estimation output
e(clustvar)	name of cluster variable
e(correlation)	correlation structure
e(stddev)	variance structure
e(chi2type)	Wald, type of model χ^2 test
e(vce)	<i>vcetype</i> specified in <code>vce()</code>
e(vcetype)	title used to label Std. err.
e(opt)	type of optimization
e(which)	max or min; whether optimizer is to perform maximization or minimization
e(ml_method)	type of ml method
e(mc_method)	technique used to generate sequences
e(mc_rngstate)	random-number state used
e(user)	name of likelihood-evaluator program
e(technique)	maximization technique
e(datasignature)	the checksum
e(datasignaturevars)	variables used in calculation of checksum
e(properties)	b V
e(estat_cmd)	program used to implement estat
e(predict)	program used to implement predict
e(marginsok)	predictions allowed by margins
e(marginsnotok)	predictions disallowed by margins
e(marginsdefault)	default <code>predict()</code> specification for margins
e(asbalanced)	factor variables <code>fvset</code> as asbalanced
e(asobserved)	factor variables <code>fvset</code> as asobserved

Matrices

e(b)	coefficient vector
e(stats)	alternative statistics
e(stdpattern)	variance pattern
e(stdfixed)	fixed and free standard deviations
e(altvals)	alternative values
e(altfreq)	alternative frequencies
e(alt_casevars)	indicators for estimated case-specific coefficients— $e(k_alt) \times e(k_casevars)$
e(corpattern)	correlation structure
e(corfixed)	fixed and free correlations
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance

Functions

e(sample)	marks estimation sample
-----------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices

r(table)	matrix containing the coefficients with their standard errors, test statistics, p -values, and confidence intervals
----------	---

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

From a computational perspective, `cmprobit` is similar to `cmmprobit`, and the two programs share many numerical tools. Therefore, we will use the notation from *Methods and formulas* in [CM] **cmm-probit** to discuss the rank-ordered probit probability model.

The utilities (latent variables) for a J -alternative model are $\eta_{ij} = \mathbf{x}_{ij}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\alpha}_j + \xi_{ij}$, for $j = 1, \dots, J$, $i = 1, \dots, n$, and $\boldsymbol{\xi}'_i = (\xi_{i,1}, \dots, \xi_{i,J}) \sim \text{MVN}(\mathbf{0}, \boldsymbol{\Omega})$. Without loss of generality, assume for the i th observation that an individual ranks the alternatives in the order of their numeric indices, $\mathbf{y}_i = (J, J-1, \dots, 1)$, so the first alternative is the most preferred, and the last alternative is the least preferred. We can then difference the utilities such that

$$\begin{aligned}
 v_{ik} &= \eta_{i,k+1} - \eta_{i,k} \\
 &= (\mathbf{x}_{i,k+1} - \mathbf{x}_{i,k})\boldsymbol{\beta} + \mathbf{z}_i(\boldsymbol{\alpha}_{k+1} - \boldsymbol{\alpha}_k) + \xi_{i,k+1} - \xi_{ik} \\
 &= \boldsymbol{\delta}_{ik}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\gamma}_k + \epsilon_{ik}
 \end{aligned}$$

for $k = 1, \dots, J-1$ and where $\epsilon_i = (\epsilon_{i1}, \dots, \epsilon_{i,J-1}) \sim \text{MVN}(\mathbf{0}, \boldsymbol{\Sigma}_{(i)})$. $\boldsymbol{\Sigma}$ is indexed by i because it is specific to the ranking of individual i . We denote the deterministic part of the model as $\lambda_{ik} = \boldsymbol{\delta}_{ik}\boldsymbol{\beta} + \mathbf{z}_i\boldsymbol{\gamma}_k$, and the probability of this event is

$$\begin{aligned}
 \Pr(\mathbf{y}_i) &= \Pr(v_{i1} \leq 0, \dots, v_{i,J-1} \leq 0) \\
 &= \Pr(\epsilon_{i1} \leq -\lambda_{i1}, \dots, \epsilon_{i,J-1} \leq -\lambda_{i,J-1}) \\
 &= (2\pi)^{-(J-1)/2} |\boldsymbol{\Sigma}_{(i)}|^{-1/2} \int_{-\infty}^{-\lambda_{i1}} \dots \int_{-\infty}^{-\lambda_{i,J-1}} \exp\left(-\frac{1}{2}\mathbf{z}'\boldsymbol{\Sigma}_{(i)}^{-1}\mathbf{z}\right) d\mathbf{z}
 \end{aligned}$$

The integral has the same form as (3) in [CM] [cmmprobit](#). See [CM] [cmmprobit](#) for details on evaluating this integral numerically by using simulation.

cmprobit handles tied ranks by enumeration. For k tied ranks, it will generate $k!$ rankings, where $!$ is the factorial operator $k! = k(k-1)(k-2) \cdots (2)(1)$. For two sets of tied ranks of size k_1 and k_2 , cmprobit will generate $k_1!k_2!$ rankings. The total probability is the sum of the probability of each ranking. For example, if there are two tied ranks such that $\mathbf{y}_i = (J, J, J-2, \dots, 1)$, then cmprobit will evaluate $\Pr(\mathbf{y}_i) = \Pr(\mathbf{y}_i^{(1)}) + \Pr(\mathbf{y}_i^{(2)})$, where $\mathbf{y}_i^{(1)} = (J, J-1, J-2, \dots, 1)$ and $\mathbf{y}_i^{(2)} = (J-1, J, J-2, \dots, 1)$.

This command supports the clustered version of the Huber/White/sandwich estimator of the variance using `vce(robust)` and `vce(cluster clustvar)`. See [P] [_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#). Specifying `vce(robust)` is equivalent to specifying `vce(cluster caseid)`, where `caseid` is the variable that identifies the cases.
