**generate — Create or change contents of variable**

**Description**

*generate* creates a new variable. The values of the variable are specified by *=exp*.

If no *type* is specified, the new variable type is determined by the type of result returned by *=exp*. A *float* variable (or a *double*, according to *set type*) is created if the result is numeric, and a string variable is created if the result is a string. In the latter case, if the string variable contains values greater than 2,045 characters or contains values with a binary 0 (\0), a *strL* variable is created. Otherwise, a *str*# variable is created, where # is the smallest string that will hold the result.

If a *type* is specified, the result returned by *=exp* must be a string or numeric according to whether *type* is string or numeric. If *str* is specified, a *strL* or a *str*# variable is created using the same rules as above.

See [D] egen for extensions to *generate*.

*replace* changes the contents of an existing variable. Because *replace* alters data, the command cannot be abbreviated.

*set type* specifies the default storage type assigned to new variables (such as those created by *generate*) when the storage type is not explicitly specified.

**Quick start**

Create numeric variable *newv1* equal to *v1 + 2*

```stata
generate newv1 = v1 + 2
```

As above, but use *type* byte and label the values of *newv1* with value label *mylabel*

```stata
generate byte newv1:mylabel = v1 + 2
```

String variable *newv2* equal to “*my text*”

```stata
generate newv2 = "my text"
```

Variable *newv3* equal to the observation number

```stata
generate newv3 = _n
```

Replace *newv3* with observation number within each value of *catvar*

```stata
by catvar: replace newv3 = _n
```

Binary indicator for first observation within each value of *catvar* after sorting on *v2*

```stata
bysort catvar (v2): generate byte first = _n==1
```

As above, but for last observation

```stata
bysort catvar (v2): generate byte last = _n==_N
```

Combined datetime variable *newv4* from %td formatted date and %tc formatted time

```stata
generate double newv4 = cofd(date) + time
```
Menu

**generate**

Data > Create or change data > Create new variable

**replace**

Data > Create or change data > Change contents of variable

Syntax

*Create new variable*

```plaintext
generate [type] newvar [ : lbname ] = exp [ if ] [ in ]
[, before(varname) after(varname)]
```

*Replace contents of existing variable*

```plaintext
replace oldvar = exp [ if ] [ in ] [, nopromote]
```

*Specify default storage type assigned to new variables*

```plaintext
set type { float | double } [, permanently]
```

where *type* is one of byte | int | long | float | double | str | str1 | str2 | ... | str2045.

See Description below for an explanation of *str*. For the other types, see [U] 12 Data.

*by* is allowed with *generate* and *replace*; see [D] *by*.

Options

*before(varname)* or *after(varname)* may be used with *generate* to place the newly generated variable in a specific position within the dataset. These options are primarily used by the Data Editor and are of limited use in other contexts. A more popular alternative for most users is *order* (see [D] *order*).

*nopromote* prevents *replace* from promoting the variable type to accommodate the change. For instance, consider a variable stored as an integer type (byte, int, or long), and assume that you *replace* some values with nonintegers. By default, *replace* changes the variable type to a floating point (float or double) and thus correctly stores the changed values. Similarly, *replace* promotes byte and int variables to longer integers (int and long) if the replacement value is an integer but is too large in absolute value for the current storage type. *replace* promotes strings to longer strings. *nopromote* prevents *replace* from doing this; instead, the replacement values are truncated to fit into the current storage type.

*permanently* specifies that, in addition to making the change right now, the new limit be remembered and become the default setting when you invoke Stata.
Remarks and examples

Remarks are presented under the following headings:

- generate and replace
- set type
- Video examples

generate and replace

*generate* and *replace* are used to create new variables and to modify the contents of existing variables, respectively. You can do anything with replace that you can do with generate. The only difference between the commands is that replace requires that the variable already exist, whereas generate requires that the variable be new. Because Stata is an interactive system, we force a distinction between replacing existing values and generating new ones so that you do not accidentally replace valuable data while thinking that you are creating a new piece of information.

Detailed descriptions of expressions are given in [U] 13 Functions and expressions.

Also see [D] edit.

Example 1

We have a dataset containing the variable age2, which we have previously defined as age\(^2\) (that is, \text{age}^2). We have changed some of the age data and now want to correct age2 to reflect the new values:

```
. use https://www.stata-press.com/data/r16/genxmpl1
   (Wages of women)
. generate age2=age^2
  variable age2 already defined
  r(110);
```

When we attempt to re-generate age2, Stata refuses, telling us that age2 is already defined. We could drop age2 and then re-generate it, or we could use the replace command:

```
. replace age2=age^2
   (204 real changes made)
```

When we use replace, we are informed of the number of actual changes made to the dataset.

You can explicitly specify the storage type of the new variable being created by putting the type, such as byte, int, long, float, double, or str8, in front of the variable name. For example, you could type `generate double revenue = qty * price`. Not specifying a type is equivalent to specifying float if the variable is numeric, or, more correctly, it is equivalent to specifying the default type set by the set type command; see below. If the variable is alphanumeric, not specifying a type is equivalent to specifying str#, where # is the length of the largest string in the variable.

You may also specify a value label to be associated with the new variable by including “:*lbname” after the variable name. This is seldom done because you can always associate the value label later by using the label values command; see [U] 12.6.3 Value labels.
Example 2

Among the variables in our dataset is *name*, which contains the first and last name of each person. We wish to create a new variable called *lastname*, which we will then use to sort the data. *name* is a string variable.

```stata
. use https://www.stata-press.com/data/r16/genxmpl2, clear
. list name
    +----------------------------------+
    |       |                |
    | 1.    | Johanna Roman  |
    | 2.    | Dawn Mikulin   |
    | 3.    | Malinda Vela   |
    | 4.    | Kevin Crow     |
    | 5.    | Zachary Bimslager |
    +----------------------------------+

. generate lastname=word(name,2)

. describe
Contains data from https://www.stata-press.com/data/r16/genxmpl2.dta
   obs: 5                                      18 Jan 2018 12:24
   vars: 2

     storage  display value
    +------------+--------+--------+
    | variable   | name   | lastname|
    | type       | %17s  | %9s   |
    +------------+--------+--------+
    | name       | str17  |        |
    | lastname   | str9   |        |
    +------------+--------+--------+

Sorted by: |
Note: Dataset has changed since last saved.
```

Stata is smart. Even though we did not specify the storage type in our *generate* statement, Stata knew to create a *str9* *lastname* variable, because the longest last name is *Bimslager*, which has nine characters.

Example 3

We wish to create a new variable, *age2*, that represents the variable *age* squared. We realize that because *age* is an integer, *age2* will also be an integer and will certainly be less than 32,740. We therefore decide to store *age2* as an *int* to conserve memory:

```stata
. use https://www.stata-press.com/data/r16/genxmpl3, clear
. generate int age2=age^2
(9 missing values generated)
```

Preceding *age2* with *int* told Stata that the variable was to be stored as an *int*. After creating the new variable, Stata informed us that nine missing values were generated. *generate* informs us whenever it produces missing values.

See [U] 13 Functions and expressions and [U] 26 Working with categorical data and factor variables for more information and examples. Also see [D] recode for a convenient way to recode categorical variables.
Technical note

If you specify the if or in qualifier, the $exp$ is evaluated only for those observations that meet the specified condition or are in the specified range (or both, if both if and in are specified). The other observations of the new variable are set to missing:

```stata
use https://www.stata-press.com/data/r16/genxmpl3, clear
generate int age2=age^2 if age>30
(290 missing values generated)
```

Example 4

replace can be used to change just one value, as well as to make sweeping changes to our data. For instance, say that we enter data on the first five odd and even positive integers and then discover that we made a mistake:

```stata
use https://www.stata-press.com/data/r16/genxmpl4, clear
list
+-----+-------+-------+
| odd | even  |
|-----|-------|-------|
| 1   | 2     |       |
| 2   | 3     | 4     |
| 3   | -8    | 6     |
| 4   | 7     | 8     |
| 5   | 9     | 10    |
+-----+-------+-------+
```

The third observation is wrong; the value of odd should be 5, not −8. We can use replace to correct the mistake:

```stata
replace odd=5 in 3
(1 real change made)
```

We could also have corrected the mistake by typing replace odd=5 if odd==−8.

set type

When you create a new numeric variable and do not specify the storage type for it, say, by typing `generate y=x+2`, the new variable is made a float if you have not previously issued the set type command. If earlier in your session you typed `set type double`, the new numeric variable would be made a double.
