Description

This entry provides a brief introduction to the basic concepts of the International Classification of Diseases (ICD). If you are not familiar with ICD terminology, we recommend that you read this entry before proceeding to the individual command entries.

This entry also provides an overview of the format of the codes from each coding system that Stata’s `icd` commands support. Stata supports 9th revision codes (ICD-9) and 10th revision codes (ICD-10). For ICD-9, Stata uses codes from the United States’s Clinical Modification, the ICD-9-CM. For ICD-10, Stata uses the World Health Organization’s (WHO’s) codes for international morbidity and mortality reporting and the United States’s Clinical Modification (ICD-10-CM) and Procedure Coding System (ICD-10-PCS). We encourage you to read this entry to ensure that you choose the correct command and that your data are properly formatted for using the `icd` suite of commands.

Finally, this entry provides information about using the `icd` commands with multiple diagnosis or procedure codes at one time. None of the commands accepts a varlist, so we illustrate methods for working with multiple codes.

If you are familiar with ICD coding and the `icd` commands in Stata, you may want to skip to the command-specific entries for details about syntax and examples.

### Commands for ICD-9 codes

- `icd9` ICD-9-CM diagnosis codes
- `icd9p` ICD-9-CM procedure codes

### Commands for ICD-10 codes

- `icd10` ICD-10 diagnosis codes
- `icd10cm` ICD-10-CM diagnosis codes
- `icd10pcs` ICD-10-PCS procedure codes

Remarks and examples

Remarks are presented under the following headings:

- Introduction to ICD coding
- Terminology
- Diagnosis codes
- Procedure codes
- Working with multiple codes
Introduction to ICD coding

The `icd` commands in Stata work with four different diagnosis and procedure coding systems: ICD-9-CM, ICD-10, ICD-10-CM, and ICD-10-PCS.

The International Classification of Diseases (ICD) coding system was developed by and is copyrighted by the World Health Organization (WHO). The ICD coding system is used for standardized mortality reporting and, by many countries, for reporting of morbidity and coding of diagnoses during healthcare encounters. Since 1999, the ICD system has been under its 10th revision, ICD-10 (World Health Organization 2011). These codes provide information only about diagnoses, not about procedures.

The United States and some other countries have also developed country-specific coding systems that are extensions of WHO’s system. These systems are used for coding information about healthcare encounters. In the United States, the coding system is referred to as the International Classification of Diseases, Clinical Modification. These codes are maintained and distributed by the National Center for Health Statistics (NCHS) at the U.S. Centers for Disease Control and Prevention (CDC) and by the Centers for Medicare and Medicaid Services (CMS).

Terminology

The `icd9` and `icd10` entries assume knowledge of common terminology used in the ICD-9-CM documentation from the NCHS or CMS or in the ICD-10 revision manuals from WHO. The following brief definitions are provided as a reference.

**edition.** The ICD-9-CM and ICD-10 each have editions, which represent major periodic changes. ICD-9-CM is currently in its sixth edition (National Center for Health Statistics 2011). ICD-10 is currently in its fifth edition (World Health Organization 2011).

**version.** In the ICD-9-CM coding system, the version number is a sequential number assigned by CMS that is updated each Federal Fiscal Year when new codes are released. The last version was 32, which was published on October 1, 2014. In ICD-10-CM/PCS, the version corresponds to the Federal Fiscal Year.

**update.** In the ICD-10 coding system, an update may occur each year. The update is not issued with a number but may be identified by the year in which it occurred.

**category code.** A category code is the portion of the ICD code that precedes the period. It may represent a single disease or a group of related diseases or conditions.

**valid code.** A valid code is one that may be used for reporting in the current version of the ICD-10-CM/PCS or current update to the ICD-10 edition. What constitutes a valid code changes over time.

**defined code.** A defined code is any code that is currently valid, was valid at a previous time, or has meaning as a grouping of codes. See [D] `icd9`, [D] `icd9p`, [D] `icd10`, [D] `icd10cm`, and [D] `icd10pcs` for information about how the individual commands treat defined codes.

Diagnosis codes

Let’s begin with the diagnostic codes processed by `icd9`. An ICD-9-CM diagnosis code may have one of two formats. Most use the format
\[
\{0-9,V\}\{0-9\}\{0-9\} [. ] [0-9][0-9]
\]
while E-codes have the format
\[
E{0-9}\{0-9\}\{0-9\} [. ] [0-9]
\]
where braces, `{ }`, indicate required items and brackets, `[]`, indicate optional items.
ICD-9-CM codes begin with a digit from 0 to 9, the letter V, or the letter E. E-codes are always followed by three digits and may have another digit in the fifth place. All other codes are followed by two digits and may have up to two more digits.

The format of an ICD-10 diagnosis code is

\{A–T,V–Z\} \{0–9\} \{0–9\} [. ] \{0–9\}

Each ICD-10 code begins with a single letter followed by two digits. It may have an additional third digit after the period.

ICD-10-CM diagnosis codes have up to seven characters; otherwise, the format is like that for ICD-10 codes. Each ICD-10-CM code begins with a single letter followed by a digit. However, ICD-10-CM permits the third character to be a digit, the letter A, or the letter B. This forms the category code. The fourth and fifth characters may be used to make up any potential subcategory code. For certain diagnoses, there exist only three-, four- or five-character codes, so the diagnosis code and (sub)category code are equivalent.

Finally, the sixth and seventh characters provide additional detail. A peculiarity of the ICD-10-CM coding system is that it is not strictly hierarchical. The letter X is used as a placeholder if a subcategory has not been defined at a particular level. For example, the code J09 indicates influenza due to an identified virus. There is no subcategory for J09, so the fourth character is an X, and additional detail about complications is provided in the fifth character.

Codes in ICD-10-CM may have up to four more alpha-numeric characters after the period. Only codes with the finest level of detail under a category code are considered valid.

Diagnosis codes must be stored in a string variable (see [D] Data types). For codes from either revision, the period separating the category code from the other digits is treated as implied if it is not present.

⚠️ Technical note

There are defined five- and six-character ICD-10 codes. However, these codes are not part of the standard four-character system codified by WHO for international morbidity and mortality reporting and are not considered valid by icd10. See [D] icd10 for additional details about these codes and options for using icd10 with them.

⚠️ Technical note

ICD-10 codes U00–U49 are reserved for use by WHO for provisional assignment of new diseases. Codes U50–U99 may be used for research to identify subjects with specific conditions under study for which there is no defined ICD-10 code (World Health Organization 2011).

If you are working in one of these specialized cases, see the technical note in Creating new variables under Remarks and examples of [D] icd10.
Procedure codes

The ICD-9-CM coding system also includes procedure codes. The format of ICD-9-CM procedure codes is

\[
\{0-9\}\{0-9\}[.][0-9\{0-9\}]
\]

The general format of an ICD-10-PCS procedure code is a three-character category code followed by four alpha-numeric characters after an (implied) period. The full codes are always seven characters long and may be any combination of letters and numbers.

Procedure codes must be stored in a string variable.

Working with multiple codes

Oftentimes, multiple diagnoses or procedures are recorded for each observation. None of the \texttt{icd} commands accepts a varlist, but you can still work with multiple diagnosis or multiple procedure records. To use the \texttt{icd} commands with more than one diagnosis or procedure variable at a time, you must either first \texttt{reshape} your data or use a loop; see \texttt{[D] reshape} and \texttt{[P] forvalues}.

\section*{Example 1: Summarizing information from multiple variables}

In example 1 of \texttt{[D] icd9}, we add a variable indicating whether each diagnosis code was invalid or undefined. Here we use the same extract from the National Hospital Discharge Survey (NHDS).

It is often more useful to add a single variable that summarizes the results from several diagnosis or procedure variables. For example, we may wish to add a variable indicating whether a particular diagnosis code or range of codes appeared in any field. Summary variables can be created from the results of the \texttt{check} subcommand with option \texttt{generate()} or the \texttt{generate} subcommand with option \texttt{range()} or option \texttt{category()}.

Suppose that we want a single variable that contains the number of improperly formatted or undefined codes that each discharge had. To illustrate, we use the \texttt{nhds2010} dataset, keeping the variables for discharge identifier (\texttt{recid}), patient age, and patient sex, as well as the three diagnosis variables. We list the first ten observations below.

\begin{verbatim}
use https://www.stata-press.com/data/r16/nhds2010
(Adult same-day discharges, 2010)
keep recid age sex dx1 dx2 dx3
list in 1/10, noobs
\end{verbatim}

\begin{tabular}{|c|c|c|c|c|c|}
\hline
age & sex & dx1 & dx2 & dx3 & recid \\
\hline
85 & Female & 4414 & 99811 & 14275 & 84 \\
23 & Male & 25013 & 3572 & -2506 & 105 \\
63 & Male & 51909 & 1489 & -V146 & 255 \\
43 & Female & 9678 & E8528 & 8 & 651 \\
25 & Female & V271 & 64421 & 16564 & 696 \\
57 & Female & 5409 & V1582 & 2V106 & 779 \\
61 & Female & 27651 & V1087 & 7V436 & 814 \\
60 & Male & 9991 & 462 & -2724 & 826 \\
22 & Male & 42789 & 5409 & -2780 & 833 \\
49 & Male & 5770 & 29181 & 14255 & 863 \\
\hline
\end{tabular}
The data are in wide form, so we specify \texttt{reshape long} with stub \texttt{dx} because our diagnosis codes are in \texttt{dx1}, \texttt{dx2}, and \texttt{dx3}. The observation identifier, \texttt{recid}, is specified in \texttt{i()}. \texttt{reshape} creates the new variable \texttt{dxnum} for us.

\begin{verbatim}
    . reshape long dx, i(recid) j(dxnum)
    (note: j = 1 2 3)
\end{verbatim}

\begin{tabular}{lcc}
\hline
 & wide & long \\
\hline
Number of obs. & 2210 & 6630 \\
Number of variables & 6 & 5 \\
j variable (3 values) & \rightarrow dxnum \\
xij variables: & dx1 dx2 dx3 & \rightarrow dx \\
\hline
\end{tabular}

The output shows that \texttt{dxnum} has 3 values, so we know that all three diagnosis variables were recognized by \texttt{reshape}.

\begin{verbatim}
    . list in 1/9, sepby(recid) noobs
\end{verbatim}

\begin{verbatim}
<table>
<thead>
<tr>
<th>recid</th>
<th>dxnum</th>
<th>age</th>
<th>sex</th>
<th>dx</th>
</tr>
</thead>
<tbody>
<tr>
<td>84</td>
<td>1</td>
<td>85</td>
<td>Female</td>
<td>4414</td>
</tr>
<tr>
<td>84</td>
<td>2</td>
<td>85</td>
<td>Female</td>
<td>99811</td>
</tr>
<tr>
<td>84</td>
<td>3</td>
<td>85</td>
<td>Female</td>
<td>14275</td>
</tr>
<tr>
<td>105</td>
<td>1</td>
<td>23</td>
<td>Male</td>
<td>25013</td>
</tr>
<tr>
<td>105</td>
<td>2</td>
<td>23</td>
<td>Male</td>
<td>3572</td>
</tr>
<tr>
<td>105</td>
<td>3</td>
<td>23</td>
<td>Male</td>
<td>-2506</td>
</tr>
<tr>
<td>255</td>
<td>1</td>
<td>63</td>
<td>Male</td>
<td>51909</td>
</tr>
<tr>
<td>255</td>
<td>2</td>
<td>63</td>
<td>Male</td>
<td>1489</td>
</tr>
<tr>
<td>255</td>
<td>3</td>
<td>63</td>
<td>Male</td>
<td>-V146</td>
</tr>
</tbody>
</table>
\end{verbatim}

Notice that our data on \texttt{recid}, \texttt{age}, and \texttt{sex} are retained and duplicated for each new observation. If you are working with a large dataset, you may wish to drop variables other than a merge key and your diagnosis (or procedure) variables to conserve space and speed up \texttt{reshape}.

After we \texttt{reshape}, we create \texttt{prob} using \texttt{icd9 check}, an indicator for whether there was a problem with a given diagnosis code. We then use \texttt{egen} to create \texttt{anyprob}, the total number of codes that had a problem within each \texttt{recid}. See \texttt{[D] egen} for information about summary functions.

\begin{verbatim}
    . icd9 check dx, generate(prob)
    (dx contains 358 missing values)
\end{verbatim}

\texttt{dx contains invalid codes:}

1. Invalid placement of period 0
2. Too many periods 0
3. Code too short 177
4. Code too long 0
5. Invalid 1st char (not 0-9, E, or V) 875
6. Invalid 2nd char (not 0-9) 128
7. Invalid 3rd char (not 0-9) 0
8. Invalid 4th char (not 0-9) 0
9. Invalid 5th char (not 0-9) 36
10. Code not defined 778

Total 1,994

\begin{verbatim}
    . generate anyprob=prob>0
    . by recid, sort: egen numprobs=total(anyprob)
\end{verbatim}
. list recid dxnum dx anyprob numprobs in 1/9, sepby(recid) noobs

<table>
<thead>
<tr>
<th>recid</th>
<th>dxnum</th>
<th>dx</th>
<th>anyprob</th>
<th>numprobs</th>
</tr>
</thead>
<tbody>
<tr>
<td>84</td>
<td>1</td>
<td>4414</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>84</td>
<td>2</td>
<td>99811</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>84</td>
<td>3</td>
<td>14275</td>
<td>1</td>
<td>1</td>
</tr>
<tr>

<td>-V146</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Before we reshape, we drop prob and anyprob because they are specific to diagnosis variables. By construction, numprobs is constant within recid, so we do not specify it when we reshape.

. drop prob anyprob
. reshape wide dx, i(recid) j(dxnum)
(note: j = 1 2 3)

Data long -> wide

<table>
<thead>
<tr>
<th></th>
<th>6630</th>
<th>2210</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of obs.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Number of variables</td>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>j variable (3 values)</td>
<td>dxnum</td>
<td>(dropped)</td>
</tr>
<tr>
<td>xij variables:</td>
<td>dx</td>
<td>dx1</td>
</tr>
</tbody>
</table>

. list in 1/3, noobs

<table>
<thead>
<tr>
<th>recid</th>
<th>dx1</th>
<th>dx2</th>
<th>dx3</th>
<th>age</th>
<th>sex</th>
<th>numprobs</th>
</tr>
</thead>
<tbody>
<tr>
<td>84</td>
<td>4414</td>
<td>99811</td>
<td>14275</td>
<td>85</td>
<td>Female</td>
<td>1</td>
</tr>
<tr>
<td>105</td>
<td>25013</td>
<td>3572</td>
<td>-2506</td>
<td>23</td>
<td>Male</td>
<td>1</td>
</tr>
<tr>
<td>255</td>
<td>51909</td>
<td>1489</td>
<td>-V146</td>
<td>63</td>
<td>Male</td>
<td>1</td>
</tr>
</tbody>
</table>

The three diagnosis variables are restored to the dataset. We have added a single variable showing the total number of codes with problems for each record.

Example 2: Adding multiple variables from ICD codes

Now suppose that rather than creating a summary variable flagging any problem as we did in example 1, we want a new variable for each diagnosis variable indicating whether there is a coding problem. In example 1 of [D] icd9, we icd9 check each diagnosis variable separately, which requires us to type the command three times. While this is not burdensome for 3 variables, the full NHDS includes 14 diagnosis variables, for which we almost certainly would not want to type separate commands.

The easiest way to accomplish this is with a loop. We use forvalues because our codes all end in a number.
use https://www.stata-press.com/data/r16/nhds2010, clear
(Adult same-day discharges, 2010)
foreach i in 1/3 {
    icd9 check dx'i', generate(dx'i'_prob)
}

(dx1 contains defined ICD-9-CM codes; no missing values)
(dx2 contains defined ICD-9-CM codes; 179 missing values)
(dx3 contains 179 missing values)

dx3 contains invalid codes:
1. Invalid placement of period
2. Too many periods
3. Code too short
4. Code too long
5. Invalid 1st char (not 0-9, E, or V)
6. Invalid 2nd char (not 0-9)
7. Invalid 3rd char (not 0-9)
8. Invalid 4th char (not 0-9)
9. Invalid 5th char (not 0-9)
10. Code not defined

Total 1,994

This is exactly what we obtain in example 1 of [D] icd9.

If our variables had not been numbered sequentially, we could have either renamed them or used foreach; see [P] foreach.

The methods shown above will work for any of the icd9, icd9p, icd10, icd10cm, or icd10pcs data management commands.
