Description

`label data` attaches a label (up to 80 characters) to the dataset in memory. Dataset labels are displayed when you use the dataset and when you `describe` it. If no label is specified, any existing label is removed.

`label variable` attaches a label (up to 80 characters) to a variable. If no label is specified, any existing variable label is removed.

`label define` creates a value label named *lblname*, which is a set of individual numeric values and their corresponding labels. *lblname* can contain up to 65,536 individual labels; each individual label can be up to 32,000 characters long.

`label values` attaches a value label to *varlist*. If `.` is specified instead of *lblname*, any existing value label is detached from that *varlist*. The value label, however, is not deleted. The syntax `label values varname` (that is, nothing following the *varname*) acts the same as specifying the `..`

`label dir` lists the names of value labels stored in memory.

`label list` lists the names and contents of value labels stored in memory.

`label copy` makes a copy of an existing value label.

`label drop` eliminates value labels.

`label save` saves value label definitions in a do-file. This is particularly useful for value labels that are not attached to a variable because these labels are not saved with the data. By default, `.do` is the filename extension used.

See [\[D\] label language](#) for information on the `label` language command.

Quick start

Label the dataset “My data”

```
label data "My data"
```

Label `v1` “First variable”

```
label variable v1 "First variable"
```

Define value label named `mylabel1`

```
label define mylabel1 1 "value 1" 2 "value 2"
```

Add labels for values 0 and 3 to `mylabel1`

```
label define mylabel1 0 "value 0" 3 "value 3", add
```

Copy `mylabel1` to `mylabel2`

```
label copy mylabel1 mylabel2
```

Redefine value 0 in mylabel2 to mean “Null”

```
label define mylabel2 0 "Null", modify
```

Apply value label mylabel1 to v1

```
label values v1 mylabel1
```

Save all currently defined value labels to mylabels.do for use with other datasets

```
label save using mylabels.do
```

List names and contents of all value labels

```
label list
```

Drop all value labels

```
label drop _all
```

Menu

Syntax

Label dataset

```
label data ["label"]
```

Label variable

```
label variable varname ["label"]
```

Define value label

```
label define lblname # "label" [# "label" ...] [, add modify replace nofix]
```

Assign value label to variables

```
label values varlist lblname [, nofix]
```

Remove value labels

```
label values varlist [.]
```

List names of value labels

```
label dir
```

List names and contents of value labels

```
label list [lblname [lblname ...]]
```

Copy value label

```
label copy lblname lblname [, replace]
```

Drop value labels

```
label drop { lblname [lblname ...] | _all }
```

Save value labels in do-file

```
label save [lblname [lblname ...]] using filename [, replace]
```

Labels for variables and values in multiple languages

```
label language ...
```

(see [\[D\] label language](#))

where # is an integer or an extended missing value (.a, .b, ..., .z).

Options

`add` allows you to add `# ↔ label` correspondences to `lblname`. If `add` is not specified, you may create only new `lblnames`. If `add` is specified, you may create new `lblnames` or add new entries to existing `lblnames`.

`modify` allows you to modify or delete existing `# ↔ label` correspondences and add new correspondences. Specifying `modify` implies `add`, even if you do not type the `add` option.

`replace`, with `label define`, allows an existing value label to be redefined. `replace`, with `label copy`, allows an existing value label to be copied over. `replace`, with `label save`, allows *filename* to be replaced.

`nofix` prevents display formats from being widened according to the maximum length of the value label. Consider `label values myvar mylab`, and say that `myvar` has a `%9.0g` display format right now. Say that the maximum length of the strings in `mylab` is 12 characters. `label values` would change the format of `myvar` from `%9.0g` to `%12.0g`. `nofix` prevents this.

`nofix` is also allowed with `label define`, but it is relevant only when you are modifying an existing value label. Without the `nofix` option, `label define` finds all the variables that use this value label and considers widening their display formats. `nofix` prevents this.

Remarks and examples

[stata.com](https://www.stata.com)

See [U] [12.6 Dataset, variable, and value labels](#) for a complete description of labels. This entry deals only with details not covered there.

Remarks are presented under the following headings:

[Overview](#)

[Video examples](#)

Overview

Value labels save us the trouble of having to remember how our variables are coded. For example, if we have a variable recording the region where people live, we might not remember if a value of 1 referred to east or west. We can use `label define` to create a value label attaching the labels east and west to numeric values 1 and 2. We can then attach these codings to our region variable with `label values` so that our labels will be displayed in the output of certain summary statistics and estimation commands instead of their corresponding numeric values. The suite of `label` commands makes it easy to create and manipulate these labels.

► Example 1: Creating a value label

Although `describe` shows the names of the value labels, those value labels may not exist. Stata does not consider it an error to label the values of a variable with a nonexistent label. When this occurs, Stata still shows the association on `describe` but otherwise acts as if the variable's values are unlabeled. This way, you can associate a value label name with a variable before creating the corresponding label. Similarly, you can define labels that you have not yet used.

```
. use http://www.stata-press.com/data/r15/hbp4
. describe
Contains data from http://www.stata-press.com/data/r15/hbp4.dta
  obs:      1,130
  vars:      7                      22 Jan 2016 11:12
  size:     19,210
```

variable name	storage type	display format	value label	variable label
id	str10	%10s		Record identification number
city	byte	%8.0g		
year	int	%8.0g		
age_grp	byte	%8.0g		
race	byte	%8.0g		
hbp	byte	%8.0g		
female	byte	%8.0g	sex1bl	

Sorted by:

The dataset is using the value label `sex1bl`. Let's define the value label `yesno`:

```
. label define yesno 0 "no" 1 "yes"
```

`label dir` shows you the value labels that you have actually defined:

```
. label dir
yesno
sex1bl
```

We have two value labels stored in memory: `yesno` and `sex1bl`.

We can display the contents of a value label with the `label list` command:

```
. label list yesno
yesno:
      0 no
      1 yes
```

The value label `yesno` labels the values 0 as no and 1 as yes.

If you do not specify the name of the value label on the `label list` command, Stata lists all the value labels:

```
. label list
yesno:
      0 no
      1 yes

sex1bl:
      0 male
      1 female
```

◀

You can add new codings to an existing value label by using the `add` option with the `label define` command. You can modify existing codings by using the `modify` option. You can redefine a value label by specifying the `replace` option.

▷ Example 2: Modifying a value label

The value label `yesno` codes 0 as no and 1 as yes. You might wish later to add a third coding: 2 as maybe. Typing `label define` with no options results in an error:

```
. label define yesno 2 maybe
label yesno already defined
r(110);
```

If you do not specify the `add`, `modify`, or `replace` options, `label define` can be used only to create *new* value labels. The `add` option lets you add codings to an existing value label:

```
. label define yesno 2 maybe, add
. label list yesno
yesno:
    0 no
    1 yes
    2 maybe
```

Perhaps you have accidentally mislabeled a value. For instance, 2 may not mean “maybe” but may instead mean “don’t know”. `add` does not allow you to change an existing label:

```
. label define yesno 2 "don't know", add
invalid attempt to modify label
r(180);
```

Instead, you would specify the `modify` option:

```
. label define yesno 2 "don't know", modify
. label list yesno
yesno:
    0 no
    1 yes
    2 don't know
```

In this way, Stata attempts to protect you from yourself. If you type `label define` with no options, you can only create a new value label—you cannot accidentally change an existing one. If you specify the `add` option, you can add new labels to an existing value label, but you cannot accidentally change any existing label. If you specify the `modify` option, which you may not abbreviate, you can change any existing label.

You can even use the `modify` option to eliminate existing labels. To do this, you map the numeric code to a *null string*, that is, “”:

```
. label define yesno 2 "", modify
. label list yesno
yesno:
    0 no
    1 yes
```

◀

You can eliminate entire value labels by using the `label drop` command.

▷ Example 3: Dropping value labels

We currently have two value labels stored in memory—`sex1bl` and `yesno`—as shown by the `label dir` command:

```
. label dir
yesno
sex1bl
```

The dataset that we have in memory uses only one of the labels—`sex1bl`. `describe` reports that `yesno` is not being used:

```
. describe
Contains data from http://www.stata-press.com/data/r15/hbp4.dta
  obs:      1,130
  vars:      7                22 Jan 2016 11:12
  size:     19,210
```

variable name	storage type	display format	value label	variable label
id	str10	%10s		Record identification number
city	byte	%8.0g		
year	int	%8.0g		
age_grp	byte	%8.0g		
race	byte	%8.0g		
hbp	byte	%8.0g		
female	byte	%8.0g	sex1bl	

Sorted by:

We can eliminate the value label `yesno` by typing

```
. label drop yesno
. label dir
sex1bl
```

We could eliminate *all* the value labels in memory by typing

```
. label drop _all
. label dir
```

The value label `sex1bl`, which no longer exists, was associated with the variable `female`. Even after dropping the value label, `sex1bl` is still associated with the variable:

```
. describe
Contains data from http://www.stata-press.com/data/r15/hbp4.dta
  obs:      1,130
  vars:      7                22 Jan 2016 11:12
  size:     19,210
```

variable name	storage type	display format	value label	variable label
id	str10	%10s		Record identification number
city	byte	%8.0g		
year	int	%8.0g		
age_grp	byte	%8.0g		
race	byte	%8.0g		
hbp	byte	%8.0g		
female	byte	%8.0g	sex1bl	

Sorted by:

If we wanted to disassociate this nonexistent value label from the variable it was attached to, we could issue the `label values` command without specifying a value label name.

▷ Example 4: Copying a value label

`label copy` is useful when you want to create a new value label that is similar to an existing value label. For example, assume that we currently have the value label `yesno` in memory:

```
. label list yesno
yesno:
      1 yes
      2 no
```

Assume that we have some variables in our dataset coded with 1 and 2 for “yes” and “no” and that we have some other variables coded with 1 for “yes”, 2 for “no”, and 3 for “maybe”.

We could make a copy of value label `yesno` and then add the new coding to that copy:

```
. label copy yesno yesnomaybe
. label define yesnomaybe 3 "maybe", add
. label list
yesnomaybe:
      1 yes
      2 no
      3 maybe
yesno:
      1 yes
      2 no
```

▷ Example 5: Saving value labels

Data and variable labels are automatically stored with your dataset when you `save` it. You might have more value labels stored in memory than are actually used in the dataset, but only those value labels that are attached to variables will be stored with a dataset unless you use `save`'s `orphans` option. Conversely, the `use` command drops all in-memory labels before loading the new dataset along with any labels it might contain. You might want to store a value label not currently in use or move a value label from one dataset to another. The `label save` command allows you to do this.

For example, assume that we currently have the value label `yesnomaybe` in memory:

```
. label list yesnomaybe
yesnomaybe:
      1 yes
      2 no
      3 maybe
```

We have a dataset stored on disk called `survey.dta` to which we wish to add this value label. We might use `survey` and then retype the `label define yesnomaybe` command. Retyping the label would not be too tedious here but if the value label in memory mapped, say, the 50 states of the United States, retyping it would be irksome. `label save` provides an alternative:

```
. label save yesnomaybe using yinfile
file yinfile.do saved
```

Typing `label save yesnomaybe using ynfile` caused Stata to create a do-file called `ynfile.do` containing the definition of the `yesnomaybe` value label. Because we did not specify an extension for our file, `.do` was assumed. Also, if we had not specified a value label name, all value labels would have been stored in `ynfile.do`.

To see the contents of the file, we can use the `type` command:

```
. type ynfile.do
label define yesnomaybe 1 "yes", modify
label define yesnomaybe 2 "no", modify
label define yesnomaybe 3 "maybe", modify
```

We can now use our new dataset, `survey.dta`:

```
. use survey
(Household survey data)
. label dir
```

Using the new dataset causes Stata to eliminate all value labels stored in memory. The label `yesnomaybe` is now gone. Because we saved it in the file `ynfile.do`, however, we can get it back by typing either `do ynfile` or `run ynfile`. If we type `do`, we will see the commands in the file execute. If we type `run`, the file will execute silently:

```
. run ynfile
. label dir
yesnomaybe
```

The value label is now restored just as if we had typed it from the keyboard.

□ Technical note

You can also use the `label save` command to more easily edit value labels. You can save a label in a file, leave Stata and use your word processor or editor to edit the label, and then return to Stata. Using `do` or `run`, you can load the edited values.

Stored results

`label list` stores the following in `r()`:

Scalars

<code>r(k)</code>	number of mapped values, including missings
<code>r(min)</code>	minimum nonmissing value label
<code>r(max)</code>	maximum nonmissing value label
<code>r(hasemiss)</code>	1 if extended missing values labeled, 0 otherwise

`label dir` stores the following in `r()`:

Macros

<code>r(names)</code>	names of value labels
