merge — Merge datasets

Description

merge joins corresponding observations from the dataset currently in memory (called the master dataset) with those from filename.dta (called the using dataset), matching on one or more key variables. merge can perform match merges (one-to-one, one-to-many, many-to-one, and many-to-many), which are often called joins by database people. merge can also perform sequential merges, which have no equivalent in the relational database world.

merge is for adding new variables from a second dataset to existing observations. You use merge, for instance, when combining hospital patient and discharge datasets. If you wish to add new observations to existing variables, then see [D] append. You use append, for instance, when adding current discharges to past discharges.

To link datasets in separate frames, you can use the frlink and fralias add commands. Linking and merging solve similar problems, and each is better than the other in some ways. You may prefer linking, for instance, when dealing with an individual-level dataset and a county-level dataset. Linking also works well when you have nested linkages such as linking a county dataset, a school-within-county dataset, and a student-within-school dataset or when you need to link a dataset to itself. See [D] frlink and [D] fralias for more information and examples.

By default, merge creates a new variable, _merge, containing numeric codes concerning the source and the contents of each observation in the merged dataset. These codes are explained below in the match results table.

Key variables cannot be strLs.

If filename is specified without an extension, then .dta is assumed.

Quick start

One-to-one merge of mydata1.dta in memory with mydata2.dta on v1

```
merge 1:1 v1 using mydata2
```

Same as above, and also treat v2 as a key variable and name the new variable indicating the merge result for each observation newv

```
merge 1:1 v1 v2 using mydata2, generate(newv)
```

Same as above, but keep only v3 from mydata2.dta and use default merge result variable _merge

```
merge 1:1 v1 v2 using mydata2, keepusing(v3)
```

Same as above, but keep only observations in both datasets

```
merge 1:1 v1 v2 using mydata2, keepusing(v3) keep(match)
```

Same as above

```
merge 1:1 v1 v2 using mydata2, keepusing(v3) keep(3)
```
Same as above, but assert that all observations should match or return an error otherwise

```
merge 1:1 v1 v2 using mydata2, keepusing(v3) assert(3)
```

Replace missing data in mydata1.dta with values from mydata2.dta

```
merge 1:1 v1 v2 using mydata2, update
```

Replace missing and conflicting data in mydata1.dta with values from mydata2.dta

```
merge 1:1 v1 v2 using mydata2, update replace
```

Many-to-one merge on v1 and v2

```
merge m:1 v1 v2 using mydata2
```

One-to-many merge on v1 and v2

```
merge 1:m v1 v2 using mydata2
```
Syntax

One-to-one merge on specified key variables

```bash
merge 1:1 varlist using filename [, options]
```

Many-to-one merge on specified key variables

```bash
merge m:1 varlist using filename [, options]
```

One-to-many merge on specified key variables

```bash
merge 1:m varlist using filename [, options]
```

Many-to-many merge on specified key variables

```bash
merge m:m varlist using filename [, options]
```

One-to-one merge by observation

```bash
merge 1:1 _n using filename [, options]
```

<table>

Options

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keepusing(varlist)</td>
<td>specifies the variables from the using dataset that are kept in the merged dataset. By default, all variables are kept. For example, if your using dataset contains 2,000 demographic characteristics but you want only sex and age, then type merge ..., keepusing(sex age) ....</td>
</tr>
</tbody>
</table>
generate(newvar) specifies that the variable containing match results information should be named newvar rather than _merge.

nogenerate specifies that _merge not be created. This would be useful if you also specified keep(match), because keep(match) ensures that all values of _merge would be 3.

nolabel specifies that value-label definitions from the using file be ignored. This option should be rare, because definitions from the master are already used.

nonotes specifies that notes in the using dataset not be added to the merged dataset; see [D] notes.

update and replace both perform an update merge rather than a standard merge. In a standard merge, the data in the master are the authority and inviolable. For example, if the master and using datasets both contain a variable age, then matched observations will contain values from the master dataset, while unmatched observations will contain values from their respective datasets.

If update is specified, then matched observations will update missing values from the master dataset with values from the using dataset. Nonmissing values in the master dataset will be unchanged.

If replace is specified, then matched observations will contain values from the using dataset, unless the value in the using dataset is missing.

Specifying either update or replace affects the meanings of the match codes. See Treatment of overlapping variables for details.

noreport specifies that merge not present its summary table of match results.

force allows string/numeric variable type mismatches, resulting in missing values from the using dataset. If omitted, merge issues an error; if specified, merge issues a warning.

---

**Results**

assert(results) specifies the required match results. The possible results are:

<table>
<thead>
<tr>
<th>Numeric code</th>
<th>Equivalent word (results)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>master</td>
<td>observation appeared in master only</td>
</tr>
<tr>
<td>2</td>
<td>using</td>
<td>observation appeared in using only</td>
</tr>
<tr>
<td>3</td>
<td>match</td>
<td>observation appeared in both</td>
</tr>
<tr>
<td>4</td>
<td>match_update</td>
<td>observation appeared in both, missing values updated</td>
</tr>
<tr>
<td>5</td>
<td>match_conflict</td>
<td>observation appeared in both, conflicting nonmissing values</td>
</tr>
</tbody>
</table>

Codes 4 and 5 can arise only if the update option is specified. If codes of both 4 and 5 could pertain to an observation, then 5 is used.

Numeric codes and words are equivalent when used in the assert() or keep() options.

The following synonyms are allowed: masters for master, usings for using, matches and matched for match, match_updates for match_update, and match_conflicts for match_conflict.

Using assert(match master) specifies that the merged file is required to include only matched master or using observations and unmatched master observations, and may not include unmatched using observations. Specifying assert() results in merge issuing an error message if there are match results you did not explicitly allow.
The order of the words or codes is not important, so all the following `assert()` specifications would be the same:

```
assert(match master)
assert(master matches)
assert(1 3)
```

When the match results contain codes other than those allowed, return code 9 is returned, and the merged dataset with the unanticipated results is left in memory to allow you to investigate.

`keep(results)` specifies which observations are to be kept from the merged dataset. Using `keep(match master)` specifies keeping only matched observations and unmatched master observations after merging.

`keep()` differs from `assert()` because it selects observations from the merged dataset rather than enforcing requirements. `keep()` is used to pare the merged dataset to a given set of observations when you do not care if there are other observations in the merged dataset. `assert()` is used to verify that only a given set of observations is in the merged dataset.

You can specify both `assert()` and `keep()`. If you require matched observations and unmatched master observations but you want only the matched observations, then you could specify `assert(match master) keep(match)`.

`assert()` and `keep()` are convenience options whose functionality can be duplicated using `_merge` directly.

```
merge ... assert(match master) keep(match)
```

is identical to

```
merge ...
assert _merge==1 | _merge==3
keep if _merge==3
```

The following option is available with `merge` but is not shown in the dialog box:

`sorted` specifies that the master and using datasets are already sorted by `varlist`. If the datasets are already sorted, then `merge` runs a little more quickly; the difference is hardly detectable, so this option is of interest only where speed is of the utmost importance.

**Remarks and examples**

Remarks are presented under the following headings:

- Overview
- Basic description
- 1:1 merges
- m:1 merges
- 1:m merges
- m:m merges
- Sequential merges
- Treatment of overlapping variables
- Sort order
- Troubleshooting m:m merges
- Working with alias variables
- Examples
- Video example
**Overview**

`merge 1:1 varlist ...` specifies a one-to-one match merge. `varlist` specifies variables common to both datasets that together uniquely identify single observations in both datasets. For instance, suppose you have a dataset of customer information, called `customer.dta`, and have a second dataset of other information about roughly the same customers, called `other.dta`. Suppose further that both datasets identify individuals by using the `pid` variable, and there is only one observation per individual in each dataset. You would merge the two datasets by typing

```
    . use customer
    . merge 1:1 pid using other
```

Reversing the roles of the two files would be fine. Choosing which dataset is the master and which is the using matters only if there are overlapping variable names. `1:1` merges are less common than `1:m` and `m:1` merges.

`merge 1:m` and `merge m:1` specify one-to-many and many-to-one match merges, respectively. To illustrate the two choices, suppose you have a dataset containing information about individual hospitals, called `hospitals.dta`. In this dataset, each observation contains information about one hospital, which is uniquely identified by the `hospitalid` variable. You have a second dataset called `discharges.dta`, which contains information on individual hospital stays by many different patients. `discharges.dta` also identifies hospitals by using the `hospitalid` variable. You would like to join all the information in both datasets. There are two ways you could do this.

`merge 1:m varlist ...` specifies a one-to-many match merge.

```
    . use hospitals
    . merge 1:m hospitalid using discharges
```

would join the discharge data to the hospital data. This is a `1:m` merge because `hospitalid` uniquely identifies individual observations in the dataset in memory (`hospitals`), but could correspond to many observations in the using dataset.

`merge m:1 varlist ...` specifies a many-to-one match merge.

```
    . use discharges
    . merge m:1 hospitalid using hospitals
```

would join the hospital data to the discharge data. This is an `m:1` merge because `hospitalid` can correspond to many observations in the master dataset, but uniquely identifies individual observations in the using dataset.

`merge m:m varlist ...` specifies a many-to-many match merge. This is allowed for completeness, but it is difficult to imagine an example of when it would be useful. For an `m:m` merge, `varlist` does not uniquely identify the observations in either dataset. Matching is performed by combining observations with equal values of `varlist`; within matching values, the first observation in the master dataset is matched with the first matching observation in the using dataset; the second, with the second; and so on. If there is an unequal number of observations within a group, then the last observation of the shorter group is used repeatedly to match with subsequent observations of the longer group. Use of `merge m:m` is not encouraged.

`merge 1:1 _n` performs a sequential merge. `_n` is not a variable name; it is Stata syntax for observation number. A sequential merge performs a one-to-one merge on observation number. The first observation of the master dataset is matched with the first observation of the using dataset; the second, with the second; and so on. If there is an unequal number of observations, the remaining observations are unmatched. Sequential merges are dangerous, because they require you to rely on sort order to know that observations belong together. Use this merge at your own risk.
Basic description

Think of merge as being master + using = merged result.

Call the dataset in memory the master dataset, and the dataset on disk the using dataset. This way we have general names that are not dependent on individual datasets.

Suppose we have two datasets,

\[
\begin{array}{|c|c|}
\hline
\text{id} & \text{age} \\
\hline
1 & 22 \\
2 & 56 \\
5 & 17 \\
\hline
\end{array}
\quad \quad \quad \quad
\begin{array}{|c|c|}
\hline
\text{id} & \text{wgt} \\
\hline
1 & 130 \\
2 & 180 \\
4 & 110 \\
\hline
\end{array}
\]

We would like to join together the age and weight information. We notice that the id variable identifies unique observations in both datasets: if you tell me the id number, then I can tell you the one observation that contains information about that id. This is true for both the master and the using datasets.

Because id uniquely identifies observations in both datasets, this is a 1:1 merge. We can bring in the dataset from disk by typing

\[. \text{merge 1:1 id using } \text{filename} \]

\[
\begin{array}{|c|c|}
\hline
\text{id} & \text{age} \\
\hline
1 & 22 \\
2 & 56 \\
5 & 17 \\
\hline
\end{array}
\quad \quad \quad \quad
\begin{array}{|c|c|}
\hline
\text{id} & \text{wgt} \\
\hline
1 & 130 \\
2 & 180 \\
4 & 110 \\
\hline
\end{array}
= \begin{array}{|c|c|c|}
\hline
\text{id} & \text{age} & \text{wgt} \\
\hline
1 & 22 & 130 \\
2 & 56 & 180 \\
4 & . & 110 \\
\hline
\end{array}
\]

The original data in memory are called the master data. The data in filename.dta are called the using data. After merge, the merged result is left in memory. The id variable is called the key variable. Stata jargon is that the datasets were merged on id.

Observations for id==1 existed in both the master and using datasets and so were combined in the merged result. The same occurred for id==2. For id==5 and id==4, however, no matches were found and thus each became a separate observation in the merged result. Thus each observation in the merged result came from one of three possible sources:

<table>
<thead>
<tr>
<th>Numeric code</th>
<th>Equivalent word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>master</td>
<td>originally appeared in master only</td>
</tr>
<tr>
<td>2</td>
<td>using</td>
<td>originally appeared in using only</td>
</tr>
<tr>
<td>3</td>
<td>match</td>
<td>originally appeared in both</td>
</tr>
</tbody>
</table>
merge encodes this information into new variable _merge, which merge adds to the merged result:

\[
\begin{array}{c|c}
\text{in memory} & \text{in \textit{filename.dta}} \\
\hline
\text{master} & \text{using} \\
\hline
1 & 22 \\
2 & 56 \\
5 & 17 \\
\end{array}
\begin{array}{c|c}
\text{+} & \text{=} \\
\hline
1 & 130 \\
2 & 180 \\
4 & 110 \\
\end{array}
\begin{array}{c|c|c|c}
\text{id} & \text{age} & \text{id} & \text{wgt} & \text{id} & \text{age} & \text{wgt} & \text{_merge} \\
\hline
1 & 22 & 1 & 130 & 1 & 22 & 130 & 3 \\
2 & 56 & 2 & 180 & 2 & 56 & 180 & 3 \\
5 & 17 & 4 & 110 & 4 & . & 110 & 2 \\
\end{array}
\]

Note: Above we show the master and using data sorted by id before merging; this was for illustrative purposes. The dataset resulting from a 1:1 merge will have the same data, regardless of the sort order of the master and using datasets.

The formal definition for merge behavior is the following: Start with the first observation of the master. Find the corresponding observation in the using data, if there is one. Record the matched or unmatched result. Proceed to the next observation in the master dataset. When you finish working through the master dataset, work through unused observations from the using data. By default, unmatched observations are kept in the merged data, whether they come from the master dataset or the using dataset.

Remember this formal definition. It will serve you well.

### 1:1 merges

The example shown above is called a 1:1 merge, because the key variable uniquely identified each observation in each of the datasets.

A variable or variable list uniquely identifies the observations if each distinct value of the variable(s) corresponds to one observation in the dataset.

In some datasets, multiple variables are required to identify the observations. Imagine data obtained by observing patients at specific points in time so that variables pid and time, taken together, identify the observations. Below we have two such datasets and run a 1:1 merge on pid and time,

\[
\text{. merge 1:1 pid time using \textit{filename}} \\
\text{master + using = merged result}
\]

\[
\begin{array}{c|c|c}
\text{pid} & \text{time} & \text{x1} \\
\hline
14 & 1 & 0 \\
14 & 2 & 0 \\
14 & 4 & 0 \\
16 & 1 & 1 \\
16 & 2 & 1 \\
17 & 1 & 0 \\
\end{array}
\begin{array}{c|c|c}
\text{pid} & \text{time} & \text{x2} \\
\hline
14 & 1 & 7 \\
14 & 2 & 9 \\
16 & 2 & 3 \\
17 & 1 & 5 \\
\end{array}
\begin{array}{c|c|c|c|c}
\text{pid} & \text{time} & \text{x1} & \text{x2} & \text{_merge} \\
\hline
14 & 1 & 0 & 7 & 3 \\
14 & 2 & 0 & 9 & 3 \\
16 & 1 & 1 & 2 & 3 \\
16 & 2 & 1 & 3 & 3 \\
17 & 1 & 0 & 5 & 3 \\
17 & 2 & . & 2 & 2 \\
\end{array}
\]

This is a 1:1 merge because the combination of the values of pid and time uniquely identifies observations in both datasets.

By default, there is nothing about a 1:1 merge that implies that all, or even any of, the observations match. Above five observations matched, one observation was only in the master (subject 14 at time 4), and another was only in the using (subject 17 at time 2).
m:1 merges

In an m:1 merge, the key variable or variables uniquely identify the observations in the using data, but not necessarily in the master data. Suppose you had person-level data within regions and you wished to bring in regional data. Here is an example:

```
. merge m:1 region using filename
    master + using = merged result
```

<table>
<thead>
<tr>
<th>id</th>
<th>region</th>
<th>a</th>
<th>region</th>
<th>x</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>26</td>
<td>1</td>
<td>15</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>29</td>
<td>2</td>
<td>13</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>22</td>
<td>3</td>
<td>12</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
<td>21</td>
<td>4</td>
<td>11</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>24</td>
<td>5</td>
<td>24</td>
</tr>
<tr>
<td>6</td>
<td>5</td>
<td>20</td>
<td>6</td>
<td>20</td>
</tr>
</tbody>
</table>

To bring in the regional information, we need to merge on region. The values of region identify individual observations in the using data, but it is not an identifier in the master data.

We show the merged dataset sorted by id because this makes it easier to see how the merged dataset was constructed. For each observation in the master data, merge finds the corresponding observation in the using data. merge combines the values of the variables in the using dataset to the observations in the master dataset.

1:m merges

1:m merges are similar to m:1, except that now the key variables identify unique observations in the master dataset. Any datasets that can be merged using an m:1 merge may be merged using a 1:m merge by reversing the roles of the master and using datasets. Here is the same example as used previously, with the master and using datasets reversed:

```
. merge 1:m region using filename
    master + using = merged result
```

<table>
<thead>
<tr>
<th>region</th>
<th>x</th>
<th>id</th>
<th>region</th>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>15</td>
<td>1</td>
<td>2</td>
<td>26</td>
</tr>
<tr>
<td>2</td>
<td>13</td>
<td>2</td>
<td>1</td>
<td>29</td>
</tr>
<tr>
<td>3</td>
<td>12</td>
<td>3</td>
<td>2</td>
<td>22</td>
</tr>
<tr>
<td>4</td>
<td>11</td>
<td>4</td>
<td>3</td>
<td>21</td>
</tr>
<tr>
<td>5</td>
<td>24</td>
<td>5</td>
<td>1</td>
<td>26</td>
</tr>
<tr>
<td>6</td>
<td>20</td>
<td>6</td>
<td>5</td>
<td>20</td>
</tr>
</tbody>
</table>

This merged result is identical to the merged result in the previous section, except for the sort order and the contents of _merge. This time, we show the merged result sorted by region rather than id. Reversing the roles of the files causes a reversal in the 1s and 2s for _merge: where _merge was previously 1, it is now 2, and vice versa. These exchanged _merge values reflect the reversed roles of the master and using data.

For each observation in the master data, merge found the corresponding observation(s) in the using data and then wrote down the matched or unmatched result. Once the master observations were exhausted, merge wrote down any observations from the using data that were never used.
**m:m merges**

m:m specifies a many-to-many merge and is a bad idea. In an m:m merge, observations are matched within equal values of the key variable(s), with the first observation being matched to the first; the second, to the second; and so on. If the master and using have an unequal number of observations within the group, then the last observation of the shorter group is used repeatedly to match with subsequent observations of the longer group. Thus m:m merges are dependent on the current sort order—something which should never happen.

Because m:m merges are such a bad idea, we are not going to show you an example. If you think that you need an m:m merge, then you probably need to work with your data so that you can use a 1:m or m:1 merge. Tips for this are given in Troubleshooting m:m merges below.

**Sequential merges**

In a sequential merge, there are no key variables. Observations are matched solely on their observation number:

```
. merge 1:1 _n using filename
master + using = merged result
```

<table>
<thead>
<tr>
<th>x1</th>
<th>x2</th>
<th>x1</th>
<th>x2</th>
<th>_merge</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>7</td>
<td>10</td>
<td>7</td>
<td>3</td>
</tr>
<tr>
<td>30</td>
<td>2</td>
<td>30</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>1</td>
<td>20</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
<td>5</td>
<td>9</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td></td>
<td>3</td>
<td>2</td>
</tr>
</tbody>
</table>

In the example above, the using data are longer than the master, but that could be reversed. In most cases where sequential merges are appropriate, the datasets are expected to be of equal length, and you should type

```
. merge 1:1 _n using filename, assert(match) nogenerate
```

Sequential merges, like m:m merges, are dangerous. Both depend on the current sort order of the data.

**Treatment of overlapping variables**

When performing merges of any type, the master and using datasets may have variables in common other than the key variables. We will call such variables overlapping variables. For instance, if the variables in the master and using datasets are

| master: | id, region, sex, age, race |
| using:   | id, sex, bp, race         |

and id is the key variable, then the overlapping variables are sex and race.

By default, merge treats values from the master as inviolable. When observations match, it is the master’s values of the overlapping variables that are recorded in the merged result.
If you specify the `update` option, however, then all missing values of overlapping variables in matched observations are replaced with values from the using data. Because of this new behavior, the merge codes change somewhat. Codes 1 and 2 keep their old meaning. Code 3 splits into codes 3, 4, and 5. Codes 3, 4, and 5 are filtered according to the following rules; the first applicable rule is used.

5 corresponds to matched observations where at least one overlapping variable had conflicting nonmissing values.
4 corresponds to matched observations where at least one missing value was updated, but there were no conflicting nonmissing values.
3 means observations matched, and there were neither updated missing values nor conflicting nonmissing values.

If you specify both the `update` and `replace` options, then the `_merge==5` cases are updated with values from the using data.

**Sort order**

As we have mentioned, in the 1:1, 1:m, and m:1 match merges, the sort orders of the master and using datasets do not affect the data in the merged dataset. This is not the case of m:m, which we recommend you never use.

Sorting is used by `merge` internally for efficiency, so the merged result can be produced most quickly when the master and using datasets are already sorted by the key variable(s) before merging. You are not required to have the dataset sorted before using `merge`, however, because `merge` will sort behind the scenes, if necessary. If the using dataset is not sorted, then a temporary copy is made and sorted to ensure that the current sort order on disk is not affected.

All of this is to reassure you that 1) your datasets on disk will not be modified by `merge` and 2) despite the fact that our discussion has ignored sort issues, `merge` is, in fact, efficient behind the scenes.

It hardly makes any difference in run times, but if you know that the master and using data are already sorted by the key variable(s), then you can specify the `sorted` option. All that will be saved is the time `merge` would spend discovering that fact for itself.

The merged result produced by `merge` orders the variables and observations in a special and sometimes useful way. If you think of datasets as tables, then the columns for the new variables appear to the right of what was the master. If the master data originally had \( k \) variables, then the new variables will be the \((k + 1)\)st, \((k + 2)\)nd, and so on. The new observations are similarly ordered so that they all appear at the end of what was the master. If the master originally had \( N \) observations, then the new observations, if any, are the \((N + 1)\)st, \((N + 2)\)nd, and so on. Thus the original master data can be found from the merged result by extracting the first \( k \) variables and first \( N \) observations. If `merge` with the `update` option was specified, however, then be aware that the extracted master may have some updated values.

If you care about the ordering of observations in the data after a merge, then you should sort the data after the merge. You should sort it in such a way that it has a unique ordering; see *Sorting with ties* in [D] `sort`. If, against this recommendation, you wish to have a reproducible ordering after a merge, then read the next paragraph. But be forewarned; just because something is reproducible does not mean it is useful. Again, see *Sorting with ties*.

The resulting dataset after any merge is unsorted. That is to say, if you type `describe`, the “Sorted by” result will be empty. That is not to say that the data will not be ordered; a dataset always has an order. After 1:1 merges, the ordering will always be in the original order of the master dataset,
with any additional observations from the using dataset at the bottom and in their order from the using dataset. For all other merges, you will need to go to some effort to ensure a reproducible ordering. For m:1, 1:m, and m:m merges, you must first sort the master and using datasets by the merge keys and by other variables that will produce a unique ordering of the dataset. You may have to create those other variables. (See Sorting with ties for obtaining a unique sort.) After m:1 merges, the ordering will be the original ordering of the master data with any unmatched observations from the using dataset appended to the bottom in their order from the using dataset. After 1:m and m:m merges, the ordering is difficult to explain. Regardless, the ordering will be the same if you repeat the merge after uniquely sorting each dataset—it is reproducible.

**Troubleshooting m:m merges**

First, if you think you need to perform an m:m merge, then we suspect you are wrong. If you would like to match every observation in the master to every observation in the using with the same values of the key variable(s), then you should be using joinby; see [D] joinby.

If you still want to use merge, then it is likely that you have forgotten one or more key variables that could be used to identify observations within groups. Perhaps you have panel data with 4 observations on each subject, and you are thinking that what you need to do is

```bash
.merge m:m subjectid using filename
```

Ask yourself if you have a variable that identifies observation within panel, such as a sequence number or a time. If you have, say, a time variable, then you probably should try something like

```bash
.merge 1:m subjectid time using filename
```

(You might need a 1:1 or m:1 merge; 1:m was arbitrarily chosen for the example.)

If you do not have a time or time-like variable, then ask yourself if there is a meaning to matching the first observations within subject, the second observations within subject, and so on. If so, then there is a concept of sequence within subject.

Suppose you do indeed have a sequence concept, but in your dataset it is recorded via the ordering of the observations. Here you are in a dangerous situation because any kind of sorting would lose the identity of the first, second, and nth observation within subject. Your first goal should be to fix this problem by creating an explicit sequence variable from the current ordering—your merge can come later.

Start with your master data. Type

```bash
.sort subjectid, stable
.by subjectid: generate seqnum = _n
```

Do not omit sort’s stable option. That is what will keep the observations in the same order within subject. Save the data. Perform these same three steps on your using data.

After fixing the datasets, you can now type

```bash
.merge 1:m subjectid seqnum using filename
```

If you do not think there is a meaning to being the first, second, and nth observation within subject, then you need to ask yourself what it means to match the first observations within subject, the second observations within subject, and so on. Would it make equal sense to match the first with the third, the second with the fourth, or any other haphazard matching? If so, then there is no real ordering, so there is no real meaning to merging. You are about to obtain a haphazard result; you need to rethink your merge.
Working with alias variables

`merge` allows alias variables in the master and using datasets, with the following restrictions. An alias variable with a broken linkage will cause `merge` to exit with an informative error message; see [D] `fralias` for examples.

If a key variable in the master dataset is an alias, then it must be an alias with the same linkage in the using dataset; otherwise, you get something like the following error message:

```
variable keyvar is alias in master data but float in using data
Key variables (on which observations are matched) may be type alias, but their alias characteristics must match between the master and using datasets for the merged data to be correct and complete. When alias characteristics do not match, or when a master key variable is alias but the using key variable is not, you could use command `frunalias` to recast the key variables in the master data to avoid this error message.
```

```
r(106);
```

If an overlapping variable in the master dataset is an alias, then it must be an alias with the same linkage in the using dataset; otherwise, you get something like the following error message:

```
variable ovar is alias in master data but float in using data
You could use command `frunalias` to recast `ovar` in the master data to avoid this error message.
```

```
r(106);
```

Examples

Example 1: A 1:1 merge

We have two datasets, one of which has information about the size of old automobiles and the other of which has information about their expense:

```
. use https://www.stata-press.com/data/r18/autosize
(1978 automobile data)
. list
```

<table>
<thead>
<tr>
<th>make</th>
<th>weight</th>
<th>length</th>
</tr>
</thead>
<tbody>
<tr>
<td>Toyota Celica</td>
<td>2,410</td>
<td>174</td>
</tr>
<tr>
<td>BMW 320i</td>
<td>2,650</td>
<td>177</td>
</tr>
<tr>
<td>Cad. Seville</td>
<td>4,290</td>
<td>204</td>
</tr>
<tr>
<td>Pont. Grand Prix</td>
<td>3,210</td>
<td>201</td>
</tr>
<tr>
<td>Datsun 210</td>
<td>2,020</td>
<td>165</td>
</tr>
<tr>
<td>Plym. Arrow</td>
<td>3,260</td>
<td>170</td>
</tr>
</tbody>
</table>

```
. use https://www.stata-press.com/data/r18/autoexpense
(1978 automobile data)
. list
```

<table>
<thead>
<tr>
<th>make</th>
<th>price</th>
<th>mpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>Toyota Celica</td>
<td>5,899</td>
<td>18</td>
</tr>
<tr>
<td>BMW 320i</td>
<td>9,735</td>
<td>25</td>
</tr>
<tr>
<td>Cad. Seville</td>
<td>15,906</td>
<td>21</td>
</tr>
<tr>
<td>Pont. Grand Prix</td>
<td>5,222</td>
<td>19</td>
</tr>
<tr>
<td>Datsun 210</td>
<td>4,589</td>
<td>35</td>
</tr>
</tbody>
</table>
We can see that these datasets contain different information about nearly the same cars—the autosize file has one more car. We would like to get all the information about all the cars into one dataset.

Because we are adding new variables to old variables, this is a job for the `merge` command. We need only to decide what type of match merge we need.

Looking carefully at the datasets, we see that the `make` variable, which identifies the cars in each of the two datasets, also identifies individual observations within the datasets. What this means is that if you tell me the make of car, I can tell you the one observation that corresponds to that car. Because this is true for both datasets, we should use a 1:1 merge.

We will start with a clean slate to show the full process:

```
. use https://www.stata-press.com/data/r18/autosize
(1978 automobile data)
. merge 1:1 make using https://www.stata-press.com/data/r18/autoexpense
Result Number of obs
Not matched 1
from master 1 (_merge==1)
from using 0 (_merge==2)
Matched 5 (_merge==3)
. list
    make     weight   length  price  mpg  _merge
1.       BMW 320i  2,650     177    9,735  25  Matched (3)
2.      Cad. Seville  4,290    204  15,906  21  Matched (3)
3.   Datsun 210  2,020     165    4,589  35  Matched (3)
4.        Plym. Arrow  3,260    170   .    .  Master only (1)
5.    Pont. Grand Prix  3,210    201  5,222  19  Matched (3)
6.  Toyota Celica  2,410     174    5,899  18  Matched (3)
```

The merge is successful—all the data are present in the combined dataset, even that from the one car that has only size information. If we wanted only those makes for which all information is present, it would be up to us to drop the observations for which `_merge` < 3.

> Example 2: Requiring matches

Suppose we had the same setup as in the previous example, but we erroneously think that we have all the information on all the cars. We could tell `merge` that we expect only matches by using the `assert` option.

```
. use https://www.stata-press.com/data/r18/autosize, clear
(1978 automobile data)
. merge 1:1 make using https://www.stata-press.com/data/r18/autoexpense,
   > assert(match)
merge: after merge, not all observations matched
   (merged result left in memory)
r(9);
```
merge tells us that there is a problem with our assumption. To see how many mismatches there were, we can tabulate _merge:

```stata
tabulate _merge

<table>
<thead>
<tr>
<th></th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>master only (1)</td>
<td>1</td>
<td>16.67</td>
<td>16.67</td>
</tr>
<tr>
<td>matched (3)</td>
<td>5</td>
<td>83.33</td>
<td>100.00</td>
</tr>
<tr>
<td>Total</td>
<td>6</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>
```

If we would like to list the problem observation, we can type

```stata
list if _merge < 3
```

<table>
<thead>
<tr>
<th>make</th>
<th>weight</th>
<th>length</th>
<th>price</th>
<th>mpg</th>
<th>_merge</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plym. Arrow</td>
<td>3,260</td>
<td>170</td>
<td>.</td>
<td>.</td>
<td>master only (1)</td>
</tr>
</tbody>
</table>

If we were convinced that all data should be complete in the two datasets, we would have to rectify the mismatch in the original datasets.

Example 3: Keeping just the matches

Once again, suppose that we had the same datasets as before, but this time we want the final dataset to have only those observations for which there is a match. We do not care if there are mismatches—all that is important are the complete observations. By using the `keep(match)` option, we will guarantee that this happens. Because we are keeping only those observations for which the key variable matches, there is no need to generate the _merge variable. We could do the following:

```stata
use https://www.stata-press.com/data/r18/autosize, clear
merge 1:1 make using https://www.stata-press.com/data/r18/autoexpense, > keep(match) nogenerate
```

<table>
<thead>
<tr>
<th>Result</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not matched</td>
<td>0</td>
</tr>
<tr>
<td>Matched</td>
<td>5</td>
</tr>
</tbody>
</table>

```stata
list
```

<table>
<thead>
<tr>
<th>make</th>
<th>weight</th>
<th>length</th>
<th>price</th>
<th>mpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>BMW 320i</td>
<td>2,650</td>
<td>177</td>
<td>9,735</td>
<td>25</td>
</tr>
<tr>
<td>Cad. Seville</td>
<td>4,290</td>
<td>204</td>
<td>15,906</td>
<td>21</td>
</tr>
<tr>
<td>Datsun 210</td>
<td>2,020</td>
<td>165</td>
<td>4,589</td>
<td>35</td>
</tr>
<tr>
<td>Pont. Grand Prix</td>
<td>3,210</td>
<td>201</td>
<td>5,222</td>
<td>19</td>
</tr>
<tr>
<td>Toyota Celica</td>
<td>2,410</td>
<td>174</td>
<td>5,899</td>
<td>18</td>
</tr>
</tbody>
</table>
Example 4: Many-to-one matches

We have two datasets: one has salespeople in regions and the other has regional data about sales. We would like to put all the information into one dataset. Here are the datasets:

```
. use https://www.stata-press.com/data/r18/sforce, clear
(Sales Force)
. list

<table>
<thead>
<tr>
<th>region</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. N Cntrl</td>
<td>Krantz</td>
</tr>
<tr>
<td>2. N Cntrl</td>
<td>Phipps</td>
</tr>
<tr>
<td>3. N Cntrl</td>
<td>Willis</td>
</tr>
<tr>
<td>4. NE</td>
<td>Ecklund</td>
</tr>
<tr>
<td>5. NE</td>
<td>Franks</td>
</tr>
<tr>
<td>6. South</td>
<td>Anderson</td>
</tr>
<tr>
<td>7. South</td>
<td>Dubnoff</td>
</tr>
<tr>
<td>8. South</td>
<td>Lee</td>
</tr>
<tr>
<td>9. South</td>
<td>McNeil</td>
</tr>
<tr>
<td>10. West</td>
<td>Charles</td>
</tr>
<tr>
<td>11. West</td>
<td>Cobb</td>
</tr>
<tr>
<td>12. West</td>
<td>Grant</td>
</tr>
</tbody>
</table>
```

. use https://www.stata-press.com/data/r18/dollars
(Regional Sales & Costs)
. list

<table>
<thead>
<tr>
<th>region</th>
<th>sales</th>
<th>cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. N Cntrl</td>
<td>419,472</td>
<td>227,677</td>
</tr>
<tr>
<td>2. NE</td>
<td>360,523</td>
<td>138,097</td>
</tr>
<tr>
<td>3. South</td>
<td>532,399</td>
<td>330,499</td>
</tr>
<tr>
<td>4. West</td>
<td>310,565</td>
<td>165,348</td>
</tr>
</tbody>
</table>

We can see that the region would be used to match observations in the two datasets, and this time we see that region identifies individual observations in the dollars dataset but not in the sforce dataset. This means we will have to use either an m:1 or a 1:m merge. Here we will open the sforce dataset and then merge the dollars dataset. This will be an m:1 merge, because region does not identify individual observations in the dataset in memory but does identify them in the using dataset. Here is the command and its result:

```
. use https://www.stata-press.com/data/r18/sforce
(Sales Force)
. merge m:1 region using https://www.stata-press.com/data/r18/dollars
(label region already defined)
Result  Number of obs
Not matched 0
Matched 12 (_merge==3)
```
We can see from the result that all the values of `region` were matched in both datasets. This is a rare occurrence in practice!

Had we had the `dollars` dataset in memory and merged in the `sforce` dataset, we would have done a 1:m merge.

We would now like to use a series of examples that shows how `merge` treats nonkey variables, which have the same names in the two datasets. We will call these “overlapping” variables.

### Example 5: Overlapping variables

Here are two datasets whose only purpose is for this illustration:

```
. use https://www.stata-press.com/data/r18/overlap1, clear
. list, sepby(id)
```

```
id   seq   x1   x2
 1.    1    1    1    1
 2.    1    2    1    .
 3.    1    3    1    2
 4.    1    4    .    2
 5.    2    1    .    1
 6.    2    2    .    2
 7.    2    3    1    1
 8.    2    4    1    2
 9.    2    5    .a   1
10.    2    6    .a   2
11.    3    1    .    .a
12.    3    2    .    1
13.    3    3    .    .
14.    3    4    .a   .a
15.   10    1    5    8
```

```
. use https://www.stata-press.com/data/r18/overlap2
```
We can see that id can be used as the key variable for putting the two datasets together. We can also see that there are two overlapping variables: x1 and x2.

We will start with a simple m:1 merge:

```
. use https://www.stata-press.com/data/r18/overlap1
. merge m:1 id using https://www.stata-press.com/data/r18/overlap2
Result Number of obs
    Not matched                      2
      from master                      1 (_merge==1)
      from using                      1 (_merge==2)
    Matched                            14 (_merge==3)

. list, sepby(id)
```

<table>
<thead>
<tr>
<th>id</th>
<th>seq</th>
<th>x1</th>
<th>x2</th>
<th>bar</th>
<th>_merge</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>4</td>
<td>2</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>7</td>
<td>2</td>
<td>3</td>
<td>1</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>8</td>
<td>2</td>
<td>4</td>
<td>1</td>
<td>2</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>9</td>
<td>2</td>
<td>5</td>
<td>.a</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>10</td>
<td>2</td>
<td>6</td>
<td>.a</td>
<td>2</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>11</td>
<td>3</td>
<td>1</td>
<td>.a</td>
<td>14</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>12</td>
<td>3</td>
<td>2</td>
<td>.</td>
<td>14</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>13</td>
<td>3</td>
<td>3</td>
<td>.</td>
<td>14</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>14</td>
<td>3</td>
<td>4</td>
<td>.a</td>
<td>.a</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>15</td>
<td>10</td>
<td>5</td>
<td>8</td>
<td>.</td>
<td>Master only (1)</td>
</tr>
<tr>
<td>16</td>
<td>20</td>
<td></td>
<td>1</td>
<td>18</td>
<td>Using only (2)</td>
</tr>
</tbody>
</table>

Careful inspection shows that for the matched id, the values of x1 and x2 are still the values that were originally in the overlap1 dataset. This is the default behavior of merge—the data in the master dataset are the authority and are kept intact.
Example 6: Updating missing data

Now we would like to investigate the update option. Used by itself, it will replace missing values in the master dataset with values from the using dataset:

```
use https://www.stata-press.com/data/r18/overlap1, clear
merge m:1 id using https://www.stata-press.com/data/r18/overlap2, update
```

<table>
<thead>
<tr>
<th>Result</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not matched</td>
<td>2</td>
</tr>
<tr>
<td>from master</td>
<td>1 (_merge==1)</td>
</tr>
<tr>
<td>from using</td>
<td>1 (_merge==2)</td>
</tr>
<tr>
<td>Matched</td>
<td>14</td>
</tr>
<tr>
<td>not updated</td>
<td>5 (_merge==3)</td>
</tr>
<tr>
<td>missing updated</td>
<td>4 (_merge==4)</td>
</tr>
<tr>
<td>nonmissing conflict</td>
<td>5 (_merge==5)</td>
</tr>
</tbody>
</table>

```
list, sepyby(id)
```

<table>
<thead>
<tr>
<th>id</th>
<th>seq</th>
<th>x1</th>
<th>x2</th>
<th>bar</th>
<th>_merge</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>2</td>
<td>1</td>
<td>1</td>
<td>Missing updated (4)</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>3</td>
<td>1</td>
<td>2</td>
<td>Nonmissing conflict (5)</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>4</td>
<td>1</td>
<td>2</td>
<td>Nonmissing conflict (5)</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
<td>1</td>
<td>.</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>2</td>
<td>.</td>
<td>2</td>
<td>Nonmissing conflict (5)</td>
</tr>
<tr>
<td>7</td>
<td>2</td>
<td>3</td>
<td>1</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>8</td>
<td>2</td>
<td>4</td>
<td>1</td>
<td>2</td>
<td>Nonmissing conflict (5)</td>
</tr>
<tr>
<td>9</td>
<td>2</td>
<td>5</td>
<td>.</td>
<td>1</td>
<td>Missing updated (4)</td>
</tr>
<tr>
<td>10</td>
<td>2</td>
<td>6</td>
<td>.</td>
<td>2</td>
<td>Nonmissing conflict (5)</td>
</tr>
<tr>
<td>11</td>
<td>3</td>
<td>1</td>
<td>.</td>
<td>a</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>12</td>
<td>3</td>
<td>2</td>
<td>.</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>13</td>
<td>3</td>
<td>3</td>
<td>.</td>
<td>a</td>
<td>Missing updated (4)</td>
</tr>
<tr>
<td>14</td>
<td>3</td>
<td>4</td>
<td>.</td>
<td>a</td>
<td>Missing updated (4)</td>
</tr>
<tr>
<td>15</td>
<td>10</td>
<td>1</td>
<td>5</td>
<td>8</td>
<td>Master only (1)</td>
</tr>
<tr>
<td>16</td>
<td>20</td>
<td>.</td>
<td>1</td>
<td>1</td>
<td>Using only (2)</td>
</tr>
</tbody>
</table>

Looking through the resulting dataset observation by observation, we can see both what the update option updated as well as how the _merge variable gets its values.

The following is a listing that shows what is happening, where x1_m and x2_m come from the master dataset (overlap1), x1_u and x2_u come from the using dataset (overlap2), and x1 and x2 are the values that appear when using merge with the update option.
From this, we can see two important facts: if there are both a conflict and an updated value, the value of `merge` will reflect that there was a conflict, and missing values in the master dataset are updated by missing values in the using dataset.

#### Example 7: Updating all common observations

We would like to see what happens if the `update` and `replace` options are specified. The `replace` option extends the action of `update` to use nonmissing values of the using dataset to replace values in the master dataset. The values of `merge` are unaffected by using both `update` and `replace`.

```stata
. use https://www.stata-press.com/data/r18/overlap1, clear
. merge m:1 id using https://www.stata-press.com/data/r18/overlap2, update replace
```

<table>

<td>using only (2)</td>
</tr>
</tbody>
</table>

From this, we can see two important facts: if there are both a conflict and an updated value, the value of `merge` will reflect that there was a conflict, and missing values in the master dataset are updated by missing values in the using dataset.
Example 8: More on the keep() option

Suppose we would like to use the update option, as we did above, but we would like to keep only those observations for which the value of the key variable, id, was found in both datasets. This will be more complicated than in our earlier example, because the update option splits the matches into matches, match_updates, and match_conflicts. We must either use all of these code words in the keep option or use their numerical equivalents, 3, 4, and 5. Here the latter is simpler.

```stata
dc https://www.stata-press.com/data/r18/overlap1, clear
dc merge m:1 id using https://www.stata-press.com/data/r18/overlap2, update > keep(3 4 5)
```

<table>
<thead>
<tr>
<th>Result</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not matched</td>
<td>0</td>
</tr>
<tr>
<td>Matched</td>
<td>14</td>
</tr>
<tr>
<td>not updated</td>
<td>5 (_merge==3)</td>
</tr>
<tr>
<td>missing updated</td>
<td>4 (_merge==4)</td>
</tr>
<tr>
<td>nonmissing conflict</td>
<td>5 (_merge==5)</td>
</tr>
</tbody>
</table>
Example 9: A one-to-many merge

As a final example, we would like show one example of a 1:m merge. There is nothing conceptually different here; what is interesting is the order of the observations in the final dataset:

```
. use https://www.stata-press.com/data/r18/overlap2, clear
. merge 1:m id using https://www.stata-press.com/data/r18/overlap1
```

<table>
<thead>
<tr>
<th>Result</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not matched</td>
<td>2</td>
</tr>
<tr>
<td>from master</td>
<td>1 (_merge==1)</td>
</tr>
<tr>
<td>from using</td>
<td>1 (_merge==2)</td>
</tr>
<tr>
<td>Matched</td>
<td>14 (_merge==3)</td>
</tr>
</tbody>
</table>

---

<table>
<thead>
<tr>
<th>id</th>
<th>seq</th>
<th>x1</th>
<th>x2</th>
<th>bar</th>
<th>_merge</th>
</tr>

<td>Matched (3)</td>
</tr>
<tr>
<td>11</td>
<td>2</td>
<td>12</td>
<td>.</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>12</td>
<td>2</td>
<td>12</td>
<td>.</td>
<td>1</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>13</td>
<td>3</td>
<td>14</td>
<td>.</td>
<td>.a</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>14</td>
<td>3</td>
<td>14</td>
<td>.</td>
<td>.a</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>15</td>
<td>3</td>
<td>14</td>
<td>.</td>
<td>.a</td>
<td>Matched (3)</td>
</tr>
<tr>
<td>16</td>
<td>10</td>
<td>.</td>
<td>5</td>
<td>8</td>
<td>Using only (2)</td>
</tr>
</tbody>
</table>

We can see here that the first four observations come from the master dataset, and all additional observations, whether matched or unmatched, come below these observations. This illustrates that the master dataset is always in the upper-left corner of the merged dataset.
