

estat stable — Check stability of system

Description	Menu for estat	Syntax	Remarks and examples
Stored results	Methods and formulas	Reference	Also see

Description

`estat stable` displays functions of the model parameters that indicate whether the model is saddle-path stable at specific parameter values. These results can help you find initial values for which the model is saddle-path stable. Saddle-path stability is required for solving and estimating the parameters of DSGE models.

estat stable
```

Remarks and examples

[stata.com](#)

DSGE models are dynamic systems that are subject to random shocks. DSGE models that do not spiral out of control or converge to a single point when shocked are said to be “saddle-path stable”. We can solve for the state-space form of DSGE models only if they are saddle-path stable, and we can estimate the parameters of models only if we can solve for the state-space form.

The structural parameter values determine whether a DSGE model is saddle-path stable. In the process of solving the structural form for the state-space form, the [Klein \(2000\)](#) solver computes the generalized eigenvalues of a matrix formed from structural parameter values. An eigenvalue is said to be stable when its absolute value is less than 1. The model is saddle-path stable when the number of stable eigenvalues equals the number of states in the model.

`estat stable` displays the generalized eigenvalues implied by the parameter values in `e(b)`, indicates which are stable and which are unstable, and displays a note indicating whether the model is saddle-path stable at these parameter values. `estat stable` can help you find initial values for the maximization routine when the default values imply a model that is not saddle-path stable; see [\[DSGE\] Intro 5](#) for details.

Stored results

`estat stable` stores the following in `r()`:

Scalars	
<code>r(stable)</code>	1 if stable, 0 otherwise
Matrices	
<code>r(eigenvalues)</code>	eigenvalues

Methods and formulas

`estat stable` displays the generalized eigenvalues computed by the [Klein \(2000\)](#) solver. Values less than 1 are labeled as stable; values greater than or equal to 1 are labeled as unstable.
