Description

vl rebuild restores system-defined and user-defined variable lists. After loading a dataset with use, run vl rebuild.

After using merge or append, run vl rebuild to merge variable lists. You only need to run vl rebuild when the using dataset has variable lists.

After dropping variables with drop, run vl rebuild to remove the dropped variables from all variable lists.

After modifying variable lists with vl modify or vl move, run vl rebuild to update variable lists created by vl substitute.

And if you are confused, know that it never hurts to run vl rebuild.

For an introduction to the vl commands, see [D] **vl**.

Quick start

Restore variable lists after loading a dataset with use

    vl rebuild

After running merge when the using dataset has variable lists, merge its variable lists into those in the master dataset

    vl rebuild

After dropping variables with drop, remove the dropped variables from all variable lists

    vl rebuild

Update a variable list created by vl substitute after modifying any of its component variable lists

    vl rebuild

Syntax

    vl rebuild

collect is allowed; see **[U] 11.1.10 Prefix commands**.

Remarks and examples

Remarks are presented under the following headings:

Reloading datasets

System-defined and user-defined variable lists are saved with the dataset. However, they are not automatically restored when you reload the data. Just type `vl rebuild` to restore them.

```
. use $...$
. vl rebuild
```

Merging datasets

Another time when `vl rebuild` is needed is when a `merge` is done and the `using` dataset has variable lists.

```
. merge $...$ using filename
. vl rebuild
```

Only when *filename* has variable lists is it necessary to run `vl rebuild`. When both the master dataset in memory and *filename* have variable lists, `vl rebuild` merges them. When the master dataset has variable lists but *filename* does not, there is no need to run `vl rebuild`. However, running `vl rebuild` is always harmless.

Dropping variables

When you drop variables from the data in memory using `drop`, the dropped variables are not automatically removed from variable lists. They can be explicitly removed by using `vl drop`.

```
. drop varlist
. vl drop (varlist)
```

Instead of running `vl drop` with the list of variables that were dropped, you can simply type

```
. vl rebuild
```

It will do the same thing, and you do not have to remember the names of the variables that were dropped.

If you drop or add observations or change any of the values of variables in variable lists, `vl rebuild` does not update the stored variable statistics, namely, the number of levels, the minimum and maximum values, and the number of nonmissing observations. If you want to update these statistics without changing the system-defined classifications, type

```
. vl set, update
```

If you want to update the statistics and redo the system-defined classifications for all variables, type

```
. vl set, clear
```

See [D] **vl set**.

vl substitute and vl rebuild

vl rebuild has another important use. It will update variable lists created by vl substitute.

For example, we created two user-defined variable lists:

```
. vl create myfactors = (x1 x2 x3)
. vl create mycontinuous = (c1 c2 c3 c4 c5)
```

Then we created a variable list using factor-variable operators:

```
. vl substitute myinteraction = i.myfactors##c.mycontinuous
```

If we modify mycontinuous,

```
. vl modify mycontinuous = mycontinuous - (c3)
```

then the global macro $myinteraction for the variable list myinteraction remains unchanged.

Running

```
. vl rebuild
```

updates the global macro $myinteraction.

Again, if you make any changes to your data or to your variable lists, and you want to make sure everything is set properly and up to date, just type

```
. vl rebuild
```

Characteristics

Advanced Stata users will likely guess how variable lists and variable statistics are stored with the dataset. They are stored as characteristics. If you want to see them, type

```
. char list
```

See [P] **char**.

Stored results

vl rebuild stores the following in r():

Scalars
r(k_system)	number of variables in system-defined variable lists
r(k_vlcategorical)	number of variables in vlcategorical
r(k_vlcontinuous)	number of variables in vlcontinuous
r(k_vluncertain)	number of variables in vluncertain
r(k_vlother)	number of variables in vlother
r(k_vldummy)	number of variables in vldummy when defined
r(k_user)	number of variables in user-defined variable lists
r(k_*vlusername*)	number of variables in *vlusername*

Macros
r(vlsysnames)	names of system-defined variable lists
r(vlusernames)	names of user-defined variable lists
