eintreg fits an interval regression model that accommodates any combination of endogenous covariates, nonrandom treatment assignment, and endogenous sample selection. Continuous, binary, and ordinal endogenous covariates are allowed. Treatment assignment may be endogenous or exogenous. A probit or tobit model may be used to account for endogenous sample selection.

xteintreg fits a random-effects interval regression model that accommodates endogenous covariates, treatment, and sample selection in the same way as eintreg and also accounts for correlation of observations within panels or within groups.

Quick start
All quick start examples use an interval-measured dependent variable with the interval’s lower bound recorded in variable y_l and its upper bound recorded in y_u.

Regression of \([y_l, y_u]\) on \(x\) with continuous endogenous covariate \(y2\) modeled by \(x\) and \(z\)
eintreg y_l y_u x, endogenous(y2 = x z)

As above, but adding continuous endogenous covariate \(y3\) modeled by \(x\) and \(z2\)
eintreg y_l y_u x, endogenous(y2 = x z) endogenous(y3 = x z2)

Regression of \([y_l, y_u]\) on \(x\) with binary endogenous covariate \(d\) modeled by \(x\) and \(z\)
eintreg y_l y_u x, endogenous(d = x z, probit)

Regression of \([y_l, y_u]\) on \(x\) with endogenous treatment recorded in \(trtvar\) and modeled by \(x\) and \(z\)
eintreg y_l y_u x, entreat(trtvar = x z)

Regression of \([y_l, y_u]\) on \(x\) with exogenous treatment recorded in \(trtvar\)
eintreg y_l y_u x, extreat(trtvar)

Random-effects regression of \([y_l, y_u]\) on \(x\) using \(xtset\) data
xteintreg y_l y_u x

Regression of \([y_l, y_u]\) on \(x\) with endogenous sample-selection indicator \(selvar\) modeled by \(x\) and \(z\)
eintreg y_l y_u x, select(selvar = x z)

As above, but adding endogenous covariate \(y2\) modeled by \(x\) and \(z2\)
eintreg y_l y_u x, select(selvar = x z) endogenous(y2 = x z2)
As above, but adding endogenous treatment recorded in `trtvar` and modeled by `x` and `z3`

```plaintext
  eintreg y_l y_u x, select(selvar = x z) endogenous(y2 = x z2) ///
  entreat(trtvar = x z3)
```

As above, but with random effects and without endogenous treatment

```plaintext
  xteintreg y_l y_u x, select(selvar = x z) endogenous(y2 = x z2)
```

enspec is depvars_en = varlist_en [ , enopts ]

where depvars_en is a list of endogenous covariates. Each variable in depvars_en specifies an endogenous covariate model using the common varlist_en and options.

entrspec is depvar_tr[ = varlist_tr ] [ , entropts ]

where depvar_tr is a variable indicating treatment assignment. varlist_tr is a list of covariates predicting treatment assignment.
extrspec is `tvar [ , extropts]`

where `tvar` is a variable indicating treatment assignment.

selsec is `depvar = varlist [ , selopts]`

where `depvar` is a variable indicating selection status. `depvar` must be coded as 0, indicating that the observation was not selected, or 1, indicating that the observation was selected. `varlist` is a list of covariates predicting selection.

tselsec is `depvar = varlist [ , tselopts]`

where `depvar` is a continuous variable. `varlist` is a list of covariates predicting `depvar`. The censoring status of `depvar` indicates selection, where a censored `depvar` indicates that the observation was not selected and a noncensored `depvar` indicates that the observation was selected.

### Options

#### Model

- `endogenous(enspec), entreat(entrspec), extreat(extrspec), select(selspec), tobitselect(tselspec)`; see [ERM] ERM options.
- `noconstant`, `offset(varname_o)`, `constraints(numlist)`; see [R] Estimation options.

#### SE/Robust

- `vce(vcetype)`; see [ERM] ERM options.

#### Reporting

- `level(#), nocnsreport`; see [R] Estimation options.

**display_options**: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels,nofvlabel, fvwrap(#), fvwrapon(style), cf\texttt{format}(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.
Integration

\[ \text{intpoints}(\#), \text{triintpoints}(\#), \text{reintpoints}(\#), \text{reintmethod}(\text{intmethod}) \]; see [ERM] ERM options.

Maximization

\[ \text{maximize} \text{ options: difficult, technique(} \text{algorithm}\_\text{spec})\], \text{iterate}(\#), \text{[no]} \log, \text{trace}, \text{gradient}, \text{showstep, hessian, showtolerance, tolerance}(\#), \text{ltolerance}(\#), \text{nrtolerance}(\#), \text{nonrtolerance, and from(} \text{init}\_\text{specs}) \]; see [R] Maximize.

The default technique for \text{eintreg} is technique(nr). The default technique for \text{xteintreg} is technique(bhhh 10 nr 2).

Setting the optimization type to technique(bhhh) resets the default \text{vcetype} to vce(opg).

The following options are available with \text{eintreg} and \text{xteintreg} but are not shown in the dialog box:

collinear, coeflegend; see [R] Estimation options.

Remarks and examples

\text{eintreg} and \text{xteintreg} fit models that we refer to as “extended interval regression models”, meaning that they accommodate endogenous covariates, nonrandom treatment assignment, endogenous sample selection, and panel data or other grouped data.

\text{eintreg} fits models for cross-sectional data (one-level models). \text{eintreg} can account for endogenous covariates, treatment, and sample selection, whether these complications arise individually or in combination.

\text{xteintreg} fits random-effects models (two-level models) for panel data or grouped data. \text{xteintreg} accounts for endogenous covariates, treatment, and sample selection in the same way as \text{eintreg} and also accounts for within-panel or within-group correlation among observations.

In this entry, you will find information on the syntax for the \text{eintreg} and \text{xteintreg} commands. You can see \text{Methods and formulas} for a full description of the models that can be fit with these commands and for details about how those models are fit.

More information on extended interval regression models is found in the separate introductions and example entries. We recommend reading those entries to learn how to use \text{eintreg} and \text{xteintreg}. Below, we provide a guide to help you locate the ones that will be helpful to you.

For an introduction to \text{eintreg}, \text{xteintreg}, and the other extended regression commands for continuous, binary, and ordinal outcomes, see [ERM] Intro 1–[ERM] Intro 9.

[ERM] Intro 1 introduces the ERM commands, the problems they address, and their syntax.

[ERM] Intro 2 provides background on the four types of models—linear regression, interval regression, probit regression, and ordered probit regression—that can be fit using ERM commands. This intro also demonstrates how to fit tobit models using \text{eintreg} by transforming your dependent variable into the required format. This same transformation can be used to fit random-effects tobit models with \text{xteintreg}.

[ERM] Intro 3 considers the problem of endogenous covariates and how to solve it using ERM commands.

[ERM] Intro 4 gives an overview of endogenous sample selection and using ERM commands to account for it.
[ERM] Intro 5 covers nonrandom treatment assignment and how to account for it using \texttt{eintreg} or any of the other ERM commands.

[ERM] Intro 6 covers random-effects models for panel data and other grouped data. It discusses \texttt{xteintreg} and the other ERM commands for panel data.

[ERM] Intro 7 discusses interpretation of results. You can interpret coefficients from \texttt{eintreg} and \texttt{xteintreg} in the usual way, but this introduction goes beyond the interpretation of coefficients. We demonstrate how to find answers to interesting questions by using \texttt{margins}. If your model includes an endogenous covariate or an endogenous treatment, the use of \texttt{margins} differs from its use after other estimation commands, so we strongly recommend reading this intro if you are fitting these types of models.

[ERM] Intro 8 will be helpful if you are familiar with \texttt{ivtobit}, \texttt{xtintreg}, \texttt{xttobit}, and other commands that address endogenous covariates, sample selection, nonrandom treatment assignment, or panel data. This introduction is a Rosetta stone that maps the syntax of those commands to the syntax of \texttt{eintreg} and \texttt{xteintreg}.

[ERM] Intro 9 walks you through an example that gives insight into the concepts of endogenous covariates, treatment assignment, and sample selection while fitting models with \texttt{eregress} that address these complications. Although the example uses \texttt{eregress}, the discussion applies equally to \texttt{eintreg}. This intro also demonstrates how to interpret results by using \texttt{margins} and \texttt{estat teffects}.

Additional examples are presented in [ERM] Example 1a–[ERM] Example 9. For examples using \texttt{eintreg}, see

[ERM] Example 1b Interval regression with continuous endogenous covariate

[ERM] Example 1c Interval regression with endogenous covariate and sample selection

See Examples in [ERM] Intro for an overview of all the examples. All examples may be interesting because they handle complications in the same way. Examples using \texttt{eregress} and \texttt{xteregress} will be of particular interest because results of models fit by \texttt{eintreg} and \texttt{xteintreg} are interpreted in the same way.

\texttt{eintreg} and \texttt{xteintreg} fit many models discussed in the literature. For instance, the tobit model was originally conceived in Tobin (1958) as a model of consumption of consumer durables, where purchases were left-censored at 0. Wooldridge (2020, sec. 17.4) introduces censored and truncated regression models. Cameron and Trivedi (2010, chap. 16) discuss the tobit model using Stata examples. \texttt{eintreg} can also fit models like the tobit regression model with continuous endogenous regressors (Newey 1987) and the censored regression model with binary endogenous regressors (Angrist 2001). \texttt{xteintreg} can fit the random-effects tobit model discussed in (Wooldridge 2010, sec. 17.8). Roodman (2011) investigated interval regression models with endogenous covariates and endogenous sample selection and demonstrated how multiple observational data complications could be addressed with a triangular model structure. He and Tamás Bartus showed how random effects could be used in the triangular model structure in Bartus and Roodman (2014). Roodman’s work has been used to model processes like the effect of innovation on labor productivity (Mairesse and Robin 2009) and the effect of insect-resistant crops on pesticide demand (Fernandez-Cornejo and Wechsler 2012).

**Stored results**

\texttt{eintreg} stores the following in \texttt{e()}:  

**Scalars**

\begin{itemize}
  \item \texttt{e(N)} number of observations
  \item \texttt{e(N_selected)} number of selected observations
\end{itemize}
e(N_nonselected) number of nonselected observations

Macros

Macros

Matrices

Functions

marks estimation sample
xteintreg stores the following in e():

Scalars

- `e(N)` number of observations
- `e(N_g)` number of groups
- `e(N_selected)` number of selected observations
- `e(N_nonselected)` number of nonselected observations
- `e(N_unc)` number of uncensored observations

- `e(Cns)` constraints matrix
Methods and formulas

The methods and formulas presented here are for the interval model. The estimators implemented in `eintreg` and `xteintreg` are maximum likelihood estimators covered by the results in chapter 13 of Wooldridge (2010) and White (1996).

The log-likelihood functions maximized by `eintreg` and `xteintreg` are implied by the triangular structure of the model. Specifically, the joint distribution of the endogenous variables is a product of conditional and marginal distributions because the model is triangular. For a few of the many relevant applications of this result in literature, see chapter 10 of Amemiya (1985); Heckman (1976, 1979); chapter 5 of Maddala (1983); Maddala and Lee (1976); sections 15.7.2, 15.7.3, 16.3.3, 17.5.2, and 19.7.1 in Wooldridge (2010); and Wooldridge (2014). Roodman (2011) and Bartus and Roodman (2014) used this result to derive the formulas discussed below.

Methods and formulas are presented under the following headings:

- Introduction
- Endogenous covariates
  - Continuous endogenous covariates
  - Binary and ordinal endogenous covariates
- Treatment
- Endogenous sample selection
  - Probit endogenous sample selection
  - Tobit endogenous sample selection
- Random effects
- Combinations of features
- Confidence intervals

Introduction

A regression model of outcome \( y_i \) on covariates \( x_i \) may be written as

\[
y_i = x_i \beta + \epsilon_i
\]

where \( \epsilon_i \) is normal with mean 0 and variance \( \sigma^2 \). Instead of observing \( y_i \), we observe the endpoints \( y_{li} \) and \( y_{ui} \).

If \( y_i \) is left-censored, the lower endpoint \( y_{li} = -\infty \) and we know that \( y_i \leq y_{ui} \). If \( y_i \) is right-censored, the upper endpoint \( y_{ui} = +\infty \) and we know that \( y_i \geq y_{li} \). If there is no censoring, \( y_{li} = y_{ui} = y_i \). When \( y_{li} \) and \( y_{ui} \) are real valued and not equal, we know that \( y_{li} \leq y_i \leq y_{ui} \).
The log likelihood is

$$\ln L = \sum_{i \in U} w_i \ln \phi(y_i - x_i \beta, \sigma^2) + \sum_{i \in L} w_i \ln \Phi\left(\frac{y_{ui} - x_i \beta}{\sigma}\right) + \sum_{i \in R} w_i \ln \Phi\left(\frac{-y_{li} + x_i \beta}{\sigma}\right) + \sum_{i \in I} w_i \ln \left\{\Phi\left(\frac{y_{ui} - x_i \beta}{\sigma}\right) - \Phi\left(\frac{y_{li} - x_i \beta}{\sigma}\right)\right\}$$

where $U$ is the set of observations where $y_i$ is not censored, $L$ is the set of observations where $y_i$ is left-censored, $R$ is the set of observations where $y_i$ is right-censored, $I$ is the set of observations where $y_i$ is interval-censored, and $w_i$ are the weights.

The conditional mean of $y_i$ is

$$E(y_i | x_i) = x_i \beta$$

If we wished to condition on the censoring, we could calculate an expectation on $y_i^* = \max\{y_{li}, \min(y_{ij}, y_{ui})\}$ or a constrained mean $E(y_i | y_{li} < y_i < y_{ui})$. See Predictions using the full model in [ERM] eprobit postestimation for details on how this is done.

If you are willing to take our word for some derivations and notation, the following is complete. Longer explanations and derivations for some terms and functions are provided in Methods and formulas of [ERM] eprobit. For example, we need the two-sided probability function $\Phi_d$ that is discussed in Introduction in [ERM] eprobit.

If you are interested in all the details, we suggest you read Methods and formulas of [ERM] eprobit in its entirety before reading this section. Here we mainly show how the complications that arise in ERMs are handled in an interval regression framework.

**Endogenous covariates**

**Continuous endogenous covariates**

An interval regression of $y_i$ on exogenous covariates $x_i$ and $C$ continuous endogenous covariates $w_{ci}$ has the form

$$y_i = x_i \beta + w_{ci} \beta_c + \epsilon_i$$

$$w_{ci} = z_{ci} A_c + \epsilon_{ci}$$

As in Introduction, we do not observe $y_i$ but instead observe the endpoints $y_{li}$ and $y_{ui}$. The vector $z_{ci}$ contains variables from $x_i$ and other covariates that affect $w_{ci}$. For the model to be identified, $z_{ci}$ must contain one extra exogenous covariate not in $x_i$ for each of the endogenous regressors in $w_{ci}$. The unobserved errors $\epsilon_i$ and $\epsilon_{ci}$ are multivariate normal with mean 0 and covariance

$$\Sigma = \begin{bmatrix} \sigma^2 & \sigma_{1c}' \\ \sigma_{1c} & \Sigma_c \end{bmatrix}$$
Conditional on the endogenous and exogenous covariates, $\epsilon_i$ has mean and variance

$$
\mu_{1|c,i} = E(\epsilon_i | w_{ci}, x_i, z_{ci}) = \sigma'_{1c} \Sigma_{c}^{-1} (w_{ci} - z_{ci} A_c)'
$$

$$
\sigma^2_{1|c} = \text{Var}(\epsilon_i | w_{ci}, x_i, z_{ci}) = \sigma^2 - \sigma'_{1c} \Sigma_{c}^{-1} \sigma_{1c}
$$

Let

$$
\begin{align*}
 r_{li} &= y_{li} - x_i \beta - w_{ci} \beta_c - \mu_{1|c,i} \\
 r_{ui} &= y_{ui} - x_i \beta - w_{ci} \beta_c - \mu_{1|c,i}
\end{align*}
$$

The log likelihood is

$$
\ln L = \sum_{i \in U} w_i \ln \phi(r_{li}, \sigma^2_{1|c}) \\
+ \sum_{i \in L} w_i \ln \Phi_1^*(r_{li}, r_{ui}, \sigma^2_{1|c}) \\
+ \sum_{i \in R} r_{li} \ln \Phi_1^*(r_{li}, r_{ui}, \sigma^2_{1|c}) \\
+ \sum_{i \in I} r_{li} \ln \Phi_1^*(r_{li}, \sigma^2_{1|c}) \\
+ \sum_{i=1}^N w_i \ln \phi_C(w_{ci} - z_{ci} A_c, \Sigma_c)
$$

where $U$ is the set of observations where $y_i$ is not censored, $L$ is the set of observations where $y_i$ is left-censored, $R$ is the set of observations where $y_i$ is right-censored, and $I$ is the set of observations where $y_i$ is interval-censored.

The conditional mean of $y_i$ is

$$
E(y_i | x_i, w_{ci}, z_{ci}) = x_i \beta + w_{ci} \beta_c + \sigma'_{1c} \Sigma_{c}^{-1} (w_{ci} - z_{ci} A_c)'
$$

### Binary and ordinal endogenous covariates

Here we begin by formulating the interval regression of $y_i$ on exogenous covariates $x_i$ and $B$ binary and ordinal endogenous covariates $w_{bi} = [w_{b1i}, \ldots, w_{bBi}]$. Indicator (dummy) variables for the levels of each binary and ordinal covariate are used in the model. You can also interact other covariates with the binary and ordinal endogenous covariates, as in treatment-effect models.

The binary and ordinal endogenous covariates $w_{bi}$ are formulated as in **Binary and ordinal endogenous covariates in [ERM] eprobit**.

The model for the outcome can be formulated with or without different variance and correlation parameters for each level of $w_{bi}$. Level-specific parameters are obtained by specifying pvariance or pocorrelation in the endogenous() option.

If the variance and correlation parameters are not level specific, we have

$$
y_i = x_i \beta + \text{wind}_{b_{1i}} b_{1} + \cdots + \text{wind}_{b_{Bi}} b_{B} + \epsilon_i
$$
The \textit{wind}_{bi} vectors are defined in \textit{Binary and ordinal endogenous covariates} in \textit{ERM} \texttt{eprobit}. As in \textit{Introduction}, we do not observe \(y_i\) but instead observe the endpoints \(y_{li}\) and \(y_{ui}\). The binary and ordinal endogenous errors \(\epsilon_{bi1}, \ldots, \epsilon_{biB}\) and outcome error \(\epsilon_i\) are multivariate normal with 0 mean and covariance

\[
\Sigma = \begin{bmatrix} \Sigma_b & \sigma_{1b} \\ \sigma_{1b} & \sigma^2 \end{bmatrix}
\]

From here, we discuss the model with ordinal endogenous covariates. The results for binary endogenous covariates are similar.

As in \textit{Binary and ordinal endogenous covariates} in \textit{ERM} \texttt{eregress}, for the uncensored observations, we write the joint density of \(y_i\) and \(w_{bi}\) using the conditional density of \(\epsilon_{bi1}, \ldots, \epsilon_{biB}\) on \(\epsilon_i\). For the censored observations, we use tools discussed in \textit{Likelihood for multiequation models} in \textit{ERM} \texttt{eprobit} to formulate the joint density directly.

For \(i \in U\), the uncensored observations, define

\[
r_i = y_i - (x_i \beta + \text{wind}_{bi1} \beta_{b1} + \cdots + \text{wind}_{biB} \beta_{bB})
\]

For the censored observations, define

\[
r_{li} = y_{li} - (x_i \beta + \text{wind}_{bi1} \beta_{b1} + \cdots + \text{wind}_{biB} \beta_{bB})
\]

\[
r_{ui} = y_{ui} - (x_i \beta + \text{wind}_{bi1} \beta_{b1} + \cdots + \text{wind}_{biB} \beta_{bB})
\]

Let

\[
\Sigma_{b|1} = \Sigma - \frac{\sigma_{1b} \sigma_{1}'}{\sigma^2}
\]

Now the log likelihood is

\[
\ln L = \sum_{i \in U} w_i \ln \left\{ \Phi^*_B (l_i, u_i; \Sigma_{b|1}) \phi \left( r_i, \sigma^2 \right) \right\}
\]

\[
+ \sum_{i \in L} w_i \ln \Phi^*_B (\left[ l_i, -\infty \right], \left[ u_i, r_{ui} \right], \Sigma)
\]

\[
+ \sum_{i \in R} w_i \ln \Phi^*_B (\left[ l_i, r_{li} \right], \left[ u_i, \infty \right], \Sigma)
\]

\[
+ \sum_{i \in I} w_i \ln \Phi^*_B (\left[ l_i, r_{li} \right], \left[ u_i, r_{ui} \right], \Sigma)
\]

where \(U\) is the set of observations where \(y_i\) is not censored, \(L\) is the set of observations where \(y_i\) is left-censored, \(R\) is the set of observations where \(y_i\) is right-censored, and \(I\) is the set of observations where \(y_i\) is interval-censored. The vectors \(l_{bi}\) and \(u_{bi}\) are the upper and lower limits for the binary and ordinal endogenous regressors defined in \textit{Binary and ordinal endogenous covariates} in \textit{ERM} \texttt{eprobit}. The vectors \(l_i\) and \(u_i\) are the upper and lower limits for the binary and ordinal endogenous regressors defined in \textit{Binary and ordinal endogenous covariates} in \textit{ERM} \texttt{eregress}.

The expected value of \(y_i\) conditional on \(w_{bi}\) can be calculated using the techniques discussed in \textit{Predictions using the full model} in \textit{ERM} \texttt{eprobit postestimation}. 

\[
\text{E}(y_i | w_{bi}) = \frac{\Phi^*_B (\left[ l_{bi}, u_{bi} \right], \Sigma_{b|1})}{\phi (r_i, \sigma^2)}
\]
When the endogenous ordinal variables are different treatments, holding the variance and correlation parameters constant over the treatment levels is a constrained form of the potential-outcome model. In an unconstrained potential-outcome model, the variance of the outcome and the correlations between the outcome and the treatments—the endogenous ordinal regressors \( w_{bi} \)—vary over the levels of each treatment.

In this unconstrained model, there is a different potential-outcome error for each level of each treatment. For example, when the endogenous treatment variable \( w_1 \) has three levels (0, 1, and 2) and the endogenous treatment variable \( w_2 \) has four levels (0, 1, 2, and 3), the unconstrained model has \( 12 = 3 \times 4 \) outcome errors. So there are 12 outcome error variance parameters. Because there is a different correlation between each potential outcome and each endogenous treatment, there are \( 2 \times 12 \) correlation parameters between the potential outcomes and the treatments in this example model.

We denote the number of different combinations of values for the endogenous treatments \( w_{bi} \) by \( M \), and we denote the vector of values in each combination by \( v_j \) (\( j \in \{1, 2, \ldots, M\} \)). Letting \( k_{wp} \) be the number of levels of endogenous ordinal treatment variable \( p \in \{1, 2, \ldots, B\} \) implies that \( M = k_{w1} \times k_{w2} \times \cdots \times k_{wB} \).

Denoting the outcome errors \( \epsilon_{1i}, \ldots, \epsilon_{Mi} \), we have

\[
\begin{align*}
y_{1i} &= x_i \beta + w_{b1i} \beta_{b1} + \cdots + w_{bBi} \beta_{bB} + \epsilon_{1i} \\
\vdots\ 

y_{Mi} &= x_i \beta + w_{b1i} \beta_{b1} + \cdots + w_{bBi} \beta_{bB} + \epsilon_{Mi} \\
y_i &= \sum_{j=1}^{M} 1(w_{bi} = v_j) y_{ji}
\end{align*}
\]

For \( j = 1, \ldots, M \), the endogenous errors \( \epsilon_{b1i}, \ldots, \epsilon_{bBi} \) and outcome error \( \epsilon_{ji} \) are multivariate normal with 0 mean and covariance

\[
\Sigma_j = \begin{bmatrix} \Sigma_b & \sigma_{j1b} \\ \sigma_{j1b} & \sigma_j^2 \end{bmatrix}
\]

Now let

\[
\begin{align*}
\sigma_{i,b} &= \sum_{j=1}^{M} 1(w_{bi} = v_j) \sigma_j \\
\Sigma_{i,b} &= \sum_{j=1}^{M} 1(w_{bi} = v_j) \Sigma_j \\
\Sigma_{i,b|1} &= \sum_{j=1}^{M} 1(w_{bi} = v_j) \left( \Sigma_b - \frac{\sigma_{j1b} \sigma'_{j1b}}{\sigma_j^2} \right)
\end{align*}
\]
Now the log likelihood for this model is
\[
\ln L = \sum_{i \in U} w_i \ln \{ \Phi^*_{B}(l, u, \Sigma_{i,b}) \} \\
+ \sum_{i \in L} w_i \ln \Phi^*_{B+1}([-\infty, r_{ui}], [u_{bi} - \infty, r_{ui}], \Sigma_{i,b}) \\
+ \sum_{i \in R} w_i \ln \Phi^*_{B+1}([l_{bi}, \infty], [u_{bi} - \infty, \infty], \Sigma_{i,b}) \\
+ \sum_{i \in I} w_i \ln \Phi^*_{B+1}([l_{bi}, r_{li}], [u_{bi}, r_{ui}], \Sigma_{i,b})
\]

As in the other case, the expected value of \( y_i \) conditional on \( w_{bi} \) can be calculated using the techniques discussed in Predictions using the full model in [ERM] eprobit postestimation.

Treatment

In the potential-outcomes framework, the treatment \( t_i \) is a discrete variable taking \( T \) values, indexing the \( T \) potential outcomes of the outcome \( y_i: y_{1i}, \ldots, y_{Ti} \).

When we observe treatment \( t_i \) with levels \( v_1, \ldots, v_T \), we have
\[
y_i = \sum_{j=1}^{T} 1(t_i = v_j)y_{ji}
\]
So for each observation, we observe only the potential outcome associated with that observation’s treatment value.

For exogenous treatments, our approach is equivalent to the regression adjustment treatment-effect estimation method. See [TE] teffects intro advanced. We do not model the treatment assignment process. The formulas for the treatment effects and potential-outcome means (POMs) are equivalent to what we provide here for endogenous treatments. The treatment effect on the treated for \( x_i \) for an exogenous treatment is equivalent to what we provide here for the endogenous treatment when the correlation parameter between the outcome and treatment errors is set to 0. The average treatment effects (ATEs) and POMs for exogenous treatments are estimated as predictive margins in an analogous manner to what we describe here for endogenous treatments. We can also obtain different variance parameters for the different exogenous treatment groups by specifying povariance in extreat().

From here, we assume an endogenous treatment \( t_i \). As in Treatment in [ERM] eprobit, we model the treatment assignment process with a probit or an ordered probit model, and we call the treatment assignment error \( \epsilon_{ti} \). An interval regression of \( y_i \) on exogenous covariates \( x_i \) and endogenous treatment \( t_i \) taking values \( v_1, \ldots, v_T \) has the form
\[ y_{1i} = x_i \beta_1 + \epsilon_{1i} \]
\[ \vdots \]
\[ y_{Ti} = x_i \beta_T + \epsilon_{Ti} \]
\[ y_i = \sum_{j=1}^{T} 1(t_i = v_j) y_{ji} \]

As in Introduction, we do not observe \( y_i \) but instead observe the endpoints \( y_{li} \) and \( y_{ui} \).

This model can be formulated with or without different variance and correlation parameters for each potential outcome. Potential-outcome specific parameters are obtained by specifying `povariance` or `pocorrelation` in the `entreat()` option.

If the variance and correlation parameters are not potential-outcome specific, for \( j = 1, \ldots, T \), \( \epsilon_{ji} \) and \( \epsilon_{ti} \) are bivariate normal with mean 0 and covariance

\[
\Sigma = \begin{bmatrix}
\sigma^2 & \sigma \rho_{1t} \\
\sigma \rho_{1t} & 1
\end{bmatrix}
\]

The treatment is exogenous if \( \rho_{1t} = 0 \). Note that we did not specify the structure of the correlations between the potential-outcome errors. We do not need information about these correlations to estimate POMs and treatment effects because all covariates and the outcome are observed in observations from each group.

From here, we discuss a model with an ordinal endogenous treatment. The results for binary treatment models are similar. The likelihood is derived in a similar manner to Binary and ordinal endogenous covariates.

For \( i \in U \), the uncensored observations, define

\[ r_i = y_i - x_i \beta_j \quad \text{if} \quad t_i = v_j \]

For the censored observations, define

\[ r_{li} = y_{li} - x_i \beta_j \quad \text{if} \quad t_i = v_j \]
\[ r_{ui} = y_{ui} - x_i \beta_j \quad \text{if} \quad t_i = v_j \]
Now the log likelihood is

\[
\ln L = \sum_{i \in U} w_i \ln \left\{ \Phi_1^* \left( l_{ti} - \frac{\rho_{1i}}{\sigma} r_i, u_{ti} - \frac{\rho_{1i}}{\sigma} r_i, 1 - \rho_{1i}^2 \right) \phi(r_i, \sigma^2) \right\}
\]

\[
+ \sum_{i \in L} w_i \ln \Phi_2^* \left( [l_{ti}, \infty], [u_{ti}, u_{ri}], \Sigma \right)
\]

\[
+ \sum_{i \in R} w_i \ln \Phi_2^* \left( [l_{ti}, r_{li}], [u_{ti}, \infty], \Sigma \right)
\]

\[
+ \sum_{i \in I} w_i \ln \Phi_2^* \left( [l_{ti}, r_{li}], [u_{ti}, u_{ri}], \Sigma \right)
\]

where \( U \) is the set of observations where \( y_i \) is not censored, \( L \) is the set of observations where \( y_i \) is left-censored, \( R \) is the set of observations where \( y_i \) is right-censored, and \( I \) is the set of observations where \( y_i \) is interval-censored. \( l_{ti} \) and \( u_{ti} \) are the limits for the treatment probability given in Treatment in [ERM] eprobit.

The treatment effect \( y_{ji} - y_{1i} \) is the difference in the outcome for individual \( i \) if the individual receives the treatment \( t_i = v_j \) and what the difference would have been if the individual received the control treatment \( t_i = v_1 \) instead.

The conditional POM for treatment group \( j \) is

\[
POM_j(x_i) = E(y_{ji}|x_i) = x_i \beta_j
\]

For treatment group \( j \), the treatment effect (TE) conditioned on \( x_i \) is

\[
TE_j(x_i) = E(y_{ji} - y_{1i}|x_i) = POM_j(x_i) - POM_1(x_i)
\]

For treatment group \( j \), the treatment effect on the treated (TET) in group \( h \) is

\[
TET_j(x_i, t_i = v_h) = E(y_{ji} - y_{1i}|x_i, t_i = v_h)
\]

\[
= x_i \beta_j - x_i \beta_1 + E(\epsilon_{ji}|x_i, t_i = v_h) - E(\epsilon_{1i}|x_i, t_i = v_h)
\]

Remembering that the outcome errors and the treatment error \( \epsilon_{ti} \) are multivariate normal, for \( j = 1, \ldots, T \), we can decompose \( \epsilon_{ji} \) such that

\[
\epsilon_{ji} = \sigma \rho_{1i} \epsilon_{ti} + \psi_{ji}
\]

where \( \psi_{ji} \) has mean 0.
It follows that
\[
TET_j(x_i, t_i = v_h) = x_i\beta_j - x_i\beta_1
\]

We can take the expectation of these conditional predictions over the covariates to get population average parameters. The `estat teffects` or `margins` command is used to estimate the expectations as predictive margins once the model is estimated with `eintreg`. The POM for treatment group \( j \) is
\[
POM_j = E(y_{ji}) = E\{POM_j(x_i)\}
\]

The ATE for treatment group \( j \) is
\[
ATE_j = E(y_{ji} - y_{1i}) = E\{TE_j(x_i)\}
\]

For treatment group \( j \), the average treatment effect on the treated (ATET) in treatment group \( h \) is
\[
ATET_{jh} = E(y_{ji} - y_{1i} | t_i = v_h) = E\{TET_j(x_i, t_i = v_h) | t_i = v_h\}
\]

The conditional mean of \( y_i \) at treatment level \( v_j \) is
\[
E(y_i|\{x_i, z_{ti}, t_i = v_j\}) = x_i\beta_j + E(\epsilon_i|\{x_i, z_{ti}, t_i = v_j\})
\]

In Predictions using the full model in [ERM] `eprobit` postestimation, we discuss how the conditional mean of \( \epsilon_i \) is calculated.

If the variance and correlation parameters are potential-outcome specific, for \( j = 1, \ldots, T \), \( \epsilon_{ji} \) and \( \epsilon_{ti} \) are bivariate normal with mean 0 and covariance
\[
\Sigma_j = \begin{bmatrix}
\sigma_j^2 & \sigma_j \rho_{jt} \\
\sigma_j \rho_{jt} & 1
\end{bmatrix}
\]

Define
\[
\rho_i = \sum_{j=1}^{T} 1(t_i = v_j)\rho_{jt}
\]
\[
\sigma_i = \sum_{j=1}^{T} 1(t_i = v_j)\sigma_j
\]
\[
\Sigma_i = \sum_{j=1}^{T} 1(t_i = v_j)\Sigma_j
\]

Now the log likelihood for the model is
\[
\ln L = \sum_{i \in U} w_i \ln \left\{ \Phi_1^*(l_{ti} - \frac{\rho_i}{\sigma_i} r_{ti}, u_{ti} - \frac{\rho_i}{\sigma_i} r_{ti}, 1 - \rho_i^2) \phi(r_i, \sigma_i^2) \right\}
\]
\[
+ \sum_{i \in L} w_i \ln \Phi_2^*([l_{ti}, -\infty], [u_{ti}, r_{ui}], \Sigma_i)
\]
\[
+ \sum_{i \in R} w_i \ln \Phi_2^*([l_{ti}, r_{ti}], [u_{ti}, \infty], \Sigma_i)
\]
\[
+ \sum_{i \in I} w_i \ln \Phi_2^*([l_{ti}, r_{ti}], [u_{ti}, r_{ui}], \Sigma_i)
\]
The definitions for the potential-outcome means and treatment effects are the same as in the case where the variance and correlation parameters did not vary by potential outcome. For the treatment effect on the treated (TET) of group \( j \) in group \( h \), we have

\[
TET_j(x_i, t_i = v_h) = E(y_{ji} - y_{1i}|x_i, t_i = v_h) = x_i\beta_j - x_i\beta_1 + E(\epsilon_{ji}|x_i, t_i = v_h) - E(\epsilon_{1i}|x_i, t_i = v_h)
\]

The outcome errors and the treatment error \( \epsilon_{ti} \) are multivariate normal, so for \( j = 1, \ldots, T \), we can decompose \( \epsilon_{ji} \) such that

\[
\epsilon_{ji} = \sigma_j \rho_j \epsilon_{ti} + \psi_{ji}
\]

where \( \psi_{ji} \) has mean 0 and is independent of \( t_i \).

It follows that

\[
TET_j(x_i, t_i = v_h) = E(y_{ji} - y_{1i}|x_i, t_i = v_h) = x_i\beta_j - x_i\beta_1 + (\sigma_j \rho_j - \sigma_1 \rho_1)E(\epsilon_{ti}|x_i, t_i = v_h)
\]

The mean of \( \epsilon_{ti} \) conditioned on \( t_i \) and the exogenous covariates \( x_i \) can be determined using the formulas discussed in Predictions using the full model in [ERM] eprobit postestimation. It is nonzero. So the treatment effect on the treated will be equal only to the treatment effect under an exogenous treatment or when the correlation and variance parameters are identical between the potential outcomes.

As in the other case, we can take the expectation of these conditional predictions over the covariates to get population-averaged parameters. The estat teffects or margins command is used to estimate the expectations as predictive margins once the model is fit with eintreg.

Endogenous sample selection
Probit endogenous sample selection

The regression for outcome \( y_i \) with selection on \( s_i \) has the form

\[
y_i = x_i\beta + \epsilon_i \\
s_i = 1(\mathbf{z}_{si}\alpha_s + \epsilon_{si} > 0)
\]

where \( x_i \) are covariates that affect the outcome and \( \mathbf{z}_{si} \) are covariates that affect selection. As in the Introduction above, we do not observe \( y_i \) but instead observe the endpoints \( y_{li} \) and \( y_{ui} \). If \( s_i = 1 \), then the observation is selected, and there is an interval regression contribution to the likelihood. If \( s_i = 0 \), then the observation is not selected, and there is no interval regression contribution to the likelihood.

The unobserved errors \( \epsilon_i \) and \( \epsilon_{si} \) are normal with mean 0 and covariance

\[
\Sigma = \begin{bmatrix}
\sigma^2 & \sigma \rho_{1s} \\
\sigma \rho_{1s} & 1
\end{bmatrix}
\]

The likelihood is derived in a similar manner to that in Treatment.

For \( i \in U \), the uncensored and selected observations, define

\[
r_i = y_i - x_i\beta
\]
Let
\[\mu_{s|1,i} = \frac{\rho_{1s}}{\sigma} r_i,\]
\[\sigma_{s|1} = 1 - \rho_{1s}^2.\]

For the selection indicator \(s_i\), the lower and upper limits on \(\epsilon_{si}\) are
\[l_{si} = \begin{cases} -\infty & s_i = 0 \\ -z_{si}\alpha_s & s_i = 1 \end{cases} \quad u_{si} = \begin{cases} -\infty & s_i = 0 \\ \infty & s_i = 1 \end{cases}

For the censored but selected observations, \(i \notin U\), define
\[r_{li} = y_{li} - x_i\beta_j,\]
\[r_{ui} = y_{ui} - x_i\beta_j.\]

Now the log likelihood is
\[
\ln L = \sum_{i \in U} w_i \ln \left\{ \Phi_1^*(l_{si} - \mu_{s|1,i}, u_{si} - \mu_{s|1,i}, \sigma_{s|1}^2) \phi(r_i, \sigma^2) \right\} \\
+ \sum_{i \in L} w_i \ln \Phi_2^*(l_{si}, -\infty, u_{si}, r_{ui}, \Sigma) \\
+ \sum_{i \in R} w_i \ln \Phi_2^*(l_{si}, r_{li}, u_{si}, \infty, \Sigma) \\
+ \sum_{i \in I} w_i \ln \Phi_2^*(l_{si}, r_{li}, u_{si}, r_{ui}, \Sigma) \\
+ \sum_{i \notin S} w_i \ln \Phi_1^*(l_{si}, u_{si}, 1)
\]

where \(U\) is the set of observations where \(y_i\) is not censored, \(L\) is the set of observations where \(y_i\) is left-censored, \(R\) is the set of observations where \(y_i\) is right-censored, \(I\) is the set of observations where \(y_i\) is interval-censored, and \(S\) is the set of selected observations.

The conditional mean of \(y_i\) is
\[E(y_i|x_i) = x_i\beta\]

**Tobit endogenous sample selection**

Instead of constraining the selection indicator to be binary, tobit endogenous sample selection uses a censored continuous endogenous sample-selection indicator. We allow the selection variable to be left-censored or right-censored.

The underlying regression model for \(y_i\) with tobit selection on \(s_i\) has the form
\[y_i = x_i\beta + \epsilon_i\]
We observe the selection indicator $s_i$, which indicates the censoring status of the latent selection variable $s_i^*$.

$$s_i^* = z_{si} \alpha_s + \epsilon_{si}$$

$$s_i = \begin{cases} 
  l_i & s_i^* \leq l_i \\
  s_i^* & l_i < s_i^* < u_i \\
  u_i & s_i^* \geq u_i 
\end{cases}$$

where $z_{si}$ are covariates that affect selection and $l_i$ and $u_i$ are fixed lower and upper limits.

As in Introduction, $y_i$ is observed via the endpoints $y_{li}$ and $y_{ui}$. If $s_i^*$ is not censored ($l_i < s_i^* < u_i$), then the observation is selected, and there is an interval regression contribution to the likelihood. Otherwise, if $s_i^*$ is left-censored ($s_i^* < l_i$) or right-censored ($s_i^* > l_i$), then the observation is not selected, and there is no interval regression contribution to the likelihood. The unobserved errors $\epsilon_i$ and $\epsilon_{si}$ are normal with mean 0 and covariance

$$\Sigma = \begin{bmatrix} \sigma^2 & \sigma_{1s} \\ \sigma_{1s} & \sigma_{s}^2 \end{bmatrix}$$

For the selected observations, we can treat $s_i$ as a continuous endogenous regressor, as in Continuous endogenous covariates. In fact, $s_i$ may even be used as a regressor for $y_i$ in eintreg (specify tobitselect(... main)). On the nonselected observations, we treat $s_i$ like the probit endogenous sample-selection indicator in Probit endogenous sample selection.

Conditional on $s_i^*$ and the exogenous covariates, $\epsilon_i$ has mean and variance

$$\mu_{1|s,i} = E(\epsilon_i|s_i^*, x_i, z_{si}) = \sigma_{1s}\sigma^{-2}_s (s_i^* - z_{si}\alpha_s)$$

$$\sigma_{1|s}^2 = \text{Var}(\epsilon_i|s_i^*, x_i, z_{si}) = \sigma^2 - \sigma_{1s}\sigma^{-2}_s\sigma_{1s}$$

Let

$$r_{li} = y_{li} - x_i\beta - \mu_{1|s,i}$$

$$r_{ui} = y_{ui} - x_i\beta - \mu_{1|s,i}$$
The log likelihood is

$$\ln L = \sum_{i \in U} w_i \ln \phi \left( r_{li}, \sigma^2_{1|s} \right) + \sum_{i \in L} w_i \ln \Phi^*_1 \left( -\infty, r_{ui}, \sigma^2_{1|s} \right) + \sum_{i \in R} w_i \ln \Phi^*_1 \left( r_{li}, \infty, \sigma^2_{1|s} \right) + \sum_{i \in I} w_i \ln \Phi^*_1 \left( r_{li}, r_{ui}, \sigma^2_{1|s} \right) + \sum_{i \in S} w_i \ln \phi \left( s_i - z_{si} \alpha_s, \sigma^2_s \right) + \sum_{i \in L_n} w_i \ln \Phi^*_1 \left( l_{li}, u_{li}, 1 \right) + \sum_{i \in R_n} w_i \ln \Phi^*_1 \left( l_{ui}, u_{ui}, 1 \right)$$

where $S$ is the set of observations for which $y_{li}$ and $y_{ui}$ are observed, $U \subset S$ is the set of observations where $y_i$ is not censored, $L \subset S$ is the set of observations where $y_i$ is left-censored, $R \subset S$ is the set of observations where $y_i$ is right-censored, $I \subset S$ is the set of observations where $y_i$ is interval-censored, $L_n$ is the set of observations for which $s^*_i$ is left-censored, and $R_n$ is the set of observations for which $s^*_i$ is right-censored. The lower and upper limits for selection—$l_{li}$, $u_{li}$, $l_{ui}$, and $u_{ui}$—are defined in Tobit endogenous sample selection in [ERM] eprobit.

When $s_i$ is not a covariate in $x_i$, we use the standard conditional mean formula,

$$E(y_i|x_i) = x_i \beta$$

Otherwise, we use

$$E(y_i|x_i, s_i, z_{si}) = x_i \beta + \frac{\sigma_{1s}}{\sigma^2_s} (s_i - z_{si} \alpha_s)$$

**Random effects**

For an interval regression with random effects, we observe panel data. For panel $i = 1, \ldots, N$ and observation $j = 1, \ldots, N_i$, an interval regression of $y_{ij}$ on exogenous covariates $x_{ij}$ with random effect $u_i$ has the form

$$y_{ij} = x_{ij} \beta + \epsilon_{ij} + u_i$$

As in Introduction, we do not observe $y_{ij}$ but instead observe endpoints $y_{lij}$ and $y_{uij}$. The random effect $u_i$ is normal with mean 0 and variance $\sigma^2_u$. It is independent of the observation-level error $\epsilon_{ij}$, which is normal with mean 0 and variance $\sigma^2$.

We derive the likelihood by using the conditional density of $y_{lij}$ and $y_{uij}$ on the random effect $u_i$ and the marginal density of $u_i$. Multiplying them together we have the joint density, which is integrated over $u_i$. 
Let

\[
l_{ij}(u) = \sum_{j \in U_i} \phi(y_{ij} - x_{ij}\beta - u, \sigma^2)
+ \sum_{j \in L_i} \Phi\left(\frac{y_{uij} - x_{ij}\beta - u}{\sigma}\right)
+ \sum_{i \in R_i} \Phi\left(\frac{-y_{lij} + x_{ij}\beta - u}{\sigma}\right)
+ \sum_{i \in I_i} \left\{ \Phi\left(\frac{y_{uij} - x_{ij}\beta - u}{\sigma}\right) - \Phi\left(\frac{y_{lij} - x_{ij}\beta - u}{\sigma}\right) \right\}
\]

where \(U_i\) is the set of observations where \(y_{ij}\) is not censored, \(L_i\) is the set of observations where \(y_{ij}\) is left-censored, \(R_i\) is the set of observations where \(y_{ij}\) is right-censored, and \(I_i\) is the set of observations where \(y_{ij}\) is interval-censored.

The likelihood for panel \(i\) is

\[
L_i = \int_{-\infty}^{\infty} \phi\left(\frac{u_i}{\sigma_u}\right) \prod_{j=1}^{N_i} l_{ij}(u_i) du_i
\]

We can approximate this integral using Gauss–Hermite quadrature. For \(q\)-point Gauss–Hermite quadrature, let the abscissa and weight pairs be denoted by \((a_{ki}, w_{ki})\), \(k = 1, \ldots, q\). The Gauss–Hermite quadrature approximation is then

\[
\int_{-\infty}^{\infty} f(x) \exp(-x^2) dx \approx \sum_{k=1}^{q} w_{ki} f(a_{ki})
\]

The default approximation used by \texttt{extreg} is mean–variance adaptive Gauss–Hermite quadrature. This chooses optimal abscissa and weights for each panel. See \textit{Likelihood for multiequation models} in [ERM] \texttt{eprobit} for more information on the use of mean–variance adaptive Gauss–Hermite quadrature.

Using the quadrature approximation, the log likelihood is

\[
\ln L = \sum_{i=1}^{N} \ln \left\{ \sum_{k=1}^{q} w_{ki} \prod_{j=1}^{N_i} l_{ij}(\sigma_u a_{ki}) \right\}
\]

The conditional mean of \(y_{ij}\) is

\[
E(y_{ij}|x_{ij}) = x_{ij}\beta
\]

\section*{Combinations of features}

Extended interval regression models that involve multiple features can be formulated using the techniques discussed in \textit{Likelihood for multiequation models} in [ERM] \texttt{eprobit}. Essentially, the density of the observed endogenous covariates can be written in terms of the unobserved normal errors. The observed endogenous and exogenous covariates determine the range of the errors, and the joint density can be evaluated as multivariate normal probabilities and densities.
Confidence intervals

The estimated variances will always be nonnegative, and the estimated correlations will always fall in \((-1, 1)\). To obtain confidence intervals that accommodate these ranges, we must use transformations.

We use the log transformation to obtain the confidence intervals for variance parameters and the atanh transformation to obtain confidence intervals for correlation parameters. For details, see Confidence intervals in [ERM] eprobit.
