graph box — Box plots				
Description	Quick start	Menu	Syntax	Options
Remarks and examples	Methods and formulas	References	Also see	

Description

graph box draws vertical box plots. In a vertical box plot, the y axis is numerical, and the x axis is categorical.

The encoding and the words used to describe the encoding are

graph hbox draws horizontal box plots. In a horizontal box plot, the numerical axis is still called the y axis, and the categorical axis is still called the x axis, but y is presented horizontally, and x vertically.

. graph hbox y1 y2, over(cat_var)

Quick start

Box plot of v1

graph box v1

Add boxes for v2 and v3

graph box v1 v2 v3

Same as above, but as a horizontal box plot graph hbox v1 v2 v3

Box plots for v1 and v2 at each level of categorical variable catvar1 graph box v1 v2, over(catvar1)

Add a box showing the overall box plots of v1 and v2 over all levels of catvar1 graph box v1 v2, over(catvar1, total)

Boxes for each level of catvar1 grouped by levels of catvar2 graph box v1, over(catvar1) over(catvar2)

Same as above, but with levels of catvar2 grouped by levels of catvar1 graph box v1, over(catvar2) over(catvar1)

A separate graph area for each level of catvar2 graph box v1 v2, by(catvar2)

Same as above, but with separate boxes for each category of catvar1 within each graph area graph box v1, over(catvar1) by(catvar2)

Change the labels for the boxes to "Group 1" and "Group 2" graph box v1, over(catvar1, relabel(1 "Group 1" 2 "Group 2"))

Menu

 ${\sf Graphics} > {\sf Box} \ {\sf plot}$

Syntax

 $\underline{\operatorname{gr}}$ aph box yvars [if][in][weight][, options]

```
graph hbox yvars [if] [in] [weight] [, options]
```

where yvars is a varlist

options	Description groups over which boxes are drawn	
group_options		
yvar_options	variables that are the boxes	
boxlook_options	how the boxes look	
legending_options	how variables are labeled	
axis_options	how numerical y axis is labeled	
title_and_other_options	titles, added text, aspect ratio, etc.	
group_options	Description	
<pre>over(varname[, over_subopts])</pre>	categories; option may be repeated	
nofill	omit empty categories	
<u>miss</u> ing	keep missing value as category	
<u>allc</u> ategories	include all categories in the dataset	
groupyvars	group boxes first by yvars instead of by the first over() variable	
yvar_options	Description	
<u>asc</u> ategory	treat yvars as first over() group	
asyvars	treat first over() group as yvars	
CW	calculate variable statistics omitting missing values of any variable	

boxlook_options	Description
nooutsides	do not plot outside values
<pre>box(#, barlook_options) pcycle(#) intensity([*]#) lintensity([*]#)</pre>	look of #th box box styles before pstyles recycle intensity of fill intensity of outline
<pre>medtype(line cline marker) medline(line_options) medmarker(marker_options)</pre>	how median is indicated in box look of line if medtype(cline) look of marker if medtype(marker)
<pre>cwhiskers lines(line_options) alsize(#) capsize(#)</pre>	use custom whiskers look of custom whiskers width of adjacent line; default is 67 height of cap on adjacent line; default is 0
<pre>marker(#, marker_options marker_label_options)</pre>	look of #th marker and label for outside values
<pre>outergap([*]#) boxgap(#)</pre>	gap between edge and first box and between last box and edge gap between boxes; default is 33
legending_options	Description
<pre>legend_options nolabel yvaroptions(over_subopts) showyvars</pre>	control of <i>yvar</i> legend use <i>yvar</i> names, not labels, in legend <i>over_subopts</i> for <i>yvars</i> ; seldom specified label <i>yvars</i> on x axis; seldom specified
axis_options	Description
yalternate <u>xalt</u> ernate <u>yreverse</u> <u>axis_scale_options</u> axis_label_options ytitle()	put numerical y axis on right (top) put categorical x axis on top (right) reverse y axis y-axis scaling and look y-axis labeling y-axis titling
title_and_other_options	Description
<pre>text() yline() aspect_option std_options by(varlist)</pre>	add text on graph; x range $[0, 100]$ add y lines to graph constrain aspect ratio of plot region titles, graph size, saving to disk repeat for subgroups
	r

The over_subopts—used in over (varname, over_subopts) and, on rare occasion, in yvaroptions (over_subopts)—are

over_subopts	Description
<u>tot</u> al	add total group
<u>re</u> label(#" <i>text</i> ")	change axis labels
<pre>label(cat_axis_label_options)</pre>	rendition of labels
<pre><u>ax</u>is(cat_axis_line_options)</pre>	rendition of axis line
gap([*]#)	gap between boxes within over() category
sort(varname)	put boxes in prespecified order
sort(#)	put boxes in median order
<u>des</u> cending	reverse default or specified box order
<pre>catlabellist(numlist)</pre>	display ticks and labels on the categorical axis only for the tick indexes listed
catlabeladdmax	display maximum tick and label on the categorical axis
<pre>catlabelformat(%fmt)</pre>	display format for labels on the categorical axis

catlabellist(), catlabeladdmax, and catlabelformat() are not allowed with
 yvaroptions().

aweights, fweights, and pweights are allowed; see [U] 11.1.6 weight and see note concerning weights in [D] collapse.

Options

Options are presented under the following headings:

group_options yvar_options boxlook_options legending_options axis_options title_and_other_options Suboptions for use with over() and yvaroptions()

group_options

- over (*varname*[, *over_subopts*]) specifies a categorical variable over which the *yvars* are to be repeated. *varname* may be string or numeric. Up to two over () options may be specified when multiple *yvars* are specified, and up to three over ()s may be specified when one *yvar* is specified; see *Examples of syntax* under *Remarks and examples below*.
- nofill specifies that missing subcategories be omitted. See the description of the nofill option in [G-2] graph bar.
- missing specifies that missing values of the over() variables be kept as their own categories, one for ., another for .a, etc. The default is to ignore such observations. An over() variable is considered to be missing if it is numeric and contains a missing value or if it is string and contains "".

- allcategories specifies that all categories in the entire dataset be retained for the over() variables. When if or in is specified without allcategories, the graph is drawn, completely excluding any categories for the over() variables that do not occur in the specified subsample. With the allcategories option, categories that do not occur in the subsample still appear in the legend, and zero-height bars are drawn where these categories would appear. Such behavior can be convenient when comparing graphs of subsamples that do not include completely common categories for all over() variables. This option has an effect only when if or in is specified or if there are missing values in the variables. allcategories may not be combined with by().
- groupyvars specifies that boxes be grouped first by *yvars* instead of by categories of the first over() variable. More specifically, the multiple *yvars* are treated as if they were categories of the first over() variable, and the categories of the first over() variable are treated as if they were multiple *yvars*. For instance, typing

. graph box y1 y2, over(catvar)

groups boxes by the categories of catvar and identifies y1 and y2 using the legend. Specifying

. graph box y1 y2, over(catvar) groupyvars

instead groups boxes by y1 and y2 and identifies categories of catvar using the legend.

yvar_options

- ascategory specifies that the *yvars* be treated as the first over () group. The important effect of this is to move the captioning of the variables from the legend to the categorical x axis. See the description of ascategory in [G-2] graph bar.
- asyvars specifies that the first over () group be treated as *yvars*. The important effect of this is to move the captioning of the first over group from the categorical x axis to the legend. See the description of asyvars in [G-2] graph bar.
- cw specifies casewise deletion. If cw is specified, observations for which any of the *yvars* are missing are ignored. The default is to calculate statistics for each box by using all the data possible.

boxlook_options

nooutsides specifies that the outside values not be plotted or used in setting the scale of the y axis.

box(#, barlook_options) specifies the look of the yvar boxes. box(1, ...) refers to the box associated with the first yvar, box(2, ...) refers to the box associated with the second, and so on.

You specify *barlook_options*. Those options are borrowed from graph bar for boxes. The most useful *barlook_option* is color(*colorstyle*), which sets the color and opacity of the box. For instance, you might specify box(1, color(green)) to make the box associated with the first *yvar* green. See [G-4] *colorstyle* for a list of color choices and see [G-3] *barlook_options* for information on the other *barlook_options*.

pcycle(#) specifies how many variables are to be plotted before the pstyle (see [G-4] *pstyle*) of the boxes for the next variable begins again at the pstyle of the first variable—p1box (with the boxes for the variable following that using p2box and so on). Put another way: # specifies how quickly the look of boxes is recycled when more than # variables are specified. The default for most schemes is pcycle(15).

intensity(#) and intensity(*#) specify the intensity of the color used to fill the inside of the box. intensity(#) specifies the intensity, and intensity(*#) specifies the intensity relative to the default.

By default, the box is filled with the color of its border, attenuated. Specify intensity (*#), # < 1, to attenuate it more and specify intensity (*#), # > 1, to amplify it.

Specify intensity(0) if you do not want the box filled at all. If you are using a scheme that draws the median line in the background color such as s2mono, also specify medtype(line) to change the median line to be in the color of the outline of the box.

lintensity(#) and lintensity(*#) specify the intensity of the line used to outline the box. lintensity(#) specifies the intensity, and lintensity(*#) specifies the intensity relative to the default.

By default, the box is outlined at the same intensity at which it is filled or at an amplification of that, which depending on your chosen scheme; see [G-4] **Schemes intro**. If you want the box outlined in the darkest possible way, specify intensity(255). If you wish simply to amplify the outline, specify intensity(*#), # > 1, and if you wish to attenuate the outline, specify intensity(*#), # < 1.

medtype(), medline(), and medmarker() specify how the median is to be indicated in the box.

medtype(line) is the default. A line is drawn across the box at the median. Here options medline() and medmarker() are irrelevant.

medtype(cline) specifies a custom line be drawn across the box at the median. The default custom line is usually a different color. You can, however, specify medline(*line_options*) to control exactly how the line is to look; see [G-3] *line_options*.

medtype(marker) specifies a marker be placed in the box at the median. Here you may also specify option medmarker(*marker_options*) to specify the look of the marker; see [G-3] *marker_options*.

cwhiskers, lines(*line_options*), alsize(#), and capsize(#) specify the look of the whiskers.

cwhiskers specifies that custom whiskers are desired. The default custom whiskers are usually dimmer, but you may specify lines(*line_options*) to specify how the custom whiskers are to look; see [G-3] *line_options*.

alsize(#) and capsize(#) specify the width of the adjacent line and the height of the cap on the adjacent line. You may specify these options whether or not you specify cwhiskers. alsize() and capsize() are specified in percentage-of-box-width units; the defaults are alsize(67) and capsize(0). Thus the adjacent lines extend two-thirds the width of a box and, by default, have no caps. Caps refer to whether the whiskers look like

If you want caps, try capsize(5).

marker (#, marker_options marker_label_options) specifies the marker and label to be used to display the outside values. See [G-3] marker_options and [G-3] marker_label_options.

outergap (*#) and outergap (#) specify the gap between the edge of the graph to the beginning of the first box and the end of the last box to the edge of the graph.

outergap(*#) specifies that the default be modified. Specifying outergap(*1.2) increases the gap by 20%, and specifying outergap(*.8) reduces the gap by 20%.

outergap(#) specifies the gap as a percentage-of-box-width units. outergap(50) specifies that the gap be half the box width.

boxgap(#) specifies the gap to be left between *yvar* boxes as a percentage-of-box-width units. The default is boxgap(33).

boxgap() affects only the *yvar* boxes. If you want to change the gap for the first, second, or third over() group, specify the *over_subopt* gap() inside the over() itself; see *Suboptions for use with over() and yvaroptions()* below.

legending_options

- *legend_options* allows you to control the legend. If more than one *yvar* is specified, a legend is produced.
 Otherwise, no legend is needed because the over() groups are labeled on the categorical x axis. See [G-3] *legend_options*, and see *Treatment of multiple yvars versus treatment of over() groups* under *Remarks and examples* below.
- nolabel specifies that, in automatically constructing the legend, the variable names of the *yvars* be used in preference to their labels.
- yvaroptions(over_subopts) allows you to specify over_subopts for the yvars. This is seldom done. over_subopts catlabellist(), catlabeladdmax, and catlabelformat() are not allowed.
- showyvars specifies that, in addition to building a legend, the identities of the *yvars* be shown on the categorical x axis. If showyvars is specified, it is typical to also specify legend(off).

axis_options

yalternate and xalternate switch the side on which the axes appear.

Used with graph box, yalternate moves the numerical y axis from the left to the right; xalternate moves the categorical x axis from the bottom to the top.

Used with graph hbox, yalternate moves the numerical y axis from the bottom to the top; xalternate moves the categorical x axis from the left to the right.

If your scheme by default puts the axes on the opposite sides, then yalternate and xalternate reverse their actions.

- yreverse specifies that the numerical y axis have its scale reversed so that it runs from maximum to minimum.
- axis_scale_options specify how the numerical y axis is scaled and how it looks; see
 [G-3] axis_scale_options. There you will also see xscale() in addition to yscale(). Ignore
 xscale(), which is irrelevant for box plots.
- axis_label_options specify how the numerical y axis is to be labeled. The axis_label_options also allow you to add and suppress grid lines; see [G-3] axis_label_options. There you will see that, in addition to options ylabel(), ytick(), ..., ymtick(), options xlabel(), ..., xmtick() are allowed. Ignore the x*() options, which are irrelevant for box plots.

ytitle() overrides the default title for the numerical y axis; see [G-3] axis_title_options. There you
will also find option xtitle() documented, which is irrelevant for box plots.

title_and_other_options

text() adds text to a specified location on the graph; see [G-3] added_text_options. The basic syntax
 of text() is

text(#_y #_x "*text*")

text() is documented in terms of two-way graphs. When used with box plots, the "numeric" x axis is scaled to run from 0 to 100.

yline() adds horizontal (box) or vertical (hbox) lines at specified y values; see

[G-3] *added_line_options*. The xline() option, also documented there, is irrelevant for box plots. If your interest is in adding grid lines, see [G-3] *axis_label_options*.

- *aspect_option* allows you to control the relationship between the height and width of a graph's plot region; see [G-3] *aspect_option*.
- *std_options* allow you to add titles, control the graph size, save the graph on disk, and much more; see [G-3] *std_options*.
- by (*varlist*, ...) draws separate plots within one graph; see [G-3] *by_option* and see Use with by() under Remarks and examples below.

Suboptions for use with over() and yvaroptions()

- total specifies that, in addition to the unique values of over (*varname*), a group be added reflecting all the observations. When multiple over ()s are specified, total may be specified in only one of them.
- relabel(# "text" ...) specifies text to override the default category labeling. See the description of the relabel() option in [G-2] graph bar for more information about this useful option.
- label(cat_axis_label_options) determines other aspects of the look of the category labels on the x axis. Except for label(labcolor()) and label(labsize()), these options are seldom specified; see [G-3] cat_axis_label_options.
- axis (*cat_axis_line_options*) specifies how the axis line is rendered. This is a seldom specified option. See [G-3] *cat_axis_line_options*.
- gap(#) and gap(*#) specify the gap between the boxes in this over() group. gap(#) is specified in percentage-of-box-width units, so gap(67) means two-thirds the width of a box. gap(*#) allows modifying the default gap. gap(*1.2) would increase the gap by 20% and gap(*.8) would decrease the gap by 20%.

To understand the distinction between over (..., gap()) and boxgap(), consider

. graph box before after, boxgap(...) over(sex, gap(...))

boxgap() sets the distance between the before and after boxes. over(,gap()) sets the distance between the boxes for males and females. Similarly, in

```
. graph box before after, boxgap(...)
over(sex, gap(...))
over(agegrp, gap(...))
```

over(sex, gap()) sets the gap between males and females, and over(agegrp, gap()) sets the gap between age groups.

sort(varname) and sort(#) control how the boxes are ordered. See How boxes are ordered and Reordering the boxes under Remarks and examples below.

sort (varname) puts the boxes in the order of varname; see Putting the boxes in a prespecified order under Remarks and examples below.

sort (#) puts the boxes in order of their medians. # refers to the *yvar* number on which the ordering should be performed; see *Putting the boxes in median order* under *Remarks and examples* below.

descending specifies that the order of the boxes-default or as specified by sort()-be reversed.

catlabellist(numlist) specifies that ticks and labels be displayed on the categorical axis only for the tick index values listed. By default, labels are displayed for all ticks on the categorical axis, but catlabellist() is useful if you want to label only some ticks. Ticks are not displayed by default for box plots, so for a simple case such as graph box yvar, over(catvar), you can think of catlabellist() as specifying the categories to be labeled. However, if you order the boxes differently or specify multiple over() options, you will realize that with catlabellist() we are referring to the ticks on the axis, not values of the categorical variable.

numlist is a list of tick indexes. For example, specifying catlabellist(2 4 6) would indicate that ticks and labels should be displayed only for the second, fourth, and sixth ticks on the categorical axis. If you use the label(ticks) suboption, you will see both ticks and labels; otherwise, you will just see labels. Note that the tick index for the categorical axis begins from the origin and progresses to the right for a vertical box plot and begins from the origin and progresses upward for a horizontal box plot. For example, we might be creating a box plot for monthly concession sales for a movie theater. Below, we display the ticks with the label(ticks) suboption.

. graph box sales, over(month, label(ticks))

This graph will contain 12 ticks and corresponding labels. If we want to label only months 2, 4, and 6, we would type

```
. graph box sales, over(month, label(ticks) catlabellist(2 4 6))
```

If we instead want a horizontal box plot, we would type

```
. graph hbox sales, over(month, label(ticks) catlabellist(7 9 11))
```

For this horizontal box plot, beginning from the origin, the 1st tick corresponds to the 12th month, the 2nd tick corresponds to the 11th month, etc. The tick at the very top of the graph is the last tick on the axis, tick 12, and it corresponds to the 1st month, January. Therefore, counting from the origin, the 7th tick corresponds to the 6th month, the 9th tick corresponds to the 4th month, and the 11th tick corresponds to the 2nd month. This is how we label the 2nd, 4th, and 6th months for the horizontal box plot.

The catlabellist() suboption is not allowed with yvaroptions().

- catlabeladdmax displays the maximum tick and corresponding label on the categorical axis. By default, labels are displayed for all ticks on the categorical axis. But this option is useful if you are displaying only some ticks and labels on the categorical axis but also want to label the maximum tick. To specify which ticks to label on the categorical axis, see catlabellist(). You can specify catlabeladdmax together with catlabellist() to label only the specified ticks, as well as the maximum tick. The catlabeladdmax suboption is not allowed with yvaroptions().
- catlabelformat(% fmt) specifies the display format to be used to format the labels on the categorical
 axis. See [D] format. The catlabelformat() suboption is not allowed with yvaroptions().

Remarks and examples

Remarks are presented under the following headings:

Introduction Examples of syntax Treatment of multiple yvars versus treatment of over() groups How boxes are ordered Reordering the boxes Putting the boxes in a prespecified order Putting the boxes in median order Use with by() Video example History

Also see [G-2] graph bar. Most of what is said there applies equally well to box plots.

Introduction

graph box draws vertical box plots:

```
. use https://www.stata-press.com/data/r19/bplong
(Fictional blood-pressure data)
```

```
. graph box bp, over(when) over(sex)
    ytitle("Systolic blood pressure")
    title("Response to treatment by sex")
    subtitle("(120 preoperative patients)")
    note("Source: Fictional drug trial")
```

graph hbox draws horizontal box plots:

Hourly wage, 1988, women aged 34 to 46

Source: 1988 data from NLS, US Dept. of Labor, Bureau of Labor Statistics

Examples of syntax

Below we show you some graph box commands and tell you what each would do:

```
graph box bp
```

One big box showing statistics on blood pressure.

```
graph box bp_before bp_after
```

Two boxes, one showing average blood pressure before, and the other, after.

```
graph box bp, over(agegrp)
```

#_of_agegrp boxes showing blood pressure for each age group.

```
graph box bp_before bp_after, over(agegrp)
```

 $2 \times #_of_agegrp$ boxes showing blood pressure, before and after, for each age group. The grouping would look like this (assuming three age groups):

graph box bp, over(agegrp) over(sex)

 $#_of_agegrps \times #_of_sexes$ boxes showing blood pressure for each age group, repeated for each sex. The grouping would look like this:

graph box bp, over(sex) over(agegrp)

Same as above, but ordered differently. In the previous example we typed over(agegrp) over(sex). This time, we reverse it:

graph box bp_before bp_after, over(agegrp) over(sex)

 $2 \times #_of_agegrps \times #_of_sexes$ boxes showing blood pressure, before and after, for each age group, repeated for each sex. The grouping would look like this:

Treatment of multiple yvars versus treatment of over() groups

Consider two datasets containing the same data but organized differently. The datasets contain blood pressure before and after an intervention. In the first dataset, the data are organized the wide way; each patient is an observation. A few of the data are

patient	sex	agegrp	bp_before	bp_after
1	Male	30-45	143	153
2	Male	30-45	163	170
3	Male	30-45	153	168

patient	sex	agegrp	when	bp
1	Male	30-45	Before	143
	Male	30-45	After	153
2	Male	30-45	Before	163
2	Male	30-45	After	170
3	Male	30-45	Before	153
3	Male	30-45	After	168

In the second dataset, the data are organized the long way; each patient is a pair of observations. The corresponding observations in the second dataset are

Using the first dataset, we might type

- . use https://www.stata-press.com/data/r19/bpwide, clear (Fictional blood-pressure data)
- . graph box bp_before bp_after, over(sex)

. graph box bp, over(when) over(sex)

Using the second dataset, we could type

(Fictional blood-pressure data)

. use https://www.stata-press.com/data/r19/bplong, clear

```
The two graphs are virtually identical. They differ in that
```

	multiple yvars	over() groups
boxes different colors	yes	no
boxes identified via	legend	axis label

Option ascategory will cause multiple *yvars* to be presented as if they were the first over() group, and asyvars will cause the first over() group to be presented as if they were multiple *yvars*. Thus

. graph box bp, over(when) over(sex) asyvars

would produce the first chart and

. graph box bp_before bp_after, over(sex) ascategory

would produce the second.

How boxes are ordered

The default is to place the boxes in the order of the *yvars* and to order each over (*varname*) group according to the values of *varname*. Let us consider some examples:

```
graph box bp_before bp_after
```

Boxes appear in the order specified, bp_before and bp_after.

```
graph box bp, over(when)
```

Boxes are ordered according to the values of variable when.

If variable when is a numeric, the lowest when number comes first, followed by the next lowest, and so on. This is true even if variable when has a value label. Say that when = 1 has been labeled "Before" and when = 2, labeled "After". The boxes will be in the order Before followed by After.

If variable when is a string, the boxes will be ordered by the sort order of the values of the variable (that is, alphabetically, but with capital letters placed before lowercase letters). If variable when contains "Before" and "After", the boxes will be in the order After followed by Before.

graph box bp_before bp_after, over(sex)

Boxes appear in the order specified, bp_before and bp_after, and are repeated for each sex, which will be ordered as explained above.

graph box bp_before bp_after, over(sex) over(agegrp)

Boxes appear in the order specified, bp_before and bp_after, repeated for sex ordered on the values of variable sex, repeated for agegrp ordered on the values of variable agegrp.

Reordering the boxes

There are two ways you may wish to reorder the boxes:

- 1. You want to control the order in which the elements of each over() group appear. String variable when might contain "After" and "Before", but you want the boxes to appear in the order Before and After.
- 2. You wish to order the boxes according to their median values. You wish to draw the graph
- . graph box wage, over(industry)

and you want the industries ordered by wage.

We will consider each of these desires separately.

Putting the boxes in a prespecified order

You have drawn the graph

```
. graph box bp, over(when) over(sex)
```

Variable when is a string containing "Before" and "After". You wish the boxes to be in that order.

To do that, you create a new numeric variable that orders the group as you would like:

. generate order = 1 if when=="Before"
. replace order = 2 if when=="After"

You may name the variable and create it however you wish, but be sure that there is a one-to-one correspondence between the new variable and the over() group's values. You then specify over()'s sort(*varname*) option:

. graph box bp, over(when, sort(order)) over(sex)

If you want to reverse the order, you may specify the descending suboption:

. graph box bp, over(when, sort(order) descending) over(sex)

Putting the boxes in median order

You have drawn the graph

. graph hbox wage, over(industry)

and now wish to put the boxes in median order, lowest first. You type

. graph hbox wage, over(industry, sort(1))

If you wanted the largest first, you would type

. graph hbox wage, over(industry, sort(1) descending)

The 1 in sort (1) refers to the first (and here only) yvar. If you had multiple yvars, you might type

. graph hbox wage benefits, over(industry, sort(1))

and you would have a chart showing wage and benefits sorted on wage. If you typed

. graph hbox wage benefits, over(industry, sort(2))

the graph would be sorted on benefits.

Use with by()

graph box and graph hbox may be used with by(), but in general, you will want to use over() in preference to by(). Box charts are explicitly categorical and do an excellent job of presenting summary statistics for multiple groups in one chart.

A good use of by (), however, is when the graph would otherwise be long. Consider the graph

. use https://www.stata-press.com/data/r19/nlsw88, clear
(NLSW, 1988 extract)
. graph hbox wage, over(ind) over(union)

In the above graph, there are 12 industry categories and two union categories, resulting in 24 separate boxes. The graph, presented at normal size, would be virtually unreadable. One way around that problem would be to make the graph longer than usual,

. graph hbox wage, over(ind) over(union) ysize(7)

See Charts with many categories in [G-2] graph bar for more information about that solution. The other solution would be to introduce union as a by() category rather than an over() category:

. graph hbox wage, over(ind) by(union)

Below we do precisely that, adding some extra options to produce a good-looking chart:

Source: 1988 data from NLS, US Dept. of Labor, Bureau of Labor Statistics

The title options were specified inside the by() so that they would not be applied to each graph separately; see [G-3] by_{option} .

Video example

Box plots in Stata

History

Box plots have been used in geography and climatology, under the name "dispersion diagrams", since at least 1933; see Crowe (1933). His figure 1 shows all the data points, medians, quartiles, and octiles by month for monthly rainfalls for Glasgow, 1868–1917. His figure 2, a map of Europe with several climatic stations, shows monthly medians, quartiles, and octiles.

Methods and formulas

For a description of box plots, see Cleveland (1993, 25–27).

Summary statistics are obtained from summarize; see [R] summarize.

The upper and lower adjacent values are as defined by Tukey (1977):

Let x represent a variable for which adjacent values are being calculated. Define $x_{(i)}$ as the *i*th ordered value of x, and define $x_{[25]}$ and $x_{[75]}$ as the 25th and 75th percentiles.

Define U as $x_{[75]} + (3/2)(x_{[75]} - x_{[25]})$. The upper adjacent value is defined as $x_{(i)}$, such that $x_{(i)} \leq U$ and $x_{(i+1)} > U$.

Define L as $x_{[25]} - (3/2)(x_{[75]} - x_{[25]})$. The lower adjacent value is defined as $x_{(i)}$, such that $x_{(i)} \ge L$ and $x_{(i-1)} < L$.
