difmh — Mantel-Haenszel DIF

DescriptionQuick startOptionsRemarks and examplesReferencesAlso see

Menu Stored results Syntax Methods and formulas

Description

difmh calculates the Mantel–Haenszel (MH) χ^2 and common odds ratio for dichotomously scored items. The MH statistics are used to determine whether an item exhibits uniform differential item functioning (DIF) between two observed groups, that is, whether an item favors one group relative to the other for all values of the latent trait.

Quick start

MH χ^2 and common odds ratio for binary items b1 to b100 using variable grpvar to identify the focal and reference groups

difmh b1-b100, group(grpvar)

Same as above, but request MH statistics for items b5, b10, and b15 only

```
difmh b1-b100, group(grpvar) items(b5 b10 b15)
```

Replay the results, but show only items with *p*-values ≤ 0.05 difmh, maxp(.05)

Menu

Statistics > IRT (item response theory)

Syntax

difmh varlist [if] [in] [weight], group(varname) [options]

options	Description
Main	
* group(<i>varname</i>)	specify variable that identifies groups
total(<i>varname</i>)	specify total score variable
<pre>items(varlist_i)</pre>	calculate MH statistics for items in $varlist_i$ only
nolistwise	do not use listwise deletion to handle missing values
noyates	do not apply Yates's correction for continuity; default is to apply the continuity correction
Reporting	
<u>l</u> evel(#)	set confidence level; default is level(95)
<pre>maxp(#)</pre>	display only items with <i>p</i> -value $\leq \#$
<u>sf</u> ormat(% <i>fmt</i>)	display format for χ^2 values; default is sformat(%9.2f)
pformat(% <i>fmt</i>)	display format for p-values; default is pformat(%9.4f)
<u>of</u> ormat(% <i>fmt</i>)	display format for odds-ratio statistics; default is oformat(%9.4f)
* group() is required.	

collect is allowed; see [U] **11.1.10 Prefix commands**. fweights are allowed; see [U] **11.1.6 weight**.

Options

Main

- group(*varname*) specifies the numeric variable that identifies the focal group and the reference group. The groups should be coded 1 and 0, respectively. group() is required.
- total (*varname*) specifies the variable to be used as a total score. By default, the total score is calculated as the row sum of the item variables.
- items (*varlist_i*) requests that MH statistics be calculated only for the specified items. *varlist_i* must be a subset of *varlist*. By default, the statistics are calculated for all the items in *varlist*.
- nolistwise specifies to omit observations where all the variables are missing. By default, observations with any missing values are omitted.
- noyates specifies that Yates's correction for continuity not be applied when calculating the MH χ^2 statistic. By default, the continuity correction is applied.

Reporting

level(#); see [R] Estimation options.

maxp(#) requests that only items with p-value \leq # be displayed.

sformat(% fmt) specifies the display format used for the χ^2 values of the output table. The default is sformat(%9.2f).

pformat(% fmt) specifies the display format used for the p-values of the output table. The default is pformat(%9.4f).

oformat (% fmt) specifies the display format used for the odds-ratio statistics of the output table. The default is oformat (% 9.4f).

Remarks and examples

The following discussion is about how to use difmh to test for uniform DIF in binary items. If you are new to DIF, we encourage you to read [IRT] **DIF** first. If you are new to item response theory or to the item response theory features in Stata, we encourage you to read [IRT] **irt** first.

Example 1: MH test of uniform DIF

To illustrate the MH DIF analysis, we use an abridged version of the mathematics and science data from De Boeck and Wilson (2004). Student responses to nine test items q1-q9 are coded 1 for correct and 0 for incorrect. We want to test for DIF based on sex. Here we tabulate the variable female.

. use https://www.stata-press.com/data/r19/masc2 (Data from De Boeck & Wilson (2004))				
. tabulate female				
Female	Freq.	Percent	Cum.	
Male	761	50.73	50.73	
Female	739	49.27	100.00	
Total	1,500	100.00		

We have 761 male and 739 female students in our dataset. The females are coded 1 and represent the focal group.

We perform the MH procedure on items q1-q9 by typing

```
. difmh q1-q9, group(female)
Mantel-Haenszel DIF analysis
```

manoor	nachbier bir a	marybro			
Item	chi2	Prob.	Odds ratio	[95% conf.	interval]
q1	12.47	0.0004	1.6053	1.2395	2.0790
q2	1.79	0.1813	1.1809	0.9354	1.4907
q3	6.58	0.0103	1.4543	1.0993	1.9238
q4	3.86	0.0496	0.7879	0.6241	0.9947
q5	5.00	0.0253	0.7011	0.5189	0.9472
q6	0.49	0.4835	1.1046	0.8567	1.4243
q7	1.77	0.1836	0.8359	0.6500	1.0750
q8	2.09	0.1478	0.7761	0.5615	1.0727
q9	2.03	0.1546	0.8294	0.6479	1.0618

The chi2 and prob. columns contain the MH χ^2 statistic with the associated significance level. Items q1, q3, q4, and q5 exhibit DIF based on a 5% significance level. However, significant statistics do not tell us anything about the amount or direction of DIF exhibited by an item.

The last three columns present the MH common odds ratio with the associated confidence interval. A common odds ratio greater than 1 indicates DIF in favor of the focal group. The results suggest that items q1 and q3 favor females, and items q4 and q5 favor males.

A visual examination of the output table becomes cumbersome even for a moderate number of items. We can ask difmh to display only items whose p-value falls below a certain significance level. Below we redisplay the results with the maxp(.05) option.

. difmh, maxp(.05)					
Mantel-Haenszel DIF analysis					
Item	chi2	Prob.	Odds ratio	[95% conf.	interval]
q1	12.47	0.0004	1.6053	1.2395	2.0790
q1 q3	6.58	0.0103	1.4543	1.0993	1.9238
q4	3.86	0.0496	0.7879	0.6241	0.9947
q5	5.00	0.0253	0.7011	0.5189	0.9472

Stored results

difmh stores the following in r():

Sc	calars r(N) r(level) r(yates)	number of observations significance level 1 if Yates's continuity correction is used, 0 otherwise
М	acros	• · · ·
	r(cmd)	difmh
	r(cmdline)	command as typed
	r(items)	names of items
	r(wtype)	weight type
	r(wexp)	weight expression
	r(group)	group variable
	r(total)	name of alternative total score variable, if specified
М	atrices	
	r(dif)	results table
	r(sigma2)	estimated variance of the common odds ratio
	r(_N)	number of observations per item

Methods and formulas

The MH test, also known as the Cochran–Mantel–Haenszel test, is used to determine whether two dichotomous variables are independent of one another after conditioning on a third variable; see Mantel and Haenszel (1959) and Holland and Thayer (1988) for details.

In item response theory, one dichotomous variable represents the reference and the focal group, and the other represents a response to an item scored as correct and incorrect. The conditioning variable is the latent trait, most commonly represented by the observed total score. For a dichotomously scored instrument of length K, the total score ranges from 0 to K.

4

The MH χ^2 statistic is based on the sum of the 2 × 2 contingency tables calculated for each value (stratum) of the total score. A single 2 × 2 table for the *k*th score is

	Correct	Incorrect	Total
Reference	n_{11k}	n_{12k}	$n_{1.k}$
Focal	n_{21k}	n_{22k}	$n_{2.k}$
Total	$n_{.1k}$	$n_{.2k}$	n_k

Incomplete contingency tables do not contribute to the MH statistic; this includes perfect scores and zero scores. For items with fewer than two complete contingency tables, difmh reports missing values.

The MH χ^2 statistic is given as

$$\mathrm{MH}_{\chi^2} = \frac{\left[\left| \sum_{k=1}^{K-1} \{ n_{11k} - E(n_{11k}) \} \right| - c \right]^2}{\sum_{k=1}^{K-1} \mathrm{var}(n_{11k})}$$

where

$$\begin{split} E(n_{11k}) &= \frac{n_{1.k}n_{.1k}}{n_k} \\ \mathrm{var}(n_{11k}) &= \frac{n_{1.k}n_{2.k}n_{.1k}n_{.2k}}{n_k^2(n_k-1)} \end{split}$$

and c = 0 when option noyates is specified; c = 1/2 otherwise.

The statistic is evaluated against a χ^2 distribution with one degree of freedom. A significant MH χ^2 statistic suggests the presence of DIF in an item, however, the statistic does not indicate the amount of DIF.

To assess the amount of DIF in an item, we can use the MH common odds-ratio (OR) statistic. The statistic is given as

$$\mathrm{OR}_{\mathrm{MH}} = \frac{\sum_{k=1}^{K-1} n_{11k} n_{22k} / n_k}{\sum_{k=1}^{K-1} n_{12k} n_{21k} / n_k}$$

Under the null hypothesis of no DIF, $OR_{MH} = 1$.

The confidence interval for OR_{MH} is based on the variance estimate of $log(OR_{MH})$ proposed by Robins, Breslow, and Greenland (1986) and Phillips and Holland (1987):

$$\begin{split} \hat{\sigma}^2 &= \widehat{\mathrm{var}}\{\log(\mathrm{OR_{MH}})\} \\ &= \frac{\sum_{k=1}^{K-1}(n_{11k}+n_{22k})(n_{11k}n_{22k})/n_k^2}{2(\sum_{k=1}^{K-1}n_{11k}n_{22k}/n_k)^2} \\ &+ \frac{\sum_{k=1}^{K-1}\{(n_{11k}+n_{22k})(n_{12k}n_{21k}) + (n_{12k}+n_{21k})(n_{11k}n_{22k})\}/n_k^2}{2(\sum_{k=1}^{K-1}n_{11k}n_{22k}/n_k)(\sum_{k=1}^{K-1}n_{12k}n_{21k}/n_k)} \\ &+ \frac{\sum_{k=1}^{K-1}(n_{12k}+n_{21k})(n_{12k}n_{21k})/n_k^2}{2(\sum_{k=1}^{K-1}n_{12k}n_{21k}/n_k)^2} \end{split}$$

The $100(1 - \alpha/2)$ % confidence interval for OR_{MH} is then given by

 $[\mathrm{OR}_{\mathrm{MH}} \times \ \exp(-z\hat{\sigma}), \ \mathrm{OR}_{\mathrm{MH}} \times \ \exp(z\hat{\sigma})]$
