Description

`irtgraph iif` plots item information functions (IIFs) for items in the currently fitted IRT model.

Quick start

2PL model for binary items b1 to b10

```
irt 2pl b1-b10
```

Plot IIFs for all items in the model

```
irtgraph iif
```

Plot IIFs for items b1 and b5

```
irtgraph iif b1 b5
```

Fit a group 2PL model

```
irt 2pl b1-b9, group(female)
```

Plot IIFs for items b1 and b5 for both groups

```
irtgraph iif b1 b5
```

Plot IIFs for item b1 for both groups and for item b5 for group 1

```
irtgraph iif (b1) (1: b5)
```

Menu

Statistics > IRT (item response theory)

Syntax

Basic syntax

```
irtgraph iif [varlist] [ , options]
```

Full syntax

```
irtgraph iif ([#:] varlist [ , line_options]) ([#:] varlist [ , line_options]) [...]  
[ , options]
```

varlist is a list of items from the currently fitted IRT model.

#: selects items in varlist for the specified group.

options	Description
Plots	
range(# #)	plot over $\theta = \#$ to $\#$
Line	
line_options	affect rendition of the plotted IIFs
Add plots	
addplot(plot)	add other plots to the IIF plot
Y axis, X axis, Titles, Legend, Overall	
tway_options	any options other than by() documented in [G-3] twoway_options
Data	
n(#)	evaluate IIFs at # points; default is n(300)
data(filename[, replace])	save plot data to a file
line_options in (varlist, line_options) override the same options specified in options.	

Options

Plots
range(# #) specifies the range of values for θ . This option requires a pair of numbers identifying the minimum and maximum. The default is range(-4 4).
Line
line_options affect the rendition of the plotted IIFs; see [G-3] line_options.
Add plots
addplot(plot) allows adding more graph twoway plots to the graph; see [G-3] addplot_option.
Y axis, X axis, Titles, Legend, Overall
tway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

Data

`n(#)` specifies the number of points at which the IIFs are to be evaluated. The default is `n(300)`.

`data(filename[, replace])` saves the plot data to a Stata data file.

Remarks and examples

`irtgraph iif` plots IIFs after estimating the parameters of an IRT model using `irt`.

In IRT, the term “information” is used to describe reliability or precision of an item or a whole instrument. More reliable items measure the latent trait around the estimated difficulty parameter with greater precision.

IIFs are useful in test development and item evaluation. Depending on the specific needs of the test, items can be chosen to cover the whole spectrum or to focus on a particular range of the ability scale.

The example below shows how to use `irtgraph iif` after a simple 2PL model; see [example 4 of \[IRT\] irtgraph icc](#) for remarks on how `irtgraph iif` behaves after a group IRT model.

► Example 1: IIF for binary items

We continue with the 2PL model from [example 1 of \[IRT\] irt 2pl](#). Recall that we fit a 2PL model to the nine binary items.

```
. use https://www.stata-press.com/data/r19/masc1
(Data from De Boeck & Wilson (2004))

. irt 2pl q1-q9
(output omitted)
```

Now we plot the IIF for each item in the fitted model.

```
. irtgraph iif
```

For binary items, the amount of information is proportional to the discrimination parameter. Items `q1` and `q8` have the two highest discrimination estimates and provide more information than the remaining items. For a 2PL model, the maximum information is provided at $\theta = b_i$.

`irtgraph iif`'s full syntax allows us to apply line styles to each item as we see fit. Let's say we expect more discrimination and therefore more information from a relatively difficult item `q5` and thus want `q5` to stand out in the IIF plot. To accomplish this, we specify thick and black line styles for `q5` to distinguish it from the other items, which we specify with red and dashed line styles.

```
. irtgraph iif (q1-q4 q6-q9, lcolor(red) lpattern(dash))
> (q5, lcolor(black) lwidth(thick)), legend(off)
```

Looking at either IIF graph, we seem to have more item information in the negative region of the latent trait than in the positive region. This suggests that the whole test provides more information about students located at the lower end of the latent trait spectrum, which we show graphically in [example 1](#) of [\[IRT\] irtgraph.tif](#).

Methods and formulas

For a given item i with categories $k = 1, \dots, K$, let $p_{ik}(\theta)$ be the probability of a respondent with latent trait value θ selecting response category k . The functional form of $p_{ik}(\theta)$ depends on the IRT model used to fit item i to the data. The category information function, for category k of item i , is defined as

$$I_{ik}(\theta) = -\frac{\partial^2 \log p_{ik}(\theta)}{\partial \theta^2}$$

The IIF for item i is the sum of its category information functions, weighted by the category probabilities.

$$I_i(\theta) = \sum_{k=1}^K I_{ik}(\theta) p_{ik}(\theta)$$

See [Birnbaum \(1968\)](#) and [Samejima \(1969, 1972, 1977\)](#) for a more detailed discussion of item information functions.
