

## Description

`irtgraph.tif` plots the test information function (TIF) for the currently fitted IRT model.

## Quick start

2PL model for binary items b1 to b10

```
irt 2pl b1-b10
```

Plot the TIF for the fitted model

```
irtgraph.tif
```

Plot the TIF and its standard error

```
irtgraph.tif, se
```

Fit a group 2PL model

```
irt 2pl b1-b9, group(female)
```

Plot the TIFs for the fitted model for both groups

```
irtgraph.tif
```

## Menu

Statistics > IRT (item response theory)

# Syntax

irtgraph tif [ , options ]	
options	Description
Plots	
se[(line_options)]	plot the standard error of the TIF
range(# #)	plot over $\theta = \#$ to $\#$
Line	
line_options	affect rendition of the plotted TIF
Add plots	
addplot(plot)	add other plots to the TIF plot
Y axis, X axis, Titles, Legend, Overall	
tway_options	any options other than by() documented in [G-3] twoway_options
Data	
n(#)	evaluate TIF at # points; default is n(300)
data(filename[ , replace])	save plot data to a file

# Options

Plots
se[(line_options)] requests the standard error of the TIF be plotted. The optional line_options specify how the lines are rendered; see [G-3] line_options.
range(# #) specifies the range of values for $\theta$ . This option requires a pair of numbers identifying the minimum and maximum. The default is range(-4 4).
Line
line_options affect the rendition of the plotted TIF; see [G-3] line_options.
Add plots
addplot(plot) allows adding more graph twoway plots to the graph; see [G-3] addplot_option.
Y axis, X axis, Titles, Legend, Overall
tway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).
Data
n(#) specifies the number of points at which the plotted lines are to be evaluated. The default is n(300).
data(filename[ , replace]) saves the plot data to a Stata data file.

## Remarks and examples

`irtgraph.tif` plots the TIF after estimating the parameters of an IRT model using `irt`.

In IRT, the term “information” is used to describe reliability or precision of an item or a whole instrument. More reliable instruments measure the latent trait around the estimated difficulty parameter with greater precision.

The TIF is useful in test development where, depending on the specific needs, the test can be chosen to cover the whole spectrum or to focus on a particular range of the ability scale. For tests with alternate formats, TIFs are used to ensure the formats carry the same information across the targeted latent trait range.

### ► Example 1: TIF for binary items

We continue with the 2PL model from [example 1](#) of [\[IRT\] irt.2pl](#). Recall that we fit a 2PL model to the nine binary items.

```
. use https://www.stata-press.com/data/r19/masc1
(Data from De Boeck & Wilson (2004))

. irt 2pl q1-q9
(output omitted)
```

In [example 1](#) of [\[IRT\] irtgraph.iif](#), we plotted IIFs and noted that items provided more information over the negative range of the latent trait than over the positive range. This asymmetry is also present in the TIF, which we plot below.

```
. irtgraph.tif, se
```

The test provides the most information around the latent trait between approximately  $-1.5$  to  $0$ . If we wished for the test to provide more information around a particular latent trait range, we could include additional items that contribute more information within the desired range. Looking at the standard error curve, we observe that the amount of information provided by the test at  $\theta$  is inversely related to the precision with which ability is estimated at that point.

## Methods and formulas

Test information is the negative of the expectation of the second derivative with respect to  $\theta$  of the log likelihood defined in *Methods and formulas* of [IRT] **irt hybrid**.

$$I(\theta) = -E\left\{\frac{\partial^2}{\partial\theta^2} \log L(\mathbf{B})\right\}$$

Given an instrument consisting of  $I$  items, the formula above reduces to

$$I(\theta) = \frac{1}{\sigma_\theta^2} + \sum_{i=1}^I I_i(\theta)$$

where  $I_i(\theta)$  is as defined in *Methods and formulas* of [IRT] **irtgraph iif**. Thus, the TIF is the sum of the individual IIFs and the prior variance of the latent trait,  $\sigma_\theta^2$ . **irt** fits IRT models with  $\sigma_\theta^2$  constrained to 1.

The standard error of the TIF is given by

$$\text{se}(\hat{\theta}) = \frac{1}{\sqrt{I(\theta)}}$$
