

hash1() — Jenkins's one-at-a-time hash function

Description	Syntax	Remarks and examples	Conformability
Diagnostics	References	Also see	

Description

`hash1(x)` returns Jenkins's one-at-a-time hash calculated over the bytes of x ; $0 \leq \text{hash1}(x) \leq 4,294,967,295$.

`hash1(x, n)` returns Jenkins's one-at-a-time hash scaled to $1 \leq \text{hash1}(x, n) \leq n$, assuming $n < .$ (missing). `hash1(x, .)` is equivalent to `hash1(x)`.

`hash1(x, n, byteorder)` returns `hash1(x, n)` performed on the bytes of x ordered as they would be on a HILO computer ($\text{byteorder} = 1$), or as they would be on a LOHI computer ($\text{byteorder} = 2$), or as they are on this computer ($\text{byteorder} \geq .$). See [M-5] [byteorder\(\)](#) for a definition of byte order.

In all cases, the values returned by `hash1()` are integers.

Syntax

real scalar `hash1`(x [$, \text{real scalar } n$ [$, \text{real scalar } \text{byteorder}$]])

where

x : any type except `struct` and any dimension

n : $1 \leq n \leq 2,147,483,647$ or `.`; default is `.` (missing)

byteorder: 1 (HILO), 2 (LOHI), `.` (natural byte order); default `.` (missing)

Remarks and examples

stata.com

Calculation is significantly faster using the natural byte order of the computer. Argument *byteorder* is included for those rare cases when it is important to calculate the same hash value across different computers, which in the case of `hash1()` is mainly for testing. `hash1()`, being a one-at-a-time method, is not sufficient for constructing digital signatures. It is sufficient for constructing hash tables; see [M-5] [asarray\(\)](#), in which case, byte order is irrelevant. Also note that because strings occur in the same order on all computers, the value of *byteorder* is irrelevant when x is a string.

For instance,

```
: hash1("this"), hash1("this",.,1), hash1("this",.,2)
      1           2           3
```

```
1 | 2385389520 2385389520 2385389520
```

```
: hash1(15), hash1(15,.,1), hash1(15,.,2)
      1           2           3
```

```
1 | 463405819 3338064604 463405819
```

The computer on which this example was run is evidently *byteorder* = 2, meaning LOHI, or least-significant byte first.

In a Mata context, it is the two-argument form of `hash1()` that is most useful. In that form, the full result is mapped onto $[1, n]$:

$$\text{hash1}(x, n) = \text{floor}((\text{hash1}(x)/4294967295)*n) + 1$$

For instance,

```
: hash1("this", 10)
6
: hash1(15, 10)
2
```

The result of `hash1(x, 10)` could be used directly to index a 10×1 array.

Conformability

```
hash1(x, n, byteorder):
  x:      r × c
  n:      1 × 1      (optional)
  byteorder: 1 × 1      (optional)
  result:  1 × 1
```

Diagnostics

None.

Note that `hash1(x[, ...])` never returns a missing result, even if *x* is or contains a missing value. In the missing case, the hash value is calculated of the missing value. Also note that *x* can be a vector or a matrix, in which case the result is calculated over the elements aligned rowwise as if they were a single element. Thus `hash1(("a", "b")) == hash1("ab")`.
