### Description

st_vlexists(name) returns 1 if value label name exists and returns 0 otherwise.

st_vldrop(name) drops value label name if it exists.

st_vlmap(name, values) maps values through value label name and returns the result.

st_vlsearch(name, text) does the reverse; it returns the value corresponding to the text.

st_vlload(name, values, text) places value label name into values and text.

st_vlmodify(name, values, text) creates a new value label or modifies an existing one.

### Syntax

<table>
<thead>
<tr>
<th>Type</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>real scalar</td>
<td>st_vlexists(name)</td>
</tr>
<tr>
<td>void</td>
<td>st_vldrop(name)</td>
</tr>
<tr>
<td>string matrix</td>
<td>st_vlmap(name, values)</td>
</tr>
<tr>
<td>real matrix</td>
<td>st_vlsearch(name, text)</td>
</tr>
<tr>
<td>void</td>
<td>st_vlload(name, values, text)</td>
</tr>
<tr>
<td>void</td>
<td>st_vlmodify(name, values, text)</td>
</tr>
</tbody>
</table>

where name is string scalar and where the types of values and text in st_vlload() are irrelevant because they are replaced.

### Remarks and examples

Value labels are named and record a mapping from numeric values to text. For instance, a value label named sexlbl might record that 1 corresponds to male and 2 to female. Values labels are attached to Stata numeric variables. If a Stata numeric variable had the value label sexlbl attached to it, then the 1s and 2s in the variable would display as male and female. How other values would appear—if there were other values—would not be affected.

Remarks are presented under the following headings:

- Value-label mapping
- Value-label creation and editing
- Loading value labels
**Value-label mapping**

Let us consider value label `sexlbl` mapping 1 to male and 2 to female. `st_vlmap("sexlbl", values)` would map the $r \times c$ matrix values through `sexlbl` and return an $r \times c$ string matrix containing the result. Any values for which there was no mapping would result in "". Thus

```plaintext
: res = st_vlmap("sexlbl", 1)
: res
male
: res = st_vlmap("sexlbl", (2,3,1))
: res
   1  2  3
   1 female  male
```

`st_vlsearch(name, text)` performs the reverse mapping:

```plaintext
: txt = st_vlsearch("sexlbl", ("female","","male"))
: txt
   1  2  3
   1 2 . 1
```

**Value-label creation and editing**

`st_vlmodify(name, values, text)` creates new value labels and modifies existing ones.

If value label `sexlbl` did not exist, coding

```plaintext
: st_vlmodify("sexlbl", (1\2), ("male"\"female"))
```

would create it. If the value label did previously exist, the above would modify it so that 1 now corresponds to male and 2 to female, regardless of what 1 or 2 previously corresponded to, if they corresponded to anything. Other mappings that might have been included in the value label remain unchanged. Thus

```plaintext
: st_vlmodify("sexlbl", 3, "unknown")
```

would add another mapping to the label. Values are deleted by specifying the text as "" so

```plaintext
: st_vlmodify("sexlbl", 3, "")
```

would remove the mapping for 3 (if there was a mapping). If you remove all the mappings, the value label itself is automatically dropped:

```plaintext
: st_vlmodify("sexlbl", (1\2), (""\""))
```

results in value label `sexlbl` being dropped if 1 and 2 were the final mappings in it.
Loading value labels

\texttt{st_vlload(name, values, text)} returns the value label in \textit{values} and \textit{text}, where you can do with it as you please. Thus you could code

\begin{verbatim}
st_vlload("sexlbl", values, text)
...
st_vldrop("sexlbl")
st_vlmodify("sexlbl", values, text)
\end{verbatim}

Conformability

\texttt{st_vlexists(name)}:
\begin{verbatim}
name: 1 \times 1
result: 1 \times 1
\end{verbatim}

\texttt{st_vldrop(name)}:
\begin{verbatim}
name: 1 \times 1
result: void
\end{verbatim}

\texttt{st_vlmap(name, values)}:
\begin{verbatim}
name: 1 \times 1
values: r \times c
result: r \times c
\end{verbatim}

\texttt{st_vlsearch(name, text)}:
\begin{verbatim}
name: 1 \times 1
text: r \times c
result: r \times c
\end{verbatim}

\texttt{st_vlload(name, values, text)}:
\begin{verbatim}
input:
name: 1 \times 1

output:
values: k \times 1
text: k \times 1
\end{verbatim}

\texttt{st_vlmodify(name, values, text)}:
\begin{verbatim}
name: 1 \times 1
values: m \times 1
text: m \times 1
result: void
\end{verbatim}

Diagnostics

The only conditions under which the above functions abort with error is when \textit{name} is malformed or Mata is out of memory. Functions tolerate all other problems.

\texttt{st_vldrop(name)} does nothing if value label \textit{name} does not exist.

\texttt{st_vlmap(name, values)} returns \textit{J(rows(values), cols(values), ")")} if value label \textit{name} does not exist. When the value label does exist, individual values for which there is no recorded mapping are returned as "".
st_vlexists(name, text): returns J(rows(values), cols(values), .) if value label name does not exist. When the value label does exist, individual text values for which there is no corresponding value are returned as . (missing).

st_vlload(name, values, text): sets values and text to be 0 × 1 when value label name does not exist.

st_vlmodify(name, values, text): creates the value label if it does not already exist. Value labels may map only integers and a, b, ..., z. Attempts to insert a mapping for . are ignored. Noninteger values are truncated to integer values. If an element of text is "", then the corresponding mapping is removed.
