mi impute intreg — Impute using interval regression

Description

mi impute intreg fills in missing values of a continuous partially observed (censored) variable using an interval regression imputation method. You can perform separate imputations on different subsets of the data by using the by() option. You can also account for analytic, frequency, importance, and sampling weights.

</tbody>
</table>

*`ll()` and `ul()` are required.

You must `mi set` your data before using `mi impute intreg`; see [MI] `mi set`.

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.

`aweights`, `fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 `weight`.

**Options**

`noconstant`; see [R] `Estimation options`.

`ll(varname)` and `ul(varname)` specify variables containing the lower and upper limits for interval censoring. You must specify both. Nonmissing observations with equal values in `ll()` and `ul()` are fully observed observations with missing values in both `ll()` and `ul()` are unobserved (missing), and the remaining observations are partially observed (censored). Partially observed cases are left-censored when `ll()` contains missing, right-censored when `ul()` contains missing, and interval-censored when `ll()` < `ul()`. Fully observed cases are also known as point data; also see Description in [R] `intreg`. In addition to `newivar`, `mi impute intreg` fills in unobserved (missing) values of variables supplied in `ll()` and `ul()`; censored values remain unchanged.

`add()`, `replace`, `rseed()`, `double`, `by()`; see [MI] `mi impute`.

`offset(varname)`; see [R] `Estimation options`.

`conditional(if)` specifies that the imputation variable be imputed conditionally on observations satisfying `exp`; see [U] 11.1.3 `if exp`. That is, missing values in a conditional sample, the sample identified by the `exp` expression, are imputed based only on data in that conditional sample. Missing values outside the conditional sample are replaced with a conditional constant, the value of the imputation variable in observations outside the conditional sample. As such, the imputation variable is required to be constant outside the conditional sample. Also, if any conditioning variables (variables involved in the conditional specification `if exp`) contain soft missing values (.), their missing values must be nested within missing values of the imputation variables. See Conditional imputation under Remarks and examples in [MI] `mi impute`.

`bootstrap` specifies that posterior estimates of model parameters be obtained using sampling with replacement; that is, posterior estimates are estimated from a bootstrap sample. The default is to sample the estimates from the posterior distribution of model parameters or from the large-sample normal approximation of the posterior distribution. This option is useful when asymptotic normality of parameter estimates is suspect.
mi impute intreg — Impute using interval regression

Reporting

dots, noisily, nolegend; see [MI] mi impute. noisily specifies that the output from the interval regression fit to the observed data be displayed. nolegend suppresses all legends that appear before the imputation table. Such legends include a legend about conditional imputation that appears when the conditional() option is specified and group legends that may appear when the by() option is specified.

Maximization

maximize_options; see [R] intreg. These options are seldom used.

Advanced

force; see [MI] mi impute.

The following option is available with mi impute but is not shown in the dialog box:

noupdate; see [MI] noupdate option.

Remarks and examples

Remarks are presented under the following headings:

Univariate imputation using interval regression
Using mi impute intreg
Example

See [MI] mi impute for a general description and details about options common to all imputation methods, impute_options. Also see [MI] Workflow for general advice on working with mi.

Univariate imputation using interval regression

The interval regression imputation method can be used to fill in missing values of a continuous partially observed (censored) variable (Royston 2007). It is a parametric method that assumes an underlying normal model for the partially observed imputed variable (given other predictors). This method is based on the asymptotic approximation of the posterior predictive distribution of the missing data.

Partially observed data arise when instead of observing an actual value, we observe the range where that value can lie. Such data include interval-censored, left-censored, and right-censored data; see [R] intreg for a more detailed discussion of censored data.

Do not confuse censoring with truncation. Truncated data are observed and are known to be in a certain range. Censored data come from a mixture of a continuous distribution and point masses at censoring limits. Truncated data come from a continuous truncated distribution. See the technical note in Remarks and examples of [R] truncreg for details. Use mi impute truncreg (see [MI] mi impute truncreg) to impute truncated data.

The imputation of censored data has certain unique characteristics. First, censored data are recorded in two variables containing the lower and the upper interval-censoring limits. So technically, there are two imputation variables. Second, in addition to complete observations (point data) and incomplete observations (“truly” missing data), there are partially complete (censored) observations for which only the lower and upper limits are known, not the values themselves. We can treat partially observed cases as “missing” and impute them along with other completely unobserved data, provided we respect
their observed limits during imputation. As a result, we will end up with a single imputed variable where missing and partially observed cases are replaced with plausible values consistent with the observed censoring limits. See *Methods and formulas* for technical details.

In what follows, when referring to missing data (or missing observations) we will mean completely unobserved, truly missing data and when referring to incomplete data (or incomplete observations) we will mean both censored and truly missing data.

### Using mi impute intreg

To accommodate the above characteristics, _mi impute intreg_ requires modifications to the standard syntax of univariate imputation methods. First, _mi impute intreg_ requires that variables containing interval-censoring limits be specified in the _ll()_ and _ul()_ options; see the description of _ll()_ and _ul()_ in *Options*. Second, _mi impute intreg_ requires you to specify a new variable name _newivar_ to store the resulting imputed values. _mi impute intreg_ creates a new variable, _newivar_, and registers it as imputed.

The values of _newivar_ are determined by _ll()_ and _ul()_. Observations of _newivar_ for which _ll()_ and _ul()_ are different or for which both contain soft missing are set to soft missing (._) and considered incomplete. Observations for which either _ll()_ or _ul()_ contains hard missing are set to the extended missing value `_a` and, as usual, are omitted from imputation. The remaining observations, corresponding to the observed point data, are complete.

After imputation, _mi impute intreg_ stores imputed values in _newivar_. It also registers variables in _ll()_ and _ul()_ as passive (see _mi register_ in [*MI* _mi set]), if they are not already registered as passive, and replaces observations for which _ll()_ and _ul()_ both contain soft missing with the corresponding imputed values. That is, only missing data are replaced in these variables; censored data are not changed.

Later, you may decide to add more imputations or to revise your imputation model and replace existing imputations with new ones. In such cases, you do not need to provide a new variable name. You can reuse the name of the variable created previously by _mi impute intreg_. _mi impute intreg_ will check that the variable is registered as imputed and that it is consistent in the observed data with the variables supplied in _ll()_ and _ul()_. That is, the variable must have the same values as _ll()_ and _ul()_ in the observations where _ll()_ and _ul()_ are equal, and soft missing values in the remaining observations. If _ll()_ or _ul()_ contain hard missing values, the variable must contain hard missing values in the corresponding observations as well.

### Example

We continue the example of imputing missing values of variable _bmi_ from [*MI* _mi impute pmm_]. The primary analysis of interest is the logistic model investigating the effect of smoking adjusted for other predictors (including _bmi_) on heart attacks; see [*MI* _Intro substantive_] for details.
The `bmi` variable is not censored in the original data. For the purpose of illustration, we use a version of the dataset in which the first three observations are censored:

```
. use https://www.stata-press.com/data/r16/mheartintreg
(Fictional heart attack data; BMI censored and missing)
. list lbmi ubmi in 1/10

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>.</td>
</tr>
<tr>
<td>2</td>
<td>.</td>
</tr>
<tr>
<td>3</td>
<td>.</td>
</tr>
<tr>
<td>4</td>
<td>.</td>
</tr>
<tr>
<td>5</td>
<td>.</td>
</tr>
<tr>
<td>6</td>
<td>.</td>
</tr>
<tr>
<td>7</td>
<td>.</td>
</tr>
<tr>
<td>8</td>
<td>.</td>
</tr>
<tr>
<td>9</td>
<td>.</td>
</tr>
<tr>
<td>10</td>
<td>.</td>
</tr>
</tbody>
</table>
```

Rather than a single `bmi` variable, we have `lbmi` and `ubmi` variables containing lower and upper interval-censoring limits of BMI. The first observation is left-censored with an upper limit of 22, the second observation is right-censored with a lower limit of 20, and the third observation is interval-censored with the range [30, 31]. Observation 8, for which both `lbmi` and `ubmi` are missing, is missing.

Let’s impute censored BMI values:

```
. mi set mlong
. mi impute intreg newbmi attack smokes age hsgrad female, add(20)>
   ll(lbmi) ul(ubmi)
```

```
Univariate imputation Imputations = 20
Interval regression added = 20
Imputed: m=1 through m=20 updated = 0
Limit: lower = lbmi Number missing = 22
    upper = ubmi Number censored = 3
      interval = 1
       left = 1
        right = 1
```

```
<table>
<thead>
<tr>
<th>Variable</th>
<th>Complete</th>
<th>Incomplete</th>
<th>Imputed</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>newbmi</td>
<td>129</td>
<td>25</td>
<td>25</td>
<td>154</td>
</tr>
</tbody>
</table>
```

Following `mi impute intreg`, we provided a new variable name, `newbmi`, to contain imputed values. Because `newbmi` did not exist we did not need to register it before using `mi impute intreg`. We also specified the lower and upper interval-censoring limits in the `ll()` and `ul()` options. These options are required with `mi impute intreg`.

`mi impute intreg` reported that 25 incomplete BMI values were imputed. Among these incomplete observations, there are 22 missing observations and 3 censored observations (one interval-censored, one left-censored, and one right-censored).
Let’s describe our mi data:

```
. mi describe, detail
Style: mlong
  last mi update 10may2019 16:35:20, 0 seconds ago
Obs.: complete 129
    incomplete 25 (M = 20 imputations)
    total 154
Vars.: imputed: 1; newbmi(25; 20*0)
    passive: 2; lbmi(23; 20*1) ubmi(23; 20*1)
    regular: 0
    system: 3; _mi_m _mi_id _mi_miss
    (there are 5 unregistered variables)
```

We used the detail option to also see missing-value counts in the imputed data.

According to `mi describe`, the new variable `newbmi` is registered as imputed and contains 25 incomplete observations in the original data. It does not contain incomplete values in any of the 20 imputations. `lbmi` and `ubmi` are registered as passive. Each of `lbmi` and `ubmi` contains 23 incomplete values in the original data and one incomplete value in each imputation. The 22 missing values for `lbmi` and `ubmi` are imputed. The incomplete value for each of these variables that is not imputed corresponds to a censored observation (left-censored observation 1 for `lbmi` and right-censored observation 2 for `ubmi`). `mi impute intreg` replaces only missing observations of `lbmi` and `ubmi` with imputed data and leaves censored observations unchanged.

As described in Methods and formulas, missing observations are simulated from an unrestricted normal distribution. So, the 22 imputed values may contain any value on the whole real line. This may not be desirable because the BMI measure is positive and, in fact, has a limited range.

To restrict imputed values to a certain range, we may replace `lbmi` and `ubmi` with lower and upper limits in observations for which these variables are missing. For example, let’s restrict imputed values to be between 17 and 39, consistent with the observed range of BMI.

```
. use https://www.stata-press.com/data/r16/mheartintreg, clear
   (Fictional heart attack data; BMI censored and missing)
. replace lbmi = 17 if lbmi==.
   (23 real changes made)
. replace ubmi = 39 if ubmi==.
   (23 real changes made)
. list lbmi ubmi in 1/10
```

<table>
<thead>
<tr>
<th>lbmi</th>
<th>ubmi</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>17</td>
</tr>
<tr>
<td>2</td>
<td>20</td>
</tr>
<tr>
<td>3</td>
<td>30</td>
</tr>
<tr>
<td>4</td>
<td>24.62917</td>
</tr>
<tr>
<td>5</td>
<td>22.52744</td>
</tr>
<tr>
<td>6</td>
<td>21.87975</td>
</tr>
<tr>
<td>7</td>
<td>17.77057</td>
</tr>
<tr>
<td>8</td>
<td>17</td>
</tr>
<tr>
<td>9</td>
<td>23.47249</td>
</tr>
<tr>
<td>10</td>
<td>24.48916</td>
</tr>
</tbody>
</table>
We replace missing lower limits with 17 and missing upper limits with 39 and proceed with imputation:

```
.mi set mlong
.mi impute intreg newbmi attack smokes age hsgrad female, add(20) > ll(lbmi) ul(ubmi)
```

Univariate imputation  Imputations =  20
Interval regression  added =  20
Imputed: m=1 through m=20  updated =  0
Limit: lower = lbmi  Number missing =  0
   upper = ubmi  Number censored =  25
       interval =  25
             left =  0
              right =  0

<table>
<thead>
<tr>
<th>Variable</th>
<th>Observations per m</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Complete</td>
<td>Incomplete</td>
<td>Imputed</td>
<td>Total</td>
</tr>
<tr>
<td>newbmi</td>
<td></td>
<td>129</td>
<td>25</td>
<td>25</td>
</tr>
</tbody>
</table>

All the incomplete observations are now interval-censored on [17, 39].

We can analyze these multiply imputed data using logistic regression with `mi estimate`:

```
.mi estimate: logit attack smokes age newbmi female hsgrad
```

In `[MI] mi impute truncreg`, we used `mi impute truncreg` to accommodate a restricted range of BMI during imputation. In the code above, we showed how to use `mi impute intreg` to ensure that imputed values are within a specified range. Which one should be used?

The answer to this question depends on our belief about the distribution of the imputation variable. If we believe that the underlying distribution of BMI is a normal distribution and we happened to only observe values within a certain range, then `mi impute intreg` should be used to impute BMI. We know, however, that BMI is positive and has an upper limit. As such, the assumption of a truncated distribution for BMI is more plausible, in which case `mi impute truncreg` should be used to impute its missing values.
mi impute intreg stores the following in r():

Scalars
- `r(M)` total number of imputations
- `r(M_add)` number of added imputations
- `r(M_update)` number of updated imputations
- `r(M_miss)` number of missing observations
- `r(M_cens)` number of censored observations
- `r(M_lcens)` number of left-censored observations
- `r(M_rcens)` number of right-censored observations
- `r(M_intcens)` number of interval-censored observations
- `r(k_ivars)` number of imputed variables (always 1)
- `r(N_g)` number of imputed groups (1 if by() is not specified)

Macros
- `r(method)` name of imputation method (intreg)
- `r(ivars)` names of imputation variables
- `r(llname)` name of variable containing lower interval-censoring limits
- `r(ulname)` name of variable containing upper interval-censoring limits
- `r(rngstate)` random-number state used
- `r(by)` names of variables specified within by()

Matrices
- `r(N)` number of observations in imputation sample in each group
- `r(N_complete)` number of complete observations in imputation sample in each group
- `r(N_incomplete)` number of incomplete observations in imputation sample in each group
- `r(N_imputed)` number of imputed observations in imputation sample in each group

Methods and formulas

Consider a latent univariate variable \( x_u = (x_{u1}, x_{u2}, \ldots, x_{un})' \) that follows a normal linear regression

\[
x_u | z_i \sim N(z_i \beta, \sigma^2)
\]  

(1)

where \( z_i = (z_{i1}, z_{i2}, \ldots, z_{iq})' \) records values of predictors of \( x_u \) for observation \( i \), \( \beta \) is the \( q \times 1 \) vector of unknown regression coefficients, and \( \sigma^2 \) is the unknown scalar variance. (When a constant is included in the model—the default—\( z_{i1} = 1, i = 1, \ldots, n \).)

Instead of \( x_u \), we observe \((x_{ll}, x_{ul})\), where \( x_{ll} = x_{ul} = x_{ij} \) for point (observed) data \( j \in C \); \( x_{ll} = -\infty \) and \( x_{ul} < +\infty \) for left-censored data \( j \in L \); \( x_{ll} > -\infty \) and \( x_{ul} = +\infty \) for right-censored data \( j \in R \); \( x_{ll} = -\infty \) and \( x_{ul} = +\infty \) for missing data \( j \in M \). Observations from subset \( C \) are considered complete and the remaining observations are considered incomplete.

Let \( x = x_u \) for observations in subset \( C \), and let \( x \) contain missing values in the remaining observations. We want to fill in missing values in \( x \). Consider the partition of \( x = (x_o', x_m') \) into \( n_o \times 1 \) and \( n_1 \times 1 \) vectors containing the complete and the incomplete observations. Consider a similar partition of \( Z = (Z_o, Z_m) \) into \( n_0 \times q \) and \( n_1 \times q \) submatrices.

mi impute intreg follows the steps below to fill in \( x_m \):

1. Fit an interval regression to the interval-censored data \((x_{ll}, x_{ul})\) to obtain the maximum likelihood estimates of parameters in (1), \( \hat{\theta} = (\hat{\beta}', \ln \hat{\sigma})' \), and their asymptotic sampling variance, \( \hat{U} \). See [R] intreg for details.

2. Simulate new parameters, \( \theta_* \), from the large-sample normal approximation, \( N(\hat{\theta}, \hat{U}) \), to its posterior distribution, assuming the noninformative prior \( \Pr(\theta) \propto \text{const} \).
3. Let $\mu_{*i} = z_i' \beta_*$. Obtain one set of imputed values, $x^1_{im}$, by simulating from a truncated normal model with the density

$$
    f(x^i_{ll}, x^i_{ul}) (x|z_i) = \frac{1}{\sigma_* \phi \left( \frac{x - \mu_{*i}}{\sigma_*} \right)} \times \left\{ \Phi \left( \frac{x^i_{ul} - \mu_{*i}}{\sigma_*} \right) - \Phi \left( \frac{x^i_{ll} - \mu_{*i}}{\sigma_*} \right) \right\},
$$

for every incomplete observation $i \notin C$. For missing observations $i \in M$, when $x^i_{ll} = -\infty$ and $x^i_{ul} = +\infty$, the above density reduces to a normal density. Thus missing observations are simulated from the corresponding unrestricted normal distribution.

4. Repeat steps 2 and 3 to obtain $M$ sets of imputed values, $x^1_{im}, x^2_{im}, \ldots, x^M_{im}$.

Steps 2 and 3 above correspond to only approximate draws from the posterior predictive distribution of the missing data, $\Pr(x_m|x_o, Z_o)$, because $\theta_*$ is drawn from the asymptotic approximation to its posterior distribution.

If weights are specified, a weighted regression model is fit to the observed data in step 1 (see [R] intreg for details). Also, in the case of aweight, $\sigma_*$ is replaced with $\sigma_* w_i^{-1/2}$ in step 3, where $w_i$ is the analytic weight for observation $i$.
