Description

mi impute mlogit fills in missing values of a nominal variable by using the multinomial (polytomous) logistic regression imputation method. You can perform separate imputations on different subsets of the data by specifying the by () option. You can also account for frequency, importance, and sampling weights.

Statistics > Multiple imputation

Syntax

 $\verb|miimpute mlogit| ivar [indepvars] [if] [weight] [, impute_options options]$

impute_options	Description
Main	
* add(#)	specify number of imputations to add; required when no imputations exist
* replace	replace imputed values in existing imputations
rseed(#)	specify random-number seed
double	store imputed values in double precision; the default is to store them as float
<pre>by(varlist[, byopts])</pre>	impute separately on each group formed by varlist
Reporting	
dots	display dots as imputations are performed
<u>noi</u> sily	display intermediate output
nolegend	suppress all table legends
Advanced	
force	proceed with imputation, even when missing imputed values are encountered
noupdate	do not perform mi update; see [MI] noupdate option

^{*}add(#) is required when no imputations exist; add(#) or replace is required if imputations exist. noupdate does not appear in the dialog box.

2

options	Description
Main	
<u>nocons</u> tant	suppress constant term
<pre>baseoutcome(#)</pre>	specify value of <i>ivar</i> that will be the base outcome
augment	perform augmented regression in the presence of perfect prediction
$\frac{\overline{\text{cond}}}{\text{cond}}$ itional(if)	perform conditional imputation
<u>boot</u> strap	estimate model parameters using sampling with replacement
Maximization	
maximize_options	control the maximization process; seldom used

You must mi set your data before using mi impute mlogit; see [MI] mi set.

You must mi register ivar as imputed before using mi impute mlogit; see [MI] mi set.

indepvars may contain factor variables; see [U] 11.4.3 Factor variables.

collect is allowed; see [U] 11.1.10 Prefix commands.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

Options

noconstant; see [R] Estimation options.

add(), replace, rseed(), double, by(); see [MI] mi impute.

baseoutcome (#) specifies the value of *ivar* to be treated as the base outcome. The default is to choose the most frequent outcome.

augment specifies that augmented regression be performed if perfect prediction is detected. By default, an error is issued when perfect prediction is detected. The idea behind the augmented-regression approach is to add a few observations with small weights to the data during estimation to avoid perfect prediction. See The issue of perfect prediction during imputation of categorical data under Remarks and examples in [MI] mi impute for more information. augment is not allowed with importance weights.

conditional (if) specifies that the imputation variable be imputed conditionally on observations satisfying exp; see [U] 11.1.3 if exp. That is, missing values in a conditional sample, the sample identified by the exp expression, are imputed based only on data in that conditional sample. Missing values outside the conditional sample are replaced with a conditional constant, the value of the imputation variable in observations outside the conditional sample. As such, the imputation variable is required to be constant outside the conditional sample. Also, if any conditioning variables (variables involved in the conditional specification if exp) contain soft missing values (.), their missing values must be nested within missing values of the imputation variables. See Conditional imputation under Remarks and examples in [MI] mi impute.

bootstrap specifies that posterior estimates of model parameters be obtained using sampling with replacement; that is, posterior estimates are estimated from a bootstrap sample. The default is to sample the estimates from the posterior distribution of model parameters or from the large-sample normal approximation of the posterior distribution. This option is useful when asymptotic normality of parameter estimates is suspect.

Reporting

dots, noisily, nolegend; see [MI] mi impute. noisily specifies that the output from the multinomial logistic regression fit to the observed data be displayed. nolegend suppresses all legends that appear before the imputation table. Such legends include a legend about conditional imputation that appears when the conditional() option is specified and group legends that may appear when the by() option is specified.

Maximization

maximize_options; see [R] mlogit. These options are seldom used. difficult, technique(), gradient, showstep, hessian, and showtolerance are not allowed when the augment option is used.

Advanced

force; see [MI] mi impute.

The following option is available with mi impute but is not shown in the dialog box:

noupdate; see [MI] noupdate option.

Remarks and examples

Remarks are presented under the following headings:

Univariate imputation using multinomial logistic regression Using mi impute mlogit

See [MI] mi impute for a general description and details about options common to all imputation methods, impute_options. Also see [MI] Workflow for general advice on working with mi.

Univariate imputation using multinomial logistic regression

The multinomial logistic regression imputation method can be used to fill in missing values of a nomial variable (for example, Raghunathan et al. [2001] and van Buuren [2007]). It is a parametric method that assumes an underlying multinomial logistic model for the imputed variable (given other predictors). Similarly to the logistic imputation method, this method is based on the asymptotic approximation of the posterior predictive distribution of the missing data.

Using mi impute mlogit

Consider the heart attack data introduced in [MI] Intro substantive and discussed in [MI] mi impute. Suppose that we want our logistic model of interest to also include information about marital status (categorical variable marstatus)—logit attack smokes age bmi female hsgrad i.marstatus.

We first tabulate values of marstatus:

- . use https://www.stata-press.com/data/r19/mheart3 (Fictional heart attack data; marstatus missing)
- . tabulate marstatus, missing

Marital			
status:			
single,			
married,			
divorced	Freq.	Percent	Cum.
Single	53	34.42	34.42
Married	48	31.17	65.58
Divorced	46	29.87	95.45
	7	4.55	100.00
Total	154	100.00	

From the output, the marstatus variable has three unique categories and seven missing observations. Because marstatus is a categorical variable, we use the multinomial logistic imputation method to fill in its missing values.

We mi set the data, register marstatus as an imputed variable, and then create 10 imputations by specifying the add(10) option with mi impute mlogit:

- . mi set mlong
- . mi register imputed marstatus
- (7 m=0 obs now marked as incomplete)
- . mi impute mlogit marstatus attack smokes age bmi female hsgrad, add(10)

Univariate imputation Imputations = 10 Multinomial logistic regression added = 10 Imputed: m=1 through m=10 updated = 0

	Observations per m			
Variable	Complete	Incomplete	Imputed	Total
marstatus	147	7	7	154

```
(Complete + Incomplete = Total; Imputed is the minimum across m
of the number of filled-in observations.)
```

We can now analyze these multiply imputed data using logistic regression via mi estimate:

. mi estimate: logit attack smokes age bmi female hsgrad i.marstatus (output omitted)

Stored results

mi impute mlogit stores the following in r():

```
Scalars
    r(M)
                         total number of imputations
                         number of added imputations
    r(M_add)
    r(M_update)
                         number of updated imputations
    r(k_ivars)
                         number of imputed variables (always 1)
                         1 if perfect prediction detected, 0 otherwise
    r(pp)
    r(N_g)
                         number of imputed groups (1 if by () is not specified)
Macros
    r(method)
                         name of imputation method (mlogit)
    r(ivars)
                         names of imputation variables
                         random-number state used
    r(rngstate)
                         names of variables specified within by ()
    r(by)
Matrices
                         number of observations in imputation sample in each group
    r(N)
                         number of complete observations in imputation sample in each group
    r(N_complete)
    r(N_incomplete)
                         number of incomplete observations in imputation sample in each group
    r(N_imputed)
                         number of imputed observations in imputation sample in each group
```

Methods and formulas

Consider a univariate variable $\mathbf{x} = (x_1, x_2, \dots, x_n)'$ that contains K categories (without loss of generality, let k = 1 be the base outcome) and follows a multinomial logistic model

$$\Pr(x_i = k | \mathbf{z}_i) = \begin{cases} \frac{1}{1 + \sum_{l=2}^K \exp(\mathbf{z}_i' \boldsymbol{\beta}_l)}, & \text{if } k = 1\\ \frac{\exp(\mathbf{z}_i' \boldsymbol{\beta}_k)}{1 + \sum_{l=2}^K \exp(\mathbf{z}_i' \boldsymbol{\beta}_l)}, & \text{if } k > 1 \end{cases} \tag{1}$$

where $\mathbf{z}_i = (z_{i1}, z_{i2}, \dots, z_{iq})'$ records values of predictors of \mathbf{x} for observation i and $\boldsymbol{\beta}_l$ is the $q \times 1$ vector of unknown regression coefficients for outcome $l=2,\ldots,K$. (When a constant is included in the model—the default— $z_{i1} = 1, i = 1, \ldots, n$.)

x contains missing values that are to be filled in. Consider the partition of $\mathbf{x} = (\mathbf{x}'_o, \mathbf{x}'_m)$ into $n_0 \times 1$ and $n_1 \times 1$ vectors containing the complete and the incomplete observations. Consider a similar partition of $\mathbf{Z} = (\mathbf{Z}_o, \mathbf{Z}_m)$ into $n_0 \times q$ and $n_1 \times q$ submatrices.

mi impute mlogit follows the steps below to fill in \mathbf{x}_m :

- 1. Fit a multinomial logistic model (1) to the observed data $(\mathbf{x}_o, \mathbf{Z}_o)$ to obtain the maximum likelihood estimates, $\widehat{\beta} = (\widehat{\beta}'_2, \dots, \widehat{\beta}'_K)'$, and their asymptotic sampling variance, \widehat{U} .
- 2. Simulate new parameters, β_{\star} , from the large-sample normal approximation, $N(\widehat{\beta}, \widehat{\mathbf{U}})$, to its posterior distribution assuming the noninformative prior $Pr(\beta) \propto const.$
- 3. Obtain one set of imputed values, \mathbf{x}_m^1 , by simulating from the multinomial logistic distribution: one of K categories is randomly assigned to a missing category, i_m , using the cumulative probabilities computed from (1) with $\beta_l = \beta_{\star l}$ and $\mathbf{z}_i = \mathbf{z}_{i_m}$.
- 4. Repeat steps 2 and 3 to obtain M sets of imputed values, $\mathbf{x}_m^1, \mathbf{x}_m^2, \dots, \mathbf{x}_m^M$.

Steps 2 and 3 above correspond to only approximate draws from the posterior predictive distribution of the missing data $Pr(\mathbf{x}_m | \mathbf{x}_o, \mathbf{Z}_o)$ because $\boldsymbol{\beta}$ is drawn from the asymptotic approximation to its posterior distribution.

If weights are specified, a weighted multinomial logistic regression model is fit to the observed data in step 1 (see [R] mlogit for details).
