mi impute nbreg — Impute using negative binomial regression				
Description	Menu	Syntax	Options	
Remarks and examples	Stored results	Methods and formulas	Reference	

## Description

mi impute nbreg fills in missing values of an overdispersed count variable using a negative binomial regression imputation method. You can perform separate imputations on different subsets of the data by specifying the by() option. You can also account for frequency, importance, and sampling weights.

## Menu

## Syntax

mi impute nbreg ivar [indepvars] [if] [weight] [, impute\_options options]

impute_options	Description	
Main		
* add(#)	specify number of imputations to add; required when no imputations exist	
* replace	replace imputed values in existing imputations	
rseed(#)	specify random-number seed	
double	store imputed values in double precision; the default is to store them as float	
by(varlist[, byopts])	impute separately on each group formed by varlist	
Reporting		
dots	display dots as imputations are performed	
<u>noi</u> sily	display intermediate output	
nolegend	suppress all table legends	
Advanced		
force	proceed with imputation, even when missing imputed values are encountered	
noupdate	do not perform mi update; see [MI] noupdate option	

\*add(#) is required when no imputations exist; add(#) or replace is required if imputations exist. noupdate does not appear in the dialog box.

options	Description
Main	
<u>nocons</u> tant	suppress constant term
<u>d</u> ispersion( <u>m</u> ean)	parameterization of dispersion; the default
<u>d</u> ispersion( <u>c</u> onstant)	constant dispersion for all observations
$exposure(varname_{e})$	include $\ln(varname_e)$ in model with coefficient constrained to 1
$\overline{offset(varname_o)}$	include varname, in model with coefficient constrained to 1
conditional( <i>if</i> )	perform conditional imputation
bootstrap	estimate model parameters using sampling with replacement
Maximization	
maximize_options	control the maximization process; seldom used

You must mi register *ivar* as imputed before using mi impute nbreg; see [MI] mi set.

indepvars may contain factor variables; see [U] 11.4.3 Factor variables.

collect is allowed; see [U] 11.1.10 Prefix commands.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

# Options

Main

noconstant; see [R] Estimation options.

add(), replace, rseed(), double, by(); see [MI] mi impute.

dispersion(mean | constant); see [R] nbreg.

 $exposure(varname_e), offset(varname_o); see [R] Estimation options.$ 

- conditional (*if*) specifies that the imputation variable be imputed conditionally on observations satisfying *exp*; see [U] **11.1.3 if exp**. That is, missing values in a conditional sample, the sample identified by the *exp* expression, are imputed based only on data in that conditional sample. Missing values outside the conditional sample are replaced with a conditional constant, the value of the imputation variable in observations outside the conditional sample. As such, the imputation variable is required to be constant outside the conditional sample. Also, if any conditioning variables (variables involved in the conditional specification if *exp*) contain soft missing values (.), their missing values must be nested within missing values of the imputation variables. See *Conditional imputation* under *Remarks* and examples in [MI] **mi impute**.
- bootstrap specifies that posterior estimates of model parameters be obtained using sampling with replacement; that is, posterior estimates are estimated from a bootstrap sample. The default is to sample the estimates from the posterior distribution of model parameters or from the large-sample normal approximation of the posterior distribution. This option is useful when asymptotic normality of parameter estimates is suspect.

Reporting

dots, noisily, nolegend; see [MI] **mi impute**. noisily specifies that the output from the negative binomial regression fit to the observed data be displayed. nolegend suppresses all legends that appear before the imputation table. Such legends include a legend about conditional imputation that appears when the conditional() option is specified and group legends that may appear when the by() option is specified.

```
Maximization
```

*maximize\_options*; see [R] **nbreg**. These options are seldom used.

Advanced

force; see [MI] mi impute.

The following option is available with mi impute but is not shown in the dialog box:

noupdate; see [MI] noupdate option.

### **Remarks and examples**

Remarks are presented under the following headings:

Univariate imputation using negative binomial regression Using mi impute nbreg

See [MI] **mi impute** for a general description and details about options common to all imputation methods, *impute\_options*. Also see [MI] **Workflow** for general advice on working with mi.

#### Univariate imputation using negative binomial regression

The negative binomial regression imputation method can be used to fill in missing values of an overdispersed count variable (Royston 2009). It is a parametric method that assumes an underlying negative binomial model (see [ $\mathbb{R}$ ] **nbreg**) for the imputed variable (given other predictors). This method is based on the asymptotic approximation of the posterior predictive distribution of the missing data.

#### Using mi impute nbreg

In [MI] **mi impute poisson**, we considered a version of the heart attack data containing a count variable, npreg, which records the number of pregnancies and is the only variable containing missing values. We imputed its missing values using mi impute poisson.

A Poisson model assumes that the mean and the variance are the same. In the presence of overdispersion, when the variance exceeds the mean, a negative binomial model is more appropriate. We can fit a negative binomial model for npreg to the observed data to see if there is any indication of overdispersion in the data.

. use https://www.stata-press.com/data/r19/mheartpois (Fictional heart attack data; npreg missing)						
. nbreg npreg attack smokes age bmi hsgrad if female==1, nolog						
Negative binomial regression Dispersion: mean Log likelihood = -54.638875			Number of ob LR chi2(5) Prob > chi2 Pseudo R2	s = 35 = 1.69 = 0.8903 = 0.0152		
npreg	Coefficient	Std. err.	Z	P> z	[95% conf.	interval]
attack smokes age bmi hsgrad _cons	.0551929 .0521987 0105877 .0194787 .5338139 0736959	.4214484 .4182004 .0174661 .0489883 .4972872 1.551417	0.13 0.12 -0.61 0.40 1.07 -0.05	0.896 0.901 0.544 0.691 0.283 0.962	7708309 7674591 0448206 0765367 4408511 -3.114417	.8812166 .8718565 .0236452 .115494 1.508479 2.967025
/lnalpha	7956602	.7987311			-2.361144	.769824
alpha	.4512832	.3604539			.0943122	2.159386
LR test of alpha=0: chibar2(01) = 3.00 Prob >= chibar2 = 0.042			r2 = 0.042			

The estimate of the overdispersion parameter alpha is 0.45 with a 95% confidence interval of [0.094, 2.16]. The confidence interval does not include a value of 0 (no overdispersion), so there is slight overdispersion in the conditional distribution of nbreg in the observed data.

We now impute npreg using mi impute nbreg:

npreg

```
. mi set mlong
. mi register imputed npreg
(10 m=0 obs now marked as incomplete)
. mi impute nbreg npreg attack smokes age bmi hsgrad, add(20)
> conditional(if female==1)
Univariate imputation
                                                                  20
                                             Imputations =
Negative binomial regression
                                                   added =
                                                                  20
Imputed: m=1 through m=20
                                                 updated =
                                                                   Ο
Dispersion: mean
Conditional imputation:
  npreg: incomplete out-of-sample obs replaced with value 0
                                    Observations per m
          Variable
                       Complete
                                   Incomplete
                                                Imputed
                                                              Total
```

(Complete + Incomplete = Total; Imputed is the minimum across m of the number of filled-in observations.)

144

We specify the conditional() option to restrict imputation of npreg only to females; see *Conditional imputation* in [MI] **mi impute** for details.

10

10

154

We can analyze these multiply imputed data using logistic regression with mi estimate:

. mi estimate: logit attack smokes age bmi female hsgrad npreg

## Stored results

Scalars

mi impute nbreg stores the following in r():

	iui o	
	r(M)	total number of imputations
	r(M_add)	number of added imputations
	r(M_update)	number of updated imputations
	r(k_ivars)	number of imputed variables (always 1)
	r(N_g)	number of imputed groups (1 if by() is not specified)
Mao	eros	
	r(method)	name of imputation method (nbreg)
	r(ivars)	names of imputation variables
	r(rngstate)	random-number state used
	r(by)	names of variables specified within by()
Mat	rices	
	r(N)	number of observations in imputation sample in each group
	r(N_complete)	number of complete observations in imputation sample in each group
	r(N_incomplete)	number of incomplete observations in imputation sample in each group
	r(N_imputed)	number of imputed observations in imputation sample in each group

## Methods and formulas

Consider a univariate variable  $\mathbf{x} = (x_1, x_2, \dots, x_n)'$  that follows a negative binomial model

$$\Pr(x_i = x | \mathbf{z}_i) = \frac{\Gamma(m_i + x)}{\Gamma(x + 1)\Gamma(m_i)} p_i^{m_i} (1 - p_i)^x, \ x = 0, 1, 2, \dots$$
(1)

where  $m_i = m = 1/\alpha$ ,  $p_i = 1/(1 + \alpha \mu_i)$  under mean-dispersion model and  $m_i = \mu_i/\delta$ ,  $p_i = p = 1/(1+\delta)$  under constant-dispersion model,  $\mu_i = \exp(\mathbf{z}'_i\boldsymbol{\beta} + \text{offset}_i)$ , and  $\alpha > 0$  and  $\delta > 0$  are unknown dispersion parameters; see [R] **nbreg** for details.  $\mathbf{z}_i = (z_{i1}, z_{i2}, \dots, z_{iq})'$  records values of predictors of  $\mathbf{x}$  for observation i and  $\boldsymbol{\beta}$  is the  $q \times 1$  vector of unknown regression coefficients. (When a constant is included in the model—the default— $z_{i1} = 1, i = 1, \dots, n$ .)

**x** contains missing values that are to be filled in. Consider the partition of  $\mathbf{x} = (\mathbf{x}'_o, \mathbf{x}'_m)$  into  $n_0 \times 1$  and  $n_1 \times 1$  vectors containing the complete and the incomplete observations. Consider a similar partition of  $\mathbf{Z} = (\mathbf{Z}_o, \mathbf{Z}_m)$  into  $n_0 \times q$  and  $n_1 \times q$  submatrices.

mi impute nbreg follows the steps below to fill in  $\mathbf{x}_m$ :

- 1. Fit a negative binomial regression model (1) to the observed data  $(\mathbf{x}_o, \mathbf{Z}_o)$  to obtain the maximum likelihood estimates,  $\hat{\boldsymbol{\theta}} = (\hat{\boldsymbol{\beta}}', \ln \hat{\alpha})'$  under a mean-dispersion model or  $\hat{\boldsymbol{\theta}} = (\hat{\boldsymbol{\beta}}', \ln \hat{\delta})'$ under a constant-dispersion model, and their asymptotic sampling variance,  $\widehat{\mathbf{U}}$ .
- 2. Simulate new parameters,  $\theta_*$ , from the large-sample normal approximation,  $N(\hat{\theta}, \widehat{\mathbf{U}})$ , to its posterior distribution, assuming the noninformative prior  $\Pr(\theta) \propto \text{const.}$
- 3. Obtain one set of imputed values,  $\mathbf{x}_m^1$ , by simulating from a negative binomial distribution (1) with parameters set to their simulated values from step 2.
- 4. Repeat steps 2 and 3 to obtain M sets of imputed values,  $\mathbf{x}_m^1, \mathbf{x}_m^2, \dots, \mathbf{x}_m^M$ .

Steps 2 and 3 above correspond to only approximate draws from the posterior predictive distribution of the missing data,  $Pr(\mathbf{x}_m | \mathbf{x}_o, \mathbf{Z}_o)$ , because  $\boldsymbol{\theta}_{\star}$  is drawn from the asymptotic approximation to its posterior distribution.

If weights are specified, a weighted negative binomial regression model is fit to the observed data in step 1 (see [R] **nbreg** for details).
