levelsof — Distinct levels of a variable

Description

levelsof displays a sorted list of the distinct values of `varname`.

Syntax

```
levelsof varname [if] [in] [ , options ]
```

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clean</td>
<td>display string values without compound double quotes</td>
</tr>
<tr>
<td>local(macname)</td>
<td>insert the list of values in the local macro <code>macname</code></td>
</tr>
<tr>
<td>missing</td>
<td>include missing values of <code>varname</code> in calculation</td>
</tr>
</tbody>
</table>
| separate(separator) | separator to serve as punctuation for the values of returned list;  
|                  | default is a space                                                          |
| matcell(matname) | save frequencies of distinct values in `matname`                             |
| matrow(matname)  | save distinct values of `varname` in `matname`                               |
| hexadecimal      | use hexadecimal format for numerical values                                 |

Options

clean displays string values without compound double quotes. By default, each distinct string value is displayed within compound double quotes, as these are the most general delimiters. If you know that the string values in `varname` do not include embedded spaces or embedded quotes, this is an appropriate option. clean does not affect the display of values from numeric variables.

local(`macname`) inserts the list of values in local macro `macname` within the calling program’s space. Hence, that macro will be accessible after `levelsof` has finished. This is helpful for subsequent use, especially with foreach; see [P] foreach.

missing specifies that missing values of `varname` be included in the tabulation. The default is to exclude them.

separate(separator) specifies a separator to serve as punctuation for the values of the returned list. The default is a space. A useful alternative is a comma.

matcell(matname) saves the frequencies of the distinct values in `matname`.

matrow(matname) saves the distinct values of `varname` in `matname`. matrow() may not be specified if `varname` is a string.
hexadecimal specifies that hexadecimal format %21x be used when varname is numeric. See [D] format. This option guarantees that the values in the macro that levelsof creates are exactly numerically equal to their values in varname. For integer data, except for extremely large integers (absolute value $\geq 10^{19}$), levelsof always produces values that give equality without this option. For noninteger data or extremely large integers, exact numerical equality may not be true in all cases by default. Specifying hexadecimal guarantees equality in all cases.

Remarks and examples

levelsof serves two different functions. First, it provides a compact list of the distinct values of varname. More commonly, it is useful when you desire to cycle through the distinct values of varname with (say) foreach; see [P] foreach. levelsof leaves behind a list in r(levels) that may be used in a subsequent command. When wanting to get the levels of noninteger data, one may use `matrow(matname)` to obtain the levels in full precision.

levelsof may hit the limits imposed by your Stata. However, it is typically used when the number of distinct values of varname is not extremely large.

The terminology of levels of a factor has long been standard in experimental design. See Cochran and Cox (1957, 148), Fisher (1942), or Yates (1937, 5).

Example 1

```
use https://www.stata-press.com/data/r16/auto
(levelsof rep78)
1 2 3 4 5
.display "'r(levels)''"
1 2 3 4 5
 leveled rep78, miss local(mylevs)
1 2 3 4 5 .
.display "'mylevs'"
1 2 3 4 5 .
 leveled rep78, sep(,) 1,2,3,4,5
.display "'r(levels)''"
1,2,3,4,5
Showing value labels when defined:
.levelsof factor, local(levels)
. foreach l of local levels {
.     di "-> factor = ' label (factor) 'l''"
.     whatever if factor == '1'
. }
```

Example 2

By default, levelsof gives exact numerical equality for all integers except extremely large ones (absolute value $\geq 10^{19}$). If you are working with integers that are not of this extreme size, levelsof will do what you want in all cases. You can test the equality of the macro values with the variable values using ==. When working with nonintegers or extremely large integers, however, using == may not always be true when it “should” be true.
levelsof fills a macro with numbers formatted in base 10, but the values of a variable are stored in base 2. The conversion of values from base 2 to base 10 may yield an approximation where an expression using `==` does not evaluate to true.

Here’s a simple example:

```
. clear
. set obs 5
  number of observations (_N) was 0, now 5
. generate double x = ln(_n + 1)
. levelsof x
  > .6931471805599453 1.09861228866811 1.386294361119891 1.6094379124341 1.791759469228055
. foreach level in `r(levels)' {
  2. count if x == `level'
  3. }
  1
  0
  0
  0
  1
```

In 3 cases out of 5, equality was not true. Using the option `hexadecimal` solves this problem. The macro values are formatted in base 16 using Stata’s hexadecimal format `%21x`. See [D] format.

```
. levelsof x, hexadecimal
  > +1.62e42fefa39efX-001 +1.9c041f7ed8d33X+000 +1.9c041f7ed8d33X+000 +1.cab0bfa2a2002X+000
. foreach level in `r(levels)' {
  2. display "x = " %10.0g `level'
  3. count if x == `level'
  4. }
  x = .69314718
  1
  x = 1.0986123
  1
  x = 1.3862944
  1
  x = 1.6094379
  1
  x = 1.7917595
  1
```

The only downside of using `hexadecimal` is that the values of the levels may be hard to read if we do not reformat them. Or we can just learn to read base 16.

---

### Stored results

levelsof stores the following in `r()`:

**Scalars**

- `r(N)` number of observations
- `r(r)` number of distinct values

**Macros**

- `r(levels)` list of distinct values
Acknowledgments

The original version of `levelsof` was written by Nicholas J. Cox of the Department of Geography at Durham University, UK, and coeditor of the `Stata Journal` and author of `Speaking Stata Graphics`. He in turn thanks Christopher F. Baum of the Department of Economics at Boston College and author of the Stata Press books `An Introduction to Modern Econometrics Using Stata` and `An Introduction to Stata Programming` and Nicholas Winter of the Department of Politics at the University of Virginia, for their input.
