To calculate the p -values, we first scale the observed value of T to the domain of beta:

$$s = \frac{T_{\text{obs}} - l}{u - l}$$

Then the lower and upper one-sided p -values are given by

$$p_{\text{lower}} = \text{ibeta}(\alpha, \beta, s)$$

$$p_{\text{upper}} = \text{ibetatail}(\alpha, \beta, s)$$

where `ibeta` is Stata's two-parameter cumulative beta distribution and `ibetatail` is the function for its upper tail; see [\[FN\] Statistical functions](#). The two-sided p -value is given by

$$p = \min\{1, 2 \min(p_{\text{lower}}, p_{\text{upper}})\}$$

Exact p-values

Exact p -values for Spearman's rank correlation are computed by `permute`. For details on the permutation computation, see [R] [permute](#).

Kendall's tau

Kendall's τ is calculated in the following manner. For any two pairs of ranks (x_i, y_i) and (x_j, y_j) , $1 \leq i, j \leq n$, define them as concordant if

$$(x_i - x_j)(y_i - y_j) > 0$$

and discordant if this product is less than zero.

Kendall's (1938; also see [Kendall and Gibbons \[1990\]](#) or [Bland \[2015\]](#), 187–188) score S is defined as $C - D$, where C (D) is the number of concordant (discordant) pairs. Let $N = n(n-1)/2$ be the total number of pairs, so τ_a is given by

$$\tau_a = \frac{S}{N}$$

and τ_b is given by

$$\tau_b = \frac{S}{\sqrt{N - U}\sqrt{N - V}}$$

where

$$U = \sum_{i=1}^{N_1} u_i(u_i - 1)/2$$

$$V = \sum_{j=1}^{N_2} v_j(v_j - 1)/2$$

and where N_1 is the number of sets of tied x values, u_i is the number of tied x values in the i th set, N_2 is the number of sets of tied y values, and v_j is the number of tied y values in the j th set.

Under the null hypothesis of independence, the variance of S is exactly ([Kendall and Gibbons 1990](#), 66)

$$\begin{aligned} \text{Var}(S) = & \frac{1}{18} \left\{ n(n-1)(2n+5) - \sum_{i=1}^{N_1} u_i(u_i-1)(2u_i+5) - \sum_{j=1}^{N_2} v_j(v_j-1)(2v_j+5) \right\} \\ & + \frac{1}{9n(n-1)(n-2)} \left\{ \sum_{i=1}^{N_1} u_i(u_i-1)(u_i-2) \right\} \left\{ \sum_{j=1}^{N_2} v_j(v_j-1)(v_j-2) \right\} \\ & + \frac{1}{2n(n-1)} \left\{ \sum_{i=1}^{N_1} u_i(u_i-1) \right\} \left\{ \sum_{j=1}^{N_2} v_j(v_j-1) \right\} \end{aligned}$$

Using a normal approximation with a continuity correction,

$$z = \frac{|S| - 1}{\sqrt{\text{Var}(S)}}$$

For the hypothesis of independence, the statistics S , τ_a , and τ_b produce equivalent tests and give the same p -value.

For Kendall's τ , the normal approximation is surprisingly accurate for sample sizes as small as 8, at least for calculating p -values under the null hypothesis for continuous variables. See [Kendall and Gibbons \[1990, chap. 4\]](#), who also present some tables for calculating exact p -values for $n < 10$.

Let v be the number of variables specified so that $k = v(v - 1)/2$ correlation coefficients are to be estimated. If `bonferroni` is specified, the adjusted p -value is $p' = \min(1, kp)$. If `sidak` is specified, $p' = \min\{1, 1 - (1 - p)^n\}$. See [Methods and formulas](#) in [\[R\] oneway](#) for a more complete description of the logic behind these adjustments.

Early work on rank correlation is surveyed by [Kruskal \(1958\)](#).

Acknowledgment

The original version of `ktau` was written by Sean Beckett, author of the Stata Press book [Introduction to Time Series Using Stata, Revised Edition](#).

Description

`spikeplot` produces a frequency plot for a variable in which the frequencies are depicted as vertical lines from zero. The frequency may be a count, a fraction, or the square root of the count (Tukey's rootogram, circa 1965). The vertical lines may also originate from a baseline other than zero at the user's option.

Quick start

Spike plot of `v1`

```
spikeplot v1
```

Same as above, but apply frequency weights `wvar`

```
spikeplot v1 [fweight = wvar]
```

Plot proportions of the total number of observations instead of frequencies

```
spikeplot v1, fraction
```

Tukey's rootogram of `v2`

```
spikeplot v2, root
```

Menu

Graphics > Distributional graphs > Spike plot and rootogram

Syntax

spikeplot *varname* [*if*] [*in*] [*weight*] [, *options*]

<i>options</i>	Description
Main	
<code>round(#)</code>	round <i>varname</i> to nearest multiple of # (bin width)
<code>fraction</code>	make vertical scale the proportion of total values; default is frequencies
<code>root</code>	make vertical scale show square roots of frequencies
Plot	
<code>spike_options</code>	affect rendition of plotted spikes
Add plots	
<code>addplot(plot)</code>	add other plots to generated graph
Y axis, X axis, Titles, Legend, Overall, By	
<code>twoway_options</code>	any options documented in [G-3] <i>twoway_options</i>

fweights, aweights, and iweights are allowed; see [U] 11.1.6 *weight*.

Options

Main

`round(#)` rounds the values of *varname* to the nearest multiple of #. This action effectively specifies the bin width.

`fraction` specifies that the vertical scale be the proportion of total values (percentage) rather than the count.

`root` specifies that the vertical scale show square roots. This option may not be specified if `fraction` is specified.

Plot

`spike_options` affect the rendition of the plotted spikes; see [G-2] *graph twoway spike*.

Add plots

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] *addplot_option*.

Y axis, X axis, Titles, Legend, Overall, By

`twoway_options` are any of the options documented in [G-3] *twoway_options*. These include options for titling the graph (see [G-3] *title_options*), options for saving the graph to disk (see [G-3] *saving_option*), and the `by()` option (see [G-3] *by_option*).

Remarks and examples

► Example 1

Cox and Brady (1997a) present an illustrative example using the age structure of the population of Ghana from the 1960 census (rounded to the nearest 1,000). The dataset has ages from 0 (less than 1 year) to 90. To view the distribution of ages, we would like to use each integer from 0 to 90 as the bins for the dataset.

```
. use https://www.stata-press.com/data/r19/ghanaage
(Age structure of population of Ghana)
. spikeplot age [fw=pop], ytitle("Population in 1,000s") xlab(0(10)90)
> xmtick(5(10)85)
```

The resulting graph shows a “heaping” of ages at the multiples of 5. Also, ages ending in even numbers are more frequent than ages ending in odd numbers (except for 5). This preference for reporting ages is well known in demography and other social sciences.

Note also that we used the `ytitle()` option to override the default title of “Frequency” and that we used the `xlab()` and `xmtick()` options with *numlists* to further customize the resulting graph. See [U] 11.1.8 *numlist* for details on specifying *numlists*.

► Example 2

The rootogram is a plot of the square-root transformation of the frequency counts. The square root of a normal distribution is a multiple of another normal distribution.

```
. clear
. set seed 1234567
. set obs 5000
Number of observations (_N) was 0, now 5,000.
. generate normal = rnormal()
. label variable normal "Gaussian(0,1) random numbers"
```

```
. spikeplot normal, round(.10) xlab(-4(1)4)
```

```
. spikeplot normal, round(.10) xlab(-4(1)4) root
```

Interpreting a histogram in terms of normality is thus similar to interpreting the rootogram for normality.

This example also shows how the `round()` option is used to bin the values for a spike plot of a continuous variable.

► Example 3

spikeplot can also be used to produce time-series plots. *varname* should be the time variable, and weights should be specified as the values for those times. To get a plot of daily rainfalls, we type

```
. spikeplot day [fw=rain] if rain, ytitle("Daily rainfall in mm")
```

The `base()` option of `graph twoway spike` may be used to set a different baseline, such as when we want to show variations relative to an average or to some other measure of level.

Acknowledgments

The original version of spikeplot was written by Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* and by Anthony R. Brady founder of Sealed Envelope, London (1997a, 1997b).

Description

`ssc` works with packages (and files) from the Statistical Software Components (SSC) Archive, which is often called the Boston College Archive and is provided by <http://repec.org>.

The SSC has become the premier Stata download site for community-contributed software on the web. `ssc` provides a convenient interface to the resources available there. For example, on Statalist (see <https://www.statalist.org/>), users will often write

The program can be found by typing `ssc install newprogramname`.

Typing that would load everything associated with `newprogramname`, including the help files.

If you are searching for what is available, type `ssc new` and `ssc hot`, and see [R] [search](#). `search` searches the SSC and other places, too. `search` provides a GUI interface from which programs can be installed, including the programs at the SSC Archive.

You can uninstall particular packages by using `ssc uninstall`. For the packages that you keep, see [R] [ado update](#) for an automated way of keeping those packages up to date.

Command overview

`ssc new` summarizes the packages made available or updated recently. Output is presented in the Stata Viewer, and from there you may click to find out more about individual packages or to install them.

`ssc hot` lists the most popular packages—popular based on a moving average of the number of downloads in the past three months. By default, 10 packages are listed.

`ssc describe pkgname` describes, but does not install, the specified package. Use `search` to find packages; see [R] [search](#). If you know the package name but do not know the exact spelling, type `ssc describe` followed by one letter, a–z or _ (underscore), to list all the packages starting with that letter.

`ssc install pkgname` installs the specified package. You do not have to describe a package before installing it. (You may also install a package by using `net install`; see [R] [net](#).)

`ssc uninstall pkgname` removes the previously installed package from your computer. It does not matter how the package was installed. (`ssc uninstall` is a synonym for `ado uninstall`, so either may be used to installed any package.)

`ssc type filename` types a specific file stored at SSC. `ssc cat` is a synonym for `ssc type`, which may appeal to those familiar with Unix.

`ssc copy filename` copies a specific file stored at SSC to your computer. By default, the file is copied to the current directory, but you can use options to change this. `ssc copy` is a rarely used alternative to `ssc install ...`, `all`. `ssc cp` is a synonym for `ssc copy`.

Options

Options are presented under the following headings:

Options for use with ssc new
Options for use with ssc hot
Option for use with ssc describe
Options for use with ssc install
Option for use with ssc type
Options for use with ssc copy

Options for use with ssc new

`saving(filename[, replace])` specifies that the “what’s new” summary be saved in *filename*. If *filename* is specified without a suffix, *filename.smcl* is assumed. If `saving()` is not specified, `saving(ssc_results.smcl)` is assumed.

`type` specifies that the “what’s new” results be displayed in the Results window rather than in the Viewer.

Options for use with ssc hot

`n(#)` specifies the number of packages to list; `n(10)` is the default. Specify `n(.)` to list all packages in order of popularity.

`author(name)` lists the 10 most popular packages by the specified author. If `n(#)` is also specified, the top # packages are listed.

Option for use with ssc describe

`saving(filename[, replace])` specifies that, in addition to the description’s being displayed on your screen, it be saved in the specified file.

If *filename* is specified without an extension, `.smcl` will be assumed, and the file will be saved as a SMCL file.

If *filename* is specified with an extension, no default extension is added. If the extension is `.log`, the file will be stored as a text file.

If `replace` is specified, *filename* is replaced if it already exists.

Options for use with ssc install

`all` specifies that any ancillary files associated with the package be downloaded to your current directory, in addition to the program and help files being installed. Ancillary files are files that do not end in `.ado` or `.sthlp` and typically contain datasets or examples of the use of the new command.

You can find out which files are associated with the package by typing `ssc describe pkgname` before or after installing. If you install without using the `all` option and then want the ancillary files, you can `ssc install` again.

`replace` specifies that any files being downloaded that already exist on your computer be replaced by the downloaded files. If `replace` is not specified and any files already exist, none of the files from the package is downloaded or installed.

It is better not to specify the `replace` option and wait to see if there is a problem. If there is a problem, it is usually better to uninstall the old package by using `ssc uninstall` or `ado uninstall` (which are, in fact, the same command).

Option for use with `ssc type`

`asis` affects how files with the suffixes `.smcl` and `.sthlp` are displayed. The default is to interpret SMCL directives the file might contain. `asis` specifies that the file be displayed in raw, uninterpreted form.

Options for use with `ssc copy`

`plus` specifies that the file be copied to the PLUS directory, the directory where community-contributed additions are installed. Typing `sysdir` will display the identity of the PLUS directory on your computer; see [P] [sysdir](#).

`personal` specifies that the file be copied to your PERSONAL directory as reported by `sysdir`; see [P] [sysdir](#).

If neither `plus` nor `personal` is specified, the default is to copy the file to the current directory.

`replace` specifies that, if the file already exists on your computer, the new file replace it.

`public` specifies that the new file be made readable by everyone; otherwise, the file will be created according to the default permission you have set with your operating system.

`binary` specifies that the file being copied is a binary file and that it is to be copied as is. The default is to assume that the file is a text file and change the end-of-line characters to those appropriate for your computer/operating system.

Remarks and examples

Users can add new features to Stata, and some users choose to make new features that they have written available to others via the web. The files that comprise a new feature are called a package, and a package usually consists of one or more ado-files and help files. The `net` command (see [R] [net](#)) makes it reasonably easy to install and uninstall packages regardless of where they are on the web. One site, the SSC, has become particularly popular as a repository for additions to Stata. Command `ssc` is an easier to use version of `net` designed especially for the SSC.

Many packages are available at the SSC. Packages have names, such as `oaxaca`, `estout`, or `egenmore`. At SSC, capitalization is not significant, so `Oaxaca`, `ESTOUT`, and `EGENmore` are ways of writing the same package names.

When you type

```
. ssc install oaxaca
```

the files associated with the package are downloaded and installed on your computer. Package names usually correspond to the names of the command being added to Stata, so one would expect that installing the package `oaxaca` will add command `oaxaca` to Stata on your computer, and expect that typing `help oaxaca` will provide the documentation. That is the situation here, but that is not always so. Before or after installing a package, type `ssc describe pkgname` to obtain the details.

► Example 1

`ssc new` summarizes the packages most recently made available or updated. Output is presented in the Viewer, from which you may click on a package name to find out more or install it. Try it for yourself! Type `ssc new` in the Command window.

`ssc hot` provides a list of the most popular packages at SSC.

```
. ssc hot
```

The author (*name*) option allows you to list the most popular packages by a specific person:

```
. ssc hot, author(baum)
```

Top 10 packages at SSC by author Baum

Feb 2025			
Rank	# hits	Package	Author(s)
7	33506.2	ivreg210	Christopher F Baum, Mark E Schaffer, Steven Stillman
8	31413.5	ivreg2	Christopher F Baum, Steven Stillman, Mark E Schaffer
(output omitted)			

(Click on package name for description)

`ssc describe pkgname` describes, but does not install, the specified package. You must already know the name of the package. See [R] [search](#) for assistance in searching for packages. Sometimes you know the package name, but you do not know the exact spelling. Then, you can type `ssc describe` followed by one letter, a–z or `_`, to list all the packages starting with that letter; even so, using `search` is better.

```
. ssc describe i
```

```
http://fmwww.bc.edu/repec/bocode/i/  
(no title)
```

PACKAGES you could **-not describe-**:

(output omitted)

ivreg2	module for extended instrumental variables/2SLS and GMM estimation
ivreg210	module for extended instrumental variables/2SLS and GMM estimation (v10)
ivreg28	module for extended instrumental variables/2SLS and GMM estimation (v8)
ivreg29	module for extended instrumental variables/2SLS and GMM estimation (v9)
ivreg2h	module to perform instrumental variables estimation using heteroskedasticity-based instruments
ivreg2hdfe	module to estimate an Instrumental Variable Linear Regression Model with two High Dimensional Fixed Effects
ivreg2m	module to identify treatment-effects estimates with potentially misreported and endogenous program participation
ivreg_ss	module to compute confidence intervals, standard errors, and p-values in an IV regression in which the excluded instrumental variable has a shift-share structure
ivreghdfe	module for extended instrumental variable regressions with multiple levels of fixed effects
ivregress2	module to export first and second-stage results similar to ivregress

(output omitted)

(type `ssc describe pkgname` for more information on *pkgname*)

The default setting for the `saving()` option is for the output to be saved with the `.smcl` extension. You could also save the file with a `log` extension, and in this case, the file would be stored as a text file. For example, we could type

```
. ssc describe i, saving(i.index)
```

or the following:

```
. ssc describe ivreg2, saving(ivreg2.log)
```

`ssc install pkgname` installs the specified package. You do not have to describe a package before installing it. There are ways of installing packages other than `ssc install`, such as `net`; see [R] [net](#). It does not matter how a package is installed. For instance, a package can be installed using `net` and still be uninstalled using `ssc`.

```
. ssc install ivreg2
checking ivreg2 consistency and verifying not already installed...
installing into C:\ado\plus\...
installation complete.
```

`ssc uninstall pkgname` removes the specified, previously installed package from your computer. You can uninstall immediately after installation or at any time in the future. (Technical note: `ssc uninstall` is a synonym for `ado uninstall`, so it can uninstall any installed package, not just packages obtained from the SSC.)

```
. ssc uninstall ivreg2
package ivreg2 from http://fmwww.bc.edu/repec/bocode/i
'IVREG2': module for extended instrumental variables/2SLS and GMM
estimation
(package uninstalled)
```

`ssc type filename` types a specific file stored at the SSC. Although not shown in the syntax diagram, `ssc cat` is a synonym for `ssc type`, which may appeal to those familiar with Unix. To view only the `ivreg2` help file from the `ivreg2` package, you would type

```
. ssc type ivreg2.sthlp
```

```
help for ivreg2
```

Extended instrumental variables/2SLS, GMM and AC/HAC, LIML and k-class regression

Full syntax
(output omitted)

`ssc copy filename` copies a specific file stored at the SSC to your computer. By default, the file is copied to the current directory, but you can use options to change this. `ssc copy` is a rarely used alternative to `ssc install ...`, `all`. `ssc cp` is a synonym for `ssc copy`.

```
. ssc copy ivreg2.ado
(file ivreg2.ado copied to current directory)
```

For more details on the SSC Archive and for information on how to submit your own programs to the SSC, see <http://repec.org/bocode/s/sscsubmit.html>.

Acknowledgments

ssc is based on `archutil` by Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* and by Christopher F. Baum of the Department of Economics at Boston College and author of the Stata Press books *An Introduction to Modern Econometrics Using Stata* and *An Introduction to Stata Programming* and coauthor of the Stata Press book *Environmental Econometrics Using Stata*. The reworking of the original was done with their blessing and their participation.

Baum maintains the Stata-related files stored at the SSC Archive. We thank him for this contribution to the Stata community.

Description

stem displays stem-and-leaf plots.

Quick start

Stem-and-leaf plot for v1

```
stem v1
```

Same as above, with 2 lines per interval of 10

```
stem v1, lines(2)
```

Specify that each stem has a width of 5 (equivalent to above)

```
stem v1, width(5)
```

Stem-and-leaf plot for v2 with an interval of 100

```
stem v2, digits(2)
```

Same as above, with 4 lines per interval of 100

```
stem v2, digits(2) lines(4)
```

Display v2 rounded to the nearest hundred

```
stem v2, round(100)
```

Do not display empty stems

```
stem v2, prune
```

Menu

Statistics > Summaries, tables, and tests > Distributional plots and tests > Stem-and-leaf display

Syntax

stem *varname* [*if*] [*in*] [, *options*]

<i>options</i>	Description
Main	
<code>prune</code>	do not print stems that have no leaves
<code>round(#)</code>	round data to this value; default is <code>round(1)</code>
<code>truncate(#)</code>	truncate data to this value
<code>digits(#)</code>	digits per leaf; default is <code>digits(1)</code>
<code>lines(#)</code>	number of stems per interval of 10^{digits}
<code>width(#)</code>	stem width; equal to $10^{\text{digits}}/\text{width}$
by and collect are allowed; see [U] 11.1.10 Prefix commands .	

Options

Main

- `prune` prevents printing any stems that have no leaves.
- `round(#)` rounds the data to this value and displays the plot in these units. If `round()` is not specified, noninteger data will be rounded automatically.
- `truncate(#)` truncates the data to this value and displays the plot in these units.
- `digits(#)` sets the number of digits per leaf. The default is 1.
- `lines(#)` sets the number of stems per every data interval of 10^{digits} . The value of `lines()` must divide 10^{digits} ; that is, if `digits(1)` is specified, then `lines()` must divide 10. If `digits(2)` is specified, then `lines()` must divide 100, etc. Only one of `lines()` or `width()` may be specified. If neither is specified, an appropriate value will be set automatically.
- `width(#)` sets the width of a stem. `lines()` is equal to $10^{\text{digits}}/\text{width}$, and this option is merely an alternative way of setting `lines()`. The value of `width()` must divide 10^{digits} . Only one of `width()` or `lines()` may be specified. If neither is specified, an appropriate value will be set automatically.

Note: If `lines()` or `width()` is not specified, `digits()` may be decreased in some circumstances to make a better-looking plot. If `lines()` or `width()` is set, the user-specified value of `digits()` will not be altered.

Remarks and examples

▷ Example 1

Stem-and-leaf displays are a compact way to present considerable information about a batch of data. For instance, using our automobile data (described in [U] 1.2.2 Example datasets):

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
```

```
. stem mpg
```

Stem-and-leaf plot for mpg (Mileage (mpg))

```
1t | 22
1f | 44444455
1s | 66667777
1. | 888888888999999999
2* | 00011111
2t | 22222333
2f | 444455555
2s | 666
2. | 8889
3* | 001
3t |
3f | 455
3s |
3. |
4* | 1
```

The stem-and-leaf display provides a way to list our data. The expression to the left of the vertical bar is called the stem; the digits to the right are called the leaves. All the stems that begin with the same digit and the corresponding leaves, written beside each other, reconstruct an observation of the data. Thus, if we look at the four stems that begin with the digit 1 and their corresponding leaves, we see that we have two cars rated at 12 mpg, 6 cars at 14, 2 at 15, and so on. The car with the highest mileage rating in our data is rated at 41 mpg.

The above plot is a five-line plot with `lines()` equal to 5 (five lines per interval of 10) and `width()` equal to 2 (two leaves per stem).

Instead, we could specify `lines(2)`:

```
. stem mpg, lines(2)
```

Stem-and-leaf plot for mpg (Mileage (mpg))

```
1* | 22444444
1. | 55666677778888888899999999
2* | 00011111222223334444
2. | 555556668889
3* | 0014
3. | 55
4* | 1
```

`stem mpg, width(5)` would produce the same plot as above.

The stem-and-leaf display provides a crude histogram of our data, one not so pretty as that produced by `histogram` (see [R] [histogram](#)), but one that is nonetheless informative.

► Example 2

The miles per gallon rating fits easily into a stem-and-leaf display because, in our data, it has two digits. However, `stem` does not require two digits.

```
. stem price, lines(1) digits(3)
Stem-and-leaf plot for price (Price)

3*** | 291,299,667,748,798,799,829,895,955,984,995
4*** | 010,060,082,099,172,181,187,195,296,389,424,425,453,482,499, ... (26)
5*** | 079,104,172,189,222,379,397,705,719,788,798,799,886,899
6*** | 165,229,295,303,342,486,850
7*** | 140,827
8*** | 129,814
9*** | 690,735
10*** | 371,372
11*** | 385,497,995
12*** | 990
13*** | 466,594
14*** | 500
15*** | 906
```

The (26) at the right of the second stem shows that there were 26 leaves on this stem—too many to display on one line.

We can make a more compact stem-and-leaf plot by rounding. To display `stem` in units of 100, we could type

```
. stem price, round(100)
Stem-and-leaf plot for price (Price)
price rounded to nearest multiple of 100
plot in units of 100

3* | 33778889
4* | 0000111222344455555667777899
5* | 11222447788899
6* | 2233359
7* | 18
8* | 18
9* | 77
10* | 44
11* | 45
12* | 0
13* | 056
14* | 5
15* | 9
```

`price`, in our data, has four or five digits. `stem` presented the display in terms of units of 100, so a car that cost \$3,291 was treated for display purposes as \$3,300.

◀

□ Technical note

Stem-and-leaf diagrams have been used in Japanese railway timetables, as shown in [Tufte \(1990, 46–47\)](#).

□

Stored results

`stem` stores the following in `r()`:

Scalars

<code>r(width)</code>	width of a stem
<code>r(digits)</code>	number of digits per leaf; default is 1

Macros

<code>r(round)</code>	number specified in <code>round()</code>
<code>r(truncate)</code>	number specified in <code>truncate()</code>

[Syntax](#)
[Methods and formulas](#)

Description

stepwise performs stepwise estimation. Typing

```
. stepwise, pr(#): command
```

performs backward-selection estimation for *command*. The stepwise selection method is determined by the following option combinations:

<i>options</i>	Description
pr(#)	backward selection
pr(#) hierarchical	backward hierarchical selection
pr(#) pe(#)	backward stepwise
pe(#)	forward selection
pe(#) hierarchical	forward hierarchical selection
pr(#) pe(#) forward	forward stepwise

command defines the estimation command to be executed. The following Stata commands are supported by stepwise:

```
betareg, clogit, cloglog, glm, intreg, logistic, logit, nbreg,  
ologit, oprobit, poisson, probit, qreg, regress, scobit, stcox,  
stcrreg, stintreg, streg, tobit
```

stepwise expects *command* to have the following form:

```
command_name [depvar] term [term ...] [if] [in] [weight] [, command_options]
```

where *term* is either *varname* or (*varlist*) (*varlist* in parentheses indicates that this group of variables is to be included or excluded together). *depvar* is not present when *command_name* is stcox, stcrreg, stintreg, or streg; otherwise, *depvar* is assumed to be present. For intreg, *depvar* is actually two dependent variable names (*depvar*₁ and *depvar*₂).

sw is a synonym for stepwise.

For model selection and estimation using lasso, see the [Stata Lasso Reference Manual](#).

Quick start

Backward selection, removing terms with $p \geq 0.2$

```
stepwise, pr(.2): regress y x1 x2 x3 x4
```

Same as above, and select from the indicators for categorical variable a

```
stepwise, pr(.2): regress y x1 x2 x3 x4 i.a
```

Same as above, but force x1 to be included in model

```
stepwise, pr(.2) lockterm1: regress y x1 x2 x3 x4 i.a
```

Consider the indicators for a as a group for inclusion in model

```
stepwise, pr(.2): regress y x1 x2 x3 x4 (i.a)
```

Add d1, d2, and d3, and force them to be included in model

```
stepwise, pr(.2) lockterm1: regress y (d1 d2 d3) x1 x2 x3 x4 (i.a)
```

Forward selection, adding terms with $p < 0.1$

```
stepwise, pe(.1): regress y x1 x2 x3 x4
```

Backward stepwise selection, removing terms with $p \geq 0.2$ and adding those with $p < 0.1$

```
stepwise, pr(.2) pe(.1): regress y x1 x2 x3 x4
```

Forward stepwise selection, adding terms with $p < 0.1$ and removing those with $p \geq 0.2$

```
stepwise, pr(.2) pe(.1) forward: regress y x1 x2 x3 x4
```

Backward hierarchical selection

```
stepwise, pr(.2) hierarchical: regress y x1 x2 x3 x4
```

Forward hierarchical selection

```
stepwise, pe(.1) hierarchical: regress y x1 x2 x3 x4
```

Note: In the above examples, regress could be replaced with any estimation command allowing the stepwise prefix.

Menu

Statistics > Other > Stepwise estimation

Syntax

stepwise [, options] : *command*

options	Description
Model	
*pr(#)	significance level for removal from the model
*pe(#)	significance level for addition to the model
Model2	
forward	perform forward-stepwise selection
hierarchical	perform hierarchical selection
lockterm1	keep the first term
lr	perform likelihood-ratio test instead of Wald test
Reporting	
display_options	control columns and column formats and line width

*At least one of pr(#)
or pe(#)
must be specified.
by is allowed; see [U] 11.1.10 Prefix commands.
Weights are allowed if *command* allows them; see [U] 11.1.6 weight.
All postestimation commands behave as they would after *command* without the *stepwise* prefix; see the postestimation manual entry for *command*.

Options

Model
pr(#) specifies the significance level for removal from the model; terms with $p \geq \text{pr}()$ are eligible for removal.
pe(#) specifies the significance level for addition to the model; terms with $p < \text{pe}()$ are eligible for addition.
Model 2
forward specifies the forward-stepwise method and may be specified only when both pr() and pe() are also specified. Specifying both pr() and pe() without forward results in backward-stepwise selection. Specifying only pr() results in backward selection, and specifying only pe() results in forward selection.
hierarchical specifies hierarchical selection.
lockterm1 specifies that the first term be included in the model and not be subjected to the selection criteria.
lr specifies that the test of term significance be the likelihood-ratio test. The default is the less computationally expensive Wald test; that is, the test is based on the estimated variance–covariance matrix of the estimators.
Reporting
display_options: noci, nopvalues, cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)
[Search logic for a step](#)
[Full search logic](#)
[Examples](#)
[Estimation sample considerations](#)
[Messages](#)
[Programming for stepwise](#)

Introduction

Typing

```
. stepwise, pr(.10): regress y1 x1 x2 d1 d2 d3 x4 x5
```

performs a backward-selection search for the regression model y_1 on x_1 , x_2 , d_1 , d_2 , d_3 , x_4 , and x_5 . In this search, each explanatory variable is said to be a term. Typing

```
. stepwise, pr(.10): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

performs a similar backward-selection search, but the variables d_1 , d_2 , and d_3 are treated as one term, as are x_4 and x_5 . That is, d_1 , d_2 , and d_3 may or may not appear in the final model, but they appear or do not appear together.

► Example 1

Using the automobile dataset, we fit a backward-selection model of `mpg`:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)

. stepwise, pr(.2): regress mpg c.weight#c.weight displ gear turn headroom
> i.foreign price
note: 0b.foreign omitted because of estimability.

Wald test, begin with full model:
p = 0.7116 >= 0.2000, removing headroom
p = 0.6138 >= 0.2000, removing displacement
p = 0.3278 >= 0.2000, removing price
```

Source	SS	df	MS	Number of obs	=	74
Model	1736.31455	5	347.262911	F(5, 68)	=	33.39
Residual	707.144906	68	10.3991898	Prob > F	=	0.0000
				R-squared	=	0.7106
				Adj R-squared	=	0.6893
Total	2443.45946	73	33.4720474	Root MSE	=	3.2248

mpg	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
weight	-.0158002	.0039169	-4.03	0.000	-.0236162	-.0079842
c.weight# c.weight	1.77e-06	6.20e-07	2.86	0.006	5.37e-07	3.01e-06
foreign						
Foreign	-3.615107	1.260844	-2.87	0.006	-6.131082	-1.099131
gear_ratio	2.011674	1.468831	1.37	0.175	-.9193321	4.94268
turn	-.3087038	.1763099	-1.75	0.084	-.6605248	.0431172
_cons	59.02133	9.3903	6.29	0.000	40.28327	77.75938

This estimation treated each variable as its own term and thus considered each one separately. The engine displacement and gear ratio should really be considered together:

```
. stepwise, pr(.2): regress mpg c.weight#c.weight (displ gear) turn headroom
> i.foreign price
note: 0b.foreign omitted because of estimability.
```

Wald test, begin with full model:

p = 0.7116 >= 0.2000, removing headroom

p = 0.3944 >= 0.2000, removing displacement gear_ratio

p = 0.2798 >= 0.2000, removing price

◀

Search logic for a step

Before discussing the complete search logic, consider the logic for a step—the first step—in detail. The other steps follow the same logic. If you type

```
. stepwise, pr(.20): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the logic is

1. Fit the model y on $x_1 x_2 d_1 d_2 d_3 x_4 x_5$.
2. Consider dropping x_1 .
3. Consider dropping x_2 .
4. Consider dropping $d_1 d_2 d_3$.
5. Consider dropping $x_4 x_5$.
6. Find the term above that is least significant. If its significance level is ≥ 0.20 , remove that term.

If you type

```
. stepwise, pr(.20) hierarchical: regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the logic would be different because the `hierarchical` option states that the terms are ordered. The initial logic would become

1. Fit the model y on $x_1 x_2 d_1 d_2 d_3 x_4 x_5$.
2. Consider dropping $x_4 x_5$ —the last term.
3. If the significance of this last term is ≥ 0.20 , remove the term.

The process would then stop or continue. It would stop if $x_4 x_5$ were not omitted, and otherwise, `stepwise` would continue to consider the significance of the next-to-last term, $d_1 d_2 d_3$.

Specifying `pe()` rather than `pr()` switches to forward estimation. If you type

```
. stepwise, pe(.20): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

`stepwise` performs forward-selection search. The logic for the first step is

1. Fit a model of y on nothing (meaning a constant).
2. Consider adding x_1 .
3. Consider adding x_2 .
4. Consider adding $d_1 d_2 d_3$.
5. Consider adding $x_4 x_5$.
6. Find the term above that is most significant. If its significance level is < 0.20 , add that term.

As with backward estimation, if you specify `hierarchical`,

```
. stepwise, pe(.20) hierarchical: regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the search for the most significant term is restricted to the next term:

1. Fit a model of y on nothing (meaning a constant).
2. Consider adding x_1 —the first term.
3. If the significance is < 0.20 , add the term.

If x_1 were added, `stepwise` would next consider x_2 ; otherwise, the search process would stop.

`stepwise` can also use a stepwise selection logic that alternates between adding and removing terms. The full logic for all the possibilities is given below.

Full search logic

Option	Logic
<code>pr()</code> (backward selection)	Fit the full model on all explanatory variables. While the least-significant term is “insignificant”, remove it and reestimate.
<code>pr() hierarchical</code> (backward hierarchical selection)	Fit full model on all explanatory variables. While the last term is “insignificant”, remove it and reestimate.
<code>pr() pe()</code> (backward stepwise)	Fit full model on all explanatory variables. If the least-significant term is “insignificant”, remove it and reestimate; otherwise, stop. Do that again: if the least-significant term is “insignificant”, remove it and reestimate; otherwise, stop. Repeatedly, if the most-significant excluded term is “significant”, add it and reestimate; if the least-significant included term is “insignificant”, remove it and reestimate; until neither is possible.
<code>pe()</code> (forward selection)	Fit “empty” model. While the most-significant excluded term is “significant”, add it and reestimate.
<code>pe() hierarchical</code> (forward hierarchical selection)	Fit “empty” model. While the next term is “significant”, add it and reestimate.
<code>pr() pe() forward</code> (forward stepwise)	Fit “empty” model. If the most-significant excluded term is “significant”, add it and reestimate; otherwise, stop. Do that again: if the most-significant excluded term is “significant”, add it and reestimate; otherwise, stop. Repeatedly, if the least-significant included term is “insignificant”, remove it and reestimate; if the most-significant excluded term is “significant”, add it and reestimate; until neither is possible.

Examples

The following two statements are equivalent; both include solely single-variable terms:

```
. stepwise, pr(.2): regress price mpg weight displ
. stepwise, pr(.2): regress price (mpg) (weight) (displ)
```

The following two statements are equivalent; the last term in each is r_1, \dots, r_4 :

```
. stepwise, pr(.2) hierarchical: regress price mpg weight displ (r1-r4)
. stepwise, pr(.2) hierarchical: regress price (mpg) (weight) (displ) (r1-r4)
```

To group variables `weight` and `displ` into one term, type

```
. stepwise, pr(.2) hierarchical: regress price mpg (weight displ) (r1-r4)
```

`stepwise` can be used with commands other than `regress`; for instance,

```
. stepwise, pr(.2): logit outcome (sex weight) treated1 treated2
. stepwise, pr(.2): logistic outcome (sex weight) treated1 treated2
```

Either statement would fit the same model because `logistic` and `logit` both perform logistic regression; they differ only in how they report results; see [\[R\] logit](#) and [\[R\] logistic](#).

We use the `lockterm1` option to force the first term to be included in the model. To keep `treated1` and `treated2` in the model no matter what, we type

```
. stepwise, pr(.2) lockterm1: logistic outcome (treated1 treated2) ...
```

After `stepwise` estimation, we can type `stepwise` without arguments to redisplay results,

```
. stepwise
(output from logistic appears)
```

or type the underlying estimation command:

```
. logistic
(output from logistic appears)
```

At estimation time, we can specify options unique to the command being stepped:

```
. stepwise, pr(.2): logit outcome (sex weight) treated1 treated2, or
```

or is `logit`'s option to report odds ratios rather than coefficients; see [\[R\] logit](#).

Estimation sample considerations

Whether you use backward or forward estimation, `stepwise` forms an estimation sample by taking observations with nonmissing values of all the variables specified (except for `depvar1` and `depvar2` for `intreg`). The estimation sample is held constant throughout the stepping. Thus, if you type

```
. stepwise, pr(.2) hierarchical: regress amount sk edul sval
```

and variable `sval` is missing in half the data, that half of the data will not be used in the reported model, even if `sval` is not included in the final model.

The function `e(sample)` identifies the sample that was used. `e(sample)` contains 1 for observations used and 0 otherwise. For instance, if you type

```
. stepwise, pr(.2) pe(.10): logistic outcome x1 x2 (x3 x4) (x5 x6 x7)
```

and the final model is outcome on x1, x5, x6, and x7, you could re-create the final regression by typing

```
. logistic outcome x1 x5 x6 x7 if e(sample)
```

You could obtain summary statistics within the estimation sample of the independent variables by typing

```
. summarize x1 x5 x6 x7 if e(sample)
```

If you fit another model, `e(sample)` will automatically be redefined. Typing

```
. stepwise, lock pr(.2): logistic outcome (x1 x2) (x3 x4) (x5 x6 x7)
```

would automatically drop `e(sample)` and re-create it.

Messages

note: _____ omitted because of estimability.

This indicates that a variable was omitted because its coefficient could not be estimated. This message is most commonly issued because the variable is collinear with other variables in the model. For instance, say that you type

```
. stepwise, pr(.2): regress y x1 x2 x3 x4
```

and x2 is collinear with x3, one of these variables will automatically be omitted. If you type

```
. stepwise, pr(.2): regress y x1 x2 i.a
```

and include indicators for factor variable `a` in your model, the set of indicators for `a` are perfectly collinear, and one will be omitted with the note indicating that it was omitted because of estimability.

note: _____ omitted because of estimability.

note: _____ obs omitted because of estimability.

You probably received this message in fitting a logistic or probit model. Regardless of estimation strategy, `stepwise` checks that the full model can be fit. The indicated variable had a 0 or infinite standard error.

For logistic, logit, and probit, this message is typically caused by one-way causation. Assume that you type

```
. stepwise, pr(.2): logistic outcome (x1 x2 x3) d1
```

and assume that variable `d1` is an indicator (dummy) variable. Further assume that whenever `d1 = 1`, `outcome = 1` in the data. Then the coefficient on `d1` is infinite. One (conservative) solution to this problem is to drop the `d1` variable and the `d1==1` observations. The underlying estimation commands `probit`, `logit`, and `logistic` report the details of the difficulty and solution; `stepwise` simply accumulates such problems and reports the above summary messages. Thus, if you see this message, you could type

```
. logistic outcome x1 x2 x3 d1
```

to see the details. Although you should think carefully about such situations, Stata's solution of dropping the offending variables and observations is, in general, appropriate.

Programming for stepwise

stepwise requires that *command_name* follow standard Stata syntax and allow the *if* qualifier; see [U] **11 Language syntax**. Furthermore, *command_name* must have *sw* or *swml* as a program property; see [P] **program properties**. If *command_name* has *swml* as a property, *command_name* must store the log-likelihood value in *e(ll)* and model degrees of freedom in *e(df_m)*.

Stored results

stepwise stores whatever is stored by the underlying estimation command.

Also, stepwise stores stepwise in *e(stepwise)*.

Methods and formulas

Some statisticians do not recommend stepwise procedures; see [Sribney \(1998\)](#) for a summary.

[LASSO] [Lasso intro](#) — Introduction to lasso

Description

Results of calculations are stored by many Stata commands so that they can be easily accessed and substituted into later commands.

`return list` lists results stored in `r()`.

`ereturn list` lists results stored in `e()`.

`sreturn list` lists results stored in `s()`.

This entry discusses using stored results. Programmers wishing to store results should see [\[P\] `return`](#) and [\[P\] `ereturn`](#).

Syntax

List results from general commands, stored in `r()`

`return list` [`,` `all`]

List results from estimation commands, stored in `e()`

`ereturn list` [`,` `all`]

List results from parsing commands, stored in `s()`

`sreturn list`

Option

`all` is for use with `return list` and `ereturn list`. `all` specifies that hidden and historical stored results be listed along with the usual stored results. This option is seldom used. See [Using hidden and historical stored results](#) and [Programming hidden and historical stored results](#) under *Remarks and examples* of [\[P\] `return`](#) for more information. These sections are written in terms of `return list`, but everything said there applies equally to `ereturn list`.

`all` is not allowed with `sreturn list` because `s()` does not allow hidden or historical results.

Remarks and examples

Stata commands are classified as being

r-class	general commands that store results in <code>r()</code>
e-class	estimation commands that store results in <code>e()</code>
s-class	parsing commands that store results in <code>s()</code>
n-class	commands that do not store in <code>r()</code> , <code>e()</code> , or <code>s()</code>

There is also a c-class, `c()`, containing the values of system parameters and settings, along with certain constants, such as the value of `pi`; see [\[P\] creturn](#). A program, however, cannot be c-class.

You can look at the *Stored results* section of the manual entry of a command to determine whether it is r-, e-, s-, or n-class, but it is easy enough to guess.

Commands producing statistical results are either r-class or e-class. They are e-class if they present estimation results and r-class otherwise. s-class is a class used by programmers and is primarily used in subprograms performing parsing. n-class commands explicitly state where the result is to go. For instance, `generate` and `replace` are n-class because their syntax is `generate varname = ...` and `replace varname = ...`.

After executing a command, you can type `return list`, `ereturn list`, or `sreturn list` to see what has been stored.

► Example 1

```
. use https://www.stata-press.com/data/r19/auto4
(1978 automobile data)

. describe

Contains data from https://www.stata-press.com/data/r19/auto4.dta
Observations:      74              1978 automobile data
Variables:         6              6 Apr 2024 00:20
```

Variable name	Storage type	Display format	Value label	Variable label
price	int	%8.0gc		Price
weight	int	%8.0gc		Weight (lbs.)
mpg	byte	%8.0g		Mileage (mpg)
make	str17	%-17s		Make and model
length	int	%8.0g		Length (in.)
rep78	byte	%8.0g		Repair record 1978

```
Sorted by:

. return list

scalars:
      r(changed) = 0
      r(width)  = 25
      r(k)      = 6
      r(N)      = 74

macros:
      r(datalabel) : "1978 automobile data"
```

To view all stored results, including those that are historical or hidden, specify the `all` option.

```
. return list, all
scalars:
      r(changed) = 0
      r(width) = 25
      r(k) = 6
      r(N) = 74

macros:
      r(datalabel) : "1978 automobile data"
Historical; used before Stata 12, may exist only under version control
scalars:
      r(widthmax) = 1048576
      r(k_max) = 5000
      r(N_max) = 2147483619
```

`r(widthmax)`, `r(k_max)`, and `r(N_max)` are historical stored results. They are no longer relevant because Stata dynamically adjusts memory beginning with Stata 12.

□ Technical note

In the above example, we stated that `r(widthmax)` and `r(N_max)` are no longer relevant. In fact, they are not useful. Stata no longer has a fixed memory size, so the methods used to calculate `r(widthmax)` and `r(N_max)` are no longer appropriate.

▷ Example 2

You can use stored results in expressions.

```
. summarize mpg
```

Variable	Obs	Mean	Std. dev.	Min	Max
mpg	74	21.2973	5.785503	12	41

```
. return list
scalars:
      r(N) = 74
      r(sum_w) = 74
      r(mean) = 21.2972972972973
      r(Var) = 33.47204738985561
      r(sd) = 5.785503209735141
      r(min) = 12
      r(max) = 41
      r(sum) = 1576

. generate double mpgstd = (mpg-r(mean))/r(sd)
. summarize mpgstd
```

Variable	Obs	Mean	Std. dev.	Min	Max
mpgstd	74	-1.64e-16	1	-1.606999	3.40553

Be careful to use results stored in `r()` soon because they will be replaced the next time you execute another `r-class` command. For instance, although `r(mean)` was 21.3 (approximately) after `summarize mpg`, it is $-1.64\text{e-}16$ now because you just ran `summarize` with `mpgstd`.

► Example 3

e-class is really no different from r-class, except for where results are stored and that, when an estimation command stores results, it tends to store a lot of them:

```
. regress mpg weight length
(output omitted)

. ereturn list

scalars:
      e(N) = 74
    e(sum_w) = 74
      e(df_m) = 2
      e(df_r) = 71
      e(F) = 69.34050004300227
      e(r2) = .6613903979336323
    e(rmse) = 3.413681741382589
      e(mss) = 1616.08062422659
      e(rss) = 827.3788352328695
    e(r2_a) = .6518520992838754
      e(ll) = -194.3267619410807
    e(ll_0) = -234.3943376482347
      e(rank) = 3

macros:
      e(cmdline) : "regress mpg weight length"
      e(title) : "Linear regression"
    e(marginsok) : "XB default"
      e(vce) : "ols"
      e(depvar) : "mpg"
      e(cmd) : "regress"
    e(properties) : "b V"
      e(predict) : "regres_p"
      e(model) : "ols"
      e(estat_cmd) : "regress_estat"

matrices:
      e(b) : 1 x 3
      e(V) : 3 x 3
      e(beta) : 1 x 2

functions:
      e(sample)
```

These e-class results will stick around until you run another estimation command. Typing `return list` and `ereturn list` is the easy way to find out what a command stores.

Both r- and e-class results come in four types: scalars, macros, matrices, and functions. (s-class results come in only one type—macros—and as earlier noted, s-class is used solely by programmers, so ignore it.)

Scalars are just that—numbers by any other name. You can subsequently refer to `r(mean)` or `e(rmse)` in numeric expressions and obtain the result to full precision.

Macros are strings. For instance, `e(depvar)` contains “mpg”. You can refer to it, too, in subsequent expressions, but really that would be of most use to programmers, who will refer to it using constructs like “`e(depvar)`”. In any case, macros are macros, and you obtain their contents just as you would a local macro, by enclosing their name in single quotes. The name here is the full name, so ‘`e(depvar)`’ is mpg.

Matrices are matrices, and all estimation commands store `e(b)` and `e(V)` containing the coefficient vector and variance–covariance matrix of the estimates (VCE).

Functions are stored by e-class commands only, and the only function existing is `e(sample)`. `e(sample)` evaluates to 1 (meaning true) if the observation was used in the previous estimation and to 0 (meaning false) otherwise.

□ Technical note

Say that some command set `r(scalar)` and `r(macro)`, the first being stored as a scalar and the second as a macro. In theory, in subsequent use you are supposed to refer to `r(scalar)` and `'r(macro)'`. In fact, however, you can refer to either one with or without quotes, so you could refer to `'r(scalar)'` and `r(macro)`. Programmers sometimes do this.

When you refer to `r(scalar)`, you are referring to the full double-precision stored result. Think of `r(scalar)` without quotes as a function returning the value of the stored result `scalar`. When you refer to `r(scalar)` in quotes, Stata understands `'r(scalar)'` to mean “substitute the printed result of evaluating `r(scalar)`”. Pretend that `r(scalar)` equals the number 23. Then, `'r(scalar)'` is 23, the character 2 followed by 3.

Referring to `r(scalar)` in quotes is sometimes useful. Say that you want to use the immediate command `cii` with `r(scalar)`. The immediate command `cii` requires its arguments to be numbers—numeric literals in programmer’s jargon—and it will not take an expression. Thus, you could not type `'cii r(scalar) ...'`. You could, however, type `'cii 'r(scalar)' ...'` because `'r(scalar)'` is just a numeric literal.

For `r(macro)`, you are supposed to refer to it in quotes: `'r(macro)'`. If, however, you omit the quotes in an expression context, Stata evaluates the macro and then pretends that it is the result of function-returning-string. There are side effects of this, the most important being that the result is trimmed to 80 characters.

Referring to `r(macro)` without quotes is never a good idea; the feature was included merely for completeness.

You can even refer to `r(matrix)` in quotes (assume that `r(matrix)` is a matrix). `'r(matrix)'` does not result in the matrix being substituted; it returns the word `matrix`. Programmers sometimes find that useful.

Description

`suest` is a postestimation command; see [\[U\] 20 Estimation and postestimation commands](#).

`suest` combines the estimation results—parameter estimates and associated (co)variance matrices—stored under *namelist* into one parameter vector and *simultaneous* (co)variance matrix of the sandwich/robust type. This (co)variance matrix is appropriate even if the estimates were obtained on the same or on overlapping data.

Typical applications of `suest` are tests for intramodel and cross-model hypotheses using `test` or `testnl`, for example, a generalized Hausman specification test. `lincom` and `nlcom` may be used after `suest` to estimate linear combinations and nonlinear functions of coefficients. `suest` may also be used to adjust a standard VCE for clustering or survey design effects.

Different estimators are allowed, for example, a `regress` model and a `probit` model; the only requirement is that `predict` produce equation-level scores with the `score` option after an estimation command. The models may be estimated on different samples, due either to explicit `if` or `in` selection or to missing values. If weights are applied, the same weights (type and values) should be applied to all models in *namelist*. The estimators should be estimated without `vce(robust)` or `vce(cluster clustvar)` options. `suest` returns the robust VCE, allows the `vce(cluster clustvar)` option, and automatically works with results from the `svy` prefix command (only for `vce(linearized)`). See [example 8](#) in [\[SVY\] svy postestimation](#) for an example using `suest` with `svy: ologit`.

Because `suest` posts its results like a proper estimation command, its results can be stored via [estimates store](#). Moreover, like other estimation commands, `suest` typed without arguments replays the results.

Quick start

Combined results for stored estimates `m1` and `m2`

```
suest m1 m2
```

Same as above, but report exponentiated coefficients and label them “Odds ratio”

```
suest m1 m2, eform(Odds ratio)
```

With cluster–robust standard errors adjusting for clustering by levels of `cvar`

```
suest m1 m2, vce(cluster cvar)
```

Use `svyset` data after specifying command prefix `svy:` to estimate `m1` and `m2`

```
suest m1 m2
```

Menu

Statistics > Postestimation

Syntax

```
suest namelist [ , options ]
```

where *namelist* is a list of one or more names under which estimation results were stored via `estimates store`; see [R] [estimates store](#). Wildcards may be used. `*` and `_all` refer to all stored results. A period (`.`) may be used to refer to the last estimation results, even if they have not (yet) been stored.

<i>options</i>	Description
SE/Robust	
<code>svy</code>	survey data estimation
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>robust</code> or <code>cluster <i>clustvar</i></code>
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>dir</code>	display a table describing the models
<code>eform(<i>string</i>)</code>	report exponentiated coefficients and label as <i>string</i>
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<code>coeflegend</code>	display legend instead of statistics
collect is allowed; see [U] 11.1.10 Prefix commands .	
<code>coeflegend</code> does not appear in the dialog box.	

Options

SE/Robust
<code>svy</code> specifies that estimation results should be modified to reflect the survey design effects according to the <code>svyset</code> specifications, see [SVY] svyset . The <code>svy</code> option is implied when <code>suest</code> encounters survey estimation results from the <code>svy</code> prefix; see [SVY] svy . Poststratification is allowed only with survey estimation results from the <code>svy</code> prefix. <code>vce(<i>vcetype</i>)</code> specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (<code>robust</code>) and that allow for intragroup correlation (<code>cluster <i>clustvar</i></code>); see [R] vce_option . The <code>vce()</code> option may not be combined with the <code>svy</code> option or estimation results from the <code>svy</code> prefix.
Reporting
<code>level(#)</code> specifies the confidence level, as a percentage, for confidence intervals of the coefficients; see [R] level . <code>dir</code> displays a table describing the models in <i>namelist</i> just like <code>estimates dir <i>namelist</i></code> .

`eform(string)` displays the coefficient table in exponentiated form: for each coefficient, $\exp(b)$ rather than b is displayed, and standard errors and confidence intervals are transformed. *string* is the table header that will be displayed above the transformed coefficients and must be 11 characters or fewer, for example, `eform("Odds ratio")`.

display_options: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

The following option is available with `suest` but is not shown in the dialog box:
`coeflegend`; see [R] [Estimation options](#).

Remarks and examples

Remarks are presented under the following headings:

Using suest

Remarks on regress

Testing the assumption of the independence of irrelevant alternatives

Testing proportionality

Testing cross-model hypotheses

Using suest

If you plan to use `suest`, you must take precautions when fitting the original models. These restrictions are relaxed when using `svy` commands; see [SVY] [svy postestimation](#).

1. `suest` works with estimation commands that allow `predict` to generate equation-level score variables when supplied with the `score` (or `scores`) option. For example, equation-level score variables are generated after running `mlogit` by typing

```
. predict sc*, scores
```

To ensure that `suest` generates the appropriate scores and therefore an appropriate VCE, you should not modify the values of the variables used in the models in between fitting the models and using `suest`.

2. Estimation should take place *without* the `vce(robust)` or `vce(cluster clustvar)` option. `suest` always computes the robust estimator of the (co)variance, and `suest` has a `vce(cluster clustvar)` option.

The within-model covariance matrices computed by `suest` are identical to those obtained by specifying a `vce(robust)` or `vce(cluster clustvar)` option during estimation. `suest`, however, also estimates the between-model covariances of parameter estimates.

3. Finally, the estimation results to be combined should be stored by `estimates store`; see [R] [estimates store](#).

After estimating and storing a series of estimation results, you are ready to combine the estimation results with `suest`,

```
. suest name1 [ name2 ... ] [, vce(cluster clustvar)]
```

and you can subsequently use postestimation commands, such as `test`, to test hypotheses. Here an important issue is how `suest` assigns names to the equations. If you specify one model *name*, the original equation names are left unchanged; otherwise, `suest` constructs new equation names. The coefficients of a single-equation model (such as `logit` and `poisson`) that was `estimate` stored under name *X* are collected under equation *X*. With a multiequation model stored under name *X*, `suest` prefixes *X_* to an original equation name *eq*, forming equation name, *X_eq*.

□ Technical note

Earlier we said that standard errors from `suest` are identical to those obtained by specifying the `vce(robust)` option with each command individually. Thus if you fit a logistic model using `logit` with the `vce(robust)` option, you will get the same standard errors when you type

```
. suest .
```

directly after `logit` using the same data without the `vce(robust)` option.

This is not true for multiple estimation results when the estimation samples are not all the same. The standard errors from `suest` will be slightly smaller than those from individual model fits using the `vce(robust)` option because `suest` uses a larger number of observations to estimate the simultaneous (co)variance matrix.

□ Technical note

In rare circumstances, `suest` may have to truncate equation names to 32 characters. When equation names are not unique because of truncation, `suest` numbers the equations within models, using equations named *X_#*.

Remarks on regress

`regress` (see [\[R\] regress](#)) does not include its ancillary parameter, the residual variance, in its coefficient vector and (co)variance matrix. Moreover, while the `score` option is allowed with `predict` after `regress`, a score variable is generated for the mean but not for the variance parameter. `suest` contains special code that assigns the equation name `mean` to the coefficients for the mean, adds the equation `lnvar` for the log variance, and computes the appropriate two score variables itself.

Testing the assumption of the independence of irrelevant alternatives

The multinomial logit model and the closely related conditional logit model satisfy a probabilistic version of the assumption of the independence of irrelevant alternatives (IIA), implying that the ratio of the probabilities for two alternatives does not depend on what other alternatives are available. [Hausman and McFadden \(1984\)](#) proposed a test for this assumption that is implemented in the `hausman` command. The standard Hausman test has several limitations. First, the test statistic may be undefined because the estimated VCE does not satisfy the required asymptotic properties of the test. Second, the classic Hausman test applies only to the test of the equality of two estimators. Third, the test requires access to a fully efficient estimator; such an estimator may not be available, for example, if you are analyzing complex survey data. Using `suest` can overcome these three limitations.

➤ Example 1

In our first example, we follow the analysis of the type of health insurance reported in [\[R\] mlogit](#) and demonstrate the `hausman` command with the `suest/test` combination. We fit the full multinomial logit model for all three alternatives and two restricted multinomial models in which one alternative is excluded. After fitting each of these models, we give them a title with the `estimates title` command and then store them with the `estimates store` command.

```
. use https://www.stata-press.com/data/r19/sysdsn4

Comparing the coefficients between models does not suggest substantial differences. We can formally test that coefficients are the same for the full model m1 and the restricted models m2 and m3 by using the `hausman` command. `hausman` expects the models to be specified in the order “always consistent” first and “efficient under H_0 ” second.

```
. hausman m2 m1, alleqs constant
```

	Coefficients		(b-B) Difference	sqrt(diag(V_b-V_B)) Std. err.
	(b) m2	(B) m1		
age	-.0101521	-.0100251	-.0001269	.
male	.5144003	.5095747	.0048256	.0123338
_cons	.2678043	.2633838	.0044205	.

b = Consistent under H_0 and H_a ; obtained from `mlogit`.

B = Inconsistent under H_a , efficient under H_0 ; obtained from `mlogit`.

Test of H_0 : Difference in coefficients not systematic

```
chi2(3) = (b-B)'[(V_b-V_B)^(-1)](b-B)
        = 0.08
```

```
Prob > chi2 = 0.9944
```

```
(V_b-V_B is not positive definite)
```

```
. hausman m3 m1, alleqs constant
```

	Coefficients		(b-B) Difference	sqrt(diag(V_b-V_B)) Std. err.

_cons	-1.801774	-1.756843	-.0449311	.1333421

b = Consistent under H0 and Ha; obtained from **mlogit**.
 B = Inconsistent under Ha, efficient under H0; obtained from **mlogit**.

Test of H0: Difference in coefficients not systematic

```
chi2(3) = (b-B)'[(V_b-V_B)^(-1)](b-B)
         = -0.18
```

Warning: chi2 < 0 ==> model fitted on these data
 fails to meet the asymptotic assumptions
 of the Hausman test; see **suest** for a
 generalized test.

According to the test of m1 against m2, we cannot reject the hypothesis that the coefficients of m1 and m2 are the same. The second Hausman test is not well defined—something that happens fairly often. The problem is due to the estimator of the variance $V(b-B)$ as $V(b)-V(B)$, which is a feasible estimator only asymptotically. Here it simply is not a proper variance matrix, and the Hausman test becomes undefined.

suest m1 m2 estimates the simultaneous (co)variance of the coefficients of models m1 and m2. Although **suest** is technically a postestimation command, it acts like an estimation command in that it stores the simultaneous coefficients in **e(b)** and the full (co)variance matrix in **e(V)**. We could have used the **estat vce** command to display the full (co)variance matrix to show that the cross-model covariances were indeed estimated. Typically, we would not have a direct interest in **e(V)**.

```
. suest m1 m2, noomitted
```

suest created equation names by combining the name under which we stored the results using estimates store with the original equation names. Thus, in the simultaneous estimation result, equation Prepaid originating in model m1 is named m1_PrePaid. According to the McFadden–Hausman specification of a test for IIA, the coefficients of the equations m1_PrePaid and m2_PrePaid should be equal. This equality can be tested easily with the test command. The cons option specifies that the intercept _cons be included in the test.

```
. test [m1_PrePaid = m2_PrePaid], cons
( 1)  [m1_PrePaid]age - [m2_PrePaid]age = 0
( 2)  [m1_PrePaid]male - [m2_PrePaid]male = 0
( 3)  [m1_PrePaid]_cons - [m2_PrePaid]_cons = 0
      chi2( 3) =      0.89
      Prob > chi2 =    0.8266
```

The Hausman test via suest is comparable with that computed by hausman, but they use different estimators of the variance of the difference of the estimates. The hausman command estimates $V(b - B)$ by $V(b) - V(B)$, whereas suest estimates $V(b - B)$ by $V(b) - \text{cov}(b, B) - \text{cov}(B, b) + V(B)$. One advantage of the second estimator is that it is always admissible, so the resulting test is always well defined. This quality is illustrated in the Hausman-type test of IIA comparing models m1 and m3.

```
. suest m1 m3, noomitted
Simultaneous results for m1, m3                                     Number of obs = 615

```

Although the classic Hausman test computed by hausman is not defined here, the suest-based test is just fine. We cannot reject the equality of the common coefficients across m1 and m3.

A second advantage of the `suest` approach is that we can estimate the (co)variance matrix of the multivariate normal distribution of the estimators of the three models `m1`, `m2`, and `m3` and test that the common coefficients are equal.

```

```

Again, we do not find evidence against the correct specification of the multinomial logit for type of insurance. The classic Hausman test assumes that one of the estimators (named `B` in `hausman`) is efficient, that is, it has minimal (asymptotic) variance. This assumption ensures that $V(b) - V(B)$ is an admissible, viable estimator for $V(b - B)$. The assumption that we have an efficient estimator is a restrictive one. It is violated, for instance, if our data are clustered. We want to adjust for clustering via a `vce(cluster clustvar)` option by requesting the cluster-adjusted sandwich estimator of variance. Consequently, in such a case, `hausman` cannot be used. This problem does not exist with the `suest`

version of the Hausman test. To illustrate this feature, we suppose that the data are clustered by city—we constructed an imaginary variable `cityid` for this illustration. If we plan to apply `suest`, we would not specify the `vce(cluster clustvar)` option at the time of estimation. `suest` has a `vce(cluster clustvar)` option. Thus, we do not need to refit the models; we can call `suest` and `test` right away.

```
. suest m1 m2, vce(cluster cityid) noomitted
Simultaneous results for m1, m2                                Number of obs = 615
                                (Std. err. adjusted for 260 clusters in cityid)

`suest` provides some descriptive information about the clustering on `cityid`. Like any other estimation command, `suest` informs us that the standard errors are adjusted for clustering. The Hausman-type test obtained from the `test` command uses a simultaneous (co)variance of `m1` and `m2` appropriately adjusted for clustering. In this example, we still do not have reason to conclude that the multinomial logit model in this application is misspecified, that is, that IIA is violated.

The multinomial logistic regression model is a special case of the conditional logistic regression model; see [R] [clogit](#). Like the multinomial logistic regression model, the conditional logistic regression model also makes the IIA assumption. Consider an example, introduced in [CM] [cmclogit](#), in which the demand for American, Japanese, and European cars is modeled in terms of the number of local dealers of the respective brands and of some individual attributes incorporated in interaction with the nationality of cars. We want to perform a Hausman-type test for IIA comparing the decision between all nationalities with the decision between non-American cars. The following code fragment demonstrates how to conduct a Hausman test for IIA via `suest` in this case.

```
. clogit choice japan europe maleJap maleEur incJap incEur dealer, group(id)
. estimates store allcars
. clogit choice japan maleJap incJap dealer if car!=1 , group(id)
. estimates store foreign
. suest allcars foreign
. test [allcars_choice=foreign_choice], common
```

Testing proportionality

The applications of `suest` that we have discussed so far concern Hausman-type tests for misspecification. To test such a hypothesis, we compared two estimators that have the same probability limit if the hypothesis holds true, but otherwise have different limits. We may also want to compare the coefficients of models (estimators) for other substantive reasons. Although we most often want to test whether coefficients differ between models or estimators, we may occasionally want to test other constraints (see [Hausman and Ruud \[1987\]](#)).

► Example 2

In this example, using simulated labor market data for siblings, we consider two dependent variables, income (`inc`) and whether a person was promoted in the last year (`promo`). We apply familiar economic arguments regarding human capital, according to which employees have a higher income and a higher probability of being promoted, by having more human capital. Human capital is acquired through formal education (`edu`) and on-the-job training experience (`exp`). We study whether income and promotion are “two sides of the same coin”, that is, whether they reflect a common latent variable, “human capital”. Accordingly, we want to compare the effects of different aspects of human capital on different outcome variables.

We estimate fairly simple labor market equations. The income model is estimated with `regress`, and the estimation results are stored under the name `Inc`.

```
. use https://www.stata-press.com/data/r19/income
. regress inc edu exp male
```

Source	SS	df	MS	Number of obs	=	277
Model	2058.44672	3	686.148908	F(3, 273)	=	42.34
Residual	4424.05183	273	16.2053181	Prob > F	=	0.0000
				R-squared	=	0.3175
				Adj R-squared	=	0.3100
Total	6482.49855	276	23.4873136	Root MSE	=	4.0256

	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
edu	2.213707	.243247	9.10	0.000	1.734828	2.692585
exp	1.47293	.231044	6.38	0.000	1.018076	1.927785
male	.5381153	.4949466	1.09	0.278	-.436282	1.512513
_cons	1.255497	.3115808	4.03	0.000	.642091	1.868904

```
. est store Inc
```

Being sibling data, the observations are clustered on family of origin, `famid`. In the estimation of the regression parameters, we did not specify a `vce(cluster famid)` option to adjust standard errors for clustering on family (`famid`). Thus, the standard errors reported by `regress` are potentially flawed. This problem will, however, be corrected by specifying a `vce(cluster clustvar)` option with `suest`.

Next, we estimate the promotion equation with probit and again store the results under an appropriate name.

```
. probit promo edu exp male, nolog
Probit regression
Log likelihood = -158.43888
Number of obs = 277
LR chi2(3) = 49.76
Prob > chi2 = 0.0000

```
. est store Promo
```

The coefficients in the income and promotion equations definitely seem to be different. However, because the scales of the two variables are different, we would not expect the coefficients to be equal. The correct hypothesis here is that the proportionality of the coefficients of the two models, apart from the constant, are equal. This formulation would still reflect that the relative effects of the different aspects of human capital do not differ between the dependent variables. We can obtain a nonlinear Wald test for the hypothesis of proportionality by using the `testnl` command on the combined estimation results of the two estimators. Thus, we first have to form the combined estimation results. At this point, we specify the `vce(cluster famid)` option to adjust for the clustering of observations on `famid`.

```
. suest Inc Promo, vce(cluster famid)
Simultaneous results for Inc, Promo
(Std. err. adjusted for 135 clusters in famid)
Number of obs = 277
```

	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
Inc_mean						
edu	2.213707	.2483907	8.91	0.000	1.72687	2.700543
exp	1.47293	.1890583	7.79	0.000	1.102383	1.843478
male	.5381153	.4979227	1.08	0.280	-.4377952	1.514026
_cons	1.255497	.3374977	3.72	0.000	.594014	1.916981
Inc_invar						
_cons	2.785339	.079597	34.99	0.000	2.629332	2.941347
Promo_promo						
edu	.4593002	.0886982	5.18	0.000	.2854549	.6331454
exp	.3593023	.079772	4.50	0.000	.2029522	.5156525
male	.2079983	.1691053	1.23	0.219	-.1234419	.5394386
_cons	-.464622	.1042169	-4.46	0.000	-.6688833	-.2603607

The standard errors reported by `suest` are identical to those reported by the respective estimation commands when invoked with the `vce(cluster famid)` option. We are now ready to test for proportionality:

$$H_0 : \frac{\beta_{\text{edu}}^{\text{Income}}}{\beta_{\text{edu}}^{\text{Promotion}}} = \frac{\beta_{\text{exp}}^{\text{Income}}}{\beta_{\text{exp}}^{\text{Promotion}}} = \frac{\beta_{\text{male}}^{\text{Income}}}{\beta_{\text{male}}^{\text{Promotion}}}$$

It is straightforward to translate this into syntax suitable for `testnl`, recalling that the coefficient of variable v in equation eq is denoted by `[eq]v`.

```
. testnl [Inc_mean]edu/[Promo_promo]edu =
> [Inc_mean]exp/[Promo_promo]exp =
> [Inc_mean]male/[Promo_promo]male
(1) [Inc_mean]edu/[Promo_promo]edu = [Inc_mean]exp/[Promo_promo]exp
(2) [Inc_mean]edu/[Promo_promo]edu = [Inc_mean]male/[Promo_promo]male
      chi2(2) =          0.61
      Prob > chi2 =      0.7385
```

From the evidence, we fail to reject the hypotheses that the coefficients of the income and promotion equations are proportional. Thus, it is not unreasonable to assume that income and promotion can be explained by the same latent variable, “labor market success”.

A disadvantage of the nonlinear Wald test is that it is not invariant with respect to representation: a Wald test for a mathematically equivalent formulation of the nonlinear constraint usually leads to a different test result. An equivalent formulation of the proportionality hypothesis is

$$H_0 : \begin{aligned} \beta_{\text{edu}}^{\text{Income}} \beta_{\text{exp}}^{\text{Promotion}} &= \beta_{\text{edu}}^{\text{Promotion}} \beta_{\text{exp}}^{\text{Income}} & \text{and} \\ \beta_{\text{edu}}^{\text{Income}} \beta_{\text{male}}^{\text{Promotion}} &= \beta_{\text{edu}}^{\text{Promotion}} \beta_{\text{male}}^{\text{Income}} \end{aligned}$$

This formulation is “more linear” in the coefficients. The asymptotic χ^2 distribution of the nonlinear Wald statistic can be expected to be more accurate for this representation.

```
. testnl ([Inc_mean]edu*[Promo_promo]exp = [Inc_mean]exp*[Promo_promo]edu
> ([Inc_mean]edu*[Promo_promo]male = [Inc_mean]male*[Promo_promo]edu)
(1) [Inc_mean]edu*[Promo_promo]exp = [Inc_mean]exp*[Promo_promo]edu
(2) [Inc_mean]edu*[Promo_promo]male = [Inc_mean]male*[Promo_promo]edu
      chi2(2) =          0.46
      Prob > chi2 =      0.7936
```

Here the two representations lead to similar test statistics and p -values. As before, we fail to reject the hypothesis of proportionality of the coefficients of the two models.

◀

Testing cross-model hypotheses

▷ Example 3

In this example, we demonstrate how some cross-model hypotheses can be tested using the facilities already available in most estimation commands. This demonstration will explain the intricate relationship between the cluster adjustment of the robust estimator of variance and the `suest` command. It will also be made clear that a new facility is required to perform more general cross-model testing.

We want to test whether the effect of x_1 on the binary variable y_1 is the same as the effect of x_2 on the binary y_2 ; see [Clogg, Petkova, and Haritou \(1995\)](#). In this setting, x_1 may equal x_2 , and y_1 may equal y_2 . We assume that logistic regression models can be used to model the responses, and for simplicity, we ignore further predictor variables in these models. If the two logit models are fit on independent samples so that the estimators are (stochastically) independent, a Wald test for `_b[x1] = _b[x2]` rejects the null hypothesis if

$$\frac{\hat{b}(x_1) - \hat{b}(x_2)}{\left[\hat{\sigma}^2 \left\{ \hat{b}(x_1) \right\} + \hat{\sigma}^2 \left\{ \hat{b}(x_2) \right\} \right]^{1/2}}$$

is larger than the appropriate χ^2_1 threshold. If the models are fit on the *same* sample (or on dependent samples), so that the estimators are stochastically dependent, the above test that ignores the covariance between the estimators is not appropriate.

It is instructive to see how this problem can be tackled by “stacking” data. In the stacked format, we doubled the number of observations. The dependent variable is y_1 in the first half of the data and is y_2 in the second half of the data. The predictor variable z_1 is set to x_1 in the first half of the expanded data and to 0 in the rest. Similarly, z_2 is 0 in the first half and x_2 in the second half. The following diagram illustrates the transformation, in the terminology of the `reshape` command, from wide to long format.

$$\begin{pmatrix} \text{id} & y_1 & y_2 & x_1 & x_2 \\ 1 & y_{11} & y_{21} & x_{11} & x_{21} \\ 2 & y_{12} & y_{22} & x_{12} & x_{22} \\ 3 & y_{13} & y_{23} & x_{13} & x_{23} \end{pmatrix} \Rightarrow \begin{pmatrix} \text{id} & y & z_1 & z_2 & \text{model} \\ 1 & y_{11} & x_{11} & 0 & 1 \\ 2 & y_{12} & x_{12} & 0 & 1 \\ 3 & y_{13} & x_{13} & 0 & 1 \\ 1 & y_{21} & 0 & x_{21} & 2 \\ 2 & y_{22} & 0 & x_{22} & 2 \\ 3 & y_{23} & 0 & x_{23} & 2 \end{pmatrix}$$

The observations in the long-format data organization are *clustered* on the original subjects and are identified with the identifier `id`. The clustering on `id` has to be accounted for when fitting a simultaneous model. The simplest way to deal with clustering is to use the cluster adjustment of the robust or sandwich estimator; see [\[P\] `_robust`](#). The data manipulation can be accomplished easily with the `stack` command; see [\[D\] `stack`](#). Subsequently, we fit a simultaneous logit model and perform a Wald test for the hypothesis that the coefficients of `z1` and `z2` are the same. A full setup to obtain the cross-model Wald test could then be as follows:

```
. generate zero = 0           // a variable that is always 0
. generate one  = 1           // a variable that is always 1
. generate two  = 2           // a variable that is always 2
. stack id y1 x1 zero one    id y2 zero x2 two, into(id y z1 z2 model)
. generate model2 = (model==2)
. logit y model2 z1 z2, vce(cluster id)
. test _b[z1] = _b[z2]
```

The coefficient of `z1` represents the effect of `x1` on `y1`, and similarly, `z2` for the effect of `x2` on `y2`. The variable `model2` is a dummy for the “second model”, which is included to allow the intercept in the second model to differ from that in the first model. The estimates of the coefficient of `z1` and its standard error in the combined model are the same as the estimates of the coefficient of `z1` and its standard error if we fit the model on the unstacked data.

```
. logit y1 x1, vce(robust)
```

The `vce(cluster clustvar)` option specified with the `logit` command for the stacked data ensures that the covariances of `_b[z1]` and `_b[z2]` are indeed estimated. This estimation ensures that the Wald test for the equality of the coefficients is correct. If we had not specified the `vce(cluster clustvar)` option, the (co)variance matrix of the coefficients would have been block-diagonal; that is, the covariances of `_b[z1]` and `_b[z2]` would have been 0. Then, `test` would have effectively used the invalid formula for the Wald test for two independent samples.

In this example, the two logit models were fit on the same data. The same setup would apply, without modification, when the two logit models were fit on overlapping data that resulted, for instance, if the *y* or *x* variables were missing in some observations.

The `suest` command allows us to obtain the above Wald test more efficiently by avoiding the data manipulation, obviating the need to fit a model with twice the number of coefficients. The test statistic produced by the above code fragment is *identical* to that obtained via `suest` on the original (unstacked) data:

```
. logit y1 x1
. estimates store M1
. logit y2 x2
. estimates store M2
. suest M1 M2
. test [M1]x1=[M2]x2
```

The stacking method can be applied not only to the testing of cross-model hypotheses for logit models but also to any estimation command that supports the `vce(cluster clustvar)` option. The stacking approach clearly generalizes to stacking more than two logit or other models, testing more general linear hypotheses, and testing nonlinear cross-model hypotheses (see [R] [testnl](#)). In all of these cases, `suest` would yield identical statistical results but at smaller costs in terms of data management, computer storage, and computer time.

Is `suest` nothing but a convenience command? No, there are two disadvantages to the stacking method, both of which are resolved via `suest`. First, if the models include ancillary parameters (in a regression model, the residual variance; in an ordinal response model, the cutpoints; and in lognormal survival-time regression, the time scale parameter), these parameters are constrained to be equal between the stacked models. In `suest`, this constraint is relaxed. Second, the stacking method does not generalize to compare different statistical models, such as a probit model and a regression model. As demonstrated in the previous section, `suest` can deal with this situation.

Stored results

suest stores the following in `e()`:

Scalars

<code>e(N)</code>	number of observations
<code>e(N_clust)</code>	number of clusters
<code>e(rank)</code>	rank of <code>e(V)</code>

Macros

<code>e(cmd)</code>	suest
<code>e(eqnames#)</code>	original names of equations of model #
<code>e(names)</code>	list of model names
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(clustvar)</code>	name of cluster variable
<code>e(vce)</code>	<i>vcetype</i> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(properties)</code>	b V

Matrices

<code>e(b)</code>	stacked coefficient vector of the models
<code>e(V)</code>	variance–covariance matrix of the estimators

Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

Methods and formulas

The estimation of the simultaneous (co)variance of a series of k estimators is a nonstandard application of the sandwich estimator, as implemented by the command `[P] _robust`. You may want to read this manual entry before reading further.

The starting point is that we have fit k different models on the *same* data—partially overlapping or nonoverlapping data are special cases. We want to derive the *simultaneous* distribution of these k estimators, for instance, to test a cross-estimator hypothesis H_0 . As in the framework of Hausman testing, H_0 will often be of the form that different estimators have the same probability limit under some hypothesis, while the estimators have different limits if the hypothesis is violated.

We consider (vector) estimators $\widehat{\beta}_i$ to be defined as “the” solution of the estimation equations \mathbf{G}_i ,

$$\mathbf{G}_i(\mathbf{b}_i) = \sum_j w_{ij} \mathbf{u}_{ij}(\mathbf{b}_i) = \mathbf{0}, \quad i = 1, \dots, k$$

We refer to the \mathbf{u}_{ij} as the “scores”. Specifying some weights $w_{ij} = 0$ trivially accommodates for partially overlapping or even disjointed data. Under “suitable regularity conditions” (see White [1982; 1996] for details), the $\widehat{\beta}_i$ are asymptotically normally distributed, with the variance estimated consistently by the sandwich estimator

$$V_i = \text{Var}(\widehat{\beta}_i) = \mathbf{D}_i^{-1} \sum_j w_{ij} \mathbf{u}_{ij} \mathbf{u}_{ij}' \mathbf{D}_i^{-1}$$

where \mathbf{D}_i is the Jacobian of \mathbf{G}_i evaluated at $\widehat{\beta}_i$. In the context of maximum likelihood estimation, \mathbf{D}_i can be estimated consistently by (minus) the Hessian of the log likelihood or by the Fisher information matrix. If the model is also well specified, the sandwiched term $(\sum_j w_{ij} \mathbf{u}_{ij} \mathbf{u}_{ij}')$ converges in probability to \mathbf{D}_i , so V_i may be consistently estimated by \mathbf{D}_i^{-1} .

To derive the simultaneous distribution of the estimators, we consider the “stacked” estimation equation,

$$\mathbf{G}(\widehat{\boldsymbol{\beta}}) = \left\{ \mathbf{G}_1(\widehat{\boldsymbol{\beta}}_1)' \quad \mathbf{G}_1(\widehat{\boldsymbol{\beta}}_2)' \quad \dots \quad \mathbf{G}_k(\widehat{\boldsymbol{\beta}}_k)' \right\}' = \mathbf{0}$$

Under “suitable regularity conditions” (see [White \[1996\]](#) for details), $\widehat{\boldsymbol{\beta}}$ is asymptotically *jointly* normally distributed. The Jacobian and scores of the simultaneous equation are easily expressed in the Jacobian and scores of the separate equations. The Jacobian of \mathbf{G} ,

$$\mathbf{D}(\widehat{\boldsymbol{\beta}}) = \left. \frac{d\mathbf{G}(\boldsymbol{\beta})}{d\boldsymbol{\beta}} \right|_{\boldsymbol{\beta}=\widehat{\boldsymbol{\beta}}}$$

is block diagonal with blocks $\mathbf{D}_1, \dots, \mathbf{D}_k$. The inverse of $\mathbf{D}(\widehat{\boldsymbol{\beta}})$ is again block diagonal, with the inverses of \mathbf{D}_i on the diagonal. The scores \mathbf{u} of \mathbf{G} are simply obtained as the *concatenated* scores of the separate equations:

$$\mathbf{u}_j = (\mathbf{u}'_{1j} \quad \mathbf{u}'_{2j} \quad \dots \quad \mathbf{u}'_{kj})'$$

Out-of-sample (that is, where $w_{ij} = 0$) values of the score variables are defined as 0 (thus we drop the i subscript from the common weight variable). The sandwich estimator for the asymptotic variance of $\widehat{\boldsymbol{\beta}}$ reads

$$V = \text{Var}(\widehat{\boldsymbol{\beta}}) = \mathbf{D}(\widehat{\boldsymbol{\beta}})^{-1} \left(\sum_j w_j \mathbf{u}_j \mathbf{u}_j' \right) \mathbf{D}(\widehat{\boldsymbol{\beta}})^{-1}$$

Taking a “partitioned” look at this expression, we see that $V(\widehat{\boldsymbol{\beta}}_i)$ is estimated by

$$\mathbf{D}_i^{-1} \left(\sum_j w_j \mathbf{u}_{ij} \mathbf{u}_{ij}' \right) \mathbf{D}_i^{-1}$$

which is, yet again, the familiar sandwich estimator for $\widehat{\boldsymbol{\beta}}_i$ based on the separate estimation equation \mathbf{G}_i . Thus, considering several estimators simultaneously in this way does not affect the estimators of the asymptotic variances of these estimators. However, as a bonus of stacking, we obtained a sandwich-type estimate of the *covariance* V_{ih} of estimators $\widehat{\boldsymbol{\beta}}_i$ and $\widehat{\boldsymbol{\beta}}_h$,

$$V_{ih} = \text{Cov}(\widehat{\boldsymbol{\beta}}_i, \widehat{\boldsymbol{\beta}}_h) = \mathbf{D}_i^{-1} \left(\sum_j w_j \mathbf{u}_{ij} \mathbf{u}_{hj}' \right) \mathbf{D}_h^{-1}$$

which is also obtained by [White \(1982\)](#).

This estimator for the covariance of estimators is an application of the cluster modification of the sandwich estimator proposed by [Rogers \(1993\)](#). Consider the stacked data format as discussed in the logit example, and assume that Stata would be able to estimate a “stacked model” in which different models apply to different observations, for example, a probit model for the first half, a regression model for the second half, and a one-to-one cluster relation between the first and second half. If there are no common parameters to both models, the score statistics of parameters for the stacked models are zero in the half of the data in which they do not occur. In Rogers’s method, we have to sum the score statistics over the observations within a cluster. This step boils down to concatenating the score statistics at the level of the cluster.

We compare the sandwich estimator of the (co)variance V_{12} of two estimators with the estimator of variance \tilde{V}_{12} applied in the classic Hausman test. Hausman (1978) showed that if $\widehat{\beta}_1$ is consistent under H_0 and $\widehat{\beta}_2$ is efficient under H_0 , then asymptotically

$$\text{Cov}(\widehat{\beta}_1, \widehat{\beta}_2) = \text{Var}(\widehat{\beta}_2)$$

and so $\text{var}(\widehat{\beta}_1 - \widehat{\beta}_2)$ is consistently estimated by $V_1 - V_2$.

Acknowledgment

suest was written by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands. This research is supported by grant PGS 50-370 by The Netherlands Organization for Scientific Research.

An earlier version of suest was published in the *Stata Technical Bulletin* (1999). The current version of suest is not backward compatible with the 1999 version because of the introduction of new ways to manage estimation results via the `estimates` command.

Description

`summarize` calculates and displays a variety of univariate summary statistics. If no *varlist* is specified, summary statistics are calculated for all the variables in the dataset.

Quick start

Basic summary statistics for continuous variable `v1`

```
summarize v1
```

Same as above, and include `v2` and `v3`

```
summarize v1-v3
```

Same as above, and provide additional detail about the distribution

```
summarize v1-v3, detail
```

Summary statistics reported separately for each level of `catvar`

```
by catvar: summarize v1
```

With frequency weight `wvar`

```
summarize v1 [fweight=wvar]
```

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Summary statistics

Syntax

```
summarize [ varlist ] [ if' ] [ in ] [ weight ] [ , options ]
```

options	Description
Main	
detail	display additional statistics
meanonly	suppress the display; calculate only the mean; programmer's option
format	use variable's display format
separator(#)	draw separator line after every # variables; default is separator(5)
display_options	control spacing, line width, and base and empty cells

varlist may contain factor variables; see [U] 11.4.3 Factor variables.

varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists.

by, collect, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.

aweight, fweight, and iweight are allowed. However, iweight may not be used with the detail option; see [U] 11.1.6 weight.

Options

Main
detail produces additional statistics, including skewness, kurtosis, the four smallest and four largest values, and various percentiles.
meanonly, which is allowed only when detail is not specified, suppresses the display of results and calculation of the variance. Ado-file writers will find this useful for fast calls.
format requests that the summary statistics be displayed using the display formats associated with the variables rather than the default g display format; see [U] 12.5 Formats: Controlling how data are displayed.
separator(#) specifies how often to insert separation lines into the output. The default is separator(5), meaning that a line is drawn after every five variables. separator(10) would draw a line after every 10 variables. separator(0) suppresses the separation line.
display_options: vsquish, noemptycells, baselevels, allbaselevels, novlabel, fvwrap(#), and fvwrapon(style); see [R] Estimation options.

Remarks and examples

summarize can produce two different sets of summary statistics. Without the detail option, the number of nonmissing observations, the mean and standard deviation, and the minimum and maximum values are presented. With detail, the same information is presented along with the variance, skewness, and kurtosis; the four smallest and four largest values; and the 1st, 5th, 10th, 25th, 50th (median), 75th, 90th, 95th, and 99th percentiles.

Also see [R] ci for calculating the standard error and confidence intervals of the mean.

► Example 1: summarize with the separator() option

We have data containing information on various automobiles, among which is the variable `mpg`, the mileage rating. We can obtain a quick summary of the `mpg` variable by typing

```
. use https://www.stata-press.com/data/r19/auto2
(1978 automobile data)
```

```
. summarize mpg
```

Variable	Obs	Mean	Std. dev.	Min	Max
mpg	74	21.2973	5.785503	12	41

We see that we have 74 observations. The mean of `mpg` is 21.3 miles per gallon, and the standard deviation is 5.79. The minimum is 12, and the maximum is 41.

If we had not specified the variable (or variables) we wanted to summarize, we would have obtained summary statistics on all the variables in the dataset:

```
. summarize, separator(4)
```

Variable	Obs	Mean	Std. dev.	Min	Max
make	0				
price	74	6165.257	2949.496	3291	15906
mpg	74	21.2973	5.785503	12	41
rep78	69	3.405797	.9899323	1	5
headroom	74	2.993243	.8459948	1.5	5
trunk	74	13.75676	4.277404	5	23
weight	74	3019.459	777.1936	1760	4840
length	74	187.9324	22.26634	142	233
turn	74	39.64865	4.399354	31	51
displacement	74	197.2973	91.83722	79	425
gear_ratio	74	3.014865	.4562871	2.19	3.89
foreign	74	.2972973	.4601885	0	1

There are only 69 observations on `rep78`, so some of the observations are missing. There are no observations on `make` because it is a string variable.

The idea of the mean is quite old ([Plackett 1958](#)), but its extension to a scheme of moment-based measures was not done until the end of the 19th century. Between 1893 and 1905, Pearson discussed and named the standard deviation, skewness, and kurtosis, but he was not the first to use any of these. [Thiele \(1889\)](#), in contrast, had earlier firmly grasped the notion that the m_r provide a systematic basis for discussing distributions. However, even earlier anticipations can also be found. For example, Euler in 1778 used m_2 and m_3 in passing in a treatment of estimation ([Hald 1998, 87](#)), but seemingly did not build on that.

Similarly, the idea of the median is quite old. The history of the interquartile range is tangled up with that of the probable error, a long-popular measure. Extending this in various ways to a more general approach based on quantiles (to use a later term) occurred to several people in the nineteenth century. [Galton \(1875\)](#) is a nice example, particularly because he seems so close to the key idea of the quantiles as a function, which took another century to reemerge strongly.

Thorvald Nicolai Thiele (1838–1910) was a Danish scientist who worked in astronomy, mathematics, actuarial science, and statistics. He made many pioneering contributions to statistics, several of which were overlooked until recently. Thiele advocated graphical analysis of residuals checking for trends, symmetry of distributions, and changes of sign, and he even warned against overinterpreting such graphs.

► Example 2: summarize with the detail option

The `detail` option provides all the information of a normal `summarize` and more. The format of the output also differs, as shown here:

```
. summarize mpg, detail
```

Mileage (mpg)				
Percentiles		Smallest		
1%	12	12		
5%	14	12		
10%	14	14	Obs	74
25%	18	14	Sum of wgt.	74
50%	20	Largest	Mean	21.2973
75%	25		Std. dev.	5.785503
90%	29		Variance	33.47205
95%	34	35	Skewness	.9487176
99%	41	41	Kurtosis	3.975005

As in the [previous example](#), we see that the mean of mpg is 21.3 miles per gallon and that the standard deviation is 5.79. We also see the various percentiles. The median of mpg (the 50th percentile) is 20 miles per gallon. The 25th percentile is 18, and the 75th percentile is 25.

When we performed `summarize`, we learned that the minimum and maximum were 12 and 41, respectively. We now see that the four smallest values in our dataset are 12, 12, 14, and 14. The four largest values are 34, 35, 35, and 41. The skewness of the distribution is 0.95, and the kurtosis is 3.98. (A normal distribution would have a skewness of 0 and a kurtosis of 3.)

Skewness is a measure of the lack of symmetry of a distribution. If the distribution is symmetric, the coefficient of skewness is 0. If the coefficient is negative, the median is usually greater than the mean and the distribution is said to be skewed left. If the coefficient is positive, the median is usually less than the mean and the distribution is said to be skewed right. *Kurtosis* (from the Greek *kyrtosis*, meaning curvature) is a measure of peakedness of a distribution. The smaller the coefficient of kurtosis, the flatter the distribution. The normal distribution has a coefficient of kurtosis of 3 and provides a convenient benchmark.

□ Technical note

The convention of calculating the median of an even number of values by averaging the central two order statistics is of long standing. (That is, given 8 values, average the 4th and 5th smallest values, or given 42, average the 21st and 22nd smallest.) [Stigler \(1977\)](#) filled a much-needed gap in the literature by naming such paired central order statistics as “comedians”, although it remains unclear how far he was joking.

▷ Example 3: summarize with the by prefix

`summarize` can usefully be combined with the `by varlist:` prefix. In our dataset, we have a variable, `foreign`, that distinguishes foreign and domestic cars. We can obtain summaries of `mpg` and `weight` within each subgroup by typing

```
. by foreign: summarize mpg weight
```

```
-> foreign = Domestic
```

Variable	Obs	Mean	Std. dev.	Min	Max
mpg	52	19.82692	4.743297	12	34
weight	52	3317.115	695.3637	1800	4840

```
-> foreign = Foreign
```

Variable	Obs	Mean	Std. dev.	Min	Max
mpg	22	24.77273	6.611187	14	41
weight	22	2315.909	433.0035	1760	3420

Domestic cars in our dataset average 19.8 miles per gallon, whereas foreign cars average 24.8.

Because `by varlist:` can be combined with `summarize`, it can also be combined with `summarize, detail`:

```
. by foreign: summarize mpg, detail
```

```
-> foreign = Domestic
```

Mileage (mpg)				
Percentiles		Smallest		
1%	12	12		
5%	14	12		
10%	14	14	Obs	52
25%	16.5	14	Sum of wgt.	52
50%	19	Largest	Mean	19.82692
75%	22		Std. dev.	4.743297
90%	26	29	Variance	22.49887
95%	29	30	Skewness	.7712432
99%	34	34	Kurtosis	3.441459

```
-> foreign = Foreign
```

Mileage (mpg)				
Percentiles		Smallest		
1%	14	14		
5%	17	17		
10%	17	17	Obs	22
25%	21	18	Sum of wgt.	22
50%	24.5	Largest	Mean	24.77273
75%	28		Std. dev.	6.611187
90%	35	35	Variance	43.70779
95%	35	35	Skewness	.657329
99%	41	41	Kurtosis	3.10734

□ Technical note

`summarize` respects display formats if we specify the `format` option. When we type `summarize price weight`, we obtain

```
. summarize price weight
```

Variable	Obs	Mean	Std. dev.	Min	Max
price	74	6165.257	2949.496	3291	15906
weight	74	3019.459	777.1936	1760	4840

The display is accurate but is not as aesthetically pleasing as we may wish, particularly if we plan to use the output directly in published work. By placing formats on the variables, we can control how the table appears:

```
. format price weight %9.2fc
. summarize price weight, format
```

Variable	Obs	Mean	Std. dev.	Min	Max
price	74	6,165.26	2,949.50	3,291.00	15,906.00
weight	74	3,019.46	777.19	1,760.00	4,840.00

□

If you specify a weight (see [\[U\] 11.1.6 weight](#)), each observation is multiplied by the value of the weighting expression before the summary statistics are calculated so that the weighting expression is interpreted as the discrete density of each observation.

▷ Example 4: summarize with factor variables

You can also use `summarize` to obtain summary statistics for factor variables. For example, if you type

```
. summarize i.rep78
```

Variable	Obs	Mean	Std. dev.	Min	Max
rep78					
Poor	69	.0289855	.1689948	0	1
Fair	69	.115942	.3225009	0	1
Average	69	.4347826	.4993602	0	1
Good	69	.2608696	.4423259	0	1
Excellent	69	.1594203	.3687494	0	1

you obtain the sample proportions for the five levels of the `rep78` variable. For example, 11.6% of the 69 cars with nonmissing values of `rep78` have a fair repair record.

We could have used `tabulate oneway rep78` to obtain the sample proportions along with the cumulative proportions. Alternatively, we could have used `proportions rep78` to obtain the sample proportions along with the standard errors of the proportions instead of the standard deviations of the proportions.

◀

➤ Example 5: summarize with weights

We have 1980 census data on each of the 50 states. Included in our variables is medage, the median age of the population of each state. If we type `summarize medage`, we obtain unweighted statistics:

```
. use https://www.stata-press.com/data/r19/census, clear
(1980 Census data by state)

. summarize medage
```

Variable	Obs	Mean	Std. dev.	Min	Max
medage	50	29.54	1.693445	24.2	34.7

Also among our variables is `pop`, the population in each state. Typing `summarize medage [w=pop]` produces population-weighted statistics:

```
. summarize medage [w=pop]
(analytic weights assumed)
```

Variable	Obs	Weight	Mean	Std. Dev.	Min	Max
medage	50	225907472	30.11047	1.66933	24.2	34.7

The number listed under `Weight` is the sum of the weighting variable, `pop`, indicating that there are roughly 226 million people in the United States. The `pop`-weighted mean of `medage` is 30.11 (compared with 29.54 for the unweighted statistic), and the weighted standard deviation is 1.67 (compared with 1.69).

➤ Example 6: summarize with weights and the detail option

We can obtain detailed summaries of weighted data as well. When we do this, *all* the statistics are weighted, including the percentiles.

```
. summarize medage [w=pop], detail
(analytic weights assumed)
```

Median age					
Percentiles			Smallest		
1%	27.1		24.2		
5%	27.7		26.1		
10%	28.2		27.1	Obs	50
25%	29.2		27.4	Sum of wgt.	225907472
50%	29.9			Mean	30.11047
				Std. dev.	1.66933
			Largest		
75%	30.9		32		
90%	32.1		32.1	Variance	2.786661
95%	32.2		32.2	Skewness	.5281972
99%	34.7		34.7	Kurtosis	4.494223

❑ Technical note

If you are writing a program and need to access the mean of a variable, the `meanonly` option provides for fast calls. For example, suppose that your program reads as follows:

```

program mean
    summarize '1', meanonly
    display "  mean = " r(mean)
end
    
```

The result of executing this is

```

. use https://www.stata-press.com/data/r19/auto2
(1978 automobile data)

. mean price
    mean = 6165.2568
    
```

Video example

[Descriptive statistics in Stata](#)

Stored results

`summarize` stores the following in `r()`:

Scalars			
<code>r(N)</code>	number of observations	<code>r(p50)</code>	50th percentile (detail only)
<code>r(mean)</code>	mean	<code>r(p75)</code>	75th percentile (detail only)
<code>r(skewness)</code>	skewness (detail only)	<code>r(p90)</code>	90th percentile (detail only)
<code>r(min)</code>	minimum	<code>r(p95)</code>	95th percentile (detail only)
<code>r(max)</code>	maximum	<code>r(p99)</code>	99th percentile (detail only)
<code>r(sum_w)</code>	sum of the weights	<code>r(Var)</code>	variance
<code>r(p1)</code>	1st percentile (detail only)	<code>r(kurtosis)</code>	kurtosis (detail only)
<code>r(p5)</code>	5th percentile (detail only)	<code>r(sum)</code>	sum of variable
<code>r(p10)</code>	10th percentile (detail only)	<code>r(sd)</code>	standard deviation
<code>r(p25)</code>	25th percentile (detail only)		

Methods and formulas

Let x denote the variable on which we want to calculate summary statistics, and let $x_i, i = 1, \dots, n$, denote an individual observation on x . Let v_i be the weight, and if no weight is specified, define $v_i = 1$ for all i .

Define the total number of observations as $N = n$ if v_i is an `aweight` and as

$$N = \sum_{i=1}^n v_i$$

otherwise.

Additionally, define the normalized weight as

$$w_i = \frac{nv_i}{\sum_{i=1}^n v_i}$$

if v_i is an `aweight` and as $w_i = v_i$ otherwise.

The *mean*, \bar{x} , is defined as

$$\bar{x} = \frac{1}{N} \sum_{i=1}^n w_i x_i$$

The *variance*, s^2 , is defined as

$$s^2 = \frac{1}{N-1} \sum_{i=1}^n w_i (x_i - \bar{x})^2$$

The *standard deviation*, s , is defined as $\sqrt{s^2}$.

Define m_r as the r th moment about the mean \bar{x} :

$$m_r = \frac{1}{N} \sum_{i=1}^n w_i (x_i - \bar{x})^r$$

The *coefficient of skewness* is then defined as $m_3 m_2^{-3/2}$. The *coefficient of kurtosis* is defined as $m_4 m_2^{-2}$.

Let $x_{(i)}$ refer to the x in ascending order, and let $w_{(i)}$ refer to the corresponding weights of $x_{(i)}$. The four smallest values are $x_{(1)}$, $x_{(2)}$, $x_{(3)}$, and $x_{(4)}$. The four largest values are $x_{(n)}$, $x_{(n-1)}$, $x_{(n-2)}$, and $x_{(n-3)}$.

To obtain the p th *percentile*, which we will denote as $x_{[p]}$, let $P = Np/100$. Let

$$W_{(i)} = \sum_{j=1}^i w_{(j)}$$

Find the first index i such that $W_{(i)} > P$. The p th percentile is then

$$x_{[p]} = \begin{cases} \frac{x_{(i-1)} + x_{(i)}}{2} & \text{if } W_{(i-1)} = P \\ x_{(i)} & \text{otherwise} \end{cases}$$

Description

`sunflower` draws density-distribution sunflower plots (Plummer and Dupont 2003). Dark sunflowers, light sunflowers, and marker symbols represent high-, medium-, and low-density regions of the data, respectively. These plots are useful for displaying bivariate data whose density is too great for conventional scatterplots to be effective.

Quick start

Density-distribution sunflower plot showing the relationship between x and y

```
sunflower y x
```

Set the center of the reference bin to $x = 5$ and $y = 8$

```
sunflower y x, xcenter(5) ycenter(8)
```

Same as above, but specify the width of the hexagonal bins to be 1.5

```
sunflower y x, xcenter(5) ycenter(8) binwidth(1.5)
```

Same as above, but set the minimum number of observations needed for a bin to be represented by a light sunflower to 4

```
sunflower y x, xcenter(5) ycenter(8) binwidth(1.5) light(4)
```

Use the `s1color` scheme

```
sunflower y x, scheme(s1color)
```

Specify that only the petals are shown and the hexagons are omitted

```
sunflower y x, floweronly
```

Suppress display of the table

```
sunflower y x, notable
```

Menu

Graphics > Smoothing and densities > Density-distribution sunflower plot

Syntax

```
sunflower yvar xvar [ if ] [ in ] [ weight ] [ , options ]
```

<i>options</i>	Description
Main	
<code>nograph</code>	do not show graph
<code>notable</code>	do not show summary table; implied when <code>by()</code> is specified
<code>marker_options</code>	affect rendition of markers drawn at the plotted points
Bins/Petals	
<code>binwidth(#)</code>	width of the hexagonal bins
<code>binar(#)</code>	aspect ratio of the hexagonal bins
<code>bin_options</code>	affect rendition of hexagonal bins
<code>light(#)</code>	minimum observations for a light sunflower; default is <code>light(3)</code>
<code>dark(#)</code>	minimum observations for a dark sunflower; default is <code>dark(13)</code>
<code>xcenter(#)</code>	<i>x</i> -coordinate of the reference bin
<code>ycenter(#)</code>	<i>y</i> -coordinate of the reference bin
<code>petalweight(#)</code>	observations in a dark sunflower petal
<code>petallength(#)</code>	length of sunflower petal as a percentage
<code>petal_options</code>	affect rendition of sunflower petals
<code>flowersonly</code>	show petals only; do not render bins
<code>nosinglepetal</code>	suppress single petals
Add plots	
<code>addplot(plot)</code>	add other plots to generated graph
Y axis, X axis, Titles, Legend, Overall, By	
<code>twoway_options</code>	any options documented in [G-3] <code>twoway_options</code>

<i>bin_options</i>	Description
<code>[1 d]bstyle(areastyle)</code>	overall look of hexagonal bins
<code>[1 d]bcolor(colorstyle)</code>	outline and fill color
<code>[1 d]bfcolor(colorstyle)</code>	fill color
<code>[1 d]blstyle(linestyle)</code>	overall look of outline
<code>[1 d]blcolor(colorstyle)</code>	outline color
<code>[1 d]blwidth(linewidthstyle)</code>	thickness of outline

<i>petal_options</i>	Description
<code>[1 d]flstyle(linestyle)</code>	overall style of sunflower petals
<code>[1 d]flcolor(colorstyle)</code>	color of sunflower petals
<code>[1 d]flwidth(linewidthstyle)</code>	thickness of sunflower petals

All options are *rightmost*; see [G-4] **Concept: repeated options**.
*fw*weights are allowed; see [U] 11.1.6 **weight**.

Options

Main

`nograph` prevents the graph from being generated.

`notable` prevents the summary table from being displayed. This option is implied when the `by()` option is specified.

`marker_options` affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker_options](#).

Bins/Petals

`binwidth(#)` specifies the horizontal width of the hexagonal bins in the same units as `xvar`. By default,

$$\text{binwidth} = \max(\text{rbw}, \text{nbw})$$

where

$$\text{rbw} = \text{range of } xvar / 40$$

$$\text{nbw} = \text{range of } xvar / \max(1, \text{nb})$$

and

$$\text{nb} = \text{int}(\min(\sqrt{n}, 10 * \log_{10}(n)))$$

where

$$n = \text{the number of observations in the dataset}$$

`binar(#)` specifies the aspect ratio for the hexagonal bins. The height of the bins is given by

$$\text{binheight} = \text{binwidth} \times \# \times 2 / \sqrt{3}$$

where `binheight` and `binwidth` are specified in the units of `yvar` and `xvar`, respectively. The default is `binar(r)`, where `r` results in the rendering of regular hexagons.

`bin_options` affect how the hexagonal bins are rendered.

`lbstyle(areastyle)` and `dbstyle(areastyle)` specify the look of the light and dark hexagonal bins, respectively. The options listed below allow you to change each attribute, but `lbstyle()` and `dbstyle()` provide the starting points. See [G-4] [areastyle](#) for a list of available area styles.

`lbcolor(colorstyle)` and `dbc_color(colorstyle)` specify one color to be used both to outline the shape and to fill the interior of the light and dark hexagonal bins, respectively. See [G-4] [colorstyle](#) for a list of color choices.

`lbfcolor(colorstyle)` and `dbfcolor(colorstyle)` specify the color to be used to fill the interior of the light and dark hexagonal bins, respectively. See [G-4] [colorstyle](#) for a list of color choices.

`lbstyle(linestyle)` and `dbstyle(linestyle)` specify the overall style of the line used to outline the area, which includes its pattern (solid, dashed, etc.), thickness, and color. The other options listed below allow you to change the line's attributes, but `lbstyle()` and `dbstyle()` are the starting points. See [G-4] [linestyle](#) for a list of choices.

`lbc_color(colorstyle)` and `dblcolor(colorstyle)` specify the color to be used to outline the light and dark hexagonal bins, respectively. See [G-4] [colorstyle](#) for a list of color choices.

`lblwidth(linewidthstyle)` and `dblwidth(linewidthstyle)` specify the thickness of the line to be used to outline the light and dark hexagonal bins, respectively. See [G-4] [linewidthstyle](#) for a list of choices.

`light(#)` specifies the minimum number of observations needed for a bin to be represented by a light sunflower. The default is `light(3)`.

`dark(#)` specifies the minimum number of observations needed for a bin to be represented by a dark sunflower. The default is `dark(13)`.

`xcenter(#)` and `ycenter(#)` specify the center of the reference bin. The default values are the median values of *xvar* and *yvar*, respectively. The centers of the other bins are implicitly defined by the location of the reference bin together with the common bin width and height.

`petalweight(#)` specifies the number of observations represented by each petal of a dark sunflower. The default value is chosen so that the maximum number of petals on a dark sunflower is 14.

`petallength(#)` specifies the length of petals in the sunflowers. The value specified is interpreted as a percentage of half the bin width. The default is 100%.

petal_options affect how the sunflower petals are rendered.

`lflstyle(linestyle)` and `dflstyle(linestyle)` specify the overall style of the light and dark sunflower petals, respectively.

`lflcolor(colorstyle)` and `dflcolor(colorstyle)` specify the color of the light and dark sunflower petals, respectively.

`lflwidth(linewidthstyle)` and `dflwidth(linewidthstyle)` specify the width of the light and dark sunflower petals, respectively.

`floweronly` suppresses rendering of the bins. This option is equivalent to specifying `lbcolor(none)` and `dbc_color(none)`.

`nosinglepetal` suppresses flowers from being drawn in light bins that contain only 1 observation and dark bins that contain as many observations as the petal weight (see the `petalweight()` option).

Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] [addplot_option](#).

Y axis, X axis, Titles, Legend, Overall, By

twoway_options are any of the options documented in [G-3] [twoway_options](#). These include options for titling the graph (see [G-3] [title_options](#)), options for saving the graph to disk (see [G-3] [saving_option](#)), and the `by()` option (see [G-3] [by_option](#)).

Remarks and examples

A sunflower is several line segments of equal length, called petals, that radiate from a central point. There are two varieties of sunflowers: light and dark. Each petal of a light sunflower represents 1 observation. Each petal of a dark sunflower represents several observations. Dark and light sunflowers represent high- and medium-density regions of the data, and marker symbols represent individual observations in low-density regions.

sunflower divides the plane defined by the variables *yvar* and *xvar* into contiguous hexagonal bins. The number of observations contained within a bin determines how the bin will be represented.

- When there are fewer than `light(#)` observations in a bin, each point is plotted using the usual marker symbols in a scatterplot.
- Bins with at least `light(#)` but fewer than `dark(#)` observations are represented by a light sunflower. Each petal of a light sunflower represents one observation in the bin.
- Bins with at least `dark(#)` observations are represented by a dark sunflower. Each petal of a dark sunflower represents multiple observations.

See [Dupont \(2009, 87–92\)](#) for a discussion of sunflower plots and how to create them using Stata.

► Example 1

Using the auto dataset, we want to examine the relationship between weight and mpg. To do that, we type

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)

. sunflower mpg weight, binwid(500) petalw(2) dark(8) scheme(stcolor)
Bin width           =      500
Bin height          =    6.50422
Bin aspect ratio    =   .0112656
Max obs in a bin    =       15
Light               =        3
Dark               =        8
X-center            =     3190
Y-center            =       20
Petal weight        =        2
```

Flower type	Petal weight	No. of petals	No. of flowers	Estimated obs	Actual obs
none				13	13
light	1	3	1	3	3
light	1	4	5	20	20
light	1	6	1	6	6
light	1	7	1	7	7
dark	2	5	1	10	10
dark	2	8	1	16	15
				75	74

The two darkly shaded sunflowers immediately catch our eyes, indicating a group of 10 cars that are heavy (nearly 4,000 pounds) and fuel inefficient and a group 16 of cars that get about 20 miles per gallon and weight in the neighborhood of 3,000 pounds. The lighter sunflowers each indicate groups of three to seven cars that share similar weight and fuel economy characteristics. To obtain the number of cars in each group, we count the number of petals in each flower and consult the graph legend to see how many observations each petal represents.

◀

Acknowledgments

We thank William D. Dupont and W. Dale Plummer Jr., both of the Department of Biostatistics at Vanderbilt University, who are the authors of the original `sunflower` command, for their assistance in producing this version.

Description

`sureg` fits seemingly unrelated regression models ([Zellner 1962](#); [Zellner and Huang 1962](#); [Zellner 1963](#)). The acronyms SURE and SUR are often used for the estimator.

Quick start

Model of `y1` and `y2` as a function of `x1`, `x2`, and `x3`

```
sureg (y1 x1 x2 x3) (y2 x1 x2 x3)
```

Same as above

```
sureg (y1 y2 = x1 x2 x3)
```

Same as above, but obtain small-sample statistics and use small-sample adjustment

```
sureg (y1 y2 = x1 x2 x3), small dfk
```

Also perform Breusch–Pagan test

```
sureg (y1 y2 = x1 x2 x3), small dfk corr
```

Model of `y1` as a function of `x1` and `x2` and `y2` as a function of `x2` and lag of `x2` using `tsset` data

```
sureg (y1 x1 x2) (y2 x2 L.x2)
```

Menu

Statistics > Linear models and related > Multiple-equation models > Seemingly unrelated regression

Syntax

Basic syntax

```
sureg (depvar1 varlist1) (depvar2 varlist2) ... (depvarN varlistN)  
[if] [in] [weight]
```

Full syntax

```
sureg ([eqname1:]depvar1a [depvar1b ... =] varlist1 [ , noconstant ] )  
([eqname2:]depvar2a [depvar2b ... =] varlist2 [ , noconstant ] )  
...  
([eqnameN:]depvarNa [depvarNb ... =] varlistN [ , noconstant ] )  
[if] [in] [weight] [ , options ]
```

Explicit equation naming (*eqname*:) cannot be combined with multiple dependent variables in an equation specification.

<i>options</i>	Description
Model	
<u>i</u> sure	iterate until estimates converge
<u>c</u> onstraints(<i>constraints</i>)	apply specified linear constraints
SE/Robust	
vce(<i>vcetype</i>)	<i>vcetype</i> may be <u>u</u> nadjusted, <u>r</u> obust, or <u>c</u> luster <i>clustvar</i>
df adj.	
<u>s</u> mall	report small-sample statistics
dfk	use small-sample adjustment
dfk2	use alternate adjustment
Reporting	
<u>l</u> evel(#)	set confidence level; default is level(95)
<u>c</u> orr	perform Breusch–Pagan test
<u>n</u> ocnsreport	do not display constraints
<i>display_options</i>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Optimization	
<i>optimization_options</i>	control the optimization process; seldom used
<u>n</u> oheader	suppress header table from above coefficient table
<u>n</u> otable	suppress coefficient table
<u>c</u> oeflegend	display legend instead of statistics

*varlist*₁, ..., *varlist*_{*N*} may contain factor variables; see [U] 11.4.3 **Factor variables**. You must have the same levels of factor variables in all equations that have factor variables.

depvars and the *varlists* may contain time-series operators; see [U] 11.4.4 **Time-series varlists**.

bootstrap, *by*, *collect*, *fp*, *jackknife*, *rolling*, and *statsby* are allowed; see [U] 11.1.10 **Prefix commands**.

Weights are not allowed with the *bootstrap* prefix; see [R] **bootstrap**.

*aweight*s are not allowed with the *jackknife* prefix; see [R] **jackknife**.

*aweight*s and *fweight*s are allowed; see [U] 11.1.6 **weight**.

noheader, *notable*, and *coeflegend* do not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

Options

Model

isure specifies that *sureg* iterate over the estimated disturbance covariance matrix and parameter estimates until the parameter estimates converge. Under seemingly unrelated regression, this iteration converges to the maximum likelihood results. If this option is not specified, *sureg* produces two-step estimates.

constraints (*constraints*); see [R] **Estimation options**.

SE/Robust

vce (*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (*unadjusted*), that are robust to some kinds of misspecification (*robust*), and that allow for intragroup correlation (*cluster* *clustvar*); see [R] **vce_option**.

vce(*unadjusted*), the default, specifies that an unadjusted (nonrobust) VCE matrix be used; this results in efficient estimates when assuming homoskedasticity.

df adj.

small specifies that small-sample statistics be computed. It shifts the test statistics from χ^2 and *z* statistics to *F* statistics and *t* statistics. Although the standard errors from each equation are computed using the degrees of freedom for the equation, the degrees of freedom for the *t* statistics are all taken to be those for the first equation.

dfk specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. As an asymptotically justified estimator, *sureg* by default uses the number of sample observations (*n*) as a divisor. When the *dfk* option is set, a small-sample adjustment is made and the divisor is taken to be $\sqrt{(n - k_i)(n - k_j)}$, where *k_i* and *k_j* are the number of parameters in equations *i* and *j*, respectively.

dfk2 specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. When the *dfk2* option is set, the divisor is taken to be the mean of the residual degrees of freedom from the individual equations.

Reporting

level (#); see [R] **Estimation options**.

corr displays the correlation matrix of the residuals between equations and performs a Breusch–Pagan test for independent equations; that is, the disturbance covariance matrix is diagonal.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

Optimization

`optimization_options` control the iterative process that minimizes the sum of squared errors when `isure` is specified. These options are seldom used.

`iterate(#)` specifies the maximum number of iterations. When the number of iterations equals `#`, the optimizer stops and presents the current results, even if the convergence tolerance has not been reached. The default is the number set using `set maxiter`, which is 300 by default.

`trace` adds to the iteration log a display of the current parameter vector.

`log` and `nolog` specify whether to display the iteration log. The iteration log is displayed by default unless you used `set iterlog off` to suppress it; see `set iterlog` in [R] [set iter](#).

`tolerance(#)` specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to `#`, the optimization process is stopped. `tolerance(1e-6)` is the default.

The following options are available with `sureg` but are not shown in the dialog box:

`noheader` suppresses display of the header reporting F statistics, R^2 , and root mean squared error above the coefficient table.

`notable` suppresses display of the coefficient table.

`coeflegend`; see [R] [Estimation options](#).

Remarks and examples

Seemingly unrelated regression models are so called because they appear to be joint estimates from several regression models, each with its own error term. The regressions are related because the (contemporaneous) errors associated with the dependent variables may be correlated. Chapter 6 of [Cameron and Trivedi \(2022\)](#) contains a discussion of the seemingly unrelated regression model and the feasible generalized least-squares estimator underlying it.

► Example 1

When we fit models with the same set of right-hand-side variables, the seemingly unrelated regression results (in terms of coefficients and standard errors) are the same as fitting the models separately (using, say, `regress`). The same is true when the models are nested. Even in such cases, `sureg` is useful when we want to perform joint tests. For instance, let us assume that we think

$$\begin{aligned}\text{price} &= \beta_0 + \beta_1 \text{foreign} + \beta_2 \text{length} + u_1 \\ \text{weight} &= \gamma_0 + \gamma_1 \text{foreign} + \gamma_2 \text{length} + u_2\end{aligned}$$

Because the models have the same set of explanatory variables, we could estimate the two equations separately. Yet, we might still choose to estimate them with `sureg` because we want to perform the joint test $\beta_1 = \gamma_1 = 0$.

We use the `small` and `dfk` options to obtain small-sample statistics comparable with `regress` or `mvreg`.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. sureg (price foreign length) (weight foreign length), small dfk
Seemingly unrelated regression
```

Equation	Obs	Params	RMSE	"R-squared"	F	P>F
price	74	2	2474.593	0.3154	16.35	0.0000
weight	74	2	250.2515	0.8992	316.54	0.0000

	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
price						
foreign	2801.143	766.117	3.66	0.000	1286.674	4315.611
length	90.21239	15.83368	5.70	0.000	58.91219	121.5126
_cons	-11621.35	3124.436	-3.72	0.000	-17797.77	-5444.93
weight						
foreign	-133.6775	77.47615	-1.73	0.087	-286.8332	19.4782
length	31.44455	1.601234	19.64	0.000	28.27921	34.60989
_cons	-2850.25	315.9691	-9.02	0.000	-3474.861	-2225.639

Note: Small-sample degrees-of-freedom adjustment applied when estimating covariance matrix of residuals.

These two equations have a common set of regressors, and we could have used a shorthand syntax to specify the equations:

```
. sureg (price weight = foreign length), small dfk
```

Here the results presented by `sureg` are the same as if we had estimated the equations separately:

```
. regress price foreign length
(output omitted)
. regress weight foreign length
(output omitted)
```

There is, however, a difference. We have allowed u_1 and u_2 to be correlated and have estimated the full variance–covariance matrix of the coefficients. `sureg` has estimated the correlations, but it does not report them unless we specify the `corr` option. We did not remember to specify `corr` when we fit the model, but we can redisplay the results:

```
. sureg, notable noheader corr
```

Note: Small-sample degrees-of-freedom adjustment applied when estimating covariance matrix of residuals.

Correlation matrix of residuals:

```
    price  weight
price  1.0000
weight  0.5840  1.0000
```

```
Breusch-Pagan test of independence: chi2(1) =    25.237, Pr = 0.0000
```

The `notable` and `noheader` options prevented `sureg` from redisplaying the header and coefficient tables. We find that, for the same cars, the correlation of the residuals in the `price` and `weight` equations is 0.5840 and that we can reject the hypothesis that this correlation is zero.

We can test that the coefficients on `foreign` are jointly zero in both equations—as we set out to do—by typing `test foreign`; see [R] [test](#). When we type a variable without specifying the equation, that variable is tested for zero in all equations in which it appears:

```
. test foreign
( 1) [price]foreign = 0
( 2) [weight]foreign = 0
      F( 2, 142) = 17.99
      Prob > F = 0.0000
```

◀

► Example 2

When the models do not have the same set of explanatory variables and are not nested, `sureg` may lead to more efficient estimates than running the models separately as well as allowing joint tests. This time, let us assume that we believe

$$\begin{aligned}\text{price} &= \beta_0 + \beta_1 \text{foreign} + \beta_2 \text{mpg} + \beta_3 \text{displ} + u_1 \\ \text{weight} &= \gamma_0 + \gamma_1 \text{foreign} + \gamma_2 \text{length} + u_2\end{aligned}$$

To fit this model, we type

```
. sureg (price foreign mpg displ) (weight foreign length), corr
Seemingly unrelated regression
```

Equation	Obs	Params	RMSE	"R-squared"	chi2	P>chi2
price	74	3	2165.321	0.4537	49.64	0.0000
weight	74	2	245.2916	0.8990	661.84	0.0000

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
price						
foreign	3058.25	685.7357	4.46	0.000	1714.233	4402.267
mpg	-104.9591	58.47209	-1.80	0.073	-219.5623	9.644042
displacement	18.18098	4.286372	4.24	0.000	9.779842	26.58211
_cons	3904.336	1966.521	1.99	0.047	50.0263	7758.645
weight						
foreign	-147.3481	75.44314	-1.95	0.051	-295.2139	.517755
length	30.94905	1.539895	20.10	0.000	27.93091	33.96718
_cons	-2753.064	303.9336	-9.06	0.000	-3348.763	-2157.365

Correlation matrix of residuals:

```
      price  weight
price  1.0000
weight 0.3285  1.0000
```

Breusch-Pagan test of independence: `chi2(1) = 7.984, Pr = 0.0047`

In comparison, if we had fit the price model separately,

```
. regress price foreign mpg displ
```

Source	SS	df	MS	Number of obs	=	74
Model	294104790	3	98034929.9	F(3, 70)	=	20.13
Residual	340960606	70	4870865.81	Prob > F	=	0.0000
				R-squared	=	0.4631
				Adj R-squared	=	0.4401
Total	635065396	73	8699525.97	Root MSE	=	2207

price	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
foreign	3545.484	712.7763	4.97	0.000	2123.897	4967.072
mpg	-98.88559	63.17063	-1.57	0.122	-224.8754	27.10426
displacement	22.40416	4.634239	4.83	0.000	13.16146	31.64686
_cons	2796.91	2137.873	1.31	0.195	-1466.943	7060.763

The coefficients are slightly different, but the standard errors are uniformly larger. This would still be true if we specified the `dfk` option to make a small-sample adjustment to the estimated covariance of the disturbances.

□ Technical note

Constraints can be applied to SURE models using Stata's standard syntax for constraints. For a general discussion of constraints, see [\[R\] constraint](#); for examples similar to seemingly unrelated regression models, see [\[R\] reg3](#).

Stored results

sureg stores the following in `e()`:

Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(mss_#)</code>	model sum of squares for equation #
<code>e(df_m#)</code>	model degrees of freedom for equation #
<code>e(rss_#)</code>	residual sum of squares for equation #
<code>e(df_r)</code>	residual degrees of freedom
<code>e(r2_#)</code>	R^2 for equation #
<code>e(F_#)</code>	F statistic for equation # (small only)
<code>e(rmse_#)</code>	root mean squared error for equation #
<code>e(dfk2_adj)</code>	divisor used with VCE when <code>dfk2</code> specified
<code>e(ll)</code>	log likelihood
<code>e(N_clust)</code>	number of clusters
<code>e(chi2_#)</code>	χ^2 for equation #
<code>e(p_#)</code>	p -value for equation #
<code>e(cons_#)</code>	1 if equation # has a constant, 0 otherwise
<code>e(chi2_bp)</code>	Breusch–Pagan χ^2
<code>e(df_bp)</code>	degrees of freedom for Breusch–Pagan χ^2 test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations

Macros

e(cmd)	sureg
e(cmdline)	command as typed
e(method)	sure or isure
e(depvar)	names of dependent variables
e(exog)	names of exogenous variables
e(eqnames)	names of equations
e(wtype)	weight type
e(wexp)	weight expression
e(corr)	correlation structure
e(small)	small, if specified
e(dfk)	dfk or dfk2, if specified
e(clustvar)	name of cluster variable
e(vce)	<i>vcetype</i> specified in <i>vce()</i>
e(vcetype)	title used to label Std. err.
e(properties)	b V
e(predict)	program used to implement predict
e(marginsok)	predictions allowed by margins
e(marginsnotok)	predictions disallowed by margins
e(marginsdefault)	default <i>predict()</i> specification for margins
e(asbalanced)	factor variables <i>fvset</i> as asbalanced
e(asobserved)	factor variables <i>fvset</i> as asobserved

Matrices

e(b)	coefficient vector
e(Cns)	constraints matrix
e(Sigma)	$\hat{\Sigma}$, covariance matrix of residuals
e(V)	variance–covariance matrix of the estimators

Functions

e(sample)	marks estimation sample
-----------	-------------------------

In addition to the above, the following is stored in *r()*:

Matrices

<i>r(table)</i>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals
-----------------	--

Note that results stored in *r()* are updated when the command is replayed and will be replaced when any *r-class* command is run after the estimation command.

Methods and formulas

sureg uses the asymptotically efficient, feasible, generalized least-squares algorithm described in [Greene \(2018, 328–339\)](#). The computing formulas are given on page 328–335.

The R^2 reported is the percent of variance explained by the predictors. It may be used for descriptive purposes, but R^2 is not a well-defined concept when GLS is used.

sureg will refuse to compute the estimators if the same equation is named more than once or the covariance matrix of the residuals is singular.

The [Breusch and Pagan \(1980\)](#) χ^2 statistic—a Lagrange multiplier statistic—is given by

$$\lambda = T \sum_{m=2}^M \sum_{n=1}^{m-1} r_{mn}^2$$

where r_{mn} is the estimated correlation between the residuals of the M equations and T is the number of observations. It is distributed as χ^2 with $M(M-1)/2$ degrees of freedom.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [_robust](#), particularly [Introduction](#) and [Methods and formulas](#).

Arnold Zellner (1927–2010) was born in New York. He studied physics at Harvard and economics at Berkeley, and then he taught economics at the Universities of Washington and Wisconsin before settling in Chicago in 1966. Among his many major contributions to econometrics and statistics are his work on seemingly unrelated regression, three-stage least squares, and Bayesian econometrics.

Postestimation commands

The following postestimation commands are available after `sureg`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>forecast</code>	dynamic forecasts and simulations
<code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	predictions and their SEs, residuals, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, residuals, and differences between the linear predictions.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , equation(eqno[ ,eqno]) statistic ]
```

statistic	Description
Main	
xb	linear prediction; the default
stdp	standard error of the linear prediction
residuals	residuals
difference	difference between the linear predictions of two equations
stddp	standard error of the difference in linear predictions

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

Main

equation(eqno[,eqno]) specifies to which equation(s) you are referring.

equation() is filled in with one eqno for the xb, stdp, and residuals options. equation(#1) would mean that the calculation is to be made for the first equation, equation(#2) would mean the second, and so on. You could also refer to the equations by their names. equation(income) would refer to the equation named income and equation(hours) to the equation named hours.

If you do not specify equation(), the results are the same as if you specified equation(#1).

difference and stddp refer to between-equation concepts. To use these options, you must specify two equations, for example, equation(#1,#2) or equation(income, hours). When two equations must be specified, equation() is required.

xb, the default, calculates the linear prediction (fitted values)—the prediction of $\mathbf{x_jb}$ for the specified equation.

stdp calculates the standard error of the prediction for the specified equation. It can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

residuals calculates the residuals.

`difference` calculates the difference between the linear predictions of two equations in the system. With `equation(#1,#2)`, `difference` computes the prediction of equation (#1) minus the prediction of equation (#2).

`stdp` is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions ($\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b}$) between equations 1 and 2 is calculated.

For more information on using `predict` after multiple-equation estimation commands, see [\[R\] predict](#).

margins

Description for margins

`margins` estimates margins of response for linear predictions and differences between the linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [, options]  
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
default	linear predictions for each equation
<code>xb</code>	linear prediction for a specified equation
<code>difference</code>	difference between the linear predictions of two equations
<code>stdp</code>	not allowed with margins
<code>residuals</code>	not allowed with margins
<code>stddp</code>	not allowed with margins

`xb` defaults to the first equation.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

Remarks and examples

For an example of cross-equation testing of parameters using the `test` command, see [example 1](#) in [\[R\] sureg](#).

► Example 1

In [example 1](#) of [\[R\] sureg](#), we fit a seemingly unrelated regressions model of price and weight. Here we obtain the fitted values.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. sureg (price foreign length) (weight foreign length), small dfk
(output omitted)
. predict phat, equation(price)
(option xb assumed; fitted values)
. predict what, equation(weight)
(option xb assumed; fitted values)
. summarize price phat weight what
```

Variable	Obs	Mean	Std. dev.	Min	Max
price	74	6165.257	2949.496	3291	15906
phat	74	6165.257	1656.407	1639.872	9398.138
weight	74	3019.459	777.1936	1760	4840
what	74	3019.459	736.9666	1481.199	4476.331

Just as in single-equation OLS regression, in a SURE model the sample mean of the fitted values for an equation equals the sample mean of the dependent variable.

► Example 2

Suppose that for whatever reason we were interested in the difference between the predicted values of price and weight. `predict` has an option to compute this difference in one step:

```
. predict diff, equation(price, weight) difference
```

`diff` is the same as `phat - what`:

```
. generate mydiff = phat - what
. summarize diff mydiff
```

Variable	Obs	Mean	Std. dev.	Min	Max
diff	74	3145.797	1233.26	-132.2275	5505.914
mydiff	74	3145.797	1233.26	-132.2275	5505.914

Description

`swilk` performs the Shapiro–Wilk W test for normality for each variable in the specified varlist. Likewise, `sfrancia` performs the Shapiro–Francia W' test for normality. See [\[MV\] mvtest normality](#) for multivariate tests of normality.

Quick start

Shapiro–Wilk test of normality

Shapiro–Wilk test for `v1`

```
swilk v1
```

Separate tests of normality for `v1` and `v2`

```
swilk v1 v2
```

Generate new variable `w` containing W test coefficients

```
swilk v1, generate(w)
```

Specify that average ranks should not be used for tied values

```
swilk v1 v2, noties
```

Test that `v3` is distributed lognormally

```
generate lnv3 = ln(v3)  
swilk lnv3
```

Shapiro–Francia test of normality

Shapiro–Francia test for `v1`

```
sfrancia v1
```

Separate tests of normality for `v1` and `v2`

```
sfrancia v1 v2
```

Same as above, but use the Box–Cox transformation

```
sfrancia v1 v2, boxcox
```

Specify that average ranks should not be used for tied values

```
sfrancia v1 v2, noties
```

Menu

sfrancia

Statistics > Summaries, tables, and tests > Distributional plots and tests > Shapiro-Francia normality test

Syntax

Shapiro–Wilk normality test

```
swilk varlist [ if ] [ in ] [ , swilk_options ]
```

Shapiro–Francia normality test

```
sfrancia varlist [ if ] [ in ] [ , sfrancia_options ]
```

swilk_options	Description
Main	
generate(<i>newvar</i>)	create <i>newvar</i> containing <i>W</i> test coefficients
lnnormal	test for three-parameter lognormality
noties	do not use average ranks for tied values

sfrancia_options	Description
Main	
boxcox	use the Box–Cox transformation for <i>W'</i> ; the default is to use the log transformation
noties	do not use average ranks for tied values

by and collect are allowed with swilk and sfrancia; see [U] 11.1.10 Prefix commands.

Options for swilk

Main

generate(*newvar*) creates new variable *newvar* containing the *W* test coefficients.

lnnormal specifies that the test be for three-parameter lognormality, meaning that $\ln(X - k)$ is tested for normality, where *k* is calculated from the data as the value that makes the skewness coefficient zero. When simply testing $\ln(X)$ for normality, do not specify this option. See [R] [lnskew0](#) for estimation of *k*.

noties suppresses use of averaged ranks for tied values when calculating the *W* test coefficients.

Options for sfrancia

Main

`boxcox` specifies that the Box–Cox transformation of [Royston \(1983\)](#) for calculating W' test coefficients be used instead of the default log transformation ([Royston 1993a](#)). Under the Box–Cox transformation, the normal approximation to the sampling distribution of W' , used by `sfrancia`, is valid for $5 \leq n \leq 1000$. Under the log transformation, it is valid for $10 \leq n \leq 5000$.

`noties` suppresses use of averaged ranks for tied values when calculating the W' test coefficients.

Remarks and examples

`swilk` can be used with $4 \leq n \leq 2000$ observations. `sfrancia` can be used with $10 \leq n \leq 5000$ observations; however, if the `boxcox` option is specified, it can be used with $5 \leq n \leq 1000$ observations.

Also see [\[R\] sktest](#) for the skewness and kurtosis test described by [D'Agostino, Belanger, and D'Agostino \(1990\)](#) with the empirical correction developed by [Royston \(1991b\)](#). While the Shapiro–Wilk and Shapiro–Francia tests for normality are, in general, preferred for nonaggregated data ([Gould and Rogers 1991](#); [Gould 1992b](#); [Royston 1991b](#)), the skewness and kurtosis test will permit more observations. Moreover, a normal quantile plot should be used with any test for normality; see [\[R\] Diagnostic plots](#) for more information.

► Example 1

Using our automobile dataset, we will test whether the variables `mpg` and `trunk` are normally distributed:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. swilk mpg trunk
```

Variable	Obs	W	V	z	Prob>z
mpg	74	0.94821	3.335	2.627	0.00430
trunk	74	0.97921	1.339	0.637	0.26215

```
. sfrancia mpg trunk
```

Variable	Obs	W'	V'	z	Prob>z
mpg	74	0.94872	3.650	2.510	0.00604
trunk	74	0.98446	1.106	0.195	0.42271

We can reject the hypothesis that `mpg` is normally distributed, but we cannot reject that `trunk` is normally distributed.

The values reported under W and W' are the Shapiro–Wilk and Shapiro–Francia test statistics. The tests also report V and V' ([Royston 1991d](#)), which are more appealing indexes for departure from normality. The median values of V and V' are 1 for samples from normal populations. Large values indicate nonnormality. There is no more information in $V(V')$ than in $W(W')$ —one is just the transform of the other.

► Example 2

We have data on a variable called `studytime`, which we suspect is distributed lognormally:

```
. use https://www.stata-press.com/data/r19/cancer
(Patient survival in drug trial)
. generate lnstudytime = ln(studytime)
. swilk lnstudytime
```

Shapiro–Wilk W test for normal data					
Variable	Obs	W	V	z	Prob>z
lnstudytime	48	0.92731	3.311	2.547	0.00543

We can reject the lognormal assumption. We do *not* specify the `lnnormal` option when testing for lognormality. The `lnnormal` option is for three-parameter lognormality.

► Example 3

Having discovered that $\ln(\text{studytime})$ is not distributed normally, we now test that $\ln(\text{studytime} - k)$ is normally distributed, where k is chosen so that the resulting skewness is zero. We obtain the estimate for k from `lnskew0`; see [R] [lnskew0](#):

```
. lnskew0 lnstudytimek = studytime, level(95)
```

Transform	k	[95% conf. interval]		Skewness
$\ln(\text{studytime} - k)$	-11.01181	-infinity	-.9477328	-.0000173

```
. swilk lnstudytimek, lnnormal
```

Shapiro–Wilk W test for 3-parameter lognormal data					
Variable	Obs	W	V	z	Prob>z
lnstudytimek	48	0.97064	1.337	1.261	0.10363

We cannot reject the hypothesis that $\ln(\text{studytime} + 11.01181)$ is distributed normally. We do specify the `lnnormal` option when using an estimated value of k .

Stored results

`swilk` and `sfrancia` store the following in `r()`:

Scalars

<code>r(N)</code>	number of observations	<code>r(W)</code>	W or W'
<code>r(p)</code>	p -value	<code>r(V)</code>	V or V'
<code>r(z)</code>	z statistic		

Methods and formulas

The Shapiro–Wilk test is based on [Shapiro and Wilk \(1965\)](#) with a new approximation accurate for $4 \leq n \leq 2000$ ([Royston 1992](#)). The calculations made by `swilk` are based on [Royston \(1982, 1992, 1993b\)](#).

The Shapiro–Francia test ([Shapiro and Francia 1972](#); [Royston 1983](#); [Royston 1993a](#)) is an approximate test that is similar to the Shapiro–Wilk test for very large samples.

The relative merits of the Shapiro–Wilk and Shapiro–Francia tests the versus skewness and kurtosis test have been a subject of debate. The interested reader is directed to the articles in the *Stata Technical Bulletin*. Our recommendation is to use the Shapiro–Francia test whenever possible, that is, whenever dealing with nonaggregated or ungrouped data ([Gould and Rogers 1991](#); [Gould 1992b](#)); see [\[R\] swilk](#). If normality is rejected, use `sktest` to determine the source of the problem. As both [D’Agostino, Belanger, and D’Agostino \(1990\)](#) and [Royston \(1991c\)](#) mention, researchers should also examine the normal quantile plot to determine normality rather than blindly relying on a few test statistics. See the `qnorm` command documented in [\[R\] Diagnostic plots](#) for more information on normal quantile plots.

Samuel Sanford Shapiro (1930–2023) earned degrees in statistics and engineering from City College of New York, Columbia, and Rutgers. After employment in the US Army and industry, he joined the faculty at Florida International University in 1972. Shapiro has coauthored various texts in statistics and published several papers on distributional testing and other statistical topics.

Acknowledgment

`swilk` and `sfrancia` were written by Patrick Royston of the MRC Clinical Trials Unit, London and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*.

Description

`symmetry` performs asymptotic symmetry and marginal homogeneity tests, as well as an exact symmetry test on $K \times K$ tables where there is a 1-to-1 matching of cases and controls (nonindependence). This testing is used to analyze matched-pair case–control data with multiple discrete levels of the exposure (outcome) variable. In genetics, the test is known as the transmission/disequilibrium test (TDT) and is used to test the association between transmitted and nontransmitted parental marker alleles to an affected child (Spieldman, McGinnis, and Ewens 1993). For 2×2 tables, the asymptotic test statistics reduce to the McNemar test statistic, and the exact symmetry test produces an exact McNemar test; see [R] [Epitab](#). For many exposure variables, `symmetry` can optionally perform a test for linear trend in the log relative risk.

`symmetry` expects the data to be in the wide format; that is, each observation contains the matched case and control values in variables *casevar* and *controlvar*. Variables can be numeric or string.

`symmi` is the immediate form of `symmetry`. The `symmi` command uses the values specified on the command line; rows are separated by ‘\’, and options are the same as for `symmetry`. See [U] [19 Immediate commands](#) for a general introduction to immediate commands.

Quick start

Symmetry and marginal homogeneity tests for 1-to-1 matched case–control studies

```
symmetry case control
```

Same as above

```
symmetry control case
```

Exact test of table symmetry

```
symmetry case control, exact
```

Report the contribution from each off-diagonal pair to the overall χ^2 -statistic

```
symmetry control case, contrib
```

Test for a linear trend in the log of the relative risk

```
symmetry control case, trend
```

Request marginal homogeneity statistics that do not require the inversion of the variance–covariance matrix

```
symmetry case control, mh
```

Using frequency weight variable *wvar*

```
symmetry case control [fweight=wvar]
```

```

options	Description
Main	
<u>notable</u>	suppress output of contingency table
<u>contrib</u>	report contribution of each off-diagonal cell pair
<u>exact</u>	perform exact test of table symmetry
<u>mh</u>	perform two marginal homogeneity tests
<u>trend</u>	perform a test for linear trend in the (log) relative risk (RR)
<u>cc</u>	use continuity correction when calculating test for linear trend

collect is allowed with symmetry; see [\[U\] 11.1.10 Prefix commands](#).

fweights are allowed; see [\[U\] 11.1.6 weight](#).

Options

Main

notable suppresses the output of the contingency table. By default, **symmetry** displays the $n \times n$ contingency table at the top of the output.

contrib reports the contribution of each off-diagonal cell pair to the overall symmetry χ^2 .

exact performs an exact test of table symmetry. This option is recommended for sparse tables. CAUTION: The exact test requires substantial amounts of time and memory for large tables.

mh performs two marginal homogeneity tests that do not require the inversion of the variance–covariance matrix.

By default, **symmetry** produces the Stuart–Maxwell test statistic, which requires the inversion of the nondiagonal variance–covariance matrix, **V**. When the table is sparse, the matrix may not be of full rank, and then the command substitutes a generalized inverse **V*** for **V**^{−1}. **mh** calculates optional marginal homogeneity statistics that do not require the inversion of the variance–covariance matrix. These tests may be preferred in certain situations. See [Methods and formulas](#) and [Bickeböllner and Clerget-Darpoux \(1995\)](#) for details on these test statistics.

trend performs a test for linear trend in the (log) relative risk (RR). This option is allowed only for numeric exposure (outcome) variables, and its use should be restricted to measurements on the ordinal or the interval scales.

cc specifies that the continuity correction be used when calculating the test for linear trend. This correction should be specified only when the levels of the exposure variable are equally spaced.

Remarks and examples

symmetry and symmi may be used to analyze 1-to-1 matched case–control data with multiple discrete levels of the exposure (outcome) variable.

► Example 1

Consider a survey of 344 individuals (BMDP 1990, 267–270) who were asked in October 1986 whether they agreed with President Reagan’s handling of foreign affairs. In January 1987, after the Iran-Contra affair became public, these same individuals were surveyed again and asked the same question. We would like to know if public opinion changed over this period.

We first describe the dataset and list a few observations.

```
. use https://www.stata-press.com/data/r19/iran
. describe
Contains data from https://www.stata-press.com/data/r19/iran.dta
Observations:      344
Variables:         2                               29 Jan 2024 02:37
```

Variable name	Storage type	Display format	Value label	Variable label
before	byte	%8.0g	vlab	Public opinion before IC
after	byte	%8.0g	vlab	Public opinion after IC

Sorted by:

```
. list in 1/5
```

	before	after
1.	Agree	Agree
2.	Agree	Disagree
3.	Agree	Unsure
4.	Disagree	Agree
5.	Disagree	Disagree

Each observation corresponds to one of the 344 individuals. The data are in wide form so that each observation has a before and an after measurement. We now perform the test without options.

```
. symmetry before after
```

Public opinion before IC	Public opinion after IC			Total
	Agree	Disagree	Unsure	
Agree	47	56	38	141
Disagree	28	61	31	120
Unsure	26	47	10	83
Total	101	164	79	344

	chi2	df	Prob>chi2
Symmetry (asymptotic)	14.87	3	0.0019
Marginal homogeneity (Stuart-Maxwell)	14.78	2	0.0006

The test first tabulates the data in a $K \times K$ table and then performs Bowker's (1948) test for table symmetry and the Stuart–Maxwell (Stuart 1955; Maxwell 1970) test for marginal homogeneity.

Both the symmetry test and the marginal homogeneity test are highly significant, thus indicating a shift in public opinion.

An exact test of symmetry is provided for use on sparse tables. This test is computationally intensive, so it should not be used on large tables. Because we are working on a fast computer, we will run the symmetry test again and this time include the exact option. We will suppress the output of the contingency table by specifying `notable` and include the `contrib` option so that we may further examine the cells responsible for the significant result.

```
. symmetry before after, contrib exact mh notable
```

Cells	Contribution to symmetry chi-squared
n1_2 & n2_1	9.3333
n1_3 & n3_1	2.2500
n2_3 & n3_2	3.2821

	chi2	df	Prob>chi2
Symmetry (asymptotic)	14.87	3	0.0019
Marginal homogeneity (Stuart-Maxwell)	14.78	2	0.0006
Marginal homogeneity (Bickenboller)	13.53	2	0.0012
Marginal homogeneity (no diagonals)	15.25	2	0.0005

```
Symmetry (exact significance probability) 0.0018
```

The largest contribution to the symmetry χ^2 is due to cells n_{12} and n_{21} . These correspond to changes between the agree and disagree categories. Of the 344 individuals, 56 (16.3%) changed from the agree to the disagree response, whereas only 28 (8.1%) changed in the opposite direction.

For these data, the results from the exact test are similar to those from the asymptotic test.

► Example 2

Breslow and Day (1980, 163) reprinted data from Mack et al. (1976) from a case–control study of the effect of exogenous estrogen on the risk of endometrial cancer. The data consist of 59 elderly women diagnosed with endometrial cancer and 59 disease-free control subjects living in the same community as the cases. Cases and controls were matched on age, marital status, and time living in the community. The data collected included information on the daily dose of conjugated estrogen therapy. Breslow and Day analyzed these data by creating four levels of the dose variable. Here are the data as entered into a Stata dataset:

```
. use https://www.stata-press.com/data/r19/bd163
. list, noobs divider
```

case	control	count
0	0	6
0	0.1–0.299	2
0	0.3–0.625	3
0	0.626+	1
0.1–0.299	0	9
0.1–0.299	0.1–0.299	4
0.1–0.299	0.3–0.625	2
0.1–0.299	0.626+	1
0.3–0.625	0	9
0.3–0.625	0.1–0.299	2
0.3–0.625	0.3–0.625	3
0.3–0.625	0.626+	1
0.626+	0	12
0.626+	0.1–0.299	1
0.626+	0.3–0.625	2
0.626+	0.626+	1

This dataset is in a different format from that of the [previous example](#). Instead of each observation representing one matched pair, each observation represents possibly multiple pairs indicated by the count variable. For instance, the first observation corresponds to six matched pairs where neither the case nor the control was on estrogen, the second observation corresponds to two matched pairs where the case was not on estrogen and the control was on 0.1 to 0.299 mg/day, etc.

To use `symmetry` to analyze this dataset, we must specify `fweight` to indicate that in our data there are observations corresponding to more than one matched pair.

```
. symmetry case control [fweight=count]
```

Dosage level for case	Dosage level for control				Total
	0	0.1-0.299	0.3-0.625	0.626+	
0	6	2	3	1	12
0.1-0.299	9	4	2	1	16
0.3-0.625	9	2	3	1	15
0.626+	12	1	2	1	16
Total	36	9	10	4	59

	chi2	df	Prob>chi2
Symmetry (asymptotic)	17.10	6	0.0089
Marginal homogeneity (Stuart-Maxwell)	16.96	3	0.0007

Both the test of symmetry and the test of marginal homogeneity are highly significant, thus leading us to reject the null hypothesis that there is no effect of exposure to estrogen on the risk of endometrial cancer.

Breslow and Day perform a test for trend assuming that the estrogen exposure levels were equally spaced by recoding the exposure levels as 1, 2, 3, and 4.

We can easily reproduce their results by recoding our data in this way and by specifying the trend option. Two new numeric variables were created, ca and co, corresponding to the variables case and control, respectively. Below, we list some of the data and our results from symmetry:

```
. encode case, gen(ca)
. encode control, gen(co)
. label values ca
. label values co
. list in 1/4
```

	case	control	count	ca	co
1.	0	0	6	1	1
2.	0	0.1-0.299	2	1	2
3.	0	0.3-0.625	3	1	3
4.	0	0.626+	1	1	4

```
. symmetry ca co [fw=count], notable trend cc
```

	chi2	df	Prob>chi2
Symmetry (asymptotic)	17.10	6	0.0089
Marginal homogeneity (Stuart-Maxwell)	16.96	3	0.0007
Linear trend in the (log) RR	14.43	1	0.0001

We requested the continuity correction by specifying cc. Doing so is appropriate because our coded exposure levels are equally spaced.

The test for trend was highly significant, indicating an increased risk of endometrial cancer with increased dosage of conjugated estrogen.

You must be cautious: the way in which you code the exposure variable affects the linear trend statistic. If instead of coding the levels as 1, 2, 3, and 4, we had instead used 0, 0.2, 0.46, and 0.7 (roughly the midpoint in the range of each level), we would have obtained a χ^2 statistic of 11.19 for these data.

Stored results

symmetry stores the following in `r()`:

Scalars

<code>r(N_pair)</code>	number of matched pairs
<code>r(chi2)</code>	asymptotic symmetry χ^2
<code>r(df)</code>	asymptotic symmetry degrees of freedom
<code>r(p)</code>	asymptotic symmetry p -value
<code>r(chi2_sm)</code>	MH (Stuart–Maxwell) χ^2
<code>r(df_sm)</code>	MH (Stuart–Maxwell) degrees of freedom
<code>r(p_sm)</code>	MH (Stuart–Maxwell) p -value
<code>r(chi2_b)</code>	MH (Bickenböller) χ^2
<code>r(df_b)</code>	MH (Bickenböller) degrees of freedom
<code>r(p_b)</code>	MH (Bickenböller) p -value
<code>r(chi2_nd)</code>	MH (no diagonals) χ^2
<code>r(df_nd)</code>	MH (no diagonals) degrees of freedom
<code>r(p_nd)</code>	MH (no diagonals) p -value
<code>r(chi2_t)</code>	χ^2 for linear trend
<code>r(p_trend)</code>	p -value for linear trend
<code>r(p_exact)</code>	exact symmetry p -value

Methods and formulas

Methods and formulas are presented under the following headings:

Asymptotic tests

Exact symmetry test

Asymptotic tests

Consider a square table with K exposure categories, that is, K rows and K columns. Let n_{ij} be the count corresponding to row i and column j of the table, $N_{ij} = n_{ij} + n_{ji}$, for $i, j = 1, 2, \dots, K$, and $n_{i\cdot}$, and let $n_{\cdot j}$ be the marginal totals for row i and column j , respectively. Asymptotic tests for symmetry and marginal homogeneity for this $K \times K$ table are calculated as follows:

The null hypothesis of complete symmetry $p_{ij} = p_{ji}$, $i \neq j$, is tested by calculating the test statistic (Bowker 1948)

$$T_{\text{cs}} = \sum_{i < j} \frac{(n_{ij} - n_{ji})^2}{n_{ij} + n_{ji}}$$

which is asymptotically distributed as χ^2 with $K(K - 1)/2 - R$ degrees of freedom, where R is the number of off-diagonal cells with $N_{ij} = 0$ as discussed in Hoenig, Morgan, and Brown (1995).

The null hypothesis of marginal homogeneity, $p_{i.} = p_{.i}$, is tested by calculating the Stuart–Maxwell test statistic (Stuart 1955; Maxwell 1970),

$$T_{\text{sm}} = \mathbf{d}' \mathbf{V}^{-1} \mathbf{d}$$

where \mathbf{d} is a column vector with elements equal to the differences $d_i = n_{i.} - n_{.i}$ for $i = 1, 2, \dots, K$, and \mathbf{V} is the variance–covariance matrix with elements

$$\begin{aligned} v_{ii} &= n_{i.} + n_{.i} - 2n_{ii} \\ v_{ij} &= -(n_{ij} + n_{ji}), \quad i \neq j \end{aligned}$$

T_{sm} is asymptotically χ^2 with $K - 1$ degrees of freedom.

This test statistic properly accounts for the dependence between the table's rows and columns. When the matrix \mathbf{V} is not of full rank, a generalized inverse \mathbf{V}^* is substituted for \mathbf{V}^{-1} .

The Bickel and Clerget-Darpoux (1995) marginal homogeneity test statistic is calculated by

$$T_{\text{mh}} = \sum_i \frac{(n_{i.} - n_{.i})^2}{n_{i.} + n_{.i}}$$

This statistic is asymptotically distributed, under the assumption of marginal independence, as χ^2 with $K - 1$ degrees of freedom.

The marginal homogeneity (no diagonals) test statistic T_{mh}^0 is calculated in the same way as T_{mh} , except that the diagonal elements do not enter into the calculation of the marginal totals. Unlike the previous test statistic, T_{mh}^0 reduces to a McNemar test statistic for 2×2 tables. The test statistic $\{(K - 1)/2\} T_{\text{mh}}^0$ is asymptotically distributed as χ^2 with $K - 1$ degrees of freedom (Cleves, Olson, and Jacobs 1997; Spielman and Ewens 1996).

Breslow and Day's test statistic for linear trend in the (log) of RR is

$$\frac{\left\{ \sum_{i < j} (n_{ij} - n_{ji})(X_j - X_i) - cc \right\}^2}{\sum_{i < j} (n_{ij} + n_{ji})(X_j - X_i)^2}$$

where the X_j are the doses associated with the various levels of exposure and cc is the continuity correction; it is asymptotically distributed as χ^2 with 1 degree of freedom.

The continuity correction option is applicable only when the levels of the exposure variable are equally spaced.

Exact symmetry test

The exact test is based on a permutation algorithm applied to the null distribution. The distribution of the off-diagonal elements n_{ij} , $i \neq j$, conditional on the sum of the complementary off-diagonal cells, $N_{ij} = n_{ij} + n_{ji}$, can be written as the product of $K(K - 1)/2$ binomial random variables,

$$P(\mathbf{n}) = \prod_{i < j} \binom{N_{ij}}{n_{ij}} \pi_{ij}^{n_{ij}} (1 - \pi_{ij})^{n_{ji}}$$

where \mathbf{n} is a vector with elements n_{ij} and $\pi_{ij} = E(n_{ij}/N_{ij}|N_{ij})$. Under the null hypothesis of complete symmetry, $\pi_{ij} = \pi_{ji} = 1/2$, and thus the permutation distribution is given by

$$P_0(\mathbf{n}) = \prod_{i < j} \binom{N_{ij}}{n_{ij}} \left(\frac{1}{2}\right)^{N_{ij}}$$

The exact significance test is performed by evaluating

$$P_{cs} = \sum_{\mathbf{n} \in p} P_0(\mathbf{n})$$

where $p = \{\mathbf{n} : P_0(\mathbf{n}) < P_0(\mathbf{n}^*)\}$ and \mathbf{n}^* is the observed contingency table data vector. The algorithm evaluates p_{cs} exactly. For information about permutation tests, see Good (2005, 2006).

Description

Tables allow us to effectively communicate information about our data and results from our analyses. The `table` command is a flexible tool for creating tables. It allows you to create tabulations, tables of summary statistics, tables of results from hypothesis tests, tables of regression results, and more. `table` also allows you to customize the table so that it effectively communicates the results.

Remarks and examples

Remarks are presented under the following headings:

Overview

Tabulations

Tables of summary statistics

Tables of results from other commands

Flexible tables combining results

Formatting, customizing, and exporting tables

Overview

The `table` command allows you to create various types of tables.

1. Tabulations of one, two, or more categorical variables, reporting frequencies, percentages, or proportions.
2. Tables of summary statistics such as means, standard deviations, medians, and the like—perhaps computed across levels of one or more categorical variables.
3. Tables of results from other Stata commands, such as regression results or results of classic hypothesis tests.
4. Tables combining summary statistics and results from other Stata commands.

`table` obtains the statistics it reports in two ways. The `table` command itself can compute summary statistics. `table` also provides a `command()` option that allows you to run any Stata command and include its results in the table.

`table` also provides much flexibility for you to arrange the results in your table in a meaningful way. You can control how the rows, columns, and potentially even separate tables are defined. For instance, you might type

```
. table (var1) (var2) ...
```

to place the levels of `var1` on the rows and the levels of `var2` on the columns. The first set of parentheses is used to define the rows, and the second set is used to define the columns. The parentheses could be omitted in this case, but for clarity we will use them in our discussion here.

We could use the levels of both `var1` and `var2` to define the rows.

```
. table (var1 var2) ...
```

If we have an additional variable, `var3`, we can define rows by both `var1` and `var2` and the columns by `var3` by typing

```
. table (var1 var2) (var3) ...
```

or we can place the levels of `var2` and `var3` on the columns,

```
. table (var1) (var2 var3) ...
```

We could even create separate tables for the levels of `var3`,

```
. table (var1) (var2) (var3) ...
```

The third set of parentheses defines the separate tables.

If our table reports multiple statistics, say, means and standard deviations, we can use the keyword `result` to specify how they are included in the table layout. To place the statistics on separate rows, we could type

```
. table (var1 result) (var2) ...
```

The flexibility of the table layout goes beyond these examples. You can add additional variables to define rows, columns, and tables as is appropriate for the table you wish to create.

In addition to controlling the layout of your table, you can customize the results by specifying formats, including stars representing significance, and selecting from styles that determine how the headers of the table are displayed.

Tabulations

Tabulations allow you to examine the distribution of your data across the levels of one or more categorical variables. Tabulations often report frequencies, percentages, and proportions.

With `table`, you can easily create one-way tabulations, two-way tabulations, three-way tabulations, and even more complex tabulations. For example, we could create a two-way tabulation of `region` and `diabetes`, reporting frequencies,

```
. table (region) (diabetes)
```

	Diabetes status		Total
	Not diabetic	Diabetic	
Region			
NE	1,997	98	2,095
MW	2,648	125	2,773
S	2,692	161	2,853
W	2,513	115	2,628
Total	9,850	499	10,349

or we can report percentages,

```
. table (region) (diabetes), statistic(percent)
```

	Diabetes status		Total
	Not diabetic	Diabetic	
Region			
NE	19.30	0.95	20.24
MW	25.59	1.21	26.79
S	26.01	1.56	27.57
W	24.28	1.11	25.39
Total	95.18	4.82	100.00

To learn how to create tabulations, see

- [R] [table oneway](#) One-way tabulation
- [R] [table twoway](#) Two-way tabulation
- [R] [table multiway](#) Multiway tables

In these entries, we provide simplified syntax for creating the specific type of tabulation you are interested in, and we provide a number of examples demonstrating how to build these tables and customize the results.

Tables of summary statistics

`table` can compute summary statistics such as minimums, maximums, means, standard deviations, medians, and interquartile ranges. Summary statistics can be computed for one or more variables. Summary statistics can also be computed separately for groups of data. For example, we can create a table reporting the means of age, height, and bmi,

```
. table, statistic(mean age height bmi)
```

Age (years)	47.57965
Height (cm)	167.6509
Body mass index (BMI)	25.5376

or we can compute these means separately for males and females,

```
. table () (sex), statistic(mean age height bmi)
```

	Sex		Total
	Male	Female	
Age (years)	47.4238	47.72057	47.57965
Height (cm)	174.7421	161.2393	167.6509
Body mass index (BMI)	25.50999	25.56256	25.5376

To learn how to create tables of summary statistics, including the simplified `table` syntax and worked examples, see

[\[R\] table summary](#)

Table of summary statistics

You can also create a table of summary statistics with `dtable`. The advantage of using `dtable` is that you can create a table with a title and notes and export it to a variety of file types, all in a single step. Unlike `table`, however, `dtable` has a predefined layout, and you will not be able to specify how the results should be arranged in the table.

Tables of results from other commands

With `table`'s `command()` option, you can run any Stata command and place statistics reported by that command in your table. For instance, you might use `test` to test for differences in means or use `regress` to fit a linear regression model. You can include any stored results from these commands in your table. For example, we can create a table to compare coefficients from linear regressions of `bpsysol` on `age` and `weight` fit separately for males and females.

```
. table (colname) (sex result), command(regress bpsystol age weight)
```

	Sex		Total
	Male	Female	
Age (years)	.4789361	.7735499	.6379892
Weight (kg)	.3346106	.4586108	.4069041
Intercept	84.08037	61.70456	71.27096

To learn how to create tables with results from other commands, including simplified table syntax and worked examples, see

[R] table hypothesis tests	Table of hypothesis tests
[R] table regression	Table of regression results

Flexible tables combining results

`table` can create tables with combinations of frequencies, other summary statistics, and results from other table commands. To see the full syntax and discussion of how `table` automates the table layout, see

[R] table	Table of frequencies, summaries, and command results
---------------------------	--

Formatting, customizing, and exporting tables

`table` allows you to customize your results by specifying the layout and with options that change the numeric formatting, add characters such as percent signs or parentheses to specific types of statistics, add stars representing significance levels, and modify the look of confidence intervals. In addition, Stata provides predefined styles that you may select from using the `style()` option. These styles control which labels are displayed in the headers of the tables, how the labels are aligned, how the statistics are aligned within the cells, and more. To learn about the predefined styles that you can select from, see [\[TABLES\] Predefined styles](#). Examples of using the `style()` and other formatting options are provided in the entries for specific types of tables listed in the previous sections.

The results from `table` can be customized even beyond what its formatting options allow. `table` is unique in that it stores its results in a format that we refer to as a “collection”. Stata’s `collect` suite of commands can be used to produce highly customized tables from results in a collection and to export those tables to presentation-ready formats such as HTML, Word, L^AT_EX, PDF, Excel, and more. Examples of using `collect` to modify labels and table layout are also provided in the entries for the specific types of tables listed in the previous sections. To learn more about the `collect` commands, see [\[TABLES\] Intro](#) and the entries discussed therein.

Description

`table` is a flexible command for creating tables of many types—tabulations, tables of summary statistics, tables of regression results, and more. `table` can calculate summary statistics to display in the table. `table` can also include results from other Stata commands.

Quick start

Two-way tabulation of `a1` and `a2`

```
table a1 a2
```

Table of means for `v1` and `v2` across the levels of `a1`

```
table a1, statistic(mean v1 v2)
```

Two-way table with `a1` defining rows and `a2` defining columns, with frequencies and pairwise correlation coefficients between `v3` and `v4` computed for every cell

```
table a1 a2, command(pwcorr v3 v4)
```

Table of regression coefficients with means of the covariates; rows correspond to covariates and columns correspond to the statistics

```
table (colname) (statcmd result),
    command(regress y x1 x2)
    statistic(mean x1 x2)
```

Same as above, and include standard deviations for the covariates

```
table (colname) (statcmd result),
    command(regress y x1 x2)
    statistic(mean x1 x2)
    statistic(sd x1 x2)
```

Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

Syntax

Basic syntax for a one-way table

```
table rowvar
table () colvar
```

Basic syntax for a two-way table

```
table rowvar colvar
```

Basic syntax for an n -way table

```
table rowvars colvar
table rowvar (colvars)
table (rowvars) (colvars)
```

Basic syntax for multiple n -way tables

```
table (rowvars) (colvars) (tabvars)
```

Full syntax

```
table (rowspec) (colspec) [(tabspec)] [if] [in] [weight] [, options]
```

rowspec, *colspec*, and *tabspec* may be empty or may include variable names or any of the following keywords:

<i>keyword</i>	Description
result	requested statistics
stars	stars denoting statistical significance
var	variables from <code>statistic()</code> option
across	index <code>across()</code> specifications
colname	column names for matrix statistics
rowname	row names for matrix statistics
coleq	column equation names for matrix statistics
roweq	row equation names for matrix statistics
command	index option <code>command()</code>
statcmd	index options <code>statistic()</code> and <code>command()</code>

<i>options</i>	Description
Main	
totals (<i>totals</i>)	report only the specified totals
nototals	suppress the marginal totals
Statistics	
<u>statistic</u> (<i>statspec</i>)	statistic to be reported; default is statistic (frequency) when no weights are specified and statistic (sumw) otherwise
Commands	
command (<i>cmds</i> <i>spec</i>)	collect results from the specified Stata command
Formats	
nformat (% <i>fmt</i> [<i>results</i>][, <i>basestyle</i>])	specify numeric format
sformat (<i>sfmt</i> [<i>results</i>])	specify string format
cidelimiter (<i>char</i>)	use character as delimiter for confidence interval limits
cridelimiter (<i>char</i>)	use character as delimiter for credible interval limits
Stars	
stars (<i>starspec</i>)	add stars to denote statistical significance
Title	
title (<i>string</i>)	add table title
<u>titlestyles</u> (<i>text_styles</i>)	change table title styles
Notes	
note (<i>string</i>)	add table note
<u>notestyles</u> (<i>text_styles</i>)	change table note styles
Export	
export (<i>filename.suffix</i> [, <i>export_opts</i>])	export table
Options	
listwise	use listwise deletion to handle missing values
<u>missing</u>	treat numeric missing values like other values
showcounts	show sample size for all variables in statistic () option
<u>zerocounts</u>	report 0 for empty cell counts
name (<i>cname</i>)	collect results into a collection named <i>cname</i>
append	append results to an existing collection
replace	replace results of an existing collection
label (<i>filename</i>)	specify the collection labels
style (<i>filename</i> [, <i>override</i>])	specify the collection style
markvar (<i>newvar</i>)	create <i>newvar</i> that identifies observations used in the tabulation
noisily	display output from each command

fweights, **awweights**, **iweights**, and **pweights** are allowed; see [U] 11.1.6 **weight**.

strL variables are not allowed; see [U] 12.4.8 **strL**.

markvar() and **noisily** do not appear in the dialog box.

<i>text_styles</i>	Description
<code>font([fontfamily][, font_opts])</code>	specify font style
<code>smcl(smcl)</code>	specify formatting for SMCL files
<code>latex(latex)</code>	specify L ^A T _E X macro
<code>shading(sspec)</code>	set background color, foreground color, and fill pattern

<i>font_opts</i>	Description
<code>size([unit])</code>	specify font size
<code>color(color)</code>	specify font color
<code>variant(variant)</code>	specify font variant and capitalization
<code>[no]bold</code>	specify whether to format text as bold
<code>[no]italic</code>	specify whether to format text as italic
<code>[no]strikeout</code>	specify whether to strike out text
<code>[no]underline</code>	specify whether to underline text

<i>suffix</i>	<i>fileformat</i>	Output format
<code>docx</code>	<code>as(docx)</code>	Microsoft Word
<code>html</code>	<code>as(html)</code>	HTML 5 with CSS
<code>pdf</code>	<code>as(pdf)</code>	PDF
<code>xlsx</code>	<code>as(xlsx)</code>	Microsoft Excel 2007/2010 or newer
<code>xls</code>	<code>as(xls)</code>	Microsoft Excel 1997/2003
<code>tex</code>	<code>as(tex)</code>	L ^A T _E X
<code>smcl</code>	<code>as(smcl)</code>	SMCL
<code>txt</code>	<code>as(txt)</code>	plain text
<code>markdown</code>	<code>as(markdown)</code>	Markdown
<code>md</code>	<code>as(md)</code>	Markdown

<i>export_opts</i>	Description
<code>as(fileformat)</code>	specify document type
<code>replace</code>	overwrite existing file
<code>docx_options</code>	available when exporting to .docx files
<code>html_options</code>	available when exporting to .html files
<code>pdf_options</code>	available when exporting to .pdf files
<code>excel_options</code>	available when exporting to .xls and .xlsx files
<code>tex_options</code>	available when exporting to .tex files
<code>smcl_option</code>	available when exporting to .smcl files
<code>txt_option</code>	available when exporting to .txt files
<code>md_option</code>	available when exporting to .markdown and .md files

<i>docx_options</i>	Description
<code>noisily</code>	show the putdocx commands used to export to the Microsoft Word file
<code>dofile(filename[, replace])</code>	save the putdocx commands used for exporting to the named do-file

<i>html_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file
cssfile(<i>cssfile</i>)	define the styles in <i>cssfile</i> instead of <i>filename</i>
prefix(<i>prefix</i>)	use <i>prefix</i> to identify style classes

<i>pdf_options</i>	Description
noisily	show the putpdf commands used to export to the PDF file
dofile(<i>filename</i> [, replace])	save the putpdf commands used for exporting to the named do-file

<i>excel_options</i>	Description
noisily	show the putexcel commands used to export to the Excel file
dofile(<i>filename</i> [, replace])	save the putexcel commands used for exporting to the named do-file
sheet(<i>sheetname</i> [, replace])	specify the worksheet to use; the default sheet name is Sheet1
cell(<i>cell</i>)	specify the Excel upper-left cell as the starting position to export the table; the default is cell(A1)
modify	modify Excel file
noopen	do not open Excel file in memory

noopen does not appear in the dialog box.

<i>tex_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file

<i>smcl_option</i>	Description
append	append to an existing file

<i>txt_option</i>	Description
append	append to an existing file

<i>md_option</i>	Description
append	append to an existing file

fontfamily specifies a valid font family.

unit may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

variant may be allcaps, smallcaps, or normal.

variant(allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

variant(smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L^AT_EX, and HTML files.

variant(normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

smcl specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.

latex specifies the name of a L^AT_EX macro to render text for L^AT_EX output. Example L^AT_EX macro names are textbf, textsf, textrm, and texttt. Custom L^AT_EX macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L^AT_EX:

`\latex {text}`

sspec is

`[background(bcolor) foreground(fgcolor) pattern(fpattern)]`

bcolor specifies the background color.

fgcolor specifies the foreground color.

fpattern specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

bcolor, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form ### ##, for example, 171 248 103; or a valid RRGGBB hex value in the form #####, for example, ABF867.

Options

Main

`totals` (*totals*) and `nototals` control which totals are to be displayed in the table. By default, all totals are reported.

`totals` (*totals*) specifies which margin totals to display in the reported table. *totals* can contain variables in *rowspec*, *colspec*, *tabspec*, and their interaction. Interactions can be specified by using the `#` operator.

`nototals` prevents table from displaying any totals.

Statistics

`statistic` (*statspec*) specifies the statistic to be displayed. Frequency statistics, summary statistics, and ratio statistics are available by specifying `statistic` (*freqstat*), `statistic` (*sumstat* *varlist*), and `statistic` (*ratiostat* [*varlist*] [*, ratio_options*]), respectively.

`statistic()` may be repeated to request multiple statistics.

`statistic` (*freqstat*) specifies that frequencies be computed.

<i>freqstat</i>	Definition
<code>frequency</code>	frequency
<code>sumw</code>	sum of weights

`statistic(sumstat varlist)` specifies that summary statistic *sumstat* be computed for the variables in *varlist*.

<i>sumstat</i>	Definition
mean	mean
semean	standard error of the mean
sebinomial	standard error of the mean, binomial
sepoisson	standard error of the mean, Poisson
variance	variance
sd	standard deviation
skewness	skewness
kurtosis	kurtosis
cv	coefficient of variation
svybv	coefficient of variation (svy)
geomean	geometric mean
geosd	geometric standard deviation
count	number of nonmissing values
median	median
p#	#th percentile
q1	first quartile
q2	second quartile
q3	third quartile
iqr	interquartile range
min	minimum value
max	maximum value
range	range
first	first value
last	last value
firstnm	first nonmissing value
lastnm	last nonmissing value
total	total
rawtotal	unweighted total
fvfrequency	frequency of each factor-variable level
fvrawfrequency	unweighted frequency of each factor-variable level
fvproportion	proportion within each factor-variable level
fvrawproportion	unweighted proportion within each factor-variable level
fvpercent	percentage within each factor-variable level
fvrawpercent	unweighted percentage within each factor-variable level

`statistic(ratiostat [varlist] [, ratio_options])` specifies that ratio statistic *ratiostat* be computed. If *varlist* is specified, ratios are computed based on the totals of the specified variables. If *varlist* is not specified, ratios are computed based on frequencies.

<i>ratiostat</i>	Definition
<u>proportion</u>	proportion
<u>percent</u>	percentage
<u>rawproportion</u>	proportion ignoring optionally specified weights
<u>rawpercent</u>	percentage ignoring optionally specified weights

<i>ratio_options</i>	Definition
<u>across(cellspec)</u>	percentages or proportions across levels of variables or interactions
<u>total</u>	compute overall percentages or proportions

cellspect may contain *rowvars*, *colvars*, *tabvars*, or an interaction between any of these variables. Interactions can be specified by using the # operator.

Commands

`command(cmdspec)` specifies the Stata commands from which to collect results. `command()` may be repeated to collect results from multiple commands.

cmdspec is `[explist:] command [arguments] [, cmdoptions]`

explist specifies which results to collect and report in the table. *explist* may include *result identifiers* and *named expressions*.

result identifiers are results stored in `r()` and `e()` by the *command*. For instance, *result identifiers* could be `r(mean)`, `r(C)`, or `e(chi2)`. After estimation commands, *result identifiers* also include the following:

Identifier	Result
<code>_r_b</code>	coefficients or transformed coefficients reported by <i>command</i>
<code>_r_se</code>	standard errors of <code>_r_b</code>
<code>_r_z</code>	test statistics for <code>_r_b</code>
<code>_r_z_abs</code>	absolute value of <code>_r_z</code>
<code>_r_p</code>	<i>p</i> -values for <code>_r_b</code>
<code>_r_lb</code>	lower bounds of confidence intervals for <code>_r_b</code>
<code>_r_ub</code>	upper bounds of confidence intervals for <code>_r_b</code>
<code>_r_ci</code>	confidence intervals for <code>_r_b</code>
<code>_r_crlb</code>	lower bounds of credible intervals for <code>_r_b</code>
<code>_r_crub</code>	upper bounds of credible intervals for <code>_r_b</code>
<code>_r_cri</code>	credible intervals for <code>_r_b</code>
<code>_r_df</code>	degrees of freedom for <code>_r_b</code>

named expressions are specified as `name = exp`, where *name* may be any valid Stata name and *exp* is an expression, typically an expression that involves one or more *result identifiers*. An example of a named expression is `sd = sqrt(r(variance))`.

For r-class commands, the default is to include all numeric scalars posted to `r()` in the table results. For e-class commands, the default is to include `_r_b` in the table results.

command is any command that follows standard Stata syntax.

arguments may be anything so long as they do not include an `if` clause, `in` range, or weight specification.

Any `if` or `in` qualifier and weights should be specified directly with `table`, not within the `command()` option.

cmdoptions may be anything supported by *command*.

Formats

`nformat(%fmt [results][, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

results may be any statistic named in option `statistic()` (that is, any *freqstat*, *sumstat*, or *ratioestat*) or may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*) or the format of factor variables specified in the `statistic()` option. The default format of these variables is taken from the dataset.

basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and `%s`. Here `%s` refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around `%s` in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s)" percent)`.

results may be any statistic named in option `statistic()` (that is, any *freqstat*, *sumstat*, or *ratioestat*) or may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include `%`, type `%%`. To include `\`, type `\\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

`cidelimiter(char)` changes the delimiter between confidence interval limits to *char*. The default is `cidelimiter(" ")`, that is, two spaces.

`cridelimiter(char)` changes the delimiter between credible interval limits to *char*. The default is `cridelimiter(" ")`, that is, two spaces.

Stars

`stars(starspec)` specifies that stars representing statistical significance be included in the table. *starspec* identifies the result whose values determine significance, which characters should represent each significance level, and where these characters should be displayed in the table. *starspec* is

```
starres [ #1 "label1" [ #2 "label2" [ #3 "label3" [ #4 "label4" [ #5 "label5" ] ] ] ] ]
[, attach(attachres) result dimension starsnoteopts]
```

starres is the name of the result whose values determine which characters, typically which number of stars, are to be displayed.

label1 specifies the characters to be displayed when *starres* < #1.

label2 specifies the characters to be displayed when *starres* < #2.

label3 specifies the characters to be displayed when *starres* < #3.

label4 specifies the characters to be displayed when *starres* < #4.

label5 specifies the characters to be displayed when *starres* < #5.

`attach(attachres)` specifies the name of the result to which the characters defined by *label1*, ..., *label5* are to be attached. If `attach()` is not specified, a new result named `stars` is created and is automatically added to the table.

`result` and `dimension` control how `collect stars` adds items when labeling significant results. These options are mutually exclusive.

`result` specifies the default behavior, and this option is necessary only if the following `dimension` behavior is in effect and you want to change back to the `result` behavior.

`dimension` specifies that dimension `stars` be added to the collection. Items will be tagged with `stars[value]`, and the labels will be tagged with `stars[label]`. Use this option for layouts where results are to be stacked within columns, and use new dimension `stars` in the column specification of the layout.

starsnoteopts control the display and composition of the stars note.

`noshownote` and `shownote` control whether to display the stars note.

`increasing` and `decreasing` control the order of *p*-values in the stars note.

`pvname(string)` specifies a name for the *p*-value in the stars note. The default is `pvname(p)`.

`delimiter(string)` specifies the delimiter between labels in the stars note. The default is `delimiter(",")`.

`nformat(%fmt)` specifies the numeric format for the cutoff values in the stars note. The default is `nformat(%9.0g)`.

`prefix(string)` specifies the prefix for the stars note. The prefix is empty by default.

`suffix(string)` specifies the suffix for the stars note. The suffix is empty by default.

For example, `stars(_r_p 0.01 "****" 0.05 "***" 0.1 "**", attach(_r_b))` could be added to a table of regression results to specify that stars be defined based on the *p*-values in `_r_p` and be attached to the reported coefficients (`_r_b`).

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline)` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Notes

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline)` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a \LaTeX , a SMCL, a `txt`, or a Markdown file. When you export to HTML and \LaTeX files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or \LaTeX document. With this option, the produced file may be included in other HTML or \LaTeX documents. By default, `table` produces complete HTML and \LaTeX documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname[, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [RPT] [putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [RPT] [putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [RPT] [putexcel](#).

Options

`listwise` handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any variable specified in a `statistic()` option is missing for that observation. By default, `table` will omit an observation only if all variables specified in all `statistic()` options are missing for that observation.

`missing` specifies that numeric missing values of any variables specified in *rowspec*, *colspec*, or *tabspec* be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

This option does not apply to factor variables specified with statistics `fvfrequency`, `fvrawfrequency`, `fvproportion`, `fvrawproportion`, `fvpercent`, or `fvrawpercent`.

`showcounts` specifies that `table` report the sample size for each variable specified in option `statistic()`.

`zerocounts` specifies that `table` report a 0 in empty cells for results `count`, `frequency`, `fvfrequency`, and `fvrawfrequency`.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table_style](#).

The following options are available with `table` but are not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

`noisily` specifies that output from the commands specified in `command()` options be displayed. By default, output from commands is suppressed.

Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Specifying the table layout](#)

[Advanced table customization](#)

Introduction

The `table` command can create many customized tables, ranging from simple one-way tabulations to multiple *n*-way tables with summary statistics and estimation results. `table` can compute and report frequencies, proportions, percentiles, and other summary statistics. It can also run other Stata commands and include their results in the table. This means you can combine the summary statistics computed

by `table` with test statistics, correlations, regression coefficients, and other results collected from Stata commands. In addition to building tables with the desired statistics, you can customize them by formatting the values in the table and applying predefined styles and labels that affect how the row headers, column headers, and values are displayed in the table.

`table` can accommodate a variety of layouts. You can define the rows, columns, and even separate table by levels of categorical variables, statistics, or Stata commands.

If your goal is simply to create a table of estimation results or descriptive statistics, you can use the `etable` and `dtable` commands, respectively. These commands allow you to create these tables and export them to a variety of file types in a single step. However, unlike `table`, these commands create tables with a predefined layout. Therefore, if you want control over the layout or you wish to include a combination of summary statistics, estimation results, and results from other Stata commands, you should use the `table` command.

In the following entries, we provide simplified syntax, examples, and discussion for specialized types of tables that can be created using `table`. If you are interested in creating one of these types of tables, we suggest reading the corresponding entry.

[R] <code>table oneway</code>	One-way tabulation
[R] <code>table twoway</code>	Two-way tabulation
[R] <code>table multiway</code>	Multiway tables
[R] <code>table summary</code>	Table of summary statistics
[R] <code>table hypothesis tests</code>	Table of hypothesis tests
[R] <code>table regression</code>	Table of regression results

All the concepts demonstrated in the entries above can be combined to create tables including combinations of tabulations, summary statistics, hypothesis tests, and regression results.

In this entry, we provide additional information on specifying the table layout and which portions of the layout `table` will automate for you. In addition, we provide resources for customizing the table and exporting the results to your preferred format.

Specifying the table layout

A table's layout is determined by our row, column, and table dimension specifications. For example, we specify variable names to define the rows and place statistics in the columns, or vice versa. Because we can include so many different statistics, we can specify keywords that we use to identify the results we have collected from commands and the statistics that `table` has calculated.

The syntax for specifying the table layout is

```
table ([rowspec]) ([colspec]) ([tabspec])
```

We refer to *rowsec*, *colspec*, and *tabspec* collectively as the “layout”. For some tables, `keywords` are required in the layout to uniquely identify the values that we want to include in our table. If you omit a necessary keyword from the layout, `table` will fill one in for you.

The rules determining whether a keyword is necessary to uniquely identify values in the table are as follows:

1. If more than one statistic is specified, then `result` is needed in the layout.
2. If more than one variable is specified in option `statistic()` and option `command()` is not specified, then `var` is needed in the layout.

3. If more than one `across()` specification is used for ratio statistics, then `across` is needed in the layout.
4. If option `command()` is specified, then `colname` is needed in the layout. If, in addition, more than one variable is specified in option `statistic()`, then `colname` is needed instead of `var`, which was required in 2.
5. If multiple `command()` options are specified and option `statistic()` is not specified, then `command` is needed in the layout.
6. If both options `command()` and `statistic()` are specified, then `statcmd` is needed in the layout.

If we do not directly specify a necessary keyword in one of *rowspec*, *colspec*, or *tabspec*, the missing keywords will be automatically added to the layout as follows:

1. If the row specification is empty, then put the missing keywords in *rowspec*.
2. If the row specification is not empty but the column specification is empty, then put the missing keywords in *colspec*.
3. If the row and column specifications are not empty but the table specification is empty and if `result` is the only missing keyword and there is only one statistic (`result`), then put `result` in *tabspec*.
4. Otherwise, append the missing keywords to *rowvars*.

Below, we demonstrate how missing keywords are added to the *layout*.

Using `auto.dta`, we create a table with the minimum and maximum `mpg` for each level of `rep78`. The keyword `result` identifies the statistics we computed. By listing an empty set of parentheses followed by `rep78`, we request that the levels of `rep78` be placed on the columns.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. table () rep78, statistic(min mpg) statistic(max mpg)
```

	Repair record 1978					Total
	1	2	3	4	5	
Minimum value	18	14	12	14	17	12
Maximum value	24	24	29	30	41	41

Based on [rule 1](#), if we request more than one statistic, `result` must be in the layout. Based on [situation 1](#), if the row specification is empty, then the missing keyword will be placed in the row specification. We could have created the same table by typing

```
. table (result) (rep78), statistic(min mpg) statistic(max mpg)
```

Now, let’s include multiple variables in our `statistic()` option. We also type `rep78` immediately after `table` to specify that the levels of `rep78` be placed on the rows.

```
. table rep78, statistic(mean mpg price)
```

	Mileage (mpg)	Price
Repair record 1978		
1	21	4564.5
2	19.125	5967.625
3	19.43333	6429.233
4	21.66667	6071.5
5	27.36364	5913
Total	21.28986	6146.043

Because we have more than one variable in the `statistic()` option, then keyword `var` must be in the layout (rule 2). If we include a row specification but leave the column specification empty, `table` will treat `var` as the column identifier. We could have equivalently typed

```
. table (rep78) (var), statistic(mean mpg price)
```

Next, let’s include both a `command()` option and a `statistic()` option with multiple variables in the same table. We want a table with coefficients and means of the independent variables. We use the `command()` option to fit the regression and obtain the means with the `statistic()` option. Now, we need both `colname` and `statcmd` to uniquely identify the values in the table. Let’s omit `statcmd` from our command.

```
. table (colname) (result[_r_b mean]),  
> command(regress mpg turn trunk) statistic(mean turn trunk)
```

	Coefficient	Mean
Turn circle (ft.)		
regress mpg turn trunk	-.7610113	
Mean		39.64865
Trunk space (cu. ft.)		
regress mpg turn trunk	-.3161825	
Mean		13.75676
Intercept		
regress mpg turn trunk	55.82001	

But based on situation 4, `table` will add `statcmd` to the row specification if we leave it out. So we could have also typed the following to create the same table:

```
. table (colname statcmd) (result[_r_b mean]),  
command(regress mpg turn trunk) statistic(mean turn trunk)
```

This table displays each of the statistics that we requested. If we simply wanted to compute some statistics quickly, it has served its purpose. However, if we wish to share these results with others or include a table in a report, we will want to make some modifications.

Advanced table customization

`table` allows you to customize the results of your table using the `stars()`, `nformat()`, `sformat()`, `cidelimiter()`, `label()`, and `style()` options. With these, you can add significance stars, change the numeric format, and attach characters such as percent signs or parentheses to values in the table, use a stored set of labels, or use a predefined style. If these options provide all the customizations you need, you can export your finalized table directly with the `export()` option. See [TABLES] [Predefined styles](#) for more information on selecting a style that adjusts elements of the table such as row header alignment, alignment of values within the cells, and which labels are included in the headers.

Customization can also go beyond the predefined styles and options available to you in the `table` command. `table` stores all of its results in a collection named `Table`. This means that you can use the specialized tools available in the `collect` suite of commands to further customize your table. With `collect`, you can modify specific labels, add borders, change the style of the headers, and the like. Once you have a publication-ready table, you can use [collect export](#) to export your table to HTML, Word, L^AT_EX, PDF, Excel, or another format appropriate for your report.

Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

Methods and formulas

Variables specified in *rowspec*, *colspec*, and *tabspec* identify groups of observations within the dataset. These groups are represented in the table by cells and cell margins (totals). For a given cell or cell margin, let n denote the number of observations (`frequency`). Let x denote the variable on which we want to calculate summary statistics, and let $x_i, i = 1, \dots, n$, denote an individual observation on x . `count` is the number of nonmissing values of x . `first` is x_1 and `last` is x_n . Let a be the smallest i such that x_i is not missing, and then `firstnm` is x_a . Let b be the largest i such that x_i is not missing, and then `lastnm` is x_b .

Let v_i be the weight, and if no weight is specified, define $v_i = 1$ for all i . Let v_{\cdot} denote the sum of the weights (`sumw`):

$$v_{\cdot} = \sum_{i=1}^n v_i$$

When `aweights` or `pweights` are specified, the normalized weights are given by $w_i = v_i(n/v_{\cdot})$ with $w_{\cdot} = n$; otherwise, $w_i = v_i$ and $w_{\cdot} = v_{\cdot}$.

The remaining summary statistics are computed according to the following formulas:

total

$$x_{\cdot} = \begin{cases} \sum_{i=1}^n v_i x_i & \text{if pweights} \\ \sum_{i=1}^n w_i x_i & \text{otherwise} \end{cases}$$

rawtotal

$$\sum_{i=1}^n x_i$$

mean

$$\bar{x} = \frac{1}{w_{\cdot}} \sum_{i=1}^n w_i x_i$$

Define m_r as the r th moment about the mean:

$$m_r = \frac{1}{w_{\cdot}} \sum_{i=1}^n w_i (x_i - \bar{x})^r$$

variance

$$s^2 = \frac{w_{\cdot}}{w_{\cdot} - 1} m_2 = \frac{1}{w_{\cdot} - 1} \sum_{i=1}^n w_i (x_i - \bar{x})^2$$

sd (standard deviation)

$$s = \sqrt{s^2}$$

semean (standard error of the mean)

$$\text{se}(\bar{x}) = \frac{s}{\sqrt{w_{\cdot}}}$$

sebinomial (standard error of the mean, binomial distribution)

$$\sqrt{\frac{\bar{x}(1 - \bar{x})}{w_{\cdot}}}$$

sepoisson (standard error of the mean, Poisson distribution)

$$\sqrt{\frac{\bar{x}}{w_{\cdot}}}$$

When pweights are specified, semean, sebinomial, and sepoisson are all computed as

$$\text{se}_{\text{pw}}(\bar{x}) = \sqrt{\frac{n}{n-1} \sum_{i=1}^n \left\{ \frac{v_i}{v_{\cdot}} (x_i - \bar{x}) \right\}^2}$$

skewness

$$m_3 m_2^{-3/2}$$

kurtosis

$$m_4 m_2^{-2}$$

cv (coefficient of variation)

$$\frac{s}{\bar{x}}$$

svycv (coefficient of variation, survey literature)

$$100 \frac{\text{se}(\bar{x})}{|\bar{x}|}$$

svycv with pweights

$$100 \frac{\text{se}_{\text{pw}}(\bar{x})}{|\bar{x}|}$$

geomean (geometric mean)

$$\bar{x}_g = \exp \left(\frac{1}{w_{\cdot}} \sum_{i=1}^n w_i \ln x_i \right)$$

geosd (geometric standard deviation)

$$\exp \left(\sqrt{\frac{1}{w_{\cdot} - 1} \sum_{i=1}^n w_i (\ln x_i - \ln \bar{x}_g)^2} \right)$$

Let $x_{(i)}$ refer to the x in ascending order, and let $w_{(i)}$ refer to the corresponding weights of $x_{(i)}$.

minimum

$$x_{(1)}$$

maximum

$$x_{(n)}$$

range

$$x_{(n)} - x_{(1)}$$

To obtain the p th *percentile*, which we will denote as $x_{[p]}$, let $P = np/100$ and

$$W_{(i)} = \frac{n}{w.} \sum_{j=1}^i w_{(j)}$$

Find the first index i such that $W_{(i)} > P$. The p th percentile is then

$$x_{[p]} = \begin{cases} \frac{x_{(i-1)} + x_{(i)}}{2} & \text{if } W_{(i-1)} = P \\ x_{(i)} & \text{otherwise} \end{cases}$$

q1 (first quartile)

$$x_{[25]}$$

q2 (second quartile)

$$x_{[50]}$$

q3 (third quartile)

$$x_{[75]}$$

iqr (interquartile range)

$$x_{[75]} - x_{[25]}$$

Let f be an indicator for a specific level of a factor variable and f_i denote an individual observation on f .

fvfrequency (frequency of the factor variable's level)

$$\sum_{i=1}^n w_i f_i$$

fvrawfrequency (unweighted frequency of the factor variable's level)

$$\sum_{i=1}^n f_i$$

fvproportion (proportion of the factor variable's level)

$$\frac{1}{w.} \sum_{i=1}^n w_i f_i$$

fvrawproportion (unweighted proportion of the factor variable's level)

$$\frac{1}{n} \sum_{i=1}^n f_i$$

`fvpercent` (percentage of the factor variable's level)

$$\frac{100}{w_{\cdot}} \sum_{i=1}^n w_i f_i$$

`fvrawpercent` (unweighted percentage of the factor variable's level)

$$\frac{100}{n} \sum_{i=1}^n f_i$$

`proportion` is computed from ratios of totals. The numerator is taken from the total for the given cell or cell margin, and the denominator is taken from the total for a cell margin that contains the given cell or cell margin. `percent` is `proportion` multiplied by 100.

`rawproportion` and `rawpercent` are similarly computed using unweighted totals.

Description

In this entry, we discuss how to use `table` to create a one-way tabulation, including frequencies, percentages, and proportions.

Quick start

One-way table of frequencies, with rows corresponding to the levels of `a1`

```
table a1
```

Same as above, but with columns corresponding to the levels of `a1`

```
table () a1
```

Same as above, but treat missing values like other values of `a1`

```
table () a1, missing
```

One-way table of frequencies, using the collection style `mystyle`

```
table a1, style(mystyle)
```

One-way table of frequencies and percentages

```
table a1, statistic(frequency) statistic(percent)
```

Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

Syntax

Basic one-way tabulation

```
table varname [if] [in] [weight] [, options]
```

Customized one-way tabulation

```
table [(rowspec)] [(colspec)] [if] [in] [weight] [, options]
```

rowspec and *colspec* may be empty or may include *varname*, *result*, or *varname* and *result*, where *result* refers to the requested statistics.

<i>options</i>	Description
Main	
nototals	suppress the marginal totals
Statistics	
<u>statistic</u> (<i>stat</i>)	statistic to be reported; default is statistic(frequency) when no weights are specified and statistic(sumw) otherwise
Formats	
nformat(<i>%fmt</i> [<i>results</i>][, basestyle])	specify numeric format
sformat(<i>sfmt</i> [<i>results</i>])	specify string format
Title	
title(<i>string</i>)	add table title
<u>titlestyles</u> (<i>text_styles</i>)	change table title styles
Notes	
note(<i>string</i>)	add table note
<u>notestyles</u> (<i>text_styles</i>)	change table note styles
Export	
export(<i>filename.suffix</i> [, <i>export_opts</i>])	export table
Options	
<u>missing</u>	treat numeric missing values of <i>varname</i> like other values
name(<i>cname</i>)	collect results into a collection named <i>cname</i>
append	append results to an existing collection
replace	replace results of an existing collection
label(<i>filename</i>)	specify the collection labels
style(<i>filename</i> [, override])	specify the collection style
markvar(<i>newvar</i>)	create <i>newvar</i> that identifies observations used in the tabulation

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 **weight**.
strL variables are not allowed; see [U] 12.4.8 **strL**.
markvar() does not appear in the dialog box.

<i>text_styles</i>	Description
<code>font([<i>fontfamily</i>][, <i>font_opts</i>])</code>	specify font style
<code>smcl(<i>smcl</i>)</code>	specify formatting for SMCL files
<code>latex(<i>latex</i>)</code>	specify L ^A T _E X macro
<code>shading(<i>sspec</i>)</code>	set background color, foreground color, and fill pattern

<i>font_opts</i>	Description
<code>size(# [<i>unit</i>])</code>	specify font size
<code>color(<i>color</i>)</code>	specify font color
<code>variant(<i>variant</i>)</code>	specify font variant and capitalization
<code>[no]bold</code>	specify whether to format text as bold
<code>[no]italic</code>	specify whether to format text as italic
<code>[no]strikeout</code>	specify whether to strike out text
<code>[no]underline</code>	specify whether to underline text

<i>suffix</i>	<i>fileformat</i>	Output format
<code>docx</code>	<code>as(docx)</code>	Microsoft Word
<code>html</code>	<code>as(html)</code>	HTML 5 with CSS
<code>pdf</code>	<code>as(pdf)</code>	PDF
<code>xlsx</code>	<code>as(xlsx)</code>	Microsoft Excel 2007/2010 or newer
<code>xls</code>	<code>as(xls)</code>	Microsoft Excel 1997/2003
<code>tex</code>	<code>as(tex)</code>	L ^A T _E X
<code>smcl</code>	<code>as(smcl)</code>	SMCL
<code>txt</code>	<code>as(txt)</code>	plain text
<code>markdown</code>	<code>as(markdown)</code>	Markdown
<code>md</code>	<code>as(md)</code>	Markdown

<i>export_opts</i>	Description
<code>as(<i>fileformat</i>)</code>	specify document type
<code>replace</code>	overwrite existing file
<i>docx_options</i>	available when exporting to .docx files
<i>html_options</i>	available when exporting to .html files
<i>pdf_options</i>	available when exporting to .pdf files
<i>excel_options</i>	available when exporting to .xls and .xlsx files
<i>tex_options</i>	available when exporting to .tex files
<i>smcl_option</i>	available when exporting to .smcl files
<i>txt_option</i>	available when exporting to .txt files
<i>md_option</i>	available when exporting to .markdown and .md files

<i>docx_options</i>	Description
<code><u>no</u>isily</code>	show the putdocx commands used to export to the Microsoft Word file
<code>dofile(<i>filename</i>[, replace])</code>	save the putdocx commands used for exporting to the named do-file

<i>html_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file
cssfile(<i>cssfile</i>)	define the styles in <i>cssfile</i> instead of <i>filename</i>
prefix(<i>prefix</i>)	use <i>prefix</i> to identify style classes

<i>pdf_options</i>	Description
noisily	show the putpdf commands used to export to the PDF file
dofile(<i>filename</i> [, replace])	save the putpdf commands used for exporting to the named do-file

<i>excel_options</i>	Description
noisily	show the putexcel commands used to export to the Excel file
dofile(<i>filename</i> [, replace])	save the putexcel commands used for exporting to the named do-file
sheet(<i>sheetname</i> [, replace])	specify the worksheet to use; the default sheet name is Sheet1
cell(<i>cell</i>)	specify the Excel upper-left cell as the starting position to export the table; the default is cell (A1)
modify	modify Excel file
noopen	do not open Excel file in memory

noopen does not appear in the dialog box.

<i>tex_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file

<i>smcl_option</i>	Description
append	append to an existing file

<i>txt_option</i>	Description
append	append to an existing file

<i>md_option</i>	Description
append	append to an existing file

fontfamily specifies a valid font family.

unit may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

variant may be allcaps, smallcaps, or normal.

variant(allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

variant(smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L^AT_EX, and HTML files.

variant(normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

smcl specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.

latex specifies the name of a L^AT_EX macro to render text for L^AT_EX output. Example L^AT_EX macro names are textbf, textsf, textrm, and texttt. Custom L^AT_EX macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L^AT_EX:

`\latex {text}`

sspec is

`[background(bcolor) foreground(fgcolor) pattern(fpattern)]`

bcolor specifies the background color.

fgcolor specifies the foreground color.

fpattern specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

bcolor, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form ### ##, for example, 171 248 103; or a valid RRGGBB hex value in the form #####, for example, ABF867.

Options

Main

`nototals` prevents table from displaying the row or column totals.

Statistics

`statistic(stat)` specifies the statistic to be displayed. `statistic()` may be repeated to request multiple statistics.

Available statistics are

<i>stat</i>	Definition
<code>frequency</code>	frequency
<code>sumw</code>	sum of weights
<code>proportion</code>	proportion
<code>percent</code>	percentage
<code>rawproportion</code>	proportion ignoring optionally specified weights
<code>rawpercent</code>	percentage ignoring optionally specified weights

Formats

`nformat(%fmt [results] [, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

results may be any statistic named in option `statistic()` (that is, any *stat*).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec* and *colspec*). The default format of these variables is taken from the dataset.

`basestyle` indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and `%s`. Here `%s` refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around `%s` in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s) percent)`.

results may be any statistic named in option `statistic()` (that is, any *stat*).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include `%`, type `%%`. To include `\`, type `\\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline)` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a \LaTeX , a SMCL, a `txt`, or a Markdown file. When you export to HTML and \LaTeX files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or \LaTeX document. By default, `table` produces complete HTML and \LaTeX documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname[, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

Options

`missing` specifies that numeric missing values of *varname* be treated as valid categories. By default, observations with a numeric missing value in *varname* are omitted.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table_style](#).

The following option is available with `table` but is not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

Remarks and examples

Remarks are presented under the following headings:

[Tabulation of one variable](#)
[Tabulation, including percentages](#)
[Customizing results](#)
[Advanced customization](#)

Tabulation of one variable

To obtain a one-way tabulation that reports the number of observations for each level of a categorical variable, we need specify only the name of the categorical variable following table.

To demonstrate, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). We tabulate the hlthstat variable, which contains individuals’ self-reported health status categories.

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. table hlthstat
```

	Frequency
Health status	
Excellent	2,407
Very good	2,591
Good	2,938
Fair	1,670
Poor	729
Total	10,335

We see that more people self-reported having excellent, very good, or good health status than reported having fair or poor health status.

Above, we see frequencies for those who reported a health status. This information is not available for some individuals in the dataset. We can determine how many missing values we have for this variable by adding the missing option

```
. table hlthstat, missing
```

	Frequency
Health status	
Excellent	2,407
Very good	2,591
Good	2,938
Fair	1,670
Poor	729
.	2
Blank but applicable	14
Total	10,351

We find that there is missing health status data for 16 individuals—2 with a generic missing value and 14 whose responses were labeled “Blank but applicable”.

Tabulation, including percentages

In addition to frequencies, we can report the proportion or percentage of observations in each health status category. By default, table reports frequencies, which is equivalent to including the `statistic(frequency)` option. Here we include that option along with the `statistic(percent)` option to report both frequencies and percentages.

```
. table hlthstat, statistic(frequency) statistic(percent)
```

	Frequency	Percent
Health status		
Excellent	2,407	23.29
Very good	2,591	25.07
Good	2,938	28.43
Fair	1,670	16.16
Poor	729	7.05
Total	10,335	100.00

Now, it is clear that 28.43% of respondents reported having good health.

Customizing results

There are a number of ways that you can customize the results in your table.

In some cases, you may prefer to place frequencies and percentages on the rows and the levels of the variable being tabulated on the columns. To do this, you can include both the row and column specifications in parentheses following table. Here we use `result` in the first set of parentheses to request that the statistics be placed on rows and the variable `hlthstat` in the second set of parentheses to request that the levels of this variable be placed on the columns.

```
. table (result) (hlthstat), statistic(frequency) statistic(percent)
```

	Health status					
	Excellent	Very good	Good	Fair	Poor	Total
Frequency	2,407	2,591	2,938	1,670	729	10,335
Percent	23.29	25.07	28.43	16.16	7.05	100.00

Alternatively, we could have omitted `result` and typed

```
. table () (hlthstat), statistic(freq) statistic(percent)
```

Because we requested that `hlthstat` be moved to the columns by specifying it in the second set of parentheses, table automatically moves the requested statistics to the rows.

If instead of a short and wide table, you prefer a tall and narrow table, you can specify that both the levels of `hlthstat` and the statistics be used to define the rows by including the variable name and result in the first set of parentheses.

```
. table (hlthstat result), statistic(frequency) statistic(percent)
```

Health status	
Excellent	
Frequency	2,407
Percent	23.29
Very good	
Frequency	2,591
Percent	25.07
Good	
Frequency	2,938
Percent	28.43
Fair	
Frequency	1,670
Percent	16.16
Poor	
Frequency	729
Percent	7.05
Total	
Frequency	10,335
Percent	100.00

In addition to modifying the layout of the table, we may want to customize the results reported within the cells of the table. For instance, we can specify that the percentages be reported using only one decimal place by using the `nformat()` option. Here we return to the two-column table layout.

```
. table hlthstat, statistic(frequency) statistic(percent)
> nformat(%5.1f percent)
```

	Frequency	Percent
Health status		
Excellent	2,407	23.3
Very good	2,591	25.1
Good	2,938	28.4
Fair	1,670	16.2
Poor	729	7.1
Total	10,335	100.0

The `table` command produces its output using a default set of styles, typically those defined in the `table` style but could be any other style that you have set as the default by using `set table_style`. When customizing our tables, we can take advantage of one of the styles described in [TABLES] **Predefined styles**. For instance, for tables with only one or two row variables, row labels that are right-aligned may be preferred. Here we use the `table-right` style.

```
. table hlthstat, statistic(frequency) statistic(percent)
> nformat(%5.1f percent) style(table-right)
```

	Frequency	Percent
Health status		
Excellent	2,407	23.3
Very good	2,591	25.1
Good	2,938	28.4
Fair	1,670	16.2
Poor	729	7.1
Total	10,335	100.0

Advanced customization

Customization can go beyond the predefined styles and options available to you in the `table` command. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to produce highly customized tables and to export those tables to presentation-ready formats such as HTML, Word, L^AT_EX, PDF, Excel, and more.

Continuing with our example above, if we want to shorten the labels on the column headings, we could use the `collect label levels` command to define our new labels. After a change using `collect`, we can use `collect preview` to see the results.

```
. collect label levels result frequency "Freq" percent "%", modify
. collect preview
```

	Freq	%
Health status		
Excellent	2,407	23.3
Very good	2,591	25.1
Good	2,938	28.4
Fair	1,670	16.2
Poor	729	7.1
Total	10,335	100.0

We could continue making style edits to this table. When we are happy with the result, we can then export it to the format of our choice using `collect export`.

See [TABLES] **collect label** for details on the `collect label` command we used here, and for an overview of the `collect` suite, see [TABLES] **Intro**.

Stored results

table stores the following in `r()`:

Scalars

`r(N)` number of observations

Description

In this entry, we discuss how to use `table` to create a two-way tabulation, including frequencies, percentages, and proportions.

Quick start

Table of frequencies, with rows defined by categories of `a1` and columns defined by categories of `a2`

```
table a1 a2
```

Same as above, but treat missing values like other values

```
table a1 a2, missing
```

Table with the percentage of observations in each cell

```
table a1 a2, statistic(percent)
```

For each category of `a1`, report the percentage of observations across levels of `a2`

```
table a1 a2, statistic(percent, across(a2))
```

Report frequencies and the proportion of observations across categories of `a1`, enclosed within parentheses

```
table a1 a2, statistic(frequency) ///  
    statistic(proportion, across(a1)) sformat("%s") proportion)
```

Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

Syntax

Basic two-way tabulation

```
table rowvar colvar [if] [in] [weight] [, options]
```

Customized two-way tabulation

```
table [ (rowspec) ] [ (colspec) ] [if] [in] [weight] [, options]
```

rowspec may be empty or may include *rowvar*, *result*, or *rowvar* and *result*, where *result* refers to the requested statistics.

colspec may be empty or may include *colvar*, *result*, or *colvar* and *result*, where *result* refers to the requested statistics.

options	Description
Main	
totals(<i>totals</i>)	report only the specified totals
nototals	suppress the marginal totals
Statistics	
<u>statistic</u> (<i>stat</i> [, <i>statopts</i>])	statistic to be reported; default is <code>statistic(frequency)</code> when no weights are specified and <code>statistic(sumw)</code> otherwise
Formats	
<code>nformat(%fmt [results] [, basestyle])</code>	specify numeric format
<code>sformat(sfmt [results])</code>	specify string format
Title	
<code>title(string)</code>	add table title
<code>titlestyles(text_styles)</code>	change table title styles
Notes	
<code>note(string)</code>	add table note
<code>notestyles(text_styles)</code>	change table note styles
Export	
<code>export(filename.suffix [, export_opts])</code>	export table
Options	
<u>missing</u>	treat numeric missing values of <i>rowvar</i> and <i>colvar</i> like other values
<u>zerocounts</u>	report 0 for empty cell counts
<code>name(cname)</code>	collect results into a collection named <i>cname</i>
<code>append</code>	append results to an existing collection
<code>replace</code>	replace results of an existing collection
<code>label(filename)</code>	specify the collection labels
<code>style(filename [, override])</code>	specify the collection style
<code>markvar(newvar)</code>	create <i>newvar</i> that identifies observations used in the tabulation

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 **weight**.
strL variables are not allowed; see [U] 12.4.8 **strL**.
markvar() does not appear in the dialog box.

<i>text_styles</i>	Description
<code>font([fontfamily][, font_opts])</code>	specify font style
<code>smcl(smcl)</code>	specify formatting for SMCL files
<code>latex(latex)</code>	specify L ^A T _E X macro
<code>shading(sspec)</code>	set background color, foreground color, and fill pattern

<i>font_opts</i>	Description
<code>size(# [unit])</code>	specify font size
<code>color(color)</code>	specify font color
<code>variant(variant)</code>	specify font variant and capitalization
<code>[no]bold</code>	specify whether to format text as bold
<code>[no]italic</code>	specify whether to format text as italic
<code>[no]strikeout</code>	specify whether to strike out text
<code>[no]underline</code>	specify whether to underline text

<i>suffix</i>	<i>fileformat</i>	Output format
<code>docx</code>	<code>as(docx)</code>	Microsoft Word
<code>html</code>	<code>as(html)</code>	HTML 5 with CSS
<code>pdf</code>	<code>as(pdf)</code>	PDF
<code>xlsx</code>	<code>as(xlsx)</code>	Microsoft Excel 2007/2010 or newer
<code>xls</code>	<code>as(xls)</code>	Microsoft Excel 1997/2003
<code>tex</code>	<code>as(tex)</code>	L ^A T _E X
<code>smcl</code>	<code>as(smcl)</code>	SMCL
<code>txt</code>	<code>as(txt)</code>	plain text
<code>markdown</code>	<code>as(markdown)</code>	Markdown
<code>md</code>	<code>as(md)</code>	Markdown

<i>export_opts</i>	Description
<code>as(fileformat)</code>	specify document type
<code>replace</code>	overwrite existing file
<code>docx_options</code>	available when exporting to .docx files
<code>html_options</code>	available when exporting to .html files
<code>pdf_options</code>	available when exporting to .pdf files
<code>excel_options</code>	available when exporting to .xls and .xlsx files
<code>tex_options</code>	available when exporting to .tex files
<code>smcl_option</code>	available when exporting to .smcl files
<code>txt_option</code>	available when exporting to .txt files
<code>md_option</code>	available when exporting to .markdown and .md files

<i>docx_options</i>	Description
<code>noisily</code>	show the putdocx commands used to export to the Microsoft Word file
<code>dofile(filename[, replace])</code>	save the putdocx commands used for exporting to the named do-file

<i>html_options</i>	Description
<code>append</code>	append to an existing file
<code>tableonly</code>	export only the table to the specified file
<code>cssfile(cssfile)</code>	define the styles in <i>cssfile</i> instead of <i>filename</i>
<code>prefix(prefix)</code>	use <i>prefix</i> to identify style classes

<i>pdf_options</i>	Description
<code>noisily</code>	show the putpdf commands used to export to the PDF file
<code>dofile(filename[, replace])</code>	save the putpdf commands used for exporting to the named do-file

<i>excel_options</i>	Description
<code>noisily</code>	show the putexcel commands used to export to the Excel file
<code>dofile(filename[, replace])</code>	save the putexcel commands used for exporting to the named do-file
<code>sheet(sheetname[, replace])</code>	specify the worksheet to use; the default sheet name is Sheet1
<code>cell(cell)</code>	specify the Excel upper-left cell as the starting position to export the table; the default is cell(A1)
<code>modify</code>	modify Excel file
<code>noopen</code>	do not open Excel file in memory

`noopen` does not appear in the dialog box.

<i>tex_options</i>	Description
<code>append</code>	append to an existing file
<code>tableonly</code>	export only the table to the specified file

<i>smcl_option</i>	Description
<code>append</code>	append to an existing file

<i>txt_option</i>	Description
<code>append</code>	append to an existing file

<i>md_option</i>	Description
<code>append</code>	append to an existing file

fontfamily specifies a valid font family.

unit may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

variant may be allcaps, smallcaps, or normal.

variant(allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

variant(smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L^AT_EX, and HTML files.

variant(normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

smcl specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.

latex specifies the name of a L^AT_EX macro to render text for L^AT_EX output. Example L^AT_EX macro names are textbf, textsf, textrm, and texttt. Custom L^AT_EX macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L^AT_EX:

`\latex {text}`

sspec is

`[background(bcolor) foreground(fgcolor) pattern(fpattern)]`

bcolor specifies the background color.

fgcolor specifies the foreground color.

fpattern specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

bcolor, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form ### ##, for example, 171 248 103; or a valid RRGGBB hex value in the form #####, for example, ABF867.

Options

Main

`totals` (*totals*) and `nototals` control which totals are to be displayed in the table. By default, all totals are reported.

`totals` (*totals*) specifies which margin totals to display in the reported table. *totals* can contain *rowvar*, *colvar*, and their interaction. Interactions can be specified by using the `#` operator.

`nototals` prevents table from displaying any totals.

Statistics

`statistic` (*stat* [, *statopts*]) specifies the statistic to be displayed. `statistic()` may be repeated to request multiple statistics.

Available statistics are

<i>stat</i>	Definition
<u>frequency</u>	frequency
<u>sumw</u>	sum of weights
<u>proportion</u>	proportion
<u>percent</u>	percentage
<u>rawproportion</u>	proportion ignoring optionally specified weights
<u>rawpercent</u>	percentage ignoring optionally specified weights

The following options may be specified in combination with statistics `proportion`, `percent`, `rawproportion`, and `rawpercent`:

<i>statopts</i>	Definition
<code>across</code> (<i>rowvar</i>)	percentages or proportions across rows
<code>across</code> (<i>colvar</i>)	percentages or proportions across columns
<code>total</code>	compute overall percentages or proportions

Formats

`nformat(%fmt [results][, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results. *results* may be any statistic named in option `statistic()` (that is, any *stat*).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec* and *colspec*). The default format of these variables is taken from the dataset.

basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and *%s*. Here *%s* refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around *%s* in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s)" percent)`.

results may be any statistic named in option `statistic()` (that is, any *stat*).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type `%%`. To include \, type `\\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and L^AT_EX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for L^AT_EX output. This style property is applicable only when publishing items from a collection to a L^AT_EX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and L^AT_EX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a \LaTeX , a SMCL, a `txt`, or a Markdown file. When you export to HTML and \LaTeX files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or \LaTeX document. By default, `table` produces complete HTML and \LaTeX documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

Options

`missing` specifies that numeric missing values of *rowvar* or *colvar* be treated as valid categories. By default, observations with a numeric missing value in *rowvar* or *colvar* are omitted.

`zerocounts` specifies that `table` report a 0 in empty cells for the frequency statistic.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table_style](#).

The following option is available with `table` but is not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

Remarks and examples

Remarks are presented under the following headings:

Tabulation of two variables
Tabulation, including percentages
Customizing results

Tabulation of two variables

To obtain a two-way tabulation that reports the number of observations across the levels of two categorical variables, we need to specify only the names of the categorical variables following `table`.

To demonstrate, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981) and create a two-way tabulation of self-reported health status (`hlthstat`) by region of the USA (`region`).

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. table hlthstat region
```

	Region				
	NE	MW	S	W	Total
Health status					
Excellent	562	730	546	569	2,407
Very good	558	721	651	661	2,591
Good	631	735	807	765	2,938
Fair	257	419	532	462	1,670
Poor	77	167	317	168	729
Total	2,085	2,772	2,853	2,625	10,335

We can examine the missing values as well by adding the `missing` option.

```
. table hlthstat region, missing
```

	Region				
	NE	MW	S	W	Total
Health status					
Excellent	562	730	546	569	2,407
Very good	558	721	651	661	2,591
Good	631	735	807	765	2,938
Fair	257	419	532	462	1,670
Poor	77	167	317	168	729
.	1	1			2
Blank but applicable	10	1		3	14
Total	2,096	2,774	2,853	2,628	10,351

We find that 16 individuals have a missing health status, and the majority of these are from individuals in the Northeast. The empty cells correspond to regions in which all the individuals have a nonmissing health status; we can fill in these empty cells with 0s:

```
. table hlthstat region, missing zerocounts
```

	NE	MW	Region S	W	Total
Health status					
Excellent	562	730	546	569	2,407
Very good	558	721	651	661	2,591
Good	631	735	807	765	2,938
Fair	257	419	532	462	1,670
Poor	77	167	317	168	729
.	1	1	0	0	2
Blank but applicable	10	1	0	3	14
Total	2,096	2,774	2,853	2,628	10,351

Tabulation, including percentages

Instead of frequencies, we can request that table report the percentage of observations in each cell of the table by specifying the `statistic(percent)` option.

```
. table hlthstat region, statistic(percent)
```

	NE	MW	Region S	W	Total
Health status					
Excellent	5.44	7.06	5.28	5.51	23.29
Very good	5.40	6.98	6.30	6.40	25.07
Good	6.11	7.11	7.81	7.40	28.43
Fair	2.49	4.05	5.15	4.47	16.16
Poor	0.75	1.62	3.07	1.63	7.05
Total	20.17	26.82	27.61	25.40	100.00

We see that 5.44% of all observations correspond to individuals in excellent health who live in the Northeast.

Rather than looking at overall percentages, we might want to examine the distribution of observations within each health status level across the four regions. To do this, we can add the `across(region)` option.

```
. table hlthstat region, statistic(percent, across(region))
```

	NE	MW	Region S	W	Total
Health status					
Excellent	23.35	30.33	22.68	23.64	100.00
Very good	21.54	27.83	25.13	25.51	100.00
Good	21.48	25.02	27.47	26.04	100.00
Fair	15.39	25.09	31.86	27.66	100.00
Poor	10.56	22.91	43.48	23.05	100.00
Total	20.17	26.82	27.61	25.40	100.00

Of individuals reporting excellent health, 23.35% live in the Northeast, while 30.33% live in the Midwest, 22.68% live in the South, and 23.64% live in the West.

We can also look at the distribution of observations across health status categories within each region.

```
. table hlthstat region, statistic(percent, across(hlthstat))
```

	Region				
	NE	MW	S	W	Total
Health status					
Excellent	26.95	26.33	19.14	21.68	23.29
Very good	26.76	26.01	22.82	25.18	25.07
Good	30.26	26.52	28.29	29.14	28.43
Fair	12.33	15.12	18.65	17.60	16.16
Poor	3.69	6.02	11.11	6.40	7.05
Total	100.00	100.00	100.00	100.00	100.00

Of individuals living in the South, 11.11% report having poor health. This is notably higher than the percentage of individuals reporting poor health in the other regions.

It is often helpful to see both frequencies and percentages in the same table. To do this, we can add the `statistic(frequency)` option to our command.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat))
```

	Region				
	NE	MW	S	W	Total
Health status					
Excellent					
Frequency	562	730	546	569	2,407
Percent	26.95	26.33	19.14	21.68	23.29
Very good					
Frequency	558	721	651	661	2,591
Percent	26.76	26.01	22.82	25.18	25.07
Good					
Frequency	631	735	807	765	2,938
Percent	30.26	26.52	28.29	29.14	28.43
Fair					
Frequency	257	419	532	462	1,670
Percent	12.33	15.12	18.65	17.60	16.16
Poor					
Frequency	77	167	317	168	729
Percent	3.69	6.02	11.11	6.40	7.05
Total					
Frequency	2,085	2,772	2,853	2,625	10,335
Percent	100.00	100.00	100.00	100.00	100.00

Customizing results

There are several ways that we can customize the results of our two-way tabulation.

For instance, in some cases, we may prefer to omit the row and column totals. We can specify the `nototals` option to suppress these totals.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat)) nototals
```

	Region			
	NE	MW	S	W
Health status				
Excellent				
Frequency	562	730	546	569
Percent	26.95	26.33	19.14	21.68
Very good				
Frequency	558	721	651	661
Percent	26.76	26.01	22.82	25.18
Good				
Frequency	631	735	807	765
Percent	30.26	26.52	28.29	29.14
Fair				
Frequency	257	419	532	462
Percent	12.33	15.12	18.65	17.60
Poor				
Frequency	77	167	317	168
Percent	3.69	6.02	11.11	6.40

Or perhaps we want to see row totals or column totals but not both. We can include the `totals(region)` option to display only the region totals.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat)) totals(region)
```

	Region			
	NE	MW	S	W
Health status				
Excellent				
Frequency	562	730	546	569
Percent	26.95	26.33	19.14	21.68
Very good				
Frequency	558	721	651	661
Percent	26.76	26.01	22.82	25.18
Good				
Frequency	631	735	807	765
Percent	30.26	26.52	28.29	29.14
Fair				
Frequency	257	419	532	462
Percent	12.33	15.12	18.65	17.60
Poor				
Frequency	77	167	317	168
Percent	3.69	6.02	11.11	6.40
Total				
Frequency	2,085	2,772	2,853	2,625
Percent	100.00	100.00	100.00	100.00

Once we have the statistics we want in our table, we can format the way that they appear. If, for instance, we want to add a percent sign to each of our percentages, we can specify the `sformat("%s%" percent)` option. The `sformat()` option specifies that we want to add string characters to the numbers in the table. Within it, we refer to the numeric values as `%s` and place any string characters we want around this. The percent sign is unique because it already has special meaning in this context. Therefore, we must type two percent signs, `%%`, to display one. Finally, by adding `percent` within the `sformat()` option, we specify that we want to apply this format only to the percent statistics.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat)) totals(region)
> smformat("%s%" percent)
```

	Region			
	NE	MW	S	W
Health status				
Excellent				
Frequency	562	730	546	569
Percent	26.95%	26.33%	19.14%	21.68%
Very good				
Frequency	558	721	651	661
Percent	26.76%	26.01%	22.82%	25.18%
Good				
Frequency	631	735	807	765
Percent	30.26%	26.52%	28.29%	29.14%
Fair				
Frequency	257	419	532	462
Percent	12.33%	15.12%	18.65%	17.60%
Poor				
Frequency	77	167	317	168
Percent	3.69%	6.02%	11.11%	6.40%
Total				
Frequency	2,085	2,772	2,853	2,625
Percent	100.00%	100.00%	100.00%	100.00%

Now that we have added the percent sign, we could argue that the labels `Frequency` and `Percent` are unnecessary. If we remove these statistic names from the row labels, we might also want to right-align the remaining labels in row headers. Finally, for readability, we could insert blank lines between levels of `hlthstat`. We could use the `collect` suite of commands to make these style changes. Fortunately, however, one of our [predefined styles](#), `table-tab2`, includes these style changes, and we can select it using the `style()` option.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat)) totals(region)
> sformat("%s%" percent) style(table-tab2)
```

	Region			
	NE	MW	S	W
Health status				
Excellent	562 26.95%	730 26.33%	546 19.14%	569 21.68%
Very good	558 26.76%	721 26.01%	651 22.82%	661 25.18%
Good	631 30.26%	735 26.52%	807 28.29%	765 29.14%
Fair	257 12.33%	419 15.12%	532 18.65%	462 17.60%
Poor	77 3.69%	167 6.02%	317 11.11%	168 6.40%
Total	2,085 100.00%	2,772 100.00%	2,853 100.00%	2,625 100.00%

You can learn more about the predefined styles described at [\[TABLES\] Predefined styles](#). If none of these provide the exact style you want for your table, you can further customize the results by using the collect suite of commands. To learn more, see [\[TABLES\] Intro](#).

If you wish to include this table in a paper, on a webpage, or in another format, you can easily export it in \LaTeX , Word, Excel, HTML, and a variety of other formats by using the `export()` option.

Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

Description

In this entry, we discuss how to use the `table` command to create tables displaying frequencies, percentages, and proportions across levels of three or more variables. Additionally, we demonstrate how a single `table` command can create multiple tables corresponding to levels of variables or different statistics.

Quick start

Table of frequencies with rows defined by the levels of `a1` and columns defined by the categories of `a2` and `a3`

```
table (a1) (a2 a3)
```

Same as above, but with rows defined by levels of `a1` and `a2` and columns defined by levels of `a3`

```
table (a1 a2) (a3)
```

Separate tables for each level `a3` with the rows of each table defined by the levels of `a1` and the columns defined by levels of `a2`

```
table (a1) (a2) (a3)
```

Report percentages of observations in each cell rather than frequencies

```
table (a1) (a2 a3), statistic(percent)
```

Report both frequencies and percentages

```
table (a1) (a2 a3), statistic(percent) statistic(frequency)
```

Report the percentages across levels of `a3`

```
table (a1) (a2 a3), statistic(percent, across(a3))
```

Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

Syntax

Table with rows defined by multiple variables

```
table rowvars colvar [if] [in] [weight] [, options]
```

Table with columns defined by multiple variables

```
table rowvar (colvars) [if] [in] [weight] [, options]
```

Table with rows and columns defined by multiple variables

```
table (rowvars) (colvars) [if] [in] [weight] [, options]
```

Multiple multiway tables

```
table (rowvars) (colvars) (tabvars) [if] [in] [weight] [, options]
```

Customized multiway tables

```
table (rowspec) (colspec) [(tabspec)] [if] [in] [weight] [, options]
```

rowspec, *colspec*, and *tabspec* may be empty or may include variable names or any of the following keywords:

<i>keyword</i>	Description
result	requested statistics
across	index across() specifications

<i>options</i>	Description
Main	
totals (<i>totals</i>)	report only the specified totals
nototals	suppress the marginal totals
Statistics	
statistic (<i>stat</i> [, <i>statopts</i>])	statistic to be reported; default is statistic (frequency) when no weights are specified and statistic (sumw) otherwise
Formats	
nformat (% <i>fmt</i> [<i>results</i>] [, <i>basestyle</i>])	specify numeric format
sformat (<i>sfmt</i> [<i>results</i>])	specify string format
Title	
title (<i>string</i>)	add table title
titlestyles (<i>text_styles</i>)	change table title styles
Notes	
note (<i>string</i>)	add table note
notestyles (<i>text_styles</i>)	change table note styles
Export	
export (<i>filename.suffix</i> [, <i>export_opts</i>])	export table
Options	
listwise	use listwise deletion to handle missing values
missing	treat numeric missing values like other values
showcounts	show sample size for all variables in statistic () option
zerocounts	report 0 for empty cell counts
name (<i>cname</i>)	collect results into a collection named <i>cname</i>
append	append results to an existing collection
replace	replace results of an existing collection
label (<i>filename</i>)	specify the collection labels
style (<i>filename</i> [, <i>override</i>])	specify the collection style
markvar (<i>newvar</i>)	create <i>newvar</i> to identify observations used to compute the statistics

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 **weight**.

strL variables are not allowed; see [U] 12.4.8 **strL**.

markvar() does not appear in the dialog box.

<i>text_styles</i>	Description
<code>font([<i>fontfamily</i>][, <i>font_opts</i>])</code>	specify font style
<code>smcl(<i>smcl</i>)</code>	specify formatting for SMCL files
<code>latex(<i>latex</i>)</code>	specify L ^A T _E X macro
<code>shading(<i>sspec</i>)</code>	set background color, foreground color, and fill pattern

<i>font_opts</i>	Description
<code>size(# [<i>unit</i>])</code>	specify font size
<code>color(<i>color</i>)</code>	specify font color
<code>variant(<i>variant</i>)</code>	specify font variant and capitalization
<code>[no]bold</code>	specify whether to format text as bold
<code>[no]italic</code>	specify whether to format text as italic
<code>[no]strikeout</code>	specify whether to strike out text
<code>[no]underline</code>	specify whether to underline text

<i>suffix</i>	<i>fileformat</i>	Output format
<code>docx</code>	<code>as(docx)</code>	Microsoft Word
<code>html</code>	<code>as(html)</code>	HTML 5 with CSS
<code>pdf</code>	<code>as(pdf)</code>	PDF
<code>xlsx</code>	<code>as(xlsx)</code>	Microsoft Excel 2007/2010 or newer
<code>xls</code>	<code>as(xls)</code>	Microsoft Excel 1997/2003
<code>tex</code>	<code>as(tex)</code>	L ^A T _E X
<code>smcl</code>	<code>as(smcl)</code>	SMCL
<code>txt</code>	<code>as(txt)</code>	plain text
<code>markdown</code>	<code>as(markdown)</code>	Markdown
<code>md</code>	<code>as(md)</code>	Markdown

<i>export_opts</i>	Description
<code>as(<i>fileformat</i>)</code>	specify document type
<code>replace</code>	overwrite existing file
<i>docx_options</i>	available when exporting to .docx files
<i>html_options</i>	available when exporting to .html files
<i>pdf_options</i>	available when exporting to .pdf files
<i>excel_options</i>	available when exporting to .xls and .xlsx files
<i>tex_options</i>	available when exporting to .tex files
<i>smcl_option</i>	available when exporting to .smcl files
<i>txt_option</i>	available when exporting to .txt files
<i>md_option</i>	available when exporting to .markdown and .md files

<i>docx_options</i>	Description
<code>noisily</code>	show the putdocx commands used to export to the Microsoft Word file
<code>dofile(<i>filename</i>[, replace])</code>	save the putdocx commands used for exporting to the named do-file

<i>html_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file
cssfile(<i>cssfile</i>)	define the styles in <i>cssfile</i> instead of <i>filename</i>
prefix(<i>prefix</i>)	use <i>prefix</i> to identify style classes

<i>pdf_options</i>	Description
noisily	show the putpdf commands used to export to the PDF file
dofile(<i>filename</i> [, replace])	save the putpdf commands used for exporting to the named do-file

<i>excel_options</i>	Description
noisily	show the putexcel commands used to export to the Excel file
dofile(<i>filename</i> [, replace])	save the putexcel commands used for exporting to the named do-file
sheet(<i>sheetname</i> [, replace])	specify the worksheet to use; the default sheet name is Sheet1
cell(<i>cell</i>)	specify the Excel upper-left cell as the starting position to export the table; the default is cell(A1)
modify	modify Excel file
noopen	do not open Excel file in memory

noopen does not appear in the dialog box.

<i>tex_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file

<i>smcl_option</i>	Description
append	append to an existing file

<i>txt_option</i>	Description
append	append to an existing file

<i>md_option</i>	Description
append	append to an existing file

fontfamily specifies a valid font family.

unit may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

variant may be allcaps, smallcaps, or normal.

variant(allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

variant(smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L^AT_EX, and HTML files.

variant(normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

smcl specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.

latex specifies the name of a L^AT_EX macro to render text for L^AT_EX output. Example L^AT_EX macro names are textbf, textsf, textrm, and texttt. Custom L^AT_EX macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L^AT_EX:

`\latex {text}`

sspec is

[background(*bcolor*) foreground(*fgcolor*) pattern(*fpattern*)]

bcolor specifies the background color.

fgcolor specifies the foreground color.

fpattern specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

bcolor, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form ### # # #, for example, 171 248 103; or a valid RRGGBB hex value in the form #####, for example, ABF867.

Options

Main

totals(*totals*) and *nototals* control which totals are to be displayed in the table. By default, all totals are reported.

totals(*totals*) specifies that totals be displayed only for the variables or interactions specified. *totals* can contain *rowvars*, *colvars*, *tabvars*, and interactions between any of these variables. Interactions can be specified by using the # operator.

nototals prevents table from displaying any totals.

Statistics

`statistic(stat[, statopts])` specifies the statistic to be displayed. `statistic()` may be repeated to request multiple statistics.

Available statistics are

<i>stat</i>	Definition
<code>frequency</code>	frequency
<code>sumw</code>	sum of weights
<code>proportion</code>	proportion
<code>percent</code>	percentage
<code>rawproportion</code>	proportion ignoring optionally specified weights
<code>rawpercent</code>	percentage ignoring optionally specified weights

The following options may be specified in combination with statistics `proportion`, `percent`, `rawproportion`, and `rawpercent`:

<i>statopts</i>	Definition
<code>across(cellspec)</code>	percentages or proportions across levels of variables or interactions
<code>total</code>	compute overall percentages or proportions

cellspect may contain *rowvars*, *colvars*, *tabvars*, or an interaction between any of these variables. Interactions can be specified by using the `#` operator.

Formats

`nformat(%fmt [results][, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results. *results* may be any statistic named in option `statistic()` (that is, any *stat*).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*). The default format of these variables is taken from the dataset.

basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and `%s`. Here `%s` refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around `%s` in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s)" percent)`.

results may be any statistic named in option `statistic()` (that is, any *stat*).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include `%`, type `%%`. To include `\`, type `\\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and L^AT_EX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for L^AT_EX output. This style property is applicable only when publishing items from a collection to a L^AT_EX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and L^AT_EX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Notes

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a \LaTeX , a SMCL, a `txt`, or a Markdown file. When you export to HTML and \LaTeX files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or \LaTeX document. By default, `table` produces complete HTML and \LaTeX documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname[, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

Options

`listwise` handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any variable specified in a `statistic()` option is missing for that observation. By default, `table` will omit an observation only if all variables specified in all `statistic()` options are missing for that observation.

`missing` specifies that numeric missing values of any *rowvars*, *colvars*, or *tabvars* be treated as valid categories. By default, observations with a numeric missing value in *rowvars*, *colvars*, or *tabvars* are omitted.

`showcounts` specifies that `table` report the sample size for each variable specified in option `statistic()`.

`zerocounts` specifies that `table` report a 0 in empty cells for the frequency statistic.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table_style](#).

The following option is available with `table` but is not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Tables with columns defined by multiple variables](#)

[Appending tables](#)

[Multiple tables with specified totals](#)

Introduction

The `table` command allows you to create complex tables beyond one- and two-way tabulations. In multiway tabulations, you can display frequencies across levels of two or more variables. You can have levels of one variable nested within levels of another variable in columns, in rows, or in both dimensions. And with a single command, you can create separate tables for levels of one or more variables or for different results.

Tables with columns defined by multiple variables

We use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). The data contain some demographic information, such as the age, sex, and race of participants. The dataset also contains some measures of health, including whether the individual has high blood pressure (`highbp`).

Before we create any tables, we will modify a few labels in our dataset so that they will appear as we wish in our tables.

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. label define yesno 0 "No" 1 "Yes"
. label values highbp diabetes heartatk yesno
. label variable diabetes "Diabetes"
```

Suppose we want to examine how many males and females in each age group have high blood pressure. Let's place the levels of age group on the rows and the levels of high blood pressure and sex on the columns.

```
. table (agegrp) (sex highbp), nototals
```

Age group	Sex			
	Male		Female	
	High blood pressure		High blood pressure	
	No	Yes	No	Yes
20–29	825	291	1,103	101
30–39	480	290	687	165
40–49	336	274	434	228
50–59	255	347	335	354
60–69	568	801	625	866
70+	147	301	180	358

By default, `table` includes the totals for each category; we added the `nototals` option to suppress them here.

To better compare the occurrence of high blood pressure, let's now compute percentages of highbp. Below, we create the same table, but within each sex and age group combination, we report the percentage of individuals with and without high blood pressure.

```
. table (agegrp) (sex highbp), nototals statistic(percent, across(highbp))
```

	Sex			
	Male		Female	
	High blood pressure		High blood pressure	
	No	Yes	No	Yes
Age group				
20-29	73.92	26.08	91.61	8.39
30-39	62.34	37.66	80.63	19.37
40-49	55.08	44.92	65.56	34.44
50-59	42.36	57.64	48.62	51.38
60-69	41.49	58.51	41.92	58.08
70+	32.81	67.19	33.46	66.54

Here we see that 26.08% of males in their 20s have high blood pressure and only 8.39% of females in their 20s have high blood pressure.

If we had simply typed `statistic(percent)`, then we would see the percentage of observations in each cell. With the suboption `across()`, we can compute the percentage within each sex and age group combination (across levels of highbp).

Next, let's request that percentages be calculated across the categories of high blood pressure and sex. We can alternatively think of this as being percentages within age group.

```
. table (agegrp) (sex highbp), nototals statistic(percent, across(highbp#sex))
```

	Sex			
	Male		Female	
	High blood pressure		High blood pressure	
	No	Yes	No	Yes
Age group				
20-29	35.56	12.54	47.54	4.35
30-39	29.59	17.88	42.36	10.17
40-49	26.42	21.54	34.12	17.92
50-59	19.75	26.88	25.95	27.42
60-69	19.86	28.01	21.85	30.28
70+	14.91	30.53	18.26	36.31

Here we see that 12.54% of individuals in their 20s are males with high blood pressure and 4.35% are females with high blood pressure.

We can reverse the order of our column variables so that we have the levels of sex nested within levels of high blood pressure. We will again request percentages across the categories of highbp.

```
. table (agegrp) (highbp sex), nototals statistic(percent, across(highbp))
```

	High blood pressure			
	No		Yes	
	Sex		Sex	
	Male	Female	Male	Female
Age group				
20–29	73.92	91.61	26.08	8.39
30–39	62.34	80.63	37.66	19.37
40–49	55.08	65.56	44.92	34.44
50–59	42.36	48.62	57.64	51.38
60–69	41.49	41.92	58.51	58.08
70+	32.81	33.46	67.19	66.54

The last two columns represent the percentage of males with high blood pressure in the age group and the percentage of females with high blood pressure in the age group. We can clearly see that, across all age groups, the percent of males who have high blood pressure is greater than the percentage of females with high blood pressure.

Perhaps we want a table that includes only the two columns on the right. To create a table with the percentages of individuals with high blood pressure, we can take advantage of a unique feature of `table`—its results are automatically stored in a “collection” and can be easily customized. Specifically, when we create a table using the `table` command, the results are stored in a collection named `Table`, and these results replace the results from any previous `table` command. The `collect` suite of commands can be used to change the layout, style, and formatting of tables created from results in collection; see [\[TABLES\] Intro](#) to learn about collections of results and creating customized tables. For our table, we will use the `collect layout` command, which specifies how items from a collection should be arranged. Below, we arrange the percentages in a table with rows defined by the categories of `agegrp` and columns defined by the categories of `sex` and category 1 of `highbp`.

```
. collect layout (agegrp) (highbp[1]#sex)
```

```
Collection: Table
```

```
Rows: agegrp
```

```
Columns: highbp[1]#sex
```

```
Table 1: 7 x 2
```

	High blood pressure	
	Yes	
	Sex	
	Male	Female
Age group		
20–29	26.07527	8.388704
30–39	37.66234	19.3662
40–49	44.91803	34.44109
50–59	57.6412	51.37881
60–69	58.50986	58.08182
70+	67.1875	66.54275

Appending tables

When we specify multiple variables for the row or column specification, the levels of one variable are nested within the levels of another. When you simply wish to join rows or columns from multiple tables, this can be easily done with the `append` option.

For example, we first create a table with the percentage of males and females in each age group with diabetes.

```
. table (sex agegrp) (diabetes), nototals statistic(percent, across(diabetes))
```

		Diabetes	
		No	Yes
Sex			
Male			
Age group			
20–29		99.64	0.36
30–39		99.61	0.39
40–49		97.38	2.62
50–59		94.68	5.32
60–69		91.96	8.04
70+		88.39	11.61
Female			
Age group			
20–29		99.09	0.91
30–39		97.88	2.12
40–49		96.07	3.93
50–59		94.19	5.81
60–69		91.42	8.58
70+		89.03	10.97

We want to include the same information for `highbp` and `heartatk` in the same table, which indicates whether someone has had a heart attack. To do this, we will run the `table` command three times, once specifying each of these variables as the column variable. We will use the `name(table1)` option to specify that the results be stored in a collection named `table1`. To the second and third `table` commands, we will add the `append` option so that all the results are stored in the same collection rather than overriding the results from the previous command.

```
. quietly: table (sex agegrp) (diabetes), nototals
> statistic(percent, across(diabetes)) name(table1)

. quietly: table (sex agegrp) (highbp), nototals
> statistic(percent, across(highbp)) name(table1) append

. quietly: table (sex agegrp) (heartatk), nototals
> statistic(percent, across(heartatk)) name(table1) append
```

With the results from all our table commands stored in one collection, we can again take advantage of the `collect` layout command to arrange results into a table. We request that `sex` and `agegroup` define the rows. By including the `#` between variable names, we specify that we want the levels of these variables to be interacted to form the rows. We request that levels of `diabetes`, `highbp`, and `heartatk` form the columns. Because we did not include `#` between the variable names, their levels will not be interacted. Instead, they will be listed one after the other.

```
. collect layout (sex#agegrp) (diabetes highbp heartatk)
Collection: table1
  Rows: sex#agegrp
  Columns: diabetes highbp heartatk
Table 1: 17 x 6
```

	Diabetes		High blood pressure		Prior heart attack	
	No	Yes	No	Yes	No	Yes
Sex						
Male						
Age group						
20–29	99.64	0.36	73.92	26.08	100.00	
30–39	99.61	0.39	62.34	37.66	99.74	0.26
40–49	97.38	2.62	55.08	44.92	98.03	1.97
50–59	94.68	5.32	42.36	57.64	92.36	7.64
60–69	91.96	8.04	41.49	58.51	86.56	13.44
70+	88.39	11.61	32.81	67.19	83.48	16.52
Female						
Age group						
20–29	99.09	0.91	91.61	8.39	99.92	0.08
30–39	97.88	2.12	80.63	19.37	99.76	0.24
40–49	96.07	3.93	65.56	34.44	98.79	1.21
50–59	94.19	5.81	48.62	51.38	96.66	3.34
60–69	91.42	8.58	41.92	58.08	94.57	5.43
70+	89.03	10.97	33.46	66.54	92.01	7.99

Multiple tables with specified totals

There may be times when instead of creating one large table for multiple variables, you would prefer to create separate tables for each level of one or more variables or for different statistics. For example, we previously had levels of age group nested within categories of sex. Now, we would like to create tables that show how males and females in each age group rate their own health. The variable `hlthstat` records how individuals self-rate their health. Let's create a table that shows what percent of males in each age group selected each of the health categories and a separate table to list the percent of females.

```
. table (agegrp) (hlthstat) (sex), statistic(percent, across(hlthstat))
```

Sex = Male

	Health status					Total
	Excellent	Very good	Good	Fair	Poor	
Age group						
20-29	39.61	32.71	20.97	5.82	0.90	100.00
30-39	36.88	29.61	26.10	5.84	1.56	100.00
40-49	28.03	25.90	29.51	12.30	4.26	100.00
50-59	17.80	21.30	35.11	15.97	9.82	100.00
60-69	13.33	19.56	28.94	23.00	15.16	100.00
70+	14.77	14.99	26.62	28.41	15.21	100.00
Total	25.50	24.71	27.30	14.71	7.78	100.00

Sex = Female

	Health status					Total
	Excellent	Very good	Good	Fair	Poor	
Age group						
20-29	32.39	34.55	24.92	6.98	1.16	100.00
30-39	29.76	30.71	28.12	9.29	2.12	100.00
40-49	26.71	23.07	29.29	15.63	5.31	100.00
50-59	17.15	20.93	33.43	20.20	8.28	100.00
60-69	10.76	20.31	33.22	25.49	10.22	100.00
70+	10.78	19.14	26.39	30.48	13.20	100.00
Total	21.29	25.40	29.45	17.47	6.40	100.00

Sex = Total

	Health status					Total
	Excellent	Very good	Good	Fair	Poor	
Age group						
20-29	35.86	33.66	23.02	6.42	1.03	100.00
30-39	33.15	30.19	27.16	7.65	1.85	100.00
40-49	27.34	24.43	29.39	14.03	4.81	100.00
50-59	17.46	21.10	34.21	18.23	9.00	100.00
60-69	11.99	19.95	31.17	24.30	12.59	100.00
70+	12.59	17.26	26.50	29.54	14.11	100.00
Total	23.29	25.07	28.43	16.16	7.05	100.00

We see that 14.77% of males in their 70s and beyond rated their health as excellent and 10.78% of females in their 70s and beyond rated their health as excellent.

Note that we actually created three tables, one for males, one for females, and one for everybody. We are mainly interested in the first two tables and would like to drop the third table. But if we use the `nototals` option, we will not get the row totals we see above. Instead, we can specify which totals we do want with the `totals()` option:

```
. table (agegrp) (hlthstat) (sex), statistic(percent, across(hlthstat))
> totals(sex#agegrp sex#hlthstat sex)
```

Sex = Male

	Health status					Total
	Excellent	Very good	Good	Fair	Poor	
Age group						
20-29	39.61	32.71	20.97	5.82	0.90	100.00
30-39	36.88	29.61	26.10	5.84	1.56	100.00
40-49	28.03	25.90	29.51	12.30	4.26	100.00
50-59	17.80	21.30	35.11	15.97	9.82	100.00
60-69	13.33	19.56	28.94	23.00	15.16	100.00
70+	14.77	14.99	26.62	28.41	15.21	100.00
Total	25.50	24.71	27.30	14.71	7.78	100.00

Sex = Female

	Health status					Total
	Excellent	Very good	Good	Fair	Poor	
Age group						
20-29	32.39	34.55	24.92	6.98	1.16	100.00
30-39	29.76	30.71	28.12	9.29	2.12	100.00
40-49	26.71	23.07	29.29	15.63	5.31	100.00
50-59	17.15	20.93	33.43	20.20	8.28	100.00
60-69	10.76	20.31	33.22	25.49	10.22	100.00
70+	10.78	19.14	26.39	30.48	13.20	100.00
Total	21.29	25.40	29.45	17.47	6.40	100.00

`sex#agegrp` gives us the row totals, the total for each age group within each category of `sex`. `sex#hlthstat` provides us with the column totals, one of which would be the total percent of females that rated their health as excellent. Finally, `sex` gives us the total in the rightmost cell in the bottom of each table.

If we wish to include one of these tables, for example, in a paper or on a webpage, we can easily export it in \LaTeX , Word, Excel, HTML, and a variety of other formats by using the `export()` option.

Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

Description

In this entry, we discuss how to use `table` to create a table of summary statistics.

Quick start

Table with the mean of `v1`, `v2`, and `v3` for each category of `a1` and `a2`; rows are defined by categories of `a1` and variables `v1`, `v2`, and `v3`

```
table a1 a2, stat(mean v1 v2 v3)
```

Same as above, but also report standard deviations and suppress the totals; rows are defined by the results for each variable within each category of `a1`

```
table (a1 var result) (a2), stat(mean v1 v2 v3) ///
stat(sd v1 v2 v3) nototals
```

Table with number of observations in each category of `a2` and `a3`, for each level of `a1`

```
table a1, stat(fvfrequency a2 a3)
```

Same as above, and report percentage of observations in each category

```
table a1, stat(fvfrequency a2 a3) ///
stat(fvpercent a2 a3)
```

Same as above, and report the percentages with a percent sign, using two decimal places, and enclose them in parentheses

```
table (a1) (var result), stat(fvfrequency a2 a3) ///
stat(fvpercent a2 a3) ///
nformat(%5.2f fvpercent) sformat("(%s%") fvpercent)
```

Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

Syntax

Basic table of summary statistics

```
table [rowvar] [colvar] [if] [in] [weight], statistic(statspec)
      [statistic(statspec) [...]] [options]
```

Customized table of summary statistics

```
table [(rowspec)] [(colspec)] [(tabspec)] [if] [in] [weight], statistic(statspec)
      [statistic(statspec) [...]] [options]
```

rowspec, *colspec*, and *tabspec* may be empty or may include variable names or any of the following keywords:

<i>keyword</i>	Description
result	requested statistics
var	variables from <code>statistic()</code> option
across	index <code>across()</code> specifications

<i>options</i>	Description
Main	
totals(<i>totals</i>)	report only the specified totals
nototals	suppress the marginal totals
Statistics	
<u>statistic</u> (<i>statspec</i>)	statistic to be reported; default is statistic(frequency) when no weights are specified and statistic(sumw) otherwise
Formats	
nformat(<i>%fmt</i> [<i>results</i>] [, basestyle])	specify numeric format
sformat(<i>sfmt</i> [<i>results</i>])	specify string format
Title	
title(<i>string</i>)	add table title
<u>titlestyles</u> (<i>text_styles</i>)	change table title styles
Notes	
note(<i>string</i>)	add table note
<u>notestyles</u> (<i>text_styles</i>)	change table note styles
Export	
export(<i>filename.suffix</i> [, <i>export_opts</i>])	export table
Options	
listwise	use listwise deletion to handle missing values
<u>missing</u>	treat numeric missing values of variables in <i>rowspec</i> , <i>colspec</i> , and <i>tabspec</i> like other values
showcounts	show sample size for all variables in statistic() option
<u>zerocounts</u>	report 0 for empty cell counts
name(<i>cname</i>)	collect results into a collection named <i>cname</i>
append	append results to an existing collection
replace	replace results of an existing collection
label(<i>filename</i>)	specify the collection labels
style(<i>filename</i> [, override])	specify the collection style
markvar(<i>newvar</i>)	create <i>newvar</i> that identifies observations used in the tabulation

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

strL variables are not allowed; see [U] 12.4.8 strL.

markvar() does not appear in the dialog box.

<i>text_styles</i>	Description
<code>font([<i>fontfamily</i>][, <i>font_opts</i>])</code>	specify font style
<code>smcl(<i>smcl</i>)</code>	specify formatting for SMCL files
<code>latex(<i>latex</i>)</code>	specify L ^A T _E X macro
<code>shading(<i>sspec</i>)</code>	set background color, foreground color, and fill pattern

<i>font_opts</i>	Description
<code>size(# [<i>unit</i>])</code>	specify font size
<code>color(<i>color</i>)</code>	specify font color
<code>variant(<i>variant</i>)</code>	specify font variant and capitalization
<code>[no]bold</code>	specify whether to format text as bold
<code>[no]italic</code>	specify whether to format text as italic
<code>[no]strikeout</code>	specify whether to strike out text
<code>[no]underline</code>	specify whether to underline text

<i>suffix</i>	<i>fileformat</i>	Output format
<code>docx</code>	<code>as(docx)</code>	Microsoft Word
<code>html</code>	<code>as(html)</code>	HTML 5 with CSS
<code>pdf</code>	<code>as(pdf)</code>	PDF

<i>export_opts</i>	Description
<code>as(<i>fileformat</i>)</code>	specify document type
<code>replace</code>	overwrite existing file
<i>docx_options</i>	available when exporting to .docx files
<i>html_options</i>	available when exporting to .html files
<i>pdf_options</i>	available when exporting to .pdf files
<i>excel_options</i>	available when exporting to .xls and .xlsx files
<i>tex_options</i>	available when exporting to .tex files
<i>smcl_option</i>	available when exporting to .smcl files
<i>txt_option</i>	available when exporting to .txt files
<i>md_option</i>	available when exporting to .markdown and .md files

<i>docx_options</i>	Description
<code>noisily</code>	show the putdocx commands used to export to the Microsoft Word file
<code>dofile(<i>filename</i>[, replace])</code>	save the putdocx commands used for exporting to the named do-file

<i>html_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file
cssfile(<i>cssfile</i>)	define the styles in <i>cssfile</i> instead of <i>filename</i>
prefix(<i>prefix</i>)	use <i>prefix</i> to identify style classes

<i>pdf_options</i>	Description
noisily	show the putpdf commands used to export to the PDF file
dofile(<i>filename</i> [, replace])	save the putpdf commands used for exporting to the named do-file

<i>excel_options</i>	Description
noisily	show the putexcel commands used to export to the Excel file
dofile(<i>filename</i> [, replace])	save the putexcel commands used for exporting to the named do-file
sheet(<i>sheetname</i> [, replace])	specify the worksheet to use; the default sheet name is Sheet1
cell(<i>cell</i>)	specify the Excel upper-left cell as the starting position to export the table; the default is cell(A1)
modify	modify Excel file
noopen	do not open Excel file in memory

noopen does not appear in the dialog box.

<i>tex_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file

<i>smcl_option</i>	Description
append	append to an existing file

<i>txt_option</i>	Description
append	append to an existing file

<i>md_option</i>	Description
append	append to an existing file

fontfamily specifies a valid font family.

unit may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

variant may be allcaps, smallcaps, or normal.

variant(allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

variant(smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L^AT_EX, and HTML files.

variant(normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

smcl specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.

latex specifies the name of a L^AT_EX macro to render text for L^AT_EX output. Example L^AT_EX macro names are textbf, textsf, textrm, and texttt. Custom L^AT_EX macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L^AT_EX:

`\latex {text}`

sspec is

`[background(bcolor) foreground(fgcolor) pattern(fpattern)]`

bcolor specifies the background color.

fgcolor specifies the foreground color.

fpattern specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

bcolor, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form ### # # #, for example, 171 248 103; or a valid RRGGBB hex value in the form #####, for example, ABF867.

Options

Main

`totals(totals)` and `nototals` control which totals are to be displayed in the table. By default, all totals are reported.

`totals(totals)` specifies which margin totals to display in the reported table. *totals* can contain variables in *rowspec*, *colspec*, *tabspec*, and their interaction. Interactions can be specified by using the `#` operator.

`nototals` prevents table from displaying any totals.

Statistics

`statistic(statspec)` specifies the statistic to be displayed. `statistic()` may be repeated to request multiple statistics. Frequency statistics, summary statistics, and ratio statistics are available by specifying `statistic(freqstat)`, `statistic(sumstat varlist)`, and `statistic(ratiostat [varlist] [, ratio_options])`, respectively.

`statistic()` may be repeated to request multiple statistics.

`statistic(freqstat)` specifies that frequencies be computed.

<i>freqstat</i>	Definition
<u>frequency</u>	frequency
<u>sumw</u>	sum of weights

`statistic(sumstat varlist)` specifies that summary statistic *sumstat* be computed for the variables in *varlist*.

<i>sumstat</i>	Definition
mean	mean
semean	standard error of the mean
sebinomial	standard error of the mean, binomial
sepoisson	standard error of the mean, Poisson
variance	variance
sd	standard deviation
skewness	skewness
kurtosis	kurtosis
cv	coefficient of variation
count	number of nonmissing values
median	median
p#	#th percentile
q1	first quartile
q2	second quartile
q3	third quartile
iqr	interquartile range
min	minimum value
max	maximum value
range	range
first	first value
last	last value
firstnm	first nonmissing value
lastnm	last nonmissing value
total	total
rawtotal	unweighted total
fvfrequency	frequency of each factor-variable level
fvrawfrequency	unweighted frequency of each factor-variable level
fvproportion	proportion within each factor-variable level
fvrawproportion	unweighted proportion within each factor-variable level
fvpercent	percentage within each factor-variable level
fvrawpercent	unweighted percentage within each factor-variable level

`statistic(ratiostat [varlist] [, ratio_options])` specifies that ratio statistic *ratiostat* be computed. If *varlist* is specified, ratios are computed based on the totals of the specified variables. If *varlist* is not specified, ratios are computed based on frequencies.

<i>ratiostat</i>	Definition
<u>proportion</u>	proportion
<u>percent</u>	percentage
<u>rawproportion</u>	proportion ignoring optionally specified weights
<u>rawpercent</u>	percentage ignoring optionally specified weights

<i>ratio_options</i>	Definition
<u>across(cellspec)</u>	percentages or proportions across levels of variables or interactions
<u>total</u>	compute overall percentages or proportions

cellspec may contain any variables in *rowspec*, *colspec*, *tabspec*, or an interaction between any of these variables. Interactions can be specified by using the # operator.

Formats

`nformat(%fmt [results] [, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

results may be any statistic named in option `statistic()` (that is, any *freqstat*, *sumstat*, or *ratiostat*).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*) or the format of factor variables specified in the `statistic()` option. The default format of these variables is taken from the dataset.

basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt [results])` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and %s. Here %s refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around %s in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s) percent)`.

results may be any statistic named in option `statistic()` (that is, any *freqstat*, *sumstat*, or *ratiostat*).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type %%. To include \, type \\. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline)` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Notes

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a \LaTeX , a SMCL, a `txt`, or a Markdown file. When you export to HTML and \LaTeX files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or \LaTeX document. By default, `table` produces complete HTML and \LaTeX documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

Options

`listwise` handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any variable specified in a `statistic()` option is missing for that observation. By default, `table` will omit an observation only if all variables specified in all `statistic()` options are missing for that observation.

`missing` specifies that numeric missing values of any variables specified in *rowspec*, *colspec*, or *tabspec* be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

This option does not apply to factor variables specified with statistics `fvfrequency`, `fvrawfrequency`, `fvproportion`, `fvrawproportion`, `fvpercent`, or `fvrawpercent`.

`showcounts` specifies that `table` report the sample size for each variable specified in option `statistic()`.

`zerocounts` specifies that `table` report a 0 in empty cells for results `count`, `frequency`, `fvfrequency`, and `fvrawfrequency`.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify *override*. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table_style](#).

The following option is available with `table` but is not shown in the dialog box:

`markvar(newvar)` generates an indicator variable that identifies the observations used in the tabulation.

Remarks and examples

Remarks are presented under the following headings:

Basic summary statistic tables
Classic Table 1

Basic summary statistic tables

The `table` command can be used to compute a variety of summary statistics and display them in a table. Summary statistics can be computed for the full dataset or across levels of one or more categorical variables.

To demonstrate, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981) and create a table reporting the mean body mass index (BMI) of individuals across four regions of the USA. We use the `statistic()` option to request that means be computed, and we specify `region` as our row variable for the table. Thus, means are computed for each region separately and for all the regions combined (Total).

```
. use https://www.stata-press.com/data/r19/nhanes21
(Second National Health and Nutrition Examination Survey)
. table region, statistic(mean bmi)
```

	Mean
Region	
NE	25.57535
MW	25.51936
S	25.63317
W	25.42299
Total	25.5376

The mean BMI is very similar across regions. We might want to look at some additional statistics. We can add the minimums and maximums in our table by repeating our `statistic()` option for each statistic; we will use the `stat()` abbreviation.

```
. table region, stat(mean bmi) stat(min bmi) stat(max bmi)
```

	Mean	Minimum value	Maximum value
Region			
NE	25.57535	15.36715	57.10803
MW	25.51936	14.1351	61.1297
S	25.63317	12.3856	55.43552
W	25.42299	15.69046	54.05056
Total	25.5376	12.3856	61.1297

If we want to include even more statistics, the table will become very wide. We can move the statistics to the rows of our table by specifying the keyword `result` in the first set of parentheses. We place `region` on the columns by specifying this variable in the second set of parentheses.

```
. table (result) (region),
> stat(mean bmi) stat(median bmi) stat(sd bmi)
> stat(min bmi) stat(max bmi)
```

	Region				
	NE	MW	S	W	Total
Mean	25.57535	25.51936	25.63317	25.42299	25.5376
Median	25.00623	24.71567	24.98451	24.66734	24.81812
Standard deviation	4.72798	4.905965	5.084678	4.883534	4.914969
Minimum value	15.36715	14.1351	12.3856	15.69046	12.3856
Maximum value	57.10803	61.1297	55.43552	54.05056	61.1297

Instead of computing many statistics for one variable, we might want to compute one statistic for multiple variables. To do this, we can include a list of variables within a single `statistic()` option. Let's compute the means of age, BMI, and systolic blood pressure (`bpsystol`).

```
. table (result) (region), stat(mean age bmi bpsystol)
```

	Region				
	NE	MW	S	W	Total
Age (years)	47.81584	46.52776	48.19068	47.83828	47.57965
Body mass index (BMI)	25.57535	25.51936	25.63317	25.42299	25.5376
Systolic blood pressure	131.3836	130.4863	131.1626	130.5936	130.8817

Classic Table 1

In many reports, the first discussion of the data is accompanied by a “Table 1”, a reporting of summary statistics for all variables of interest. Often the table includes a mixture of continuous and categorical variables. We may also want to specify these in a particular order based on importance. In many cases, the table has multiple columns with the summary statistics reported for each level of a categorical variable of interest.

Here we will demonstrate how to create one variety of such a table. We have two factor variables of interest, `diabetes` and `hlthstat`, for which we would like to compute the percentage of individuals in each category. We will use the `fvpercent` statistic to obtain these percentages. We also have three continuous variables, `age`, `bmi`, and `bpsystol`, for which we would like to compute means. We specify the `statistic()` options in the order we wish to see the results in the table. To specify that the variables in the `statistic()` options appear on the rows, we include the keyword `var` in the first set of parentheses. We place `region` on the columns by listing it in the second set of parentheses.

```
. table (var) (region),
> statistic(fvpercent diabetes)
> statistic(mean age bmi)
> statistic(fvpercent hlthstat)
> statistic(mean bpsystol)
```

	Region				
	NE	MW	S	W	Total
Diabetes status=Not diabetic					
Factor-variable percent	95.32	95.49	94.36	95.62	95.18
Diabetes status=Diabetic					
Factor-variable percent	4.68	4.51	5.64	4.38	4.82
Age (years)					
Mean	47.81584	46.52776	48.19068	47.83828	47.57965
Body mass index (BMI)					
Mean	25.57535	25.51936	25.63317	25.42299	25.5376
Health status=Excellent					
Factor-variable percent	26.95	26.33	19.14	21.68	23.29
Health status=Very good					
Factor-variable percent	26.76	26.01	22.82	25.18	25.07
Health status=Good					
Factor-variable percent	30.26	26.52	28.29	29.14	28.43
Health status=Fair					
Factor-variable percent	12.33	15.12	18.65	17.60	16.16
Health status=Poor					
Factor-variable percent	3.69	6.02	11.11	6.40	7.05
Systolic blood pressure					
Mean	131.3836	130.4863	131.1626	130.5936	130.8817

We have the statistics we want, but clearly our table could be improved. Let's start by applying one of the [predefined styles](#), `table-1`, by adding the `style()` option.

```
. table (var) (region),
> statistic(fvpercent diabetes)
> statistic(mean age bmi)
> statistic(fvpercent hlthstat)
> statistic(mean bpsystol) style(table-1)
```

	Region				
	NE	MW	S	W	Total
Diabetes status					
Not diabetic	95.32	95.49	94.36	95.62	95.18
Diabetic	4.68	4.51	5.64	4.38	4.82
Age (years)	47.81584	46.52776	48.19068	47.83828	47.57965
Body mass index (BMI)	25.57535	25.51936	25.63317	25.42299	25.5376
Health status					
Excellent	26.95	26.33	19.14	21.68	23.29
Very good	26.76	26.01	22.82	25.18	25.07
Good	30.26	26.52	28.29	29.14	28.43
Fair	12.33	15.12	18.65	17.60	16.16
Poor	3.69	6.02	11.11	6.40	7.05
Systolic blood pressure	131.3836	130.4863	131.1626	130.5936	130.8817

This style removes the labels for the type of statistic being reported, cleans up the reporting of factor variables in the row headers, and right-aligns the content in the row headers. In addition, we may want to specify that the means be reported to two decimal places using the `nformat(%6.2f mean)` option.

```
. table (var) (region),
> statistic(fvpercent diabetes)
> statistic(mean age bmi)
> statistic(fvpercent hlthstat )
> statistic(mean bpsystol) style(table-1) nformat(%6.2f mean)
```

	NE	MW	Region S	W	Total
Diabetes status					
Not diabetic	95.32	95.49	94.36	95.62	95.18
Diabetic	4.68	4.51	5.64	4.38	4.82
Age (years)	47.82	46.53	48.19	47.84	47.58
Body mass index (BMI)	25.58	25.52	25.63	25.42	25.54
Health status					
Excellent	26.95	26.33	19.14	21.68	23.29
Very good	26.76	26.01	22.82	25.18	25.07
Good	30.26	26.52	28.29	29.14	28.43
Fair	12.33	15.12	18.65	17.60	16.16
Poor	3.69	6.02	11.11	6.40	7.05
Systolic blood pressure	131.38	130.49	131.16	130.59	130.88

Let's go one step further. Perhaps we want the mean and standard deviation of each continuous variable, and we want the frequency and percent for each factor variable. We need to specify a few more `statistic()` options.

```
. table (var) (region),
> stat(fvfreq diabetes) statistic(fvpercent diabetes)
> statistic(mean age bmi) statistic(sd age bmi)
> statistic(fvfreq hlthstat) statistic(fvpercent hlthstat)
> statistic(mean bpsystol) statistic(sd bpsystol)
> style(table-1) nformat(%6.2f mean sd)
```

	4.73	4.91	5.08	4.88	4.91
Health status					
Excellent	562	730	546	569	2,407
	26.95	26.33	19.14	21.68	23.29
Very good	558	721	651	661	2,591
	26.76	26.01	22.82	25.18	25.07
Good	631	735	807	765	2,938
	30.26	26.52	28.29	29.14	28.43
Fair	257	419	532	462	1,670
	12.33	15.12	18.65	17.60	16.16
Poor	77	167	317	168	729
	3.69	6.02	11.11	6.40	7.05
Systolic blood pressure	131.38	130.49	131.16	130.59	130.88
	24.31	22.50	24.21	22.42	23.33

Finally, to distinguish among our statistics, we can use the `sformat()` option to add parentheses around our standard deviations and percent signs to our percentages.

```
. table (var) (region),
> stat(fvfreq diabetes) statistic(fvpercent diabetes)
> statistic(mean age bmi) statistic(sd age bmi)
> statistic(fvfreq hlthstat) statistic(fvpercent hlthstat)
> statistic(mean bpsystol) statistic(sd bpsystol)
> style(table-1) nformat(%6.2f mean sd)
> sformat("(%s" sd) sformat("%s%" fvpercent)
```

	NE	MW	Region S	W	Total
Diabetes status					
Not diabetic	1,997 95.32%	2,648 95.49%	2,692 94.36%	2,513 95.62%	9,850 95.18%
Diabetic	98 4.68%	125 4.51%	161 5.64%	115 4.38%	499 4.82%
Age (years)	47.82 (17.02)	46.53 (17.38)	48.19 (16.86)	47.84 (17.53)	47.58 (17.21)
Body mass index (BMI)	25.58 (4.73)	25.52 (4.91)	25.63 (5.08)	25.42 (4.88)	25.54 (4.91)
Health status					
Excellent	562 26.95%	730 26.33%	546 19.14%	569 21.68%	2,407 23.29%
Very good	558 26.76%	721 26.01%	651 22.82%	661 25.18%	2,591 25.07%
Good	631 30.26%	735 26.52%	807 28.29%	765 29.14%	2,938 28.43%
Fair	257 12.33%	419 15.12%	532 18.65%	462 17.60%	1,670 16.16%
Poor	77 3.69%	167 6.02%	317 11.11%	168 6.40%	729 7.05%
Systolic blood pressure	131.38 (24.31)	130.49 (22.50)	131.16 (24.21)	130.59 (22.42)	130.88 (23.33)

We have added many customizations to our table. However, you may prefer a different look. For another style, you can select from the predefined styles described in [\[TABLES\] Predefined styles](#). If none of these provide the exact style you want for your table, you can further customize the results by using the collect suite of commands. To learn more, see [\[TABLES\] Intro](#).

If you wish to include this table in a paper, on a webpage, or in another format, you can easily export it in \LaTeX , Word, Excel, HTML, and a variety of other formats by using the `export()` option.

Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

Description

In this entry, we discuss how to use `table` to create tables with results of hypothesis tests.

Quick start

Table with pairwise correlations stored in matrix `r(C)`

```
table (rowname) (colname), command(r(C): pwcrr v1 v2 v3)
```

Table with all the numeric scalars returned by `ttest`; rows correspond to the different results

```
table (result) (command), command(ttest v1, by(catvar))
```

Table with means and two-sided p -values; columns correspond to the different results

```
table (command) (result), ///
command(r(mu_1) r(mu_2) r(p): ttest v1, by(catvar))
```

Same as above, but with statistics for `v1` and `v2`

```
table (command) (result), ///
command(r(mu_1) r(mu_2) r(p): ttest v1, by(catvar)) ///
command(r(mu_1) r(mu_2) r(p): ttest v2, by(catvar))
```

Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

Syntax

```
table ([rowspec]) ([colspec]) [(tabspec)] [if] [in] [weight],
      command(cmdspec) [command(cmdspec) ...] [options]
```

rowspec, colspec, and tabspec may be empty or may include variable names or any of the following keywords:

keyword	Description
result	requested statistics
stars	stars denoting statistical significance
command	index option command()
colname	column names for matrix statistics
rowname	row names for matrix statistics

options	Description
Commands	
command(<i>cmdspec</i>)	collect results from the specified Stata command
Formats	
nformat(<i>%fmt</i> [<i>results</i>][, basestyle])	specify numeric format
sformat(<i>sfmt</i> [<i>results</i>])	specify string format
Stars	
stars(<i>starspec</i>)	add stars to denote statistical significance
Title	
title(<i>string</i>)	add table title
titlestyles(<i>text_styles</i>)	change table title styles
Notes	
note(<i>string</i>)	add table note
notestyles(<i>text_styles</i>)	change table note styles
Export	
export(<i>filename.suffix</i> [, <i>export_opts</i>])	export table
Options	
missing	treat numeric missing values like other values
name(<i>cname</i>)	collect results into a collection named <i>cname</i>
append	append results to an existing collection
replace	replace results of an existing collection
label(<i>filename</i>)	specify the collection labels
style(<i>filename</i> [, <i>override</i>])	specify the collection style
noisily	display output from each command

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

strL variables are not allowed; see [U] 12.4.8 strL.

noisily does not appear in the dialog box.

<i>text_styles</i>	Description
<code>font([<i>fontfamily</i>][, <i>font_opts</i>])</code>	specify font style
<code>smcl(<i>smcl</i>)</code>	specify formatting for SMCL files
<code>latex(<i>latex</i>)</code>	specify L ^A T _E X macro
<code>shading(<i>sspec</i>)</code>	set background color, foreground color, and fill pattern

<i>font_opts</i>	Description
<code>size(# [<i>unit</i>])</code>	specify font size
<code>color(<i>color</i>)</code>	specify font color
<code>variant(<i>variant</i>)</code>	specify font variant and capitalization
<code>[no]bold</code>	specify whether to format text as bold
<code>[no]italic</code>	specify whether to format text as italic
<code>[no]strikeout</code>	specify whether to strike out text
<code>[no]underline</code>	specify whether to underline text

<i>suffix</i>	<i>fileformat</i>	Output format
<code>docx</code>	<code>as(docx)</code>	Microsoft Word
<code>html</code>	<code>as(html)</code>	HTML 5 with CSS
<code>pdf</code>	<code>as(pdf)</code>	PDF
<code>xlsx</code>	<code>as(xlsx)</code>	Microsoft Excel 2007/2010 or newer
<code>xls</code>	<code>as(xls)</code>	Microsoft Excel 1997/2003
<code>tex</code>	<code>as(tex)</code>	L ^A T _E X
<code>smcl</code>	<code>as(smcl)</code>	SMCL
<code>txt</code>	<code>as(txt)</code>	plain text
<code>markdown</code>	<code>as(markdown)</code>	Markdown
<code>md</code>	<code>as(md)</code>	Markdown

<i>export_opts</i>	Description
<code>as(<i>fileformat</i>)</code>	specify document type
<code>replace</code>	overwrite existing file
<i>docx_options</i>	available when exporting to .docx files
<i>html_options</i>	available when exporting to .html files
<i>pdf_options</i>	available when exporting to .pdf files
<i>excel_options</i>	available when exporting to .xls and .xlsx files
<i>tex_options</i>	available when exporting to .tex files
<i>smcl_option</i>	available when exporting to .smcl files
<i>txt_option</i>	available when exporting to .txt files
<i>md_option</i>	available when exporting to .markdown and .md files

<i>docx_options</i>	Description
<code>noisily</code>	show the putdocx commands used to export to the Microsoft Word file
<code>dofile(<i>filename</i>[, replace])</code>	save the putdocx commands used for exporting to the named do-file

<i>html_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file
cssfile(<i>cssfile</i>)	define the styles in <i>cssfile</i> instead of <i>filename</i>
prefix(<i>prefix</i>)	use <i>prefix</i> to identify style classes

<i>pdf_options</i>	Description
noisily	show the putpdf commands used to export to the PDF file
dofile(<i>filename</i> [, replace])	save the putpdf commands used for exporting to the named do-file

<i>excel_options</i>	Description
noisily	show the putexcel commands used to export to the Excel file
dofile(<i>filename</i> [, replace])	save the putexcel commands used for exporting to the named do-file
sheet(<i>sheetname</i> [, replace])	specify the worksheet to use; the default sheet name is Sheet1
cell(<i>cell</i>)	specify the Excel upper-left cell as the starting position to export the table; the default is cell(A1)
modify	modify Excel file
noopen	do not open Excel file in memory

noopen does not appear in the dialog box.

<i>tex_options</i>	Description
append	append to an existing file
tableonly	export only the table to the specified file

<i>smcl_option</i>	Description
append	append to an existing file

<i>txt_option</i>	Description
append	append to an existing file

<i>md_option</i>	Description
append	append to an existing file

fontfamily specifies a valid font family.

unit may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

variant may be allcaps, smallcaps, or normal.

variant(allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

variant(smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L^AT_EX, and HTML files.

variant(normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

smcl specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.

latex specifies the name of a L^AT_EX macro to render text for L^AT_EX output. Example L^AT_EX macro names are textbf, textsf, textrm, and texttt. Custom L^AT_EX macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L^AT_EX:

`\latex {text}`

sspec is

`[background(bcolor) foreground(fgcolor) pattern(fpattern)]`

bcolor specifies the background color.

fgcolor specifies the foreground color.

fpattern specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

bcolor, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form ### ##, for example, 171 248 103; or a valid RRGGBB hex value in the form #####, for example, ABF867.

Options

Commands

`command(cmdspec)` specifies the Stata commands from which to collect results. `command()` may be repeated to collect results from multiple commands.

cmdspec is `[explist:] command [arguments] [, cmdoptions]`

explist specifies which results to collect and report in the table. *explist* may include *result identifiers* and *named expressions*.

result identifiers are results stored in `r()` and `e()` by the *command*. For instance, *result identifiers* could be `r(mean)`, `r(C)`, or `e(chi2)`. After estimation commands, *result identifiers* also include the following:

Identifier	Result
<code>_r_b</code>	coefficients or transformed coefficients reported by <i>command</i>
<code>_r_se</code>	standard errors of <code>_r_b</code>
<code>_r_z</code>	test statistics for <code>_r_b</code>
<code>_r_z_abs</code>	absolute value of <code>_r_z</code>
<code>_r_p</code>	<i>p</i> -values for <code>_r_b</code>
<code>_r_lb</code>	lower bounds of confidence intervals for <code>_r_b</code>
<code>_r_ub</code>	upper bounds of confidence intervals for <code>_r_b</code>
<code>_r_ci</code>	confidence intervals for <code>_r_b</code>
<code>_r_crlb</code>	lower bounds of credible intervals for <code>_r_b</code>
<code>_r_crub</code>	upper bounds of credible intervals for <code>_r_b</code>
<code>_r_cri</code>	credible intervals for <code>_r_b</code>
<code>_r_df</code>	degrees of freedom for <code>_r_b</code>

named expressions are specified as *name* = *exp*, where *name* may be any valid Stata name and *exp* is an expression, typically an expression that involves one or more *result identifiers*. An example of a named expression is `sd = sqrt(r(variance))`.

For *r*-class commands, the default is to include all numeric scalars posted to `r()` in the table results. For *e*-class commands, the default is to include `_r_b` in the table results.

command is any command that follows standard Stata syntax.

arguments may be anything so long as they do not include an *if* clause, *in* range, or weight specification.

Any *if* or *in* qualifier and weights should be specified directly with `table`, not within the `command()` option. Weights are passed to *command* only if they are specified.

cmdoptions may be anything supported by *command*.

Formats

`nformat(%fmt [results] [, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

results may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*). The default format of these variables is taken from the dataset.

basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

sformat(sfmt [results]) changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and %s. Here %s refers to the numeric value that is formatted as specified using *nformat()*. The text will be placed around the numeric values in your table as it is placed around %s in this option. For instance, to place parentheses around the percent statistics, you can specify *sformat("(%s)" percent)*.

results may be any name in the *e()* or *r()* results produced by commands specified in option *command()*.

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type %%. To include \, type \\. For instance, to place a percent sign following percent statistics, you can specify *sformat("%s%" percent)*.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

Stars

stars(starspec) specifies that stars representing statistical significance be included in the table. *starspec* identifies the result whose values determine significance, which characters should represent each significance level, and where these characters should be displayed in the table. *starspec* is

```
starres [#1 "label1" [#2 "label2" [#3 "label3" [#4 "label4" [#5 "label5" ]]]]]
[, attach(attachres) result dimension starsnoteopts ]
```

starres is the name of the result whose values determine which characters, typically which number of stars, are to be displayed.

label1 specifies the characters to be displayed when *starres* < #1.

label2 specifies the characters to be displayed when *starres* < #2.

label3 specifies the characters to be displayed when *starres* < #3.

label4 specifies the characters to be displayed when *starres* < #4.

label5 specifies the characters to be displayed when *starres* < #5.

attach(attachres) specifies the name of the result to which the characters defined by *label1*, ..., *label5* are to be attached. If *attach()* is not specified, a new result named *stars* is created and is automatically added to the table.

result and *dimension* control how *collect stars* adds items when labeling significant results. These options are mutually exclusive.

result specifies the default behavior, and this option is necessary only if the following *dimension* behavior is in effect and you want to change back to the *result* behavior.

dimension specifies that dimension *stars* be added to the collection. Items will be tagged with *stars[value]*, and the labels will be tagged with *stars[label]*. Use this option for layouts where results are to be stacked within columns, and use *new dimension stars* in the column specification of the layout.

starsnoteopts control the display and composition of the stars note.

noshownote and *shownote* control whether to display the stars note.

increasing and *decreasing* control the order of *p*-values in the stars note.

pvname(string) specifies a name for the *p*-value in the stars note. The default is *pvname(p)*.

delimiter(string) specifies the delimiter between labels in the stars note. The default is *delimiter(",")*.

nformat(%fmt) specifies the numeric format for the cutoff values in the stars note. The default is *nformat(%9.0g)*.

prefix(string) specifies the prefix for the stars note. The prefix is empty by default.

suffix(string) specifies the suffix for the stars note. The suffix is empty by default.

For example, `stars(_r_p 0.01 "***" 0.05 "**" 0.1 "*", attach(_r_b))` could be added to a table of regression results to specify that stars be defined based on the *p*-values in *_r_p* and be attached to the reported coefficients (*_r_b*).

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and L^AT_EX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for L^AT_EX output. This style property is applicable only when publishing items from a collection to a L^AT_EX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and L^AT_EX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Notes

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline)` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a \LaTeX , a SMCL, a `txt`, or a Markdown file. When you export to HTML and \LaTeX files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or \LaTeX document. By default, `table` produces complete HTML and \LaTeX documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

Options

`missing` specifies that numeric missing values of any variables specified in *rowspec*, *colspec*, or *tabspec* be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table_style](#).

The following option is available with `table` but is not shown in the dialog box:

`noisily` specifies that output from the commands specified in `command()` options be displayed. By default, output from commands is suppressed.

Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)
[Creating tables from scalars](#)
[Creating tables from matrices](#)

Introduction

The `table` command can be used to create tables with results of hypothesis tests. For example, you can create a table with results from a mean-comparison test, a test of proportions, or a test of normality.

`table` does not perform hypothesis tests directly. Rather, `table` will run any Stata command that you include in its `command()` option and place results from that command into the table. You determine which results you would like to see in the table. You can select any of the results stored by the command.

Creating tables from scalars

We have data from the Second National Health and Nutrition Examination Survey (NHANES II) ([McDowell et al. 1981](#)). The data contain some demographic information, such as the age, sex, and race of participants. The data also contain some measures of health, including whether the individual has high blood pressure (`highbp`), has diabetes, or has had a heart attack previously (`heartatk`).

Suppose we want to examine the proportion of males and females that have high blood pressure, that have diabetes, and that have had a heart attack previously. With `prtest`, we can test whether the proportions are equal between males and females. For example, let's perform a test of proportions for diabetes:

```
. use https://www.stata-press.com/data/r19/nhanes2l
(Second National Health and Nutrition Examination Survey)
. prtest diabetes, by(sex)
```

Two-sample test of proportions

					Male: Number of obs =	4915
					Female: Number of obs =	5434

Group	Mean	Std. err.	z	P> z	[95% conf. interval]	
Male	.0441506	.0029302			.0384074	.0498937
Female	.0518955	.0030091			.0459978	.0577932
diff	-.0077449	.0042001			-.0159769	.0004871
	under H0:	.0042169	-1.84	0.066		

```
diff = prop(Male) - prop(Female)                                z = -1.8366
H0: diff = 0
Ha: diff < 0                                                    Ha: diff != 0
Pr(Z < z) = 0.0331                                           Pr(|Z| > |z|) = 0.0663          Ha: diff > 0
                                                                    Pr(Z > z) = 0.9669
```

We would like to create a table that includes the proportion of men who have diabetes, the proportion of women who have diabetes, the difference in these proportions, and the p -value for a two-sided test. First, we need to determine how to refer to these statistics.

```

. return list
scalars:
      r(N1) = 4915
      r(N2) = 5434
      r(P1) = .0441505595116989
      r(P2) = .0518954729481045
      r(P_diff) = -.0077449134364056
      r(se1) = .0029302258134317
      r(se2) = .003009075122777
      r(se_diff0) = .0042169418903878
      r(se_diff) = .0042000900481081
      r(lb1) = .0384074224508032
      r(ub1) = .0498936965725946
      r(lb2) = .0459977940806861
      r(ub2) = .0577931518155229
      r(lb_diff) = -.0159769386625226
      r(ub_diff) = .0004871117897114
      r(z) = -1.836618487454034
      r(p_l) = .0331331180748532
      r(p) = .0662662361497065
      r(p_u) = .9668668819251468
      r(level) = 95

```

The statistics we want to see are stored as `r(P1)`, `r(P2)`, `r(P_diff)`, and `r(p)`. We can specify this in the `command()` option by typing

```
. table ..., command(r(P1) r(P2) r(P_diff) r(p): prtest diabetes, by(sex))
```

This will get the results we want into our table. Furthermore, because we know what these values represent, we can give them names that will appear in the table headers. We can, for instance, type

```
. table ..., command(Males=r(P1) Females=r(P2) Difference=r(P_diff) ///
      r(p): prtest diabetes, by(sex))
```

We can specify similar `command()` options for `heartatk` and `highbp` as well.

In addition, we need to specify how our results will be laid out in the table. Below, we type `command` in the first set of parentheses so that the rows correspond to the different commands. We type `result` in the second set of parentheses to specify that statistics appear in the columns.

Finally, we add two options to customize the results. We specify a numeric format so that the statistics be displayed only with three digits after the decimal. We also choose the predefined style `table-right` so that our row headers will be right-aligned. See [\[TABLES\] Predefined styles](#) for information on this and other styles.

```

. table (command) (result),
> command(Males=r(P1) Females=r(P2) Difference=r(P_diff) r(p):
> prtest diabetes, by(sex))
> command(Males=r(P1) Females=r(P2) Difference=r(P_diff) r(p):
> prtest heartatk, by(sex))
> command(Males=r(P1) Females=r(P2) Difference=r(P_diff) r(p):
> prtest highbp, by(sex))
> nformat(%5.3f) style(table-right)

```

	Males	Females	Difference	Two-sided p-value
prtest diabetes, by(sex)	0.044	0.052	-0.008	0.066
prtest heartatk, by(sex)	0.065	0.029	0.036	0.000
prtest highbp, by(sex)	0.469	0.381	0.088	0.000

Our table now includes all the statistics we want. If we are happy with it, we can export it to another format, such as HTML, Word, \LaTeX , PDF, and Excel using the `export()` option. But first we want to make some modifications. Table customization can go beyond the predefined styles and options available to you in the `table` command. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to produce highly customized tables and to export those tables to presentation-ready formats, such as HTML, Word, \LaTeX , PDF, Excel, and more.

For this table, we want to modify the labels in our row headers. Instead of showing the full command that was run, row headers will identify the variable we are testing. In addition, we will modify the label for our p -value. We want to use the label `p-value`. Because this is not a valid Stata name, we could not specify it in the `table` command as we did with `Males`. However, we can use `collect label levels` to modify the label on our p -values.

After applying the label updates, we use `collect preview` to see our updated table.

```
. collect label levels command 1 "Diabetes" 2 "Heart attack" 3 "High BP", modify
. collect label levels result p "p-value", modify
. collect preview
```

	Males	Females	Difference	p-value
Diabetes	0.044	0.052	-0.008	0.066
Heart attack	0.065	0.029	0.036	0.000
High BP	0.469	0.381	0.088	0.000

Creating tables from matrices

You may find that the results you want to include in your table are stored in a matrix; these results can also be easily included in a table.

To demonstrate, we create a table with p -values for tests of normality for height, weight, and diastolic blood pressure (`bpdiast`). The command `sktest` performs tests based on skewness, kurtosis, and a combined test statistic.

```
. sktest height weight bpdiast
Skewness and kurtosis tests for normality
```

Variable	Obs	Pr(skewness)	Pr(kurtosis)	Joint test	
				Adj chi2(2)	Prob>chi2
height	10,351	0.0000	0.0000	147.47	0.0000
weight	10,351	0.0000	0.0000	801.40	0.0000
bpdiast	10,351	0.0000	0.0000	362.54	0.0000

Let's look at the returned results.

```
. return list
scalars:
      r(N) = 10351
      r(p_skew) = 1.58706287446e-72
      r(p_kurt) = 6.22330331716e-26
      r(chi2) = 362.5385838320567
      r(p_chi2) = 1.88689086684e-79

matrices:
      r(table) : 3 x 5
```

The statistics we want plus a few others are stored in `r(table)`.

Now, let's place these values in a table. We specify that our table be arranged with the row names (`rowname`) of the matrix defining the rows of the table. Similarly, the column names (`colname`) of the matrix define the columns of the table. Then, we specify that we want to collect the results from the matrix `r(table)` from the `sktest` command.

```
. table (rowname) (colname),  
> command(r(table): sktest height weight bpdiastr)
```

	N	p_skew	p_kurt	chi2	p_chi2
Height (cm)	10351	.0000179	1.87e-35	147.4712	9.48e-33
Weight (kg)	10351	1.6e-166	1.63e-49	801.3958	9.5e-175
Diastolic blood pressure	10351	1.59e-72	6.22e-26	362.5386	1.89e-79

Because the row names in `r(table)` corresponded to variables, our table automatically put the variable labels in the row headers. However, the column headers are not nicely labeled.

We can create better labels and modify our table in many other ways. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to further customize tables.

To clean up our table, let's use `collect label levels` to modify the labels for the p -values for the skewness, kurtosis, and joint tests; these are the statistics we will include in our table below. To use `collect label levels`, we need to know just a little about the `collect` system. In collections, values are organized according to dimensions and levels within those dimensions. In fact, we use these dimensions in `table`. The keywords that we can use to define our rows and columns are dimensions. Here `colname` is our dimension that defines the columns, and its levels are `N`, `p_skew`, To modify labels, we need to tell `collect label levels` which dimension (`colname`) we would like to change and then specify labels for levels of that dimension.

We specify the dimension and then the label for each level:

```
. collect label levels colname p_skew "Skewness p-value"  
> p_kurt "Kurtosis p-value" p_chi2 "Joint p-value", modify
```

To learn more about modifying labels, see [\[TABLES\] collect label](#).

Let's also change the numeric format of our p -values. With `collect style cell`, we can modify all cells in the table, all cells in a particular dimension, or particular cells of a particular dimension. Below, we specify the numeric formatting for only three levels of `colname`.

```
. collect style cell colname[p_skew p_kurt p_chi2], nformat(%7.3f)
```

Finally, we want to show only the three p -values in our table. We can use `collect layout` to specify the statistics we want to include in our final table.

```
. collect layout (rowname) (colname[p_skew p_kurt p_chi2])
Collection: Table
  Rows: rowname
  Columns: colname[p_skew p_kurt p_chi2]
Table 1: 3 x 3
```

	Skewness p-value	Kurtosis p-value	Joint p-value
Height (cm)	0.000	0.000	0.000
Weight (kg)	0.000	0.000	0.000
Diastolic blood pressure	0.000	0.000	0.000

Notably, all p -values for all tests are very small, so this is not a particularly exciting table. However, our table customizations made it easy to quickly see the results of tests of normality for all our variables.

Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

Description

In this entry, we discuss how to create tables of regression results. These tables can include coefficients, standard errors, confidence intervals, and many more results stored by estimation commands.

Quick start

Table of regression coefficients; rows correspond to covariates (`colname`)

```
table colname, command(regress y x1 x2 x3)
```

Table of coefficients and confidence intervals; columns correspond to the statistics (`result`)

```
table (colname) (result), command(_r_b _r_ci: regress y x1 x2 x3)
```

Same as above, but use the labels defined in `mylabels.stjson` and the styles in `mystyle.stjson`

```
table (colname) (result), ///
    command(_r_b _r_ci: regress y x1 x2 x3) ///
    label(mylabels) style(mystyle)
```

Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results

Syntax

```
table ([rowspec]) ([colspec]) ([tabspec]) [if] [in] [weight],
      command(cmdspec) [command(cmdspec) ...] [options]
```

rowspec, *colspec*, and *tabspec* may be empty or may include variable names or any of the following keywords:

keyword	Description
result	requested statistics
stars	stars denoting statistical significance
command	index option command()
colname	column names for matrix statistics
rowname	row names for matrix statistics
coleq	column equation names for matrix statistics
roweq	row equation names for matrix statistics

options	Description
Commands	
command(<i>cmdspec</i>)	collect results from the specified Stata command
Formats	
nformat(<i>%fmt</i> [<i>results</i>][, <i>basestyle</i>])	specify numeric format
sformat(<i>sfmt</i> [<i>results</i>])	specify string format
cidelimiter(<i>char</i>)	use character as delimiter for confidence interval limits
cridelimiter(<i>char</i>)	use character as delimiter for credible interval limits
Stars	
stars(<i>starspec</i>)	add stars to denote statistical significance
Title	
title(<i>string</i>)	add table title
titlestyles(<i>text_styles</i>)	change table title styles
Notes	
note(<i>string</i>)	add table note
notestyles(<i>text_styles</i>)	change table note styles
Export	
export(<i>filename.suffix</i> [, <i>export_opts</i>])	export table
Options	
missing	treat numeric missing values like other values
name(<i>cname</i>)	collect results into a collection named <i>cname</i>
append	append results to an existing collection
replace	replace results of an existing collection
label(<i>filename</i>)	specify the collection labels
style(<i>filename</i> [, <i>override</i>])	specify the collection style
noisily	display output from each command

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 **weight**.

strL variables are not allowed; see [U] 12.4.8 **strL**.

noisily does not appear in the dialog box.

<i>text_styles</i>	Description
<code>font([<i>fontfamily</i>][, <i>font_opts</i>])</code>	specify font style
<code>smcl(<i>smcl</i>)</code>	specify formatting for SMCL files
<code>latex(<i>latex</i>)</code>	specify L ^A T _E X macro
<code>shading(<i>sspec</i>)</code>	set background color, foreground color, and fill pattern

<i>font_opts</i>	Description
<code>size(# [<i>unit</i>])</code>	specify font size
<code>color(<i>color</i>)</code>	specify font color
<code>variant(<i>variant</i>)</code>	specify font variant and capitalization
<code>[no]bold</code>	specify whether to format text as bold
<code>[no]italic</code>	specify whether to format text as italic
<code>[no]strikeout</code>	specify whether to strike out text
<code>[no]underline</code>	specify whether to underline text

<i>suffix</i>	<i>fileformat</i>	Output format
<code>docx</code>	<code>as(docx)</code>	Microsoft Word
<code>html</code>	<code>as(html)</code>	HTML 5 with CSS
<code>pdf</code>	<code>as(pdf)</code>	PDF
<code>xlsx</code>	<code>as(xlsx)</code>	Microsoft Excel 2007/2010 or newer
<code>xls</code>	<code>as(xls)</code>	Microsoft Excel 1997/2003
<code>tex</code>	<code>as(tex)</code>	L ^A T _E X
<code>smcl</code>	<code>as(smcl)</code>	SMCL
<code>txt</code>	<code>as(txt)</code>	plain text
<code>markdown</code>	<code>as(markdown)</code>	Markdown
<code>md</code>	<code>as(md)</code>	Markdown

<i>export_opts</i>	Description
<code>as(<i>fileformat</i>)</code>	specify document type
<code>replace</code>	overwrite existing file
<i>docx_options</i>	available when exporting to .docx files
<i>html_options</i>	available when exporting to .html files
<i>pdf_options</i>	available when exporting to .pdf files
<i>excel_options</i>	available when exporting to .xls and .xlsx files
<i>tex_options</i>	available when exporting to .tex files
<i>smcl_option</i>	available when exporting to .smcl files
<i>txt_option</i>	available when exporting to .txt files
<i>md_option</i>	available when exporting to .markdown and .md files

<i>docx_options</i>	Description
<code>noisily</code>	show the putdocx commands used to export to the Microsoft Word file
<code>dofile(filename[, replace])</code>	save the putdocx commands used for exporting to the named do-file

<i>html_options</i>	Description
<code>append</code>	append to an existing file
<code>tableonly</code>	export only the table to the specified file
<code>cssfile(cssfile)</code>	define the styles in <i>cssfile</i> instead of <i>filename</i>
<code>prefix(prefix)</code>	use <i>prefix</i> to identify style classes

<i>pdf_options</i>	Description
<code>noisily</code>	show the putpdf commands used to export to the PDF file
<code>dofile(filename[, replace])</code>	save the putpdf commands used for exporting to the named do-file

<i>excel_options</i>	Description
<code>noisily</code>	show the putexcel commands used to export to the Excel file
<code>dofile(filename[, replace])</code>	save the putexcel commands used for exporting to the named do-file
<code>sheet(sheetname[, replace])</code>	specify the worksheet to use; the default sheet name is Sheet1
<code>cell(cell)</code>	specify the Excel upper-left cell as the starting position to export the table; the default is cell (A1)
<code>modify</code>	modify Excel file
<code>noopen</code>	do not open Excel file in memory

`noopen` does not appear in the dialog box.

<i>tex_options</i>	Description
<code>append</code>	append to an existing file
<code>tableonly</code>	export only the table to the specified file

<i>smcl_option</i>	Description
<code>append</code>	append to an existing file

<i>txt_option</i>	Description
<code>append</code>	append to an existing file

<i>md_option</i>	Description
<code>append</code>	append to an existing file

fontfamily specifies a valid font family.

unit may be in (inch), pt (point), or cm (centimeter). An inch is equivalent to 72 points and 2.54 centimeters. The default is pt.

variant may be allcaps, smallcaps, or normal.

variant(allcaps) changes the text to all uppercase letters; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

variant(smallcaps) changes the text to use large capitals for uppercase letters and smaller capitals for lowercase letters; applicable when publishing items from a collection to Microsoft Word, L^AT_EX, and HTML files.

variant(normal) changes the font variant back to normal and leaves the capitalization unchanged from the original text; applicable when publishing items from a collection to Microsoft Word, PDF, L^AT_EX, and HTML files.

smcl specifies the name of the SMCL directive to render text for SMCL output. The supported SMCL directives are input, error, result, and text.

latex specifies the name of a L^AT_EX macro to render text for L^AT_EX output. Example L^AT_EX macro names are textbf, textsf, textrm, and texttt. Custom L^AT_EX macros are also allowed. If *text* is to be rendered in a cell, title, or note, then *latex* is translated to the following when you export to L^AT_EX:

`\latex {text}`

sspec is

`[background(bcolor) foreground(fgcolor) pattern(fpattern)]`

bcolor specifies the background color.

fgcolor specifies the foreground color.

fpattern specifies the fill pattern. A complete list of fill patterns is shown in the [Appendix](#).

bcolor, *fgcolor*, and *color* may be one of the colors listed in the [Appendix](#); a valid RGB value in the form ### ##, for example, 171 248 103; or a valid RRGGBB hex value in the form #####, for example, ABF867.

Options

Commands

`command(cmds spec)` specifies the Stata commands from which to collect results. `command()` may be repeated to collect results from multiple commands.

cmds spec is `[explist:] command [arguments] [, cmdoptions]`

explist specifies which results to collect and report in the table. *explist* may include *result identifiers* and *named expressions*.

result identifiers are results stored in `r()` and `e()` by the *command*. For instance, *result identifiers* could be `r(mean)`, `r(C)`, or `e(chi2)`. After estimation commands, *result identifiers* also include the following:

Identifier	Result
<code>_r_b</code>	coefficients or transformed coefficients reported by <i>command</i>
<code>_r_se</code>	standard errors of <code>_r_b</code>
<code>_r_z</code>	test statistics for <code>_r_b</code>
<code>_r_z_abs</code>	absolute value of <code>_r_z</code>
<code>_r_p</code>	<i>p</i> -values for <code>_r_b</code>
<code>_r_lb</code>	lower bounds of confidence intervals for <code>_r_b</code>
<code>_r_ub</code>	upper bounds of confidence intervals for <code>_r_b</code>
<code>_r_ci</code>	confidence intervals for <code>_r_b</code>
<code>_r_crlb</code>	lower bounds of credible intervals for <code>_r_b</code>
<code>_r_crub</code>	upper bounds of credible intervals for <code>_r_b</code>
<code>_r_cri</code>	credible intervals for <code>_r_b</code>
<code>_r_df</code>	degrees of freedom for <code>_r_b</code>

named expressions are specified as *name* = *exp*, where *name* may be any valid Stata name and *exp* is an expression, typically an expression that involves one or more *result identifiers*. An example of a named expression is `sd = sqrt(r(variance))`.

For *r*-class commands, the default is to include all numeric scalars posted to `r()` in the table results. For *e*-class commands, the default is to include `_r_b` in the table results.

command is any command that follows standard Stata syntax.

arguments may be anything so long as they do not include an *if* clause, *in* range, or weight specification.

Any *if* or *in* qualifier and weights should be specified directly with `table`, not within the `command()` option. Weights are passed to *command* only if they are specified.

cmdoptions may be anything supported by *command*.

Formats

`nformat(%fmt [results] [, basestyle])` changes the numeric format, such as the number of decimal places, for specified results. If *results* are not specified, the numeric format is changed for all results.

results may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (*rowspec*, *colspec*, and *tabspec*). The default format of these variables is taken from the dataset.

basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

sformat(*sfmt* [*results*]) changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and %s. Here %s refers to the numeric value that is formatted as specified using *nformat*(). The text will be placed around the numeric values in your table as it is placed around %s in this option. For instance, to place parentheses around the percent statistics, you can specify *sformat*("(%s)" percent).

results may be any name in the *e*() or *r*() results produced by commands specified in option *command*().

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type %%. To include \, type \\. For instance, to place a percent sign following percent statistics, you can specify *sformat*("%%%" percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

cidelimiter(*char*) changes the delimiter between confidence interval limits to *char*. The default is *cidelimiter*(" "), that is, two spaces.

cridelimiter(*char*) changes the delimiter between credible interval limits to *char*. The default is *cridelimiter*(" "), that is, two spaces.

Stars

stars(*starspec*) specifies that stars representing statistical significance be included in the table. *starspec* identifies the result whose values determine significance, which characters should represent each significance level, and where these characters should be displayed in the table. *starspec* is

```
starres [#1 "label1" [#2 "label2" [#3 "label3" [#4 "label4" [#5 "label5"]]]]]
[, attach(attachres) result dimension starsnoteopts]
```

starres is the name of the result whose values determine which characters, typically which number of stars, are to be displayed.

label1 specifies the characters to be displayed when *starres* < #1.

label2 specifies the characters to be displayed when *starres* < #2.

label3 specifies the characters to be displayed when *starres* < #3.

label4 specifies the characters to be displayed when *starres* < #4.

label5 specifies the characters to be displayed when *starres* < #5.

attach(attachres) specifies the name of the result to which the characters defined by *label1*, ..., *label5* are to be attached. If *attach*() is not specified, a new result named *stars* is created and is automatically added to the table.

result and *dimension* control how *collect stars* adds items when labeling significant results. These options are mutually exclusive.

result specifies the default behavior, and this option is necessary only if the following *dimension* behavior is in effect and you want to change back to the *result* behavior.

`dimension` specifies that dimension stars be added to the collection. Items will be tagged with `stars[value]`, and the labels will be tagged with `stars[label]`. Use this option for layouts where results are to be stacked within columns, and use new dimension stars in the column specification of the layout.

`starsnoteopts` control the display and composition of the stars note.

`noshownote` and `shownote` control whether to display the stars note.

`increasing` and `decreasing` control the order of p -values in the stars note.

`pvname(string)` specifies a name for the p -value in the stars note. The default is `pvname(p)`.

`delimiter(string)` specifies the delimiter between labels in the stars note. The default is `delimiter(",")`.

`nformat(%fmt)` specifies the numeric format for the cutoff values in the stars note. The default is `nformat(%9.0g)`.

`prefix(string)` specifies the prefix for the stars note. The prefix is empty by default.

`suffix(string)` specifies the suffix for the stars note. The suffix is empty by default.

For example, `stars(_r_p 0.01 "****" 0.05 "***" 0.1 "**", attach(_r_b))` could be added to a table of regression results to specify that stars be defined based on the p -values in `_r_p` and be attached to the reported coefficients (`_r_b`).

Title

`title(string)` adds the text *string* as a title to the table.

`titlestyles(text_styles)` changes the style for the table title. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the title. `strikeout` adds a strikeout mark to the title; `nostrikeout` changes the title back to normal.

`underline` and `nounderline` specify whether to underline the table title. `underline` adds a single line under the title; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table title for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table title for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Notes

`note(string)` adds the text *string* as a note to the table. `note()` may be specified multiple times to add multiple notes. Each note is placed on a new line.

`notestyles(text_styles)` changes the style for the table notes. *text_styles* are the following:

`font([fontfamily] [, size(# [unit]) color(color) variant(variant) [no]bold [no]italic [no]strikeout [no]underline])` specifies the font style. These font style properties are applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files, unless otherwise specified.

fontfamily specifies a valid font family. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`size(# [unit])` specifies the font size as a number optionally followed by units. This font style property is applicable when publishing items from a collection to Microsoft Word, Microsoft Excel, PDF, and HTML files.

`color(color)` specifies the text color.

`variant(variant)` specifies the font variant and capitalization.

`bold` and `nobold` specify the font weight. `bold` changes the font weight to bold; `nobold` changes the font weight back to normal.

`italic` and `noitalic` specify the font style. `italic` changes the font style to italic; `noitalic` changes the font style back to normal.

`strikeout` and `nostrikeout` specify whether to add a strikeout mark to the notes. `strikeout` adds a strikeout mark to the note; `nostrikeout` changes the note back to normal.

`underline` and `nounderline` specify whether to underline the table notes. `underline` adds a single line under the notes; `nounderline` removes the underline.

Only one of `strikeout` or `underline` is allowed when publishing to HTML files.

`smcl(smcl)` specifies how to render the table notes for SMCL output. This style property is applicable only when publishing items from a collection to a SMCL file.

`latex(latex)` specifies how to render the table notes for \LaTeX output. This style property is applicable only when publishing items from a collection to a \LaTeX file.

`shading(sspec)` sets the background color, foreground color, and fill pattern. The background color is applicable when exporting the table to Microsoft Word, Microsoft Excel, PDF, HTML, and \LaTeX files. The foreground color and fill pattern are applicable when exporting the table to Microsoft Word and Microsoft Excel.

Export

`export(filename.suffix[, export_opts])` exports the table to the specified file. *export_opts* are the following:

`as(fileformat)` specifies the file format to which the table is to be exported. This option is rarely specified because, by default, `table` determines the format from the suffix of the file being created.

`replace` permits `table` to overwrite an existing file.

`noisily` specifies that `table` show the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files. The `putdocx`, `putexcel`, or `putpdf` command used to export the table will be displayed.

`dofile(filename[, replace])` specifies that `table` save to *filename* the commands used to export the table to Microsoft Word, Microsoft Excel, and PDF files.

If *filename* already exists, it can be overwritten by specifying `replace`. If *filename* is specified without an extension, `.do` is assumed.

`append` specifies that `table` append the table to an existing file.

This option is applicable when you export the table to an HTML, a \LaTeX , a SMCL, a `txt`, or a Markdown file. When you export to HTML and \LaTeX files, the `append` option implies the `tableonly` option. Furthermore, when you export to HTML files, if the target CSS file already exists, `table` will also append to it.

`tableonly` specifies that only the table be exported to the specified HTML or \LaTeX document. By default, `table` produces complete HTML and \LaTeX documents.

When you export to an HTML file, if the `cssfile()` option is not specified, a CSS filename is constructed from *filename*, with the extension replaced with `.css`.

`cssfile(cssfile)` specifies that `table` define the styles in *cssfile* instead of *filename* when you export to HTML.

`prefix(prefix)` specifies that `table` use *prefix* to identify style classes when you export to HTML.

`sheet(sheetname [, replace])` saves to the worksheet named *sheetname*. For more information about this option, see [\[RPT\] putexcel](#).

`cell(cell)` specifies an Excel upper-left cell as the starting position to publish the table. The default is `cell(A1)`.

`modify` permits `putexcel` set to modify an Excel file. For more information about this option, see [\[RPT\] putexcel](#).

`noopen` prevents `putexcel` from opening the Excel file in memory for modification. It does not appear in the dialog box. For more information about this option, see [\[RPT\] putexcel](#).

Options

`missing` specifies that numeric missing values of any variables specified in `rowspec`, `colspec`, or `tabspec` be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

`name(cname)` specifies that a collection named *cname* be associated with the collected statistics and results. The default is `name(Table)`.

`append` specifies that `table` append its collection information into the collection named in `name()`.

`replace` permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded for the table, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] [set collect_label](#).

`style(filename [, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify `override`. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(table_style)`; see [TABLES] [set table_style](#).

The following option is available with `table` but is not shown in the dialog box:

`noisily` specifies that output from the commands specified in `command()` options be displayed. By default, output from commands is suppressed.

Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Tables with results from a single command](#)

[Tables with results from multiple estimation commands](#)

[Regression results with factor variables](#)

Introduction

The `table` command allows us to create tables of regression results. You can create a table that reports coefficients, standard errors, test statistics, confidence intervals, and other statistics from a single model or a table that compares results from multiple models.

`table` does not fit models directly. Rather, `table` will run any Stata command that you include in its `command()` option and place results from that command into the table. You determine which results you would like to see in the table. You can select any of the results stored by the command.

You can also create a table of regression results with `etable`. However, `etable` will create tables only with active estimation results, results from margins, or results stored with `estimates store`. If you are working with any of these results, you can use `etable` to create and export a table of regression results. However, if you want to include results from other commands, you should use the `table` command.

Tables with results from a single command

We have data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). The data contain some demographic information, such as the participants' age. The data also contain some measures of health, including the individual's weight, systolic blood pressure (bpsystol), and whether the individual has diabetes.

Here we will create a table with results from a linear regression model for systolic blood pressure as a function of age and weight. We type the command to fit the model in the `command()` option. In the first set of parentheses following `table`, we specify that we want the rows to correspond to the levels of `colname`—this is how we refer to the list of covariates in our regression model. In the second set of parentheses, we specify that we want the columns to correspond to the statistics (`result`).

```
. use https://www.stata-press.com/data/r19/nhanes2l
(Second National Health and Nutrition Examination Survey)
. table (colname) (result), command(regress bpsystol age weight)
```

	Coefficient
Age (years)	.6379892
Weight (kg)	.4069041
Intercept	71.27096

Our table is fairly simple. By default, `table` includes only the reported coefficients when an estimation command is specified in the `command()` option.

The `table` command can easily be used to compare results across groups in our data. For instance, if we want to fit the same model for males and females, we can add `sex` to our column specification.

```
. table (colname) (sex result), command(regress bpsystol age weight)
```

	Sex		
	Male	Female	Total
Age (years)	.4789361	.7735499	.6379892
Weight (kg)	.3346106	.4586108	.4069041
Intercept	84.08037	61.70456	71.27096

We can now easily compare results for males, females, and both together.

We may want to see additional statistics reported. Let's extend our table to include both coefficients and standard errors. We can refer to the reported coefficients using the keyword `_r_b` and to the reported standard errors as `_r_se`, and we can list these in the `command()` option before our regression command. Here we also move `result` to the first set of parentheses so that coefficients and standard errors will be displayed on separate rows.

```
. table (colname result) (sex),
> command(_r_b _r_se: regress bpsystol age weight)
```

	Sex		
	Male	Female	Total
Age (years)			
Coefficient	.4789361	.7735499	.6379892
Std. error	.0156578	.0155743	.0111315
Weight (kg)			
Coefficient	.3346106	.4586108	.4069041
Std. error	.0197112	.0182401	.0124786
Intercept			
Coefficient	84.08037	61.70456	71.27096
Std. error	1.74867	1.376067	1.041742

We now have the statistics we want in this table, but we may want to modify the look a bit. `table` allows us to customize the results in our table in a number of ways. We can use the `nformat()` option to report all results to two decimal places, and we can use the `sformat()` option to place parentheses around our standard errors.

```
. table (colname result) (sex),
> command(_r_b _r_se: regress bpsystol age weight)
> nformat(%6.2f) sformat("(%s)" _r_se)
```

	Sex		
	Male	Female	Total
Age (years)			
Coefficient	0.48	0.77	0.64
Std. error	(0.02)	(0.02)	(0.01)
Weight (kg)			
Coefficient	0.33	0.46	0.41
Std. error	(0.02)	(0.02)	(0.01)
Intercept			
Coefficient	84.08	61.70	71.27
Std. error	(1.75)	(1.38)	(1.04)

Now that we have the parentheses to distinguish standard errors from coefficients, we may not want to see those labels in the row header. We add the `style(table-reg3)` option to use the [predefined style table-reg3](#), which hides the names of these statistics, right-aligns the names of the variables in the row headers, center aligns the statistics horizontally within each column, and adds vertical space between variables.

```
. table (colname result) (sex),
> command(_r_b _r_se: regress bpsystol age weight)
> nformat(%05.3f) sformat("(%s)" _r_se) style(table-reg3)
```

	Male	Sex Female	Total
Age (years)	0.479 (0.016)	0.774 (0.016)	0.638 (0.011)
Weight (kg)	0.335 (0.020)	0.459 (0.018)	0.407 (0.012)
Intercept	84.080 (1.749)	61.705 (1.376)	71.271 (1.042)

Tables with results from multiple estimation commands

Above, we fit the same model to the full dataset and then to groups of observations within that dataset. We may alternatively want to fit different models and display their results in a single table. To do this, we specify multiple `command()` options.

```
. table (colname result) (command),
> command(_r_b _r_se: regress bpsystol age weight)
> command(_r_b _r_se: regress bpsystol age weight iron vitaminc zinc)
> nformat(%6.2f) sformat("(%s)" _r_se) style(table-reg3)
```

	1	2
Age (years)	0.64 (0.01)	0.64 (0.01)
Weight (kg)	0.41 (0.01)	0.40 (0.01)
Serum iron (mcg/dL)		-0.01 (0.01)
Serum vitamin C (mg/dL)		-0.79 (0.36)
Serum zinc (mcg/dL)		-0.05 (0.01)
Intercept	71.27 (1.04)	77.50 (1.75)

We may want to modify this table a bit further. Customization of tables can go beyond the predefined styles and options available to you in the `table` command. `table` creates a collection of results that can be used in combination with the [collect](#) suite of commands to produce highly customized tables.

If we want to add more descriptive labels for the two models, we can use the `collect label levels` command to define our new labels. After a change using `collect`, we can type `collect preview` to see the results.

```
. collect label levels command 1 "Model 1" 2 "Model 2", modify
. collect style header command, level(label)
. collect preview
```

	Model 1	Model 2
Age (years)	0.64 (0.01)	0.64 (0.01)
Weight (kg)	0.41 (0.01)	0.40 (0.01)
Serum iron (mcg/dL)		-0.01 (0.01)
Serum vitamin C (mg/dL)		-0.79 (0.36)
Serum zinc (mcg/dL)		-0.05 (0.01)
Intercept	71.27 (1.04)	77.50 (1.75)

Regression results with factor variables

The examples above included only continuous covariates in the models. When we include factor variables, there are a variety of ways that they can be displayed in the headers of the tables. In [\[TABLES\] Pre-defined styles](#), you will find a number of styles that you can choose from. We demonstrate a few here.

We will start with the `table-reg1` style. This style is our default table style, except that it identifies the commands in the headers using values 1, 2, ... rather than labeling them with the full command we typed in the `command()` option.

```
. table (colname) (command result),
> command(regress bpsystol i.agegrp i.sex weight)
> command(regress bpsystol i.agegrp##i.sex weight)
> style(table-reg1)
```

	1	2
Age group=20-29	0	0
Age group=30-39	1.195226	-.7808968
Age group=40-49	7.251555	2.749774
Age group=50-59	15.94216	10.43724
Age group=60-69	22.83932	16.53001
Age group=70+	30.46609	23.3076
Sex=Male	0	0
Sex=Female	1.040833	-6.777535
Weight (kg)	.4359741	.4242392
Age group=20-29 # Sex=Male		0
Age group=20-29 # Sex=Female		0
Age group=30-39 # Sex=Male		0
Age group=30-39 # Sex=Female		3.942553
Age group=40-49 # Sex=Male		0
Age group=40-49 # Sex=Female		8.79336
Age group=50-59 # Sex=Male		0
Age group=50-59 # Sex=Female		10.6501
Age group=60-69 # Sex=Male		0
Age group=60-69 # Sex=Female		12.20669
Age group=70+ # Sex=Male		0
Age group=70+ # Sex=Female		13.51823
Intercept	86.71019	91.57774

In some cases, for clarity, it is helpful to see both the factor variables and their levels. The `table-reg1` style provides this in the output.

When we have nice value labels on our factor variables, we may want to see only those. The `table-reg1-fv1` style removes the extra labels. Our table above also reports zero-valued coefficients for base categories in both the main effects of the factor variables and in their interactions. The `table-reg1-fv1` style omits the rows for the base categories in the interactions.

```
. table (colname) (command result),
> command(regress bpsystol i.agegrp i.sex weight)
> command(regress bpsystol i.agegrp##i.sex weight)
> style(table-reg1-fv1)
```

	1	2
20-29	0	0
30-39	1.195226	-.7808968
40-49	7.251555	2.749774
50-59	15.94216	10.43724
60-69	22.83932	16.53001
70+	30.46609	23.3076
Male	0	0
Female	1.040833	-6.777535
Weight (kg)	.4359741	.4242392
30-39 # Female		3.942553
40-49 # Female		8.79336
50-59 # Female		10.6501
60-69 # Female		12.20669
70+ # Female		13.51823
Intercept	86.71019	91.57774

Sometimes, the tables are more readable when the row headers are right aligned. We can use the `table-reg2-fv1` style in this case. Let's also change the numeric format of all the results so that they report only two decimal places.

```
. table (colname) (command result),
> command(regress bpsystol i.agegrp i.sex weight)
> command(regress bpsystol i.agegrp##i.sex weight)
> style(table-reg2-fv1) nformat(%6.2f)
```

	1	2
20-29	0.00	0.00
30-39	1.20	-0.78
40-49	7.25	2.75
50-59	15.94	10.44
60-69	22.84	16.53
70+	30.47	23.31
Male	0.00	0.00
Female	1.04	-6.78
Weight (kg)	0.44	0.42
30-39 # Female		3.94
40-49 # Female		8.79
50-59 # Female		10.65
60-69 # Female		12.21
70+ # Female		13.52
Intercept	86.71	91.58

There are many ways that we can further customize our table using the `collect` suite of commands. We can add column titles for our models as we did above. In addition, we can use `collect style row` to specify a character to be used between terms in an interaction.

```
. collect label levels command 1 "Model 1" 2 "Model 2", modify
. collect style header command, level(label)
. collect style row stack, delimiter(" X ")
. collect preview
```

	Model 1	Model 2
20–29	0.00	0.00
30–39	1.20	–0.78
40–49	7.25	2.75
50–59	15.94	10.44
60–69	22.84	16.53
70+	30.47	23.31
Male	0.00	0.00
Female	1.04	–6.78
Weight (kg)	0.44	0.42
30–39 X Female		3.94
40–49 X Female		8.79
50–59 X Female		10.65
60–69 X Female		12.21
70+ X Female		13.52
Intercept	86.71	91.58

If one of the predefined styles in [TABLES] **Predefined styles** does not suit your needs for factor-variable results (or for any other table customization), you can create your own style. To do this, you will use series of `collect style` commands, and then you can save the style to use later; see [TABLES] **collect style save**.

If you wish to include your table in a paper, on a webpage, or in another format, you can easily export it in \LaTeX , Word, Excel, HTML, and a variety of other formats by using `collect export`.

Stored results

`table` stores the following in `r()`:

Scalars

`r(N)` number of observations

Description

tabstat displays summary statistics for a series of numeric variables in one table. It allows you to specify the list of statistics to be displayed. Statistics can be calculated (conditioned on) another variable. tabstat allows substantial flexibility in terms of the statistics presented and the format of the table.

Quick start

Mean of v1 displayed using v1’s display format

```
tabstat v1, format
```

Same as above, but use format with 2 significant digits and a comma

```
tabstat v1, format(%9.2fc)
```

Nonmissing observations, mean, standard error, and coefficient of variation for v1

```
tabstat v1, statistics(n mean semean cv)
```

Quartiles and interquartile range of v1 and v2

```
tabstat v1 v2, statistics(q iqr)
```

Same as above, but report statistics separately for each level of catvar

```
tabstat v1 v2, by(catvar) statistics(q iqr)
```

Same as above, but display a separate column for each statistic

```
tabstat v1 v2, by(catvar) statistics(q iqr) columns(statistics)
```

Menu

Statistics > Summaries, tables, and tests > Other tables > Compact table of summary statistics

Syntax

```
tabstat varlist [ if ] [ in ] [ weight ] [ , options ]
```

options	Description
Main	
by(varname)	group statistics by variable
statistics(statname[...])	report specified statistics
Options	
labelwidth(#)	width for by() variable labels; default is labelwidth(16)
varwidth(#)	variable width; default is varwidth(12)
columns(variables)	display variables in table columns; the default
columns(statistics)	display statistics in table columns
format(%fmt)	display format for statistics; default format is %9.0g
casewise	perform casewise deletion of observations
nototal	do not report overall statistics; use with by()
missing	report statistics for missing values of by() variable
noseparator	do not use separator line between by() categories
longstub	make left table stub wider
save	store summary statistics in r()

by is allowed; see [D] by.
aweight and fweight are allowed; see [U] 11.1.6 weight.

Options

Main

`by(varname)` specifies that the statistics be displayed separately for each unique value of *varname*; *varname* may be numeric or string. For instance, `tabstat height` would present the overall mean of height. `tabstat height, by(sex)` would present the mean height of males, and of females, and the overall mean height. Do not confuse the `by()` option with the `by prefix` (see [D] [by](#)); both may be specified.

`statistics(statname [...])` specifies the statistics to be displayed; the default is equivalent to specifying `statistics(mean)`. (`stats()` is a synonym for `statistics()`.) Multiple statistics may be specified and are separated by white space, such as `statistics(mean sd)`. Available statistics are

<i>statname</i>	Definition	<i>statname</i>	Definition
<u>m</u> ean	mean	p1	1st percentile
<u>c</u> ount	count of nonmissing observations	p5	5th percentile
<u>n</u>	same as count	p10	10th percentile
<u>s</u> um	sum	p25	25th percentile
<u>m</u> ax	maximum	<u>m</u> edian	median (same as p50)
<u>m</u> in	minimum	p50	50th percentile (same as median)
<u>r</u> ange	range = max – min	p75	75th percentile
<u>s</u> d	standard deviation	p90	90th percentile
<u>v</u> ariance	variance	p95	95th percentile
<u>c</u> v	coefficient of variation (sd/mean)	p99	99th percentile
<u>s</u> emean	standard error of mean (sd/ \sqrt{n})	iqr	interquartile range = p75 – p25
<u>s</u> kewness	skewness	q	equivalent to specifying p25 p50 p75
<u>k</u> urtosis	kurtosis		

Options

`labelwidth(#)` specifies the maximum width to be used within the stub to display the labels of the `by()` variable. The default is `labelwidth(16)`. $8 \leq \# \leq 32$.

`varwidth(#)` specifies the maximum width to be used within the stub to display the names of the variables. The default is `varwidth(12)`. `varwidth()` is effective only with `columns(statistics)`. Setting `varwidth()` implies `longstub`. $8 \leq \# \leq 32$.

`columns(variables | statistics)` specifies whether to display variables or statistics in the columns of the table. `columns(variables)` is the default when more than one variable is specified.

`format` and `format(%fmt)` specify how the statistics are to be formatted. The default is to use a `%9.0g` format.

`format` specifies that each variable’s statistics be formatted with the variable’s display format; see [D] [format](#).

`format(%fmt)` specifies the format to be used for all statistics.

The column width is the maximum width of these formats. The minimum column width is nine display characters.

`casewise` specifies casewise deletion of observations. Statistics are to be computed for the sample that is not missing for any of the variables in *varlist*. The default is to use all the nonmissing values for each variable.

`nototal` is for use with `by()`; it specifies that the overall statistics not be reported.

`missing` specifies that missing values of the `by()` variable be treated just like any other value and that statistics should be displayed for them. The default is not to report the statistics for the `by() == missing` group. If the `by()` variable is a string variable, `by() == ""` is considered to mean missing.

`noseparator` specifies that a separator line between the `by()` categories not be displayed.

`longstub` specifies that the left stub of the table be made wider so that it can include names of the statistics or variables in addition to the categories of `by(varname)`. The default is to describe the statistics or variables in a header. `longstub` is ignored if `by(varname)` is not specified.

`save` specifies that the summary statistics be returned in `r()`. The overall (unconditional) statistics are returned in matrix `r(StatTotal)` (rows are statistics, columns are variables). The conditional statistics are returned in the matrices `r(Stat1)`, `r(Stat2)`, ..., and the names of the corresponding variables are returned in the macros `r(name1)`, `r(name2)`, ...

Remarks and examples

This command is probably most easily understood by going through a series of examples.

► Example 1

We have data on the price, weight, mileage rating, and repair record of 22 foreign and 52 domestic 1978 automobiles. We want to summarize these variables for the different origins of the automobiles.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)

. tabstat price weight mpg rep78, by(foreign)

Summary statistics: Mean
Group variable: foreign (Car origin)
```

foreign	price	weight	mpg	rep78
Domestic	6072.423	3317.115	19.82692	3.020833
Foreign	6384.682	2315.909	24.77273	4.285714
Total	6165.257	3019.459	21.2973	3.405797

More summary statistics can be requested via the `statistics()` option. The group totals can be suppressed with the `nototal` option.

```
. tabstat price weight mpg rep78, by(foreign) stat(mean sd min max) nototal
```

Summary statistics: Mean, SD, Min, Max

Group variable: foreign (Car origin)

foreign	price	weight	mpg	rep78
Domestic	6072.423	3317.115	19.82692	3.020833
	3097.104	695.3637	4.743297	.837666
	3291	1800	12	1
	15906	4840	34	5
Foreign	6384.682	2315.909	24.77273	4.285714
	2621.915	433.0035	6.611187	.7171372
	3748	1760	14	3
	12990	3420	41	5

Although the header of the table describes the statistics running vertically in the “cells”, the table may become hard to read, especially with many variables or statistics. The `longstub` option specifies that a column be added describing the contents of the cells. The `format` option can be issued to specify that `tabstat` display the statistics by using the display format of the variables rather than the overall default `%9.0g`.

```
. tabstat price weight mpg rep78, by(foreign) stat(mean sd min max) long format
```

foreign	Stats	price	weight	mpg	rep78
Domestic	Mean	6,072.4	3,317.1	19.8269	3.02083
	SD	3,097.1	695.364	4.7433	.837666
	Min	3,291	1,800	12	1
	Max	15,906	4,840	34	5
Foreign	Mean	6,384.7	2,315.9	24.7727	4.28571
	SD	2,621.9	433.003	6.61119	.717137
	Min	3,748	1,760	14	3
	Max	12,990	3,420	41	5
Total	Mean	6,165.3	3,019.5	21.2973	3.4058
	SD	2,949.5	777.194	5.7855	.989932
	Min	3,291	1,760	12	1
	Max	15,906	4,840	41	5

We can specify a layout of the table in which the statistics run horizontally and the variables run vertically by specifying the `col(statistics)` option.

```
. tabstat price weight mpg rep78, by(foreign) stat(min mean max) col(stat) long
```

foreign	Variable	Min	Mean	Max
Domestic	price	3291	6072.423	15906
	weight	1800	3317.115	4840
	mpg	12	19.82692	34
	rep78	1	3.020833	5
Foreign	price	3748	6384.682	12990
	weight	1760	2315.909	3420
	mpg	14	24.77273	41
	rep78	3	4.285714	5
Total	price	3291	6165.257	15906
	weight	1760	3019.459	4840
	mpg	12	21.2973	41
	rep78	1	3.405797	5

Finally, `tabstat` can also be used to enhance `summarize` so we can specify the statistics to be displayed. For instance, we can display the number of observations, the mean, the coefficient of variation, and the 25%, 50%, and 75% quantiles for a list of variables.

```
. tabstat price weight mpg rep78, stat(n mean cv q) col(stat)
```

variable	N	mean	cv	p25	p50	p75
price	74	6165.257	.478406	4195	5006.5	6342
weight	74	3019.459	.2573949	2240	3190	3600
mpg	74	21.2973	.2716543	18	20	25
rep78	69	3.405797	.290661	3	3	4

Because we did not specify the `by()` option, these statistics were not displayed for the subgroups of the data formed by the categories of the `by()` variable.

Description

`tabulate` produces a one-way table of frequency counts.

For information on a two-way table of frequency counts along with measures of association, including the common Pearson χ^2 , the likelihood-ratio χ^2 , Cramér's V , Fisher's exact test, Goodman and Kruskal's gamma, and Kendall's τ_b , see [\[R\] tabulate twoway](#).

`tab1` produces a one-way tabulation for each variable specified in *varlist*.

Also see [\[R\] table](#) and [\[R\] tabstat](#) if you want one-, two-, or n -way table of frequencies and a wide variety of statistics. See [\[R\] tabulate, summarize\(\)](#) for a description of `tabulate` with the `summarize()` option; it produces a table (breakdowns) of means and standard deviations. `table` is better than `tabulate`, `summarize()`, but `tabulate, summarize()` is faster. See [\[R\] Epitab](#) for a 2×2 table with statistics of interest to epidemiologists.

Quick start

One-way table of frequencies for `v1`

```
tabulate v1
```

Sort table in descending order of frequency

```
tabulate v1, sort
```

Generate indicator variables `v1_1`, `v1_2`, ... representing the levels of `v1`

```
tabulate v1, generate(v1_)
```

Treat missing values like other values of `v1`

```
tabulate v1, missing
```

Display numeric values of `v1` rather than value labels

```
tabulate v1, nolabel
```

Create one-way tables for `v1`, `v2`, and `v3`

```
tab1 v1 v2 v3
```

Menu

tabulate oneway

Statistics > Summaries, tables, and tests > Frequency tables > One-way table

tabulate ..., generate()

Data > Create or change data > Other variable-creation commands > Create indicator variables

tab1

Statistics > Summaries, tables, and tests > Frequency tables > Multiple one-way tables

Syntax

One-way table

```
tabulate varname [ if ] [ in ] [ weight ] [ , options advanced_options ]
```

One-way table for each variable—a convenience tool

```
tab1 varlist [ if ] [ in ] [ weight ] [ , options ]
```

options	Description
Main	
subpop(<i>varname</i>)	exclude observations for which <i>varname</i> = 0
missing	treat missing values like other values
nofreq	do not display frequencies
nolabel	display numeric codes rather than value labels
plot	produce a bar chart of the relative frequencies
sort	display the table in descending order of frequency
Collect	
collect	post results to collection Tabulate
collect([<i>cname</i>][, <i>collect_options</i>])	post results to a named collection
collect_options	Description
append	append results to an existing collection
replace	replace results of an existing collection
label(<i>filename</i>)	specify the collection labels
style(<i>filename</i> [, <i>override</i>])	specify the collection style
advanced_options	Description
Advanced	
generate(<i>stubname</i>)	create indicator variables for <i>stubname</i>
matcell(<i>matname</i>)	save frequencies in <i>matname</i>
matrow(<i>matname</i>)	save unique values of <i>varname</i> in <i>matname</i>

by is allowed with tabulate and tab1; see [U] 11.1.10 Prefix commands.
fweights, aweights, and iweights are allowed; see [U] 11.1.6 weight.

Options

Main

`subpop(varname)` excludes observations for which *varname* = 0 in tabulating frequencies. The mathematical results of `tabulate ...`, `subpop(myvar)` are the same as `tabulate ...` if *myvar* != 0, but the table may be presented differently. The identities of the rows and columns will be determined from all the data, including the *myvar* = 0 group, so there may be entries in the table with frequency 0.

Consider tabulating *answer*, a variable that takes on values 1, 2, and 3, but consider tabulating it just for the *male*==1 subpopulation. Assume that *answer* is never 2 in this group. `tabulate answer if male==1` produces a table with two rows: one for *answer* 1 and one for *answer* 3. There will be no row for *answer* 2 because *answer* 2 was never observed. `tabulate answer, subpop(male)` produces a table with three rows. The row for *answer* 2 will be shown as having 0 frequency.

`missing` requests that missing values be treated like other values — in calculations of counts, percentages, and other statistics.

`nofreq` suppresses the printing of the frequencies.

`no label` causes the numeric codes to be displayed rather than the value labels.

`plot` produces a bar chart of the relative frequencies in a one-way table. (Also see [\[R\] histogram.](#))

`sort` puts the table in descending order of frequency (and ascending order of the variable within equal values of frequency).

Collect

`collect` and `collect([cname][, collect_options])` specify that results be posted to a collection. This collection produces a table that you can customize and publish to Microsoft Word, Microsoft Excel, PDF, HTML, L^AT_EX, [SMCL](#), or Markdown. Output does not change when these options are specified. Use `collect preview` to see the customizable table.

`collect` is a shortcut for `collect(Tabulate)`.

cname specifies that a collection named *cname* be associated with the collected results. The default is `Tabulate`.

`append` specifies that results be appended to collection *cname*.

`replace` permits `tabulate` to overwrite an existing collection. This option is implied for collection `Tabulate` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded into the collection, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [\[TABLES\] set collect_label](#).

`style(filename[, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify *override*. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(tabulate_style)`; see [TABLES] [set tabulate_style](#).

Advanced

`generate(stubname)` creates a set of indicator variables (*stubname1*, *stubname2*, ...) reflecting the observed values of the tabulated variable. The `generate()` option may not be used with the `by` prefix.

`matcell(matname)` saves the reported frequencies in *matname*.

`matrow(matname)` saves the numeric values of the $r \times 1$ row stub in *matname*. `matrow()` may not be specified if the row variable is a string.

Limits

A one-way table may have a maximum of 12,000 rows (Stata/MP and Stata/SE) or 3,000 rows (Stata/BE).

Remarks and examples

Remarks are presented under the following headings:

[tabulate](#)
[tab1](#)
[Publish your tables](#)
[Video example](#)

For each value of a specified variable, `tabulate` reports the number of observations with that value. The number of times a value occurs is called its *frequency*.

tabulate

► Example 1

We have data summarizing the speed limit and the accident rate per million vehicle miles along various Minnesota highways in 1973. The variable containing the speed limit is called `spdlimit`. If we summarize the variable, we obtain its mean and standard deviation:

```
. use https://www.stata-press.com/data/r19/hiway
(Minnesota highway data, 1973)
. summarize spdlimit
```

Variable	Obs	Mean	Std. dev.	Min	Max
spdlimit	39	55	5.848977	40	70

The average speed limit is 55 miles per hour. We can learn more about this variable by tabulating it:

```
. tabulate spdlimit
```

Speed limit	Freq.	Percent	Cum.
40	1	2.56	2.56
45	3	7.69	10.26
50	7	17.95	28.21
55	15	38.46	66.67
60	11	28.21	94.87
65	1	2.56	97.44
70	1	2.56	100.00
Total	39	100.00	

We see that one highway has a speed limit of 40 miles per hour, three have speed limits of 45, 7 of 50, and so on. The column labeled *Percent* shows the percentage of highways in the dataset that have the indicated speed limit. For instance, 38.46% of highways in our dataset have a speed limit of 55 miles per hour. The final column shows the cumulative percentage. We see that 66.67% of highways in our dataset have a speed limit of 55 miles per hour or less.

◀

► Example 2

The `plot` option places a sideways histogram alongside the table:

```
. tabulate spdlimit, plot
```

Speed limit	Freq.	
40	1	*
45	3	***
50	7	*****
55	15	*****
60	11	*****
65	1	*
70	1	*
Total	39	

Of course, `graph` can produce better-looking histograms; see [\[R\] histogram](#).

◀

► Example 3

`tabulate` labels tables using *variable* and *value labels* if they exist. To demonstrate how this works, let's add a new variable to our dataset that categorizes `spdlimit` into three categories. We will call this new variable `spdcat`:

```
. generate spdcat=recode(spdlimit,50,60,70)
```

The `recode()` function divides `spdlimit` into 50 miles per hour or below, 51–60, and above 60; see [\[FN\] Programming functions](#). We specified the breakpoints in the arguments (`spdlimit,50,60,70`). The first argument is the variable to be recoded. The second argument is the first breakpoint, the third argument is the second breakpoint, and so on. We can specify as many breakpoints as we wish.

`recode()` used our arguments not only as the breakpoints but also to label the results. If `spdlimit` is less than or equal to 50, `spdcat` is set to 50; if `spdlimit` is between 51 and 60, `spdcat` is 60; otherwise, `spdcat` is arbitrarily set to 70. (See [\[U\] 26 Working with categorical data and factor variables](#).)

Because we just created the variable `spdcats`, it is not yet labeled. When we make a table using this variable, `tabulate` uses the variable's name to label it:

```
. tabulate spdcats
```

spdcats	Freq.	Percent	Cum.
50	11	28.21	28.21
60	26	66.67	94.87
70	2	5.13	100.00
Total	39	100.00	

Even though the table is not well labeled, `recode()`'s coding scheme provides us with clues as to the table's meaning. The first line of the table corresponds to 50 miles per hour and below, the next to 51 through 60 miles per hour, and the last to above 60 miles per hour.

We can improve this table by labeling the values and variables:

```
. label define scat 50 "40 to 50" 60 "55 to 60" 70 "Above 60"
. label values spdcats scat
. label variable spdcats "Speed Limit Category"
```

We define a *value label* called `scat` that attaches labels to the numbers 50, 60, and 70 using the `label define` command; see [U] 12.6.3 **Value labels**. We label the value 50 as “40 to 50”, because we looked back at our original tabulation in the first example and saw that the speed limit was never less than 40. Similarly, we could have labeled the last category “65 to 70” because the speed limit is never greater than 70 miles per hour.

Next, we requested that Stata label the values of the new variable `spdcats` using the value label `scat`. Finally, we labeled our variable `Speed Limit Category`. We are now ready to tabulate the result:

```
. tabulate spdcats
```

Speed Limit Category	Freq.	Percent	Cum.
40 to 50	11	28.21	28.21
55 to 60	26	66.67	94.87
Above 60	2	5.13	100.00
Total	39	100.00	

► Example 4

If we have missing values in our dataset, `tabulate` ignores them unless we explicitly indicate otherwise. We have no missing data in our example, so let's add some:

```
. replace spdcat=. in 39
(1 real change made, 1 to missing)
```

We changed the first observation on `spdcat` to *missing*. Let's now `tabulate` the result:

```
. tabulate spdcat
```

Speed Limit Category	Freq.	Percent	Cum.
40 to 50	11	28.95	28.95
55 to 60	26	68.42	97.37
Above 60	1	2.63	100.00
Total	38	100.00	

Comparing this output with that in the previous example, we see that the total frequency count is now one less than it was—38 rather than 39. Also, the 'Above 60' category now has only one observation where it used to have two, so we evidently changed a road with a high speed limit.

We want `tabulate` to treat missing values just as it treats numbers, so we specify the `missing` option:

```
. tabulate spdcat, missing
```

Speed Limit Category	Freq.	Percent	Cum.
40 to 50	11	28.21	28.21
55 to 60	26	66.67	94.87
Above 60	1	2.56	97.44
.	1	2.56	100.00
Total	39	100.00	

We now see our missing value—the last category, labeled '.', shows a frequency count of 1. The table sum is once again 39.

Let's put our dataset back as it was originally:

```
. replace spdcat=70 in 39
(1 real change made)
```

□ Technical note

tabulate also can automatically create indicator variables from categorical variables. We will briefly review that capability here, but see [U] 26 Working with categorical data and factor variables for a complete description. Let’s begin by describing our highway dataset:

```
. describe
Contains data from https://www.stata-press.com/data/r19/hiway.dta
Observations:      39      Minnesota highway data, 1973
Variables:         3      16 Nov 2024 12:39
```

Variable name	Storage type	Display format	Value label	Variable label
spdlimit	byte	%8.0g		Speed limit
rate	byte	%9.0g	rcat	Accident rate per million vehicle miles
spdcat	float	%9.0g	scat	Speed Limit Category

```
Sorted by:
Note: Dataset has changed since last saved.
```

Our dataset contains three variables. We will type tabulate spdcat, generate(spd), describe our data, and then explain what happened.

```
. tabulate spdcat, generate(spd)
```

Speed Limit Category	Freq.	Percent	Cum.
40 to 50	11	28.21	28.21
55 to 60	26	66.67	94.87
Above 60	2	5.13	100.00
Total	39	100.00	

```
. describe
Contains data from https://www.stata-press.com/data/r19/hiway.dta
Observations:      39      Minnesota highway data, 1973
Variables:         6      16 Nov 2024 12:39
```

Variable name	Storage type	Display format	Value label	Variable label
spdlimit	byte	%8.0g		Speed limit
rate	byte	%9.0g	rcat	Accident rate per million vehicle miles
spdcat	float	%9.0g	scat	Speed Limit Category
spd1	byte	%8.0g		spdcat==40 to 50
spd2	byte	%8.0g		spdcat==55 to 60
spd3	byte	%8.0g		spdcat==Above 60

```
Sorted by:
Note: Dataset has changed since last saved.
```

When we typed tabulate with the generate() option, Stata responded by producing a one-way frequency table, so it appeared that the option did nothing. Yet when we describe our dataset, we find that we now have six variables instead of the original three. The new variables are named spd1, spd2, and spd3.

When we specify the `generate()` option, we are telling Stata to not only produce the table but also create a set of indicator variables that correspond to that table. Stata adds a numeric suffix to the name we specify in the parentheses. `spd1` refers to the first line of the table, `spd2` to the second line, and so on. Also, Stata labels the variables so that we know what they mean. `spd1` is an indicator variable that is *true* (takes on the value 1) when `spdcat` is between 40 and 50; otherwise, it is zero. (There is an exception: if `spdcat` is missing, so are the `spd1`, `spd2`, and `spd3` variables. This did not happen in our dataset.)

We want to prove our claim. Because we have not yet introduced two-way tabulations, we will use the `summarize` statement:

```
. summarize spdlimit if spd1==1
```

Variable	Obs	Mean	Std. dev.	Min	Max
spdlimit	11	47.72727	3.437758	40	50

```
. summarize spdlimit if spd2==1
```

Variable	Obs	Mean	Std. dev.	Min	Max
spdlimit	26	57.11538	2.519157	55	60

```
. summarize spdlimit if spd3==1
```

Variable	Obs	Mean	Std. dev.	Min	Max
spdlimit	2	67.5	3.535534	65	70

Notice the indicated minimum and maximum in each of the tables above. When we restrict the sample to `spd1`, `spdlimit` is between 40 and 50; when we restrict the sample to `spd2`, `spdlimit` is between 55 and 60; when we restrict the sample to `spd3`, `spdlimit` is between 65 and 70.

Thus `tabulate` provides an easy way to create indicator (sometimes called dummy) variables. For an overview of indicator and categorical variables, see [\[U\] 26 Working with categorical data and factor variables](#).

tab1

`tab1` is a convenience tool. Typing

```
. tab1 myvar thisvar thatvar, plot
```

is equivalent to typing

```
. tabulate myvar, plot
. tabulate thisvar, plot
. tabulate thatvar, plot
```

Publish your tables

With the `collect` option, `tabulate` posts the tabulated values to a collection named `Tabulate` and sets it as the current collection. `tab1` appends the resulting tabulations into a single collection named `Tabulate` and sets it as the current collection. With collections, you can customize the look of your table, then publish it to HTML, Word, L^AT_EX, PDF, Excel, or another format appropriate for your report.

With the `by` prefix, `tabulate` and `tab1` append the resulting tabulations into a single collection, and the default layout produces a separate table for each by group.

If you are not familiar with collections, see [\[TABLES\] Intro](#). The predefined styles for `tabulate` are documented in [\[TABLES\] Predefined styles](#).

► Example 5

Recall our value-labeled variable `spdcat`. Let's use `tabulate` with the `collect` option to produce a collection with its tabulated values.

```
. tabulate spdcat, collect
```

Speed Limit Category	Freq.	Percent	Cum.
40 to 50	11	28.21	28.21
55 to 60	26	66.67	94.87
Above 60	2	5.13	100.00
Total	39	100.00	

The output does not change; however, we can use the `collect dir` command to see that `tabulate` created a collection named `Tabulate`.

```
. collect dir
```

Collections in memory	
Current: Tabulate	
Name	No. items
Tabulate	11

In this collection, frequencies are tagged with `result[frequency]`, percentages with `result[percent]`, and cumulative percentages with `result[cumulative]`. Here we use `collect label list` to show the levels and labels of the `result` dimension.

```
. collect label list result
```

Collection: Tabulate	
Dimension: result	
Label: Result	
Level labels:	
cumulative	Cumulative
frequency	Frequency
percent	Percent

The tabulated variable (that is, `spdcat`) is added to the collection as a dimension and is used to tag the collected results. In addition to the name, label, level values, and value labels of the tabulated variable, this dimension also has the `__margCode__` level with the `Total` label for tagging the total frequency and percentage. Here we use `collect label list` to show the levels and labels of the tabulated variable dimension.

```
. collect label list spdcat
      Collection: Tabulate
      Dimension: spdcat
      Label: Speed Limit Category
Level labels:
      50  40 to 50
      60  55 to 60
      70  Above 60
__margCode__ Total
```

tabulate constructs a default layout, so you can view your customizable table with the `collect preview` command. Here we use the `collect layout` command to report the default layout specification and corresponding table.

```
. collect layout
Collection: Tabulate
      Rows: cmdset#spdcat
      Columns: result
Table 1: 5 x 3
```

	Frequency	Percent	Cumulative
Speed Limit Category			
40 to 50	11	28.21	28.21
55 to 60	26	66.67	94.87
Above 60	2	5.13	100.00
Total	39	100.00	

We can make further changes to the table with the `collect` suite of commands. But we are happy with this layout and ready to publish the table to a PDF file with `collect export`. We simply specify the filename to which we want to export it.

```
. collect export tab1.pdf
(collection Tabulate exported to file tab1.pdf)
```

With `collect export` you can publish the table to several formats, such as HTML, PDF, and \LaTeX files, by specifying the appropriate file extension.

[Tables and cross-tabulations in Stata](#)

Stored results

`tabulate` and `tab1` store the following in `r()`:

Scalars

<code>r(N)</code>	number of observations
<code>r(r)</code>	number of rows

Macros

<code>r(collection)</code>	name of collection
----------------------------	--------------------

`r(collection)` is defined only when the `collect()` option is specified.

Description

`tabulate` produces a two-way table of frequency counts, along with various measures of association, including the common Pearson's χ^2 , the likelihood-ratio χ^2 , Cramér's V , Fisher's exact test, Goodman and Kruskal's gamma, and Kendall's τ_b .

Line size is respected. That is, if you resize the Results window before running `tabulate`, the resulting two-way tabulation will take advantage of the available horizontal space. Stata for Unix(console) users can instead use the `set linesize` command to take advantage of this feature.

`tab2` produces all possible two-way tabulations of the variables specified in *varlist*.

`tabi` displays the $r \times c$ table, using the values specified; rows are separated by '\'. If no options are specified, it is as if `exact` were specified for a 2×2 table and `chi2` were specified otherwise. See [U] 19 **Immediate commands** for a general description of immediate commands. See *Tables with immediate data* below for examples using `tabi`.

See [R] **tabulate oneway** if you want a one-way table of frequencies. See [R] **table** and [R] **tabstat** if you want one-, two-, or n -way table of frequencies and a wide variety of summary statistics. See [R] **tabulate, summarize()** for a description of `tabulate` with the `summarize()` option; it produces a table (breakdowns) of means and standard deviations. `table` is better than `tabulate`, `summarize()`, but `tabulate`, `summarize()` is faster. See [R] **Epitab** for a 2×2 table with statistics of interest to epidemiologists.

Quick start

Two-way table of frequencies for `v1` and `v2`

```
tabulate v1 v2
```

Add row percentages

```
tabulate v1 v2, row
```

Frequencies only for observations where `v3 = 1`

```
tabulate v1 v2 if v3==1
```

Weighted cell counts using frequency weights defined by `wvar`

```
tabulate v1 v2 [fweight=wvar]
```

Pearson's χ^2 test and each cell's contribution

```
tabulate v1 v2, chi2 cchi2
```

All available measures of association

```
tabulate v1 v2, all
```

All possible two-way tables for v1, v2, and v3

tab2 v1 v2 v3

Input cell frequencies and perform χ^2 test

matcol(<i>matname</i>)	save unique values of <i>varname</i> ₂ in <i>matname</i>
‡replace	replace current data with given cell frequencies

‡replace is available only for tabi.

Options

Main

chi2 calculates and displays Pearson’s χ^2 for the hypothesis that the rows and columns in a two-way table are independent. chi2 may not be specified if aweights or iweights are specified.

exact[*(#)*] displays the significance calculated by Fisher’s exact test and may be applied to $r \times c$ as well as to 2×2 tables. For 2×2 tables, both one- and two-sided probabilities are displayed. For $r \times c$ tables, two-sided probabilities are displayed. The optional positive integer # is a multiplier on the amount of memory that the command is permitted to consume. The default is 1. This option should not be necessary for reasonable $r \times c$ tables. If the command terminates with error 910, try exact(2). The maximum row or column dimension allowed when computing Fisher’s exact test is the maximum row or column dimension for tabulate (see [R] Limits).

gamma displays Goodman and Kruskal’s gamma along with its asymptotic standard error. gamma is appropriate only when both variables are ordinal. gamma may not be specified if aweights or iweights are specified.

lrchi2 displays the likelihood-ratio χ^2 statistic. lrchi2 may not be specified if aweights or iweights are specified.

taub displays Kendall’s τ_b along with its asymptotic standard error. taub is appropriate only when both variables are ordinal. taub may not be specified if aweights or iweights are specified.

V (note capitalization) displays Cramér’s V. V may not be specified if aweights or iweights are specified.

cchi2 displays each cell’s contribution to Pearson’s χ^2 in a two-way table.

column displays the relative frequency of each cell within its column in a two-way table.

row displays the relative frequency of each cell within its row in a two-way table.

clrchi2 displays each cell’s contribution to the likelihood-ratio χ^2 in a two-way table.

cell displays the relative frequency of each cell in a two-way table.

expected displays the expected frequency of each cell in a two-way table.

`nofreq` suppresses the printing of the frequencies.

`rowSORT` and `colSORT` specify that the rows and columns, respectively, be presented in order of observed frequency.

By default, rows and columns are presented in ascending order of the row and column variable. For instance, if you type `tabulate a b` and `a` takes on the values 2, 3, and 5, then the first row of the table will correspond to `a = 2`; the second row will correspond to `a = 3`; and the third row will correspond to `a = 5`.

`rowSORT` specifies that the rows instead be presented in descending order of observed frequency of the values. If you type `twoway a b, rowSORT`, the most frequently observed value of `a` will be listed in the first row, the second most frequently observed value of `a` in the second row, and so on. If there are rows with equal frequencies, they will be presented in ascending order of the values of `a`. If `a = 5` occurs with frequency 1,000 and values `a = 2` and `a = 3` each occur with frequency 500, the rows will be presented in the order `a = 5`, `a = 2`, and `a = 3`.

`colSORT` does the same as `rowSORT`, except with the columns and the column variable.

`rowSORT` and `colSORT` may be specified together.

`missing` requests that missing values be treated like other values in calculations of counts, percentages, and other statistics.

`wrap` requests that Stata take no action on wide, two-way tables to make them readable. Unless `wrap` is specified, wide tables are broken into pieces to enhance readability.

`[no]key` suppresses or forces the display of a key above two-way tables. The default is to display the key if more than one cell statistic is requested, and otherwise to omit it. `key` forces the display of the key. `nokey` suppresses its display.

`noLabel` causes the numeric codes to be displayed rather than the value labels.

`nolog` suppresses the display of the log for Fisher's exact test. Using Fisher's exact test requires counting all tables that have a probability exceeding that of the observed table given the observed row and column totals. The log counts down each stage of the network computations, starting from the number of columns and counting down to 1, displaying the number of nodes in the network at each stage. A log is not displayed for 2×2 tables.

`firstonly`, available only with `tab2`, restricts the output to only those tables that include the first variable in *varlist*. Use this option to interact one variable with a set of others.

Collect

`collect` and `collect([cname][, collect_options])` specify that results be posted to a collection. This collection produces a table that you can customize and publish to Microsoft Word, Microsoft Excel, PDF, HTML, \LaTeX , [SMCL](#), or Markdown. Output does not change when these options are specified. Use `collect preview` to see the customizable table.

`collect` is a shortcut for `collect(Tabulate)`.

cname specifies that a collection named *cname* be associated with the collected results. The default is `Tabulate`.

`append` specifies that results be appended to collection *cname*.

`replace` permits `tabulate` to overwrite an existing collection. This option is implied for collection `Tabulate` when `append` is not specified.

`label(filename)` specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded into the collection, and any labels not specified in *filename* will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [\[TABLES\] set collect_label](#).

`style(filename[, override])` specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify *override*. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in `c(tabulate_style)`; see [\[TABLES\] set tabulate_style](#).

Advanced

`matcell(matname)` saves the reported frequencies in *matname*. This option is for use by programmers.

`matrow(matname)` saves the numeric values of the $r \times 1$ row stub in *matname*. This option is for use by programmers. `matrow()` may not be specified if the row variable is a string.

`matcol(matname)` saves the numeric values of the $1 \times c$ column stub in *matname*. This option is for use by programmers. `matcol()` may not be specified if the column variable is a string.

`replace` indicates that the immediate data specified as arguments to the `tabi` command be left as the current data in place of whatever data were there.

The following option is available with `tabulate` but is not shown in the dialog box:

`all` is equivalent to specifying `chi2 lrchi2 V gamma taub`. Note the omission of `exact`. When `all` is specified, no `may` be placed in front of the other options. `all noV` requests all association measures except Cramér's *V* (and Fisher's exact). `all exact` requests all association measures, including Fisher's exact test. `all` may not be specified if `aweights` or `iweights` are specified.

Limits

Two-way tables may have a maximum of 1,200 rows and 80 columns (Stata/MP and Stata/SE) or 300 rows and 20 columns (Stata/BE). If larger tables are needed, see [\[R\] table](#).

Remarks and examples

Remarks are presented under the following headings:

[tabulate](#)
[Measures of association](#)
[N-way tables](#)
[Weighted data](#)
[Tables with immediate data](#)
[tab2](#)
[Publish your tables](#)
[Video examples](#)

For each value of a specified variable (or a set of values for a pair of variables), `tabulate` reports the number of observations with that value. The number of times a value occurs is called its *frequency*.

tabulate

► Example 1

`tabulate` will make two-way tables if we specify two variables following the word `tabulate`. In our highway dataset, we have a variable called `rate` that divides the accident rate into three categories: below 4, 4–7, and above 7 per million vehicle miles. Let's make a table of the speed limit category and the accident-rate category:

```
. use https://www.stata-press.com/data/r19/hiway2
(Minnesota highway data, 1973)
. tabulate spdcat rate
```

Speed limit category	Accident rate per million vehicle miles			Total
	Below 4	4–7	Above 7	
40 to 50	3	5	3	11
55 to 50	19	6	1	26
Above 60	2	0	0	2
Total	24	11	4	39

The table indicates that three stretches of highway have an accident rate below 4 and a speed limit of 40 to 50 miles per hour. The table also shows the row and column sums (called the *marginals*). The number of highways with a speed limit of 40 to 50 miles per hour is 11, which is the same result we obtained in our previous one-way tabulations.

Stata can present this basic table in several ways—16, to be precise—and we will show just a few below. It might be easier to read the table if we included the row percentages. For instance, of 11 highways in the lowest speed limit category, three are also in the lowest accident-rate category. Three-elevenths amounts to some 27.3%. We can ask Stata to fill in this information for us by using the `row` option:

```
. tabulate spdcat rate, row
```

Key
<i>frequency</i>
<i>row percentage</i>

Speed limit category	Accident rate per million vehicle miles			Total
	Below 4	4-7	Above 7	
40 to 50	3	5	3	11
	27.27	45.45	27.27	100.00
55 to 50	19	6	1	26
	73.08	23.08	3.85	100.00
Above 60	2	0	0	2
	100.00	0.00	0.00	100.00
Total	24	11	4	39
	61.54	28.21	10.26	100.00

The number listed below each frequency is the percentage of cases that each cell represents out of its row. That is easy to remember because we see 100% listed in the “Total” column. The bottom row is also informative. We see that 61.54% of all the highways in our dataset fall into the lowest accident-rate category, that 28.21% are in the middle category, and that 10.26% are in the highest.

tabulate can calculate column percentages and cell percentages, as well. It does so when we specify the column or cell options, respectively. We can even specify them together. Below is a table that includes everything:

```
. tabulate spdcat rate, row column cell
```

Key
<i>frequency</i>
<i>row percentage</i>
<i>column percentage</i>
<i>cell percentage</i>

Speed limit category	Accident rate per million vehicle miles			Total
	Below 4	4-7	Above 7	
40 to 50	3	5	3	11
	27.27	45.45	27.27	100.00
	12.50	45.45	75.00	28.21
	7.69	12.82	7.69	28.21
55 to 50	19	6	1	26
	73.08	23.08	3.85	100.00
	79.17	54.55	25.00	66.67
	48.72	15.38	2.56	66.67
Above 60	2	0	0	2
	100.00	0.00	0.00	100.00
	8.33	0.00	0.00	5.13
	5.13	0.00	0.00	5.13
Total	24	11	4	39
	61.54	28.21	10.26	100.00
	100.00	100.00	100.00	100.00
	61.54	28.21	10.26	100.00

The number at the top of each cell is the frequency count. The second number is the row percentage—they sum to 100% going across the table. The third number is the column percentage—they sum to 100% going down the table. The bottom number is the cell percentage—they sum to 100% going down all the columns and across all the rows. For instance, highways with a speed limit above 60 miles per hour and in the lowest accident rate category account for 100% of highways with a speed limit above 60 miles per hour; 8.33% of highways in the lowest accident-rate category; and 5.13% of all our data.

A fourth option, `nofreq`, tells Stata not to print the frequency counts. To construct a table consisting of only row percentages, we type

```
. tabulate spdcat rate, row nofreq
```

Speed limit category	Accident rate per million vehicle miles			Total
	Below 4	4-7	Above 7	
40 to 50	27.27	45.45	27.27	100.00
55 to 50	73.08	23.08	3.85	100.00
Above 60	100.00	0.00	0.00	100.00
Total	61.54	28.21	10.26	100.00

◀

Measures of association

► Example 2

`tabulate` will calculate the Pearson χ^2 test for the independence of the rows and columns if we specify the `chi2` option. Suppose that we have 1980 census data on 956 cities in the United States and wish to compare the age distribution across regions of the country. Assume that `agecat` is the median age in each city and that `region` denotes the region of the country in which the city is located.

```
. use https://www.stata-press.com/data/r19/citytemp2
(City temperature data)
```

```
. tabulate region agecat, chi2
```

Census region	Age category			Total
	19-29	30-34	35+	
NE	46	83	37	166
N Cntrl	162	92	30	284
South	139	68	43	250
West	160	73	23	256
Total	507	316	133	956

```
Pearson chi2(6) = 61.2877 Pr = 0.000
```

We obtain the standard two-way table and, at the bottom, a summary of the χ^2 test. Stata informs us that the χ^2 associated with this table has 6 degrees of freedom and is 61.29. The observed differences are significant.

The table is, perhaps, easier to understand if we suppress the frequencies and print just the row percentages:

```
. tabulate region agecat, row nofreq chi2
```

Census region	Age category			Total
	19–29	30–34	35+	
NE	27.71	50.00	22.29	100.00
N Cntrl	57.04	32.39	10.56	100.00
South	55.60	27.20	17.20	100.00
West	62.50	28.52	8.98	100.00
Total	53.03	33.05	13.91	100.00

Pearson chi2(6) = 61.2877 Pr = 0.000

◀

► Example 3

We have data on dose level and outcome for a set of patients and wish to evaluate the association between the two variables. We can obtain all the association measures by specifying the `all` and `exact` options:

```
. use https://www.stata-press.com/data/r19/dose
. tabulate dose function, all exact
Enumerating sample-space combinations:
stage 3: enumerations = 1
stage 2: enumerations = 9
stage 1: enumerations = 0
```

Dosage	Function			Total
	< 1 hr	1 to 4	4+	
1/day	20	10	2	32
2/day	16	12	4	32
3/day	10	16	6	32
Total	46	38	12	96

Pearson chi2(4) = 6.7780 Pr = 0.148
Likelihood-ratio chi2(4) = 6.9844 Pr = 0.137
Cramér's V = 0.1879
gamma = 0.3689 ASE = 0.129
Kendall's tau-b = 0.2378 ASE = 0.086
Fisher's exact = 0.145

We find evidence of association but not enough to be truly convincing.

If we had not also specified the `exact` option, we would not have obtained Fisher's exact test. Stata can calculate this statistic both for 2×2 tables and for $r \times c$. For 2×2 tables, the calculation is almost instant. On more general tables, however, the calculation can take longer.

We carefully constructed our example so that `all` would be meaningful. Kendall's τ_b and Goodman and Kruskal's gamma are relevant only when both dimensions of the table can be ordered, say, from low to high or from worst to best. The other statistics, however, are always applicable.

◀

❑ Technical note

Be careful when attempting to compute the p -value for Fisher’s exact test because the number of tables that contribute to the p -value can be extremely large and a solution may not be feasible. The errors that are indicative of this situation are errors 910, exceeded memory limitations, and 1401, integer overflow due to large row-margin frequencies. If execution terminates because of memory limitations, use `exact (2)` to permit the algorithm to consume twice the memory, `exact (3)` for three times the memory, etc. The default memory usage should be sufficient for reasonable tables.

N-way tables

If you need more than two-way tables, your best alternative to is use `table`, not `tabulate`; see [R] `table`.

The [technical note](#) below shows you how to use `tabulate` to create a sequence of two-way tables that together form, in effect, a three-way table, but using `table` is easy and produces prettier results:

```
. use https://www.stata-press.com/data/r19/birthcat
(City data)
. table (agecat birthcat) (region), nototals
```

	Census region			
	NE	N Cntrl	South	West
Age category				
19–29				
Birth-rate category				
29–136	11	23	11	11
137–195	31	97	65	46
196–529	4	38	59	91
30–34				
Birth-rate category				
29–136	34	27	10	8
137–195	48	58	45	42
196–529	1	3	12	21
35+				
Birth-rate category				
29–136	34	26	27	18
137–195	3	4	7	4
196–529			4	

□ Technical note

We can make n -way tables by combining the [by varlist](#): prefix with `tabulate`. Continuing with the dataset of 956 cities, say that we want to make a table of age category by birth-rate category by region of the country. The birth-rate category variable is named `birthcat` in our dataset. To make separate tables for each age category, we would type

```
. by agecat, sort: tabulate birthcat region
```

```
-> agecat = 19-29
```

Birth-rate category	Census region				Total
	NE	N Cntrl	South	West	
29-136	11	23	11	11	56
137-195	31	97	65	46	239
196-529	4	38	59	91	192
Total	46	158	135	148	487

```
-> agecat = 30-34
```

Birth-rate category	Census region				Total
	NE	N Cntrl	South	West	
29-136	34	27	10	8	79
137-195	48	58	45	42	193
196-529	1	3	12	21	37
Total	83	88	67	71	309

```
-> agecat = 35+
```

Birth-rate category	Census region				Total
	NE	N Cntrl	South	West	
29-136	34	26	27	18	105
137-195	3	4	7	4	18
196-529	0	0	4	0	4
Total	37	30	38	22	127

Weighted data

► Example 4

tabulate can process weighted as well as unweighted data. As with all Stata commands, we indicate the weight by specifying the `[weight]` modifier; see [\[U\] 11.1.6 weight](#).

Continuing with our dataset of 956 cities, we also have a variable called `pop`, the population of each city. We can make a table of region by age category, weighted by population, by typing

```
. tabulate region agecat [fweight=pop]
```

Census region	Age category			Total
	19–29	30–34	35+	
NE	4721387	10421387	5323610	20466384
N Cntrl	16901550	8964756	4015593	29881899
South	13894254	7686531	4141863	25722648
West	16698276	7755255	2375118	26828649
Total	52215467	34827929	15856184	102899580

If we specify the `cell`, `column`, or `row` options, they will also be appropriately weighted. Below, we repeat the table, suppressing the counts and substituting row percentages:

```
. tabulate region agecat [fweight=pop], nofreq row
```

Census region	Age category			Total
	19–29	30–34	35+	
NE	23.07	50.92	26.01	100.00
N Cntrl	56.56	30.00	13.44	100.00
South	54.02	29.88	16.10	100.00
West	62.24	28.91	8.85	100.00
Total	50.74	33.85	15.41	100.00

Tables with immediate data

► Example 5

`tabi` ignores the dataset in memory and uses as the table the values that we specify on the command line:

```
. tabi 30 18 \ 38 14
```

row	col		Total
	1	2	
1	30	18	48
2	38	14	52
Total	68	32	100

Fisher's exact = 0.289
 1-sided Fisher's exact = 0.179

We may specify any of the options of tabulate and are not limited to 2×2 tables:

```
. tabi 30 18 38 \ 13 7 22, chi2 exact
Enumerating sample-space combinations:
stage 3: enumerations = 1
stage 2: enumerations = 3
stage 1: enumerations = 0
```

row	col			Total
	1	2	3	
1	30	18	38	86
2	13	7	22	42
Total	43	25	60	128

Pearson chi2(2) = 0.7967 Pr = 0.671
Fisher's exact = 0.707

```
. tabi 30 13 \ 18 7 \ 38 22, all exact col
```

Key
<i>frequency</i>
<i>column percentage</i>

```
Enumerating sample-space combinations:
stage 3: enumerations = 1
stage 2: enumerations = 3
stage 1: enumerations = 0
```

row	col		Total
	1	2	
1	30	13	43
	34.88	30.95	33.59
2	18	7	25
	20.93	16.67	19.53
3	38	22	60
	44.19	52.38	46.88
Total	86	42	128
	100.00	100.00	100.00

Pearson chi2(2) = 0.7967 Pr = 0.671
Likelihood-ratio chi2(2) = 0.7985 Pr = 0.671
Cramér's V = 0.0789
gamma = 0.1204 ASE = 0.160
Kendall's tau-b = 0.0630 ASE = 0.084
Fisher's exact = 0.707

For 2×2 tables, both one- and two-sided Fisher's exact probabilities are displayed; this is true of both tabulate and tabi. See [Cumulative incidence data](#) and [Case-control data](#) in [R] **EpiTab** for more discussion on the relationship between one- and two-sided probabilities.

❏ Technical note

tabi, as with all immediate commands, leaves any data in memory undisturbed. With the replace option, however, the data in memory are replaced by the data from the table:

```
. tabi 30 18 \ 38 14, replace
```

row	col		Total
	1	2	
1	30	18	48
2	38	14	52
Total	68	32	100

```

      Fisher's exact =          0.289
1-sided Fisher's exact =        0.179

. list
```

	row	col	pop
1.	1	1	30
2.	1	2	18
3.	2	1	38
4.	2	2	14

With this dataset, you could re-create the above table by typing

```
. tabulate row col [fweight=pop], exact
```

row	col		Total
	1	2	
1	30	18	48
2	38	14	52
Total	68	32	100

```

      Fisher's exact =          0.289
1-sided Fisher's exact =        0.179
```

tab2

tab2 is a convenience tool. Typing

```
. tab2 myvar thisvar thatvar, chi2
```

is equivalent to typing

```

. tabulate myvar thisvar, chi2
. tabulate myvar thatvar, chi2
. tabulate thisvar thatvar, chi2
```

Publish your tables

With the `collect` option, `tabulate` and `tabi` post the tabulated values to a collection named `Tabulate` and set it as the current collection. `tab2` appends the resulting tabulations into a single collection named `Tabulate` and sets it as the current collection. With collections, you can customize the look of your table, then publish it to HTML, Word, L^AT_EX, PDF, Excel, or another format appropriate for your report.

The default `collect` layout for `tab2` when the `firstonly` option is not specified produces a table for the first pair of variables. You must specify the corresponding layout to get a table for the other two-way tabulations.

With the `by` prefix, `tabulate` and `tab2` append the resulting tabulations into a single collection, and the default layout produces a separate table for each `by` group.

If you are not familiar with collections, see [\[TABLES\] Intro](#). The predefined styles for `tabulate` are documented in [\[TABLES\] Predefined styles](#).

► Example 6

Recall the [example](#) where we used the `all` option to show all the supported measures of association. Let's use `tabulate` with the `collect` option to produce a collection with its tabulated values.

```
. tabulate dose function, all exact collect
Enumerating sample-space combinations:
stage 3: enumerations = 1
stage 2: enumerations = 9
stage 1: enumerations = 0
```

Dosage	Function			Total
	< 1 hr	1 to 4	4+	
1/day	20	10	2	32
2/day	16	12	4	32
3/day	10	16	6	32
Total	46	38	12	96
Pearson chi2(4) = 6.7780 Pr = 0.148				
Likelihood-ratio chi2(4) = 6.9844 Pr = 0.137				
Cramér's V = 0.1879				
gamma = 0.3689 ASE = 0.129				
Kendall's tau-b = 0.2378 ASE = 0.086				
Fisher's exact = 0.145				

The output does not change; however, we can use the `collect dir` command to see that `tabulate` created a collection named `Tabulate`.

```
. collect dir
Collections in memory
Current: Tabulate
```

Name	No. items
Tabulate	28

In this collection, frequencies are tagged with `result [frequency]`. The tabulated variables (that is, `dose` and `function`) are added to the collection as dimensions and are used to tag the collected results. In addition to the names, labels, level values, and value labels of the tabulated variables, these dimensions each have the `__margCode__` level with the `Total` label for tagging the marginal frequencies. Here we use `collect label list` to show the levels and labels of each tabulated variable dimension.

```
. collect label list dose
      Collection: Tabulate
      Dimension: dose
      Label: Dosage
Level labels:
      1  1/day
      2  2/day
      3  3/day
__margCode__  Total

. collect label list function
      Collection: Tabulate
      Dimension: function
      Label: Function
Level labels:
      1  < 1 hr
      2  1 to 4
      3  4+
__margCode__  Total
```

When measures of association are requested, `tabulate` uses a style that defines composite results for them. Each measure of association has a corresponding composite result that composes it in a single cell of a second table.

Measure of association	Option	Composite result
Pearson's χ^2	<code>chi2</code>	<code>Pearson_ma</code>
Fisher's exact	<code>exact</code>	<code>Fisher_ma</code>
1-sided Fisher's exact	<code>exact</code>	<code>Fisher1_ma</code>
Likelihood ratio	<code>lr</code>	<code>LR_ma</code>
Cramér's V	<code>V</code>	<code>Cramer_ma</code>
Goodman and Kruskal's γ	<code>gamma</code>	<code>GoodmanKruskal_ma</code>
Kendall's τ_b	<code>taub</code>	<code>Pearson_ma</code>

`tabulate` constructs a default layout, so you can view your customizable table with the `collect preview` command. Here we use the `collect layout` command to report the default layout specification and corresponding table.

```
. collect layout
Collection: Tabulate
  Rows: dose#result result
Columns: function _overall
  Tables: cmdset#item_type
Table 1: 5 x 4
Table 2: 6 x 1
```

	Function			Total
	< 1 hr	1 to 4	4+	
Dosage				
1/day	20	10	2	32
2/day	16	12	4	32
3/day	10	16	6	32
Total	46	38	12	96

```

Pearson  $\chi^2(4) = 6.7780$  Pr = 0.1481
LR  $\chi^2(4) = 6.9844$  Pr = 0.1367
Cramér's V = 0.1879
Goodman and Kruskal's  $\gamma = 0.3689$  ASE = 0.1287
Kendall's  $\tau_b = 0.2378$  ASE = 0.0865
Fisher's exact = 0.1449
```

We can make further changes to the table with the `collect` suite of commands. But we are happy with this layout and ready to publish the table to an HTML file with `collect export`. We simply specify the filename to which we want to export it.

```
. collect export tab2.html
(collection Tabulate exported to file tab2.html)
```

With `collect export`, you can publish the table to several formats, such as HTML, PDF, and \LaTeX files, by specifying the appropriate file extension.

Stored results

tabulate, tab2, and tabi store the following in `r()`:

Scalars

<code>r(N)</code>	number of observations	<code>r(p_exact)</code>	Fisher's exact p
<code>r(r)</code>	number of rows	<code>r(chi2_lr)</code>	likelihood-ratio χ^2
<code>r(c)</code>	number of columns	<code>r(p_lr)</code>	p -value for likelihood-ratio test
<code>r(chi2)</code>	Pearson's χ^2 test	<code>r(CramersV)</code>	Cramér's V
<code>r(p)</code>	p -value for of Pearson's χ^2 test	<code>r(ase_gam)</code>	ASE of gamma
<code>r(gamma)</code>	gamma	<code>r(ase_taub)</code>	ASE of τ_b
<code>r(p1_exact)</code>	one-sided Fisher's exact p	<code>r(taub)</code>	τ_b

Macros

`r(collection)` name of collection

`r(p1_exact)` is defined only for 2×2 tables. `r(collection)` is defined only when the `collect()` option is specified. Also, the `matrow()`, `matcol()`, and `matcell()` options allow you to obtain the row values, column values, and frequencies, respectively.

Methods and formulas

Let n_{ij} , $i = 1, \dots, I$ and $j = 1, \dots, J$, be the number of observations in the i th row and j th column. If the data are not weighted, n_{ij} is just a count. If the data are weighted, n_{ij} is the sum of the weights of all data corresponding to the (i, j) cell.

Define the row and column marginals as

$$n_{i\cdot} = \sum_{j=1}^J n_{ij} \qquad n_{\cdot j} = \sum_{i=1}^I n_{ij}$$

and let $n = \sum_i \sum_j n_{ij}$ be the overall sum. Also, define the concordance and discordance as

$$A_{ij} = \sum_{k>i} \sum_{l>j} n_{kl} + \sum_{k<i} \sum_{l<j} n_{kl} \qquad D_{ij} = \sum_{k>i} \sum_{l<j} n_{kl} + \sum_{k<i} \sum_{l>j} n_{kl}$$

along with twice the number of concordances $P = \sum_i \sum_j n_{ij} A_{ij}$ and twice the number of discordances $Q = \sum_i \sum_j n_{ij} D_{ij}$.

The Pearson χ^2 statistic with $(I-1)(J-1)$ degrees of freedom (so called because it is based on [Pearson \(1900\)](#); see [Conover \[1999, 240\]](#) and [Fienberg \[1980, 9\]](#)) is defined as

$$X^2 = \sum_i \sum_j \frac{(n_{ij} - m_{ij})^2}{m_{ij}}$$

where $m_{ij} = n_{i\cdot} n_{\cdot j} / n$.

The likelihood-ratio χ^2 statistic with $(I-1)(J-1)$ degrees of freedom ([Fienberg 1980, 40](#)) is defined as

$$G^2 = 2 \sum_i \sum_j n_{ij} \ln(n_{ij} / m_{ij})$$

Cramér's V ([Cramér 1946](#)) is a measure of association designed so that the attainable upper bound is 1. For 2×2 tables, $-1 \leq V \leq 1$, and otherwise, $0 \leq V \leq 1$.

$$V = \begin{cases} (n_{11}n_{22} - n_{12}n_{21}) / (n_{1\cdot}n_{2\cdot}n_{\cdot 1}n_{\cdot 2})^{1/2} & \text{for } 2 \times 2 \\ \{(X^2/n) / \min(I-1, J-1)\}^{1/2} & \text{otherwise} \end{cases}$$

Gamma (Goodman and Kruskal 1954, 1959, 1963, 1972; also see Agresti [2010,186–188]) ignores tied pairs and is based only on the number of concordant and discordant pairs of observations, $-1 \leq \gamma \leq 1$,

$$\gamma = (P - Q)/(P + Q)$$

with asymptotic variance

$$16 \sum_i \sum_j n_{ij} (QA_{ij} - PD_{ij})^2 / (P + Q)^4$$

Kendall's τ_b (Kendall 1945; also see Agresti 2010, 188–189), $-1 \leq \tau_b \leq 1$, is similar to gamma, except that it uses a correction for ties,

$$\tau_b = (P - Q)/(w_r w_c)^{1/2}$$

with asymptotic variance

$$\frac{\sum_i \sum_j n_{ij} (2w_r w_c d_{ij} + \tau_b v_{ij})^2 - n^3 \tau_b^2 (w_r + w_c)^2}{(w_r w_c)^4}$$

where

$$\begin{aligned} w_r &= n^2 - \sum_i n_{i.}^2 \\ w_c &= n^2 - \sum_j n_{.j}^2 \\ d_{ij} &= A_{ij} - D_{ij} \\ v_{ij} &= n_{i.} w_c + n_{.j} w_r \end{aligned}$$

Fisher's exact test (Fisher 1935; Finney 1948; see Zelterman and Louis [1992, 293–301] for the 2×2 case) yields the probability of observing a table that gives at least as much evidence of association as the one actually observed under the assumption of no association. Holding row and column marginals fixed, the hypergeometric probability P of every possible table A is computed, and the

$$P = \sum_{T \in A} \Pr(T)$$

where A is the set of all tables with the same marginals as the observed table, T^* , such that $\Pr(T) \leq \Pr(T^*)$. For 2×2 tables, the one-sided probability is calculated by further restricting A to tables in the same tail as T^* . The first algorithm extending this calculation to $r \times c$ tables was Pagano and Halvorsen (1981); the one implemented here is the FEXACT algorithm by Mehta and Patel (1986). This is a search-tree clipping method originally published by Mehta and Patel (1983) with further refinements by Joe (1988) and Clarkson, Fan, and Joe (1993). Fisher's exact test is a permutation test. For more information on permutation tests, see Good (2005 and 2006) and Pesarin (2001).

[Description](#)
[Options](#)[Quick start](#)
[Remarks and examples](#)[Menu](#)
[Also see](#)[Syntax](#)

Description

`tabulate`, `summarize()` produces one- and two-way tables (breakdowns) of means and standard deviations. See [\[R\] tabulate oneway](#) and [\[R\] tabulate twoway](#) for one- and two-way frequency tables. See [\[R\] table](#) for a more flexible command that produces one-, two-, and n -way tables of frequencies and a wide variety of summary statistics. `table` is better, but `tabulate`, `summarize()` is faster. Also see [\[R\] tabstat](#) for yet another alternative.

Quick start

Tabulation of `v1`, reporting means and standard deviations of `x` and frequencies

```
tabulate v1, summarize(x)
```

Same as above, but report summary statistics for the two-way tabulation of `v1` and `v2`

```
tabulate v1 v2, summarize(x)
```

Weighted summary statistics using frequency weight `wvar`

```
tabulate v1 v2 [fweight=wvar], summarize(x)
```

Report only the mean of `x` for each group

```
tabulate v1 v2, summarize(x) means
```

Do not report standard deviations

```
tabulate v1 v2, summarize(x) nostandard
```

Show numeric values of `v1` and `v2` rather than value labels

```
tabulate v1 v2, summarize(x) nolabel
```

Menu

Statistics > Summaries, tables, and tests > Other tables > Table of means, std. dev., and frequencies

[no]freq includes or suppresses only the frequencies from the table; see [no]means option above.

[no]obs includes or suppresses only the reported number of observations from the table. If the data are not weighted, the number of observations is identical to the frequency, and by default only the frequency is reported. If the data are weighted, the frequency refers to the sum of the weights. See [no]means option above.

no label causes the numeric codes to be displayed rather than the label values.

wrap requests that no action be taken on wide tables to make them readable. Unless wrap is specified, wide tables are broken into pieces to enhance readability.

missing requests that missing values of *varname*₁ and *varname*₂ be treated as categories rather than as observations to be omitted from the analysis.

Collect

collect and collect([*cname*][, *collect_options*]) specify that results be posted to a collection. This collection produces a table that you can customize and publish to Microsoft Word, Microsoft Excel, PDF, HTML, L^AT_EX, SMCL, or Markdown. Output does not change when these options are specified. Use collect preview to see the customizable table.

collect is a shortcut for collect(Tabulate).

cname specifies that a collection named *cname* be associated with the collected results. The default is Tabulate.

append specifies that results be appended to collection *cname*.

replace permits tabulate to overwrite an existing collection. This option is implied for collection Tabulate when append is not specified.

label(*filename*) specifies the *filename* containing the collection labels to use for your table. Labels in *filename* will be loaded into the collection, and any labels not specified in *filename* will be taken from the labels defined in c(collect_label). The default is to use only the collection labels set in c(collect_label); see [TABLES] set collect_label.

style(*filename*[, *override*]) specifies the *filename* containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in *filename* will be applied.

If you prefer the default collection styles but also want to apply any styles in *filename*, specify *override*. If there are conflicts between the default collection styles and those in *filename*, the ones in *filename* will take precedence.

The default is to use only the collection styles set in c(tabulate_style); see [TABLES] set tabulate_style.

Remarks and examples

tabulate with the summarize() option produces one- and two-way tables of summary statistics. When combined with the by prefix, it can produce *n*-way tables as well.

Remarks are presented under the following headings:

One-way tables
Two-way tables
Publish your tables

One-way tables

► Example 1

We have data on 74 automobiles. Included in our dataset are the variables `foreign`, which marks domestic and foreign cars, and `mpg`, the car's mileage rating. Typing `tabulate foreign` displays a breakdown of the number of observations we have by the values of the `foreign` variable.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
```

```
. tabulate foreign
```

Car origin	Freq.	Percent	Cum.
Domestic	52	70.27	70.27
Foreign	22	29.73	100.00
Total	74	100.00	

We discover that we have 52 domestic cars and 22 foreign cars in our dataset. If we add the `summarize(varname)` option, however, `tabulate` produces a table of summary statistics for `varname`:

```
. tabulate foreign, summarize(mpg)
```

Car origin	Summary of Mileage (mpg)		Freq.
	Mean	Std. dev.	
Domestic	19.826923	4.7432972	52
Foreign	24.772727	6.6111869	22
Total	21.297297	5.7855032	74

We also discover that the average gas mileage for domestic cars is about 20 mpg and the average foreign is almost 25 mpg. Overall, the average is 21 mpg in our dataset.

▢ Technical note

We might now wonder if the difference in gas mileage between foreign and domestic cars is statistically significant. We can use the oneway command to find out; see [R] oneway. To obtain an analysis-of-variance table of mpg on foreign, we type

```
. oneway mpg foreign
```

Source	Analysis of variance			F	Prob > F
	SS	df	MS		
Between groups	378.153515	1	378.153515	13.18	0.0005
Within groups	2065.30594	72	28.6848048		
Total	2443.45946	73	33.4720474		

Bartlett's equal-variances test: chi2(1) = 3.4818 Prob>chi2 = 0.062

The *F* statistic is 13.18, and the difference between foreign and domestic cars' mileage ratings is significant at the 0.05% level.

There are several ways that we could have statistically compared mileage ratings—see, for instance, [R] anova, [R] oneway, [R] regress, and [R] ttest—but oneway seemed the most convenient.

Two-way tables

▷ Example 2

tabulate, summarize can be used to obtain two-way as well as one-way breakdowns. For instance, we obtained summary statistics on mpg decomposed by foreign by typing tabulate foreign, summarize(mpg). We can specify up to two variables before the comma:

```
. generate wgtcat = autocode(weight,4,1760,4840)
. tabulate wgtcat foreign, summarize(mpg)
```

Means, Standard Deviations and Frequencies of Mileage (mpg)

wgtcat	Car origin		Total
	Domestic	Foreign	
2530	28.285714	27.0625	27.434783
	3.0937725	5.9829619	5.2295149
	7	16	23
3300	21.75	19.6	21.238095
	2.4083189	3.4351128	2.7550819
	16	5	21
4070	17.26087	14	17.125
	1.8639497	0	1.9406969
	23	1	24
4840	14.666667	.	14.666667
	3.32666	.	3.32666
	6	0	6
Total	19.826923	24.772727	21.297297
	4.7432972	6.6111869	5.7855032
	52	22	74

In addition to the means, standard deviations, and frequencies for each weight–mileage cell, also reported are the summary statistics by weight, by mileage, and overall. For instance, the last row of the table reveals that the average mileage of domestic cars is 19.83 and that of foreign cars is 24.77—domestic cars yield poorer mileage than foreign cars. But we now see that domestic cars yield better gas mileage within weight class—the reason domestic cars yield poorer gas mileage is because they are, on average, heavier.

► Example 3

If we do not specify the statistics to be included in a table, `tabulate` reports the mean, standard deviation, and frequency. We can specify the statistics that we want to see using the `means`, `standard`, and `freq` options:

```
. tabulate wgtcat foreign, summarize(mpg) means
                        Means of Mileage (mpg)
```

wgtcat	Car origin		Total
	Domestic	Foreign	
2530	28.285714	27.0625	27.434783
3300	21.75	19.6	21.238095
4070	17.26087	14	17.125
4840	14.666667	.	14.666667
Total	19.826923	24.772727	21.297297

When we specify one or more of the `means`, `standard`, and `freq` options, only those statistics are displayed. Thus, we could obtain a table containing just the means and standard deviations by typing `means standard` after the `summarize(mpg)` option. We can also suppress selected statistics by placing `no` in front of the option name. Another way of obtaining only the means and standard deviations is to add the `nofreq` option:

```
. tabulate wgtcat foreign, summarize(mpg) nofreq
                        Means and Standard Deviations of Mileage (mpg)
```

wgtcat	Car origin		Total
	Domestic	Foreign	
2530	28.285714 3.0937725	27.0625 5.9829619	27.434783 5.2295149
3300	21.75 2.4083189	19.6 3.4351128	21.238095 2.7550819
4070	17.26087 1.8639497	14 0	17.125 1.9406969
4840	14.666667 3.32666	. .	14.666667 3.32666
Total	19.826923 4.7432972	24.772727 6.6111869	21.297297 5.7855032

Publish your tables

With the `collect` option, `tabulate` posts the tabulated values to a collection named `Tabulate` and sets it as the current collection. With collections, you can customize the look of your table, then publish it to HTML, Word, L^AT_EX, PDF, Excel, or another format appropriate for your report.

With the `by` prefix, `tabulate` appends the resulting tabulations into a single collection, and the default layout produces a separate table for each by group.

If you are not familiar with collections, see [\[TABLES\] Intro](#). The predefined styles for `tabulate` are documented in [\[TABLES\] Predefined styles](#).

► Example 4

Recall our table from the [previous example](#). Let’s add the `collect` option in the call to `tabulate` to produce a collection with its tabulated values.

```
. tabulate wgtcat foreign, summarize(mpg) collect
      Means, Standard Deviations and Frequencies of Mileage (mpg)
```

wgtcat	Car origin		Total
	Domestic	Foreign	
2530	28.285714	27.0625	27.434783
	3.0937725	5.9829619	5.2295149
	7	16	23
3300	21.75	19.6	21.238095
	2.4083189	3.4351128	2.7550819
	16	5	21
4070	17.26087	14	17.125
	1.8639497	0	1.9406969
	23	1	24
4840	14.666667	.	14.666667
	3.32666	.	3.32666
	6	0	6
Total	19.826923	24.772727	21.297297
	4.7432972	6.6111869	5.7855032
	52	22	74

The output does not change; however, we can use the `collect dir` command to see that `tabulate` created a collection named `Tabulate`.

```
. collect dir
Collections in memory
Current: Tabulate
```

Name	No. items
Table	51
Tabulate	45

In this collection, means are tagged with `result[mean]`, standard deviations with `result[sd]`, and frequencies with `result[frequency]`. When weights are specified, observation counts are tagged with `result[count]`. Here we use `collect label list` to show the levels and labels of the result dimension.

```
. collect label list result
      Collection: Tabulate
      Dimension: result
      Label: Result
Level labels:
      frequency  Frequency
      mean      Mean
      sd        Std. dev.
```

The tabulated variables (that is, `wgtcat` and `foreign`) are added to the collection as dimensions and are used to tag the collected results. In addition to the name, label, level values, and value labels of the tabulated variables, these dimensions each have the `__margCode__` level with the Total label for tagging the marginal summary statistics. Here we use `collect label list` to show the levels and labels of each tabulated variable dimension. For `wgtcat`, we add the `all` option to show the levels without labels.

```
. collect label list wgtcat, all
      Collection: Tabulate
      Dimension: wgtcat
      Label:
Level labels:
      2530
      3300
      4070
      4840
__margCode__  Total
. collect label list foreign
      Collection: Tabulate
      Dimension: foreign
      Label: Car origin
Level labels:
      0  Domestic
      1  Foreign
__margCode__  Total
```

tabulate constructs a default layout, so you can view your customizable table with the collect preview command. Here we use the collect layout command to report the default layout specification and corresponding table.

```
. collect layout
Collection: Tabulate
  Rows: wgtcat#result
Columns: var#foreign
  Tables: cmdset
Table 1: 21 x 3
```

	Mileage (mpg)		
	Car origin		
	Domestic	Foreign	Total
wgtcat			
2530			
Mean	28.3	27.1	27.4
Std. dev.	3.1	6.0	5.2
Frequency	7	16	23
3300			
Mean	21.8	19.6	21.2
Std. dev.	2.4	3.4	2.8
Frequency	16	5	21
4070			
Mean	17.3	14.0	17.1
Std. dev.	1.9	0.0	1.9
Frequency	23	1	24
4840

Std. dev.	3.3	.	3.3
Frequency	6	0	6
Total			
Mean	19.8	24.8	21.3
Std. dev.	4.7	6.6	5.8
Frequency	52	22	74

We now change some cell formats, remove the summary statistic labels from the row header, and add a note suggesting the table’s cell contents.

```
. collect style cell result[mean], nformat(%9.2f)
. collect style cell result[sd], nformat(%9.2f) sformat("(%s)")
. collect style header result, level(hide)
. collect note "Mean (SD) N"
. collect preview
```

	Mileage (mpg)		
	Car origin		
	Domestic	Foreign	Total
wgtcat			
2530	28.29	27.06	27.43
	(3.09)	(5.98)	(5.23)
	7	16	23
3300	21.75	19.60	21.24
	(2.41)	(3.44)	(2.76)
	16	5	21
4070	17.26	14.00	17.12
	(1.86)	(0.00)	(1.94)
	23	1	24
4840	14.67	.	14.67
	(3.33)	(.)	(3.33)
	6	0	6
Total	19.83	24.77	21.30
	(4.74)	(6.61)	(5.79)
	52	22	74

Mean (SD) N

We can make further changes to the table with the `collect` suite of commands. But we are happy with this layout and ready to publish the table to a \LaTeX file with `collect export`. We simply specify the filename to which we want to export it.

```
. collect export tab2.tex
(collection Tabulate exported to file tab2.tex)
```

With `collect export`, you can publish the table to several formats, such as HTML, PDF, and \LaTeX files, by specifying the appropriate file extension.

[Description](#)[Options for testparm](#)[Methods and formulas](#)[Quick start](#)[Options for test](#)[Acknowledgment](#)[Menu](#)[Remarks and examples](#)[References](#)[Syntax](#)[Stored results](#)[Also see](#)

Description

`test` performs Wald tests of simple and composite linear hypotheses about the parameters of the most recently fit model.

`test` supports `svy` estimators (see [\[SVY\] svy estimation](#)), carrying out an adjusted Wald test by default in such cases. `test` can be used with `svy` estimation results, see [\[SVY\] svy postestimation](#).

`testparm` provides a useful alternative to `test` that permits *varlist* rather than a list of coefficients (which is often nothing more than a list of variables), allowing the use of standard Stata notation, including ‘-’ and ‘*’, which are given the expression interpretation by `test`.

`test` and `testparm` perform Wald tests. For likelihood-ratio tests, see [\[R\] lrtest](#). For Wald-type tests of nonlinear hypotheses, see [\[R\] testnl](#). To display estimates for one-dimensional linear or nonlinear expressions of coefficients, see [\[R\] lincom](#) and [\[R\] nlcom](#).

See [\[R\] anova postestimation](#) for additional `test` syntax allowed after `anova`.

See [\[MV\] manova postestimation](#) for additional `test` syntax allowed after `manova`.

Quick start

Linear tests after single-equation models

Joint test that the coefficients on `x1` and `x2` are equal to 0

```
test x1 x2
```

Joint test that coefficients on [factor indicators](#) `2.a` and `3.a` are equal to 0

```
test 2.a 3.a
```

Test that coefficients on indicators `2.a` and `3.a` are equal

```
test 2.a = 3.a
```

Joint test that coefficients on indicators `1.a`, `2.a`, and `3.a` are all equal

```
test (1.a=2.a) (1.a=3.a)
```

Same as above

```
test 1.a=2.a=3.a
```

Same as above, but add separate tests for each pairing

```
test 1.a=2.a=3.a, mtest
```

Same as above, but with *p*-values adjusted for multiple comparisons using Šidák’s method

```
test (1.a=2.a) (1.a=3.a), mtest(sidak)
```

Test that the sum of the coefficients for x_1 and x_2 is equal to 4

```
test x1 + x2 = 4
```

Test the equality of two linear expressions involving coefficients on x_1 and x_2

```
test 2*x1 = 3*x2
```

Shorthand varlist notation

Joint test that all coefficients on the indicators for a are equal to 0

```
testparm i.a
```

Joint test that all coefficients on the indicators for a and b are equal to 0

```
testparm i.a i.b
```

Joint test that all coefficients associated with the interaction of factor variables a and b are equal to 0

```
testparm i.a#i.b
```

Joint test that the coefficients on all variables x^* are equal to 0

```
testparm x*
```

Linear tests after multiple-equation models

Joint test that the coefficient on x_1 is equal to 0 in all equations

```
test x1
```

Joint test that the coefficients for x_1 and x_2 are equal to 0 in equation y_3

```
test [y3]x1 [y3]x2
```

Test that the coefficients for x_1 are equal in equations y_1 and y_3

```
test [y1]x1=[y3]x1
```

Same as above

```
test [y1=y3]: x1
```

Joint test of the equality of coefficients for x_1 and x_2 across equations y_1 and y_3

```
test [y1=y3]: x1 x2
```

Add coefficients for x_1 and x_2 from equation y_4 to test

```
test [y1=y3=y4]: x1 x2
```

Test that all coefficients in the equation for y_1 are equal to those in the equation for y_2

```
test [y1=y2]
```

Same as above, but only for coefficients on variables common to both equations

```
test [y1=y2], common
```

Shorthand varlist notation

Joint test that all coefficients on the indicators for a are 0 in all equations

```
testparm i.a
```

Joint test that all coefficients on the indicators for a are equal to each other in the first equation

```
testparm i.a, equal
```

Same as above, but for the equation for y4

```
testparm i.a, equal equation(y4)
```

Joint test that the coefficients on the indicators for a and b are equal to 0 in all equations

```
testparm i.a i.b
```

Joint test that all coefficients associated with the interaction of factors a and b are 0

```
testparm i.a#i.b
```

Statistics > Postestimation

Syntax

Basic syntax

```
test coeflist (Syntax 1)
test exp=exp[=...] (Syntax 2)
test [eqno] [: coeflist] (Syntax 3)
test [eqno=eqno[=...]] [: coeflist] (Syntax 4)
testparm varlist [ , testparm_options ]
```

Full syntax

```
test (spec) [(spec) ...] [ , test_options ]
```

<i>testparm_options</i>	Description
<u>equal</u>	hypothesize that the coefficients are equal to each other
<u>equation</u> (<i>eqno</i>)	specify equation name or number for which the hypothesis is tested
<u>nosvyadjust</u>	compute unadjusted Wald tests for survey results
<u>df</u> (#)	use <i>F</i> distribution with # denominator degrees of freedom for the reference distribution of the test statistic; for survey data, # specifies the design degrees of freedom unless <u>nosvyadjust</u> is specified

df (#) does not appear in the dialog box.

<i>test_options</i>	Description
---------------------	-------------

Options

<u>mtest</u> [(<i>opt</i>)]	test each condition separately
<u>coef</u>	report estimated constrained coefficients
<u>accumulate</u>	test hypothesis jointly with previously tested hypotheses
<u>notest</u>	suppress the output
<u>common</u>	test only variables common to all the equations
<u>constant</u>	include the constant in coefficients to be tested
<u>nosvyadjust</u>	compute unadjusted Wald tests for survey results
<u>minimum</u>	perform test with the constant, drop terms until the test becomes nonsingular, and test without the constant on the remaining terms; highly technical
<u>matvlc</u> (<i>matname</i>)	save the variance–covariance matrix; programmer’s option
<u>df</u> (#)	use <i>F</i> distribution with # denominator degrees of freedom for the reference distribution of the test statistic; for survey data, # specifies the design degrees of freedom unless <u>nosvyadjust</u> is specified

matvlc(*matname*) and df (#) do not appear in the dialog box.

coeflist and *varlist* may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.

collect is allowed with test; see [U] 11.1.10 Prefix commands.

Syntax 1 tests that coefficients are 0.

Syntax 2 tests that linear expressions are equal.

Syntax 3 tests that coefficients in *eqno* are 0.

Syntax 4 tests equality of coefficients between equations.

spec is one of

```
coeflist
exp=exp[=exp]
[eqno] [:coeflist]
[eqno1=eqno2[=. . .]] [:coeflist]
```

coeflist is

```
coef [coef ...]
[eqno]coef [ [eqno]coef . . . ]
[eqno] _b[coef] [ [eqno] _b[coef] . . . ]
```

exp is a linear expression containing

```
coef
_b[coef]
_b[eqno:coef]
[eqno]coef
[eqno] _b[coef]
```

eqno is

```
##
name
```

coef identifies a coefficient in the model. *coef* is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [\[U\] 11.4.3 Factor variables](#). *coef* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

Distinguish between `[]`, which are to be typed, and `[]`, which indicate optional arguments.

Although not shown in the syntax diagram, parentheses around *spec* are required only with multiple specifications. Also, the diagram does not show that `test` may be called without arguments to redisplay the results from the last test.

`anova` and `manova` (see [\[R\] anova](#) and [\[MV\] manova](#)) allow the `test` syntax above plus more (see [\[R\] anova postestimation](#) for `test` after `anova`; see [\[MV\] manova postestimation](#) for `test` after `manova`).

Options for testparm

`equal` tests that the variables appearing in *varlist*, which also appear in the previously fit model, are equal to each other rather than jointly equal to zero.

`equation` (*eqno*) is relevant only for multiple-equation models, such as `mvreg`, `mlogit`, and `heckman`. It specifies the equation for which the all-zero or all-equal hypothesis is tested. `equation(#1)` specifies that the test be conducted regarding the first equation #1. `equation(price)` specifies that the test concern the equation named `price`.

`nosvyadjust` is for use with `svy` estimation commands; see [SVY] [svy estimation](#). It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as $W/k \sim F(k, d)$ rather than as $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$, where k = the dimension of the test and d = the total number of sampled PSUs minus the total number of strata. When the `df()` option is used, it will override the default design degrees of freedom.

The following option is available with `testparm` but is not shown in the dialog box:

`df(#)` specifies that the F distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. The default is to use `e(df_r)` degrees of freedom or the χ^2 distribution if `e(df_r)` is missing. With survey data, # is the design degrees of freedom unless `nosvyadjust` is specified.

Options for test

Options

`mtest` [*opt*] specifies that tests be performed for each condition separately. *opt* specifies the method for adjusting p -values for multiple testing. Valid values for *opt* are

<code>bonferroni</code>	Bonferroni's method
<code>holm</code>	Holm's method
<code>sidak</code>	Šidák's method
<code>noadjust</code>	no adjustment is to be made

Specifying `mtest` without an argument is equivalent to `mtest(noadjust)`.

`coef` specifies that the constrained coefficients be displayed.

`accumulate` allows a hypothesis to be tested jointly with the previously tested hypotheses.

`notest` suppresses the output. This option is useful when you are interested only in the joint test of several hypotheses, specified in a subsequent call of `test`, `accumulate`.

`common` specifies that when you use the [*eqno*₁=*eqno*₂[=. . .]] form of *spec*, the variables common to the equations *eqno*₁, *eqno*₂, etc., be tested. The default action is to complain if the equations have variables not in common.

`constant` specifies that `_cons` be included in the list of coefficients to be tested when using the [*eqno*₁=*eqno*₂[=. . .]] or [*eqno*] forms of *spec*. The default is not to include `_cons`.

`nosvyadjust` is for use with `svy` estimation commands; see [\[SVY\] svy estimation](#). It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as $W/k \sim F(k, d)$ rather than as $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$, where k = the dimension of the test and d = the total number of sampled PSUs minus the total number of strata. When the `df()` option is used, it will override the default design degrees of freedom.

`minimum` is a highly technical option. It first performs the test with the constant added. If this test is singular, coefficients are dropped until the test becomes nonsingular. Then the test without the constant is performed with the remaining terms.

The following options are available with `test` but are not shown in the dialog box:

`matvlc(matname)`, a programmer's option, saves the variance–covariance matrix of the linear combinations involved in the suite of tests. For the test of the linear constraints $Lb = c$, `matname` contains LVL' , where V is the estimated variance–covariance matrix of b .

`df(#)` specifies that the F distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. The default is to use `e(df_r)` degrees of freedom or the χ^2 distribution if `e(df_r)` is missing. With survey data, # is the design degrees of freedom unless `nosvyadjust` is specified.

Remarks and examples

Remarks are presented under the following headings:

[Introductory examples](#)

[Special syntaxes after multiple-equation estimation](#)

[Constrained coefficients](#)

[Multiple testing](#)

Introductory examples

`test` performs F or χ^2 tests of linear restrictions applied to the most recently fit model (for example, `regress` or `svy: regress` in the linear regression case; `logit`, `stcox`, `svy: logit`, ... in the single-equation maximum-likelihood case; and `mlogit`, `mvreg`, `streg`, ... in the multiple-equation maximum-likelihood case). `test` may be used after *any* estimation command, although for maximum likelihood techniques, `test` produces a Wald test that depends only on the estimate of the covariance matrix—you may prefer to use the more computationally expensive likelihood-ratio test; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] lrtest](#).

There are several variations on the syntax for `test`. The second syntax,

```
test exp=exp[=...]
```

is allowed after any form of estimation. After fitting a model of `depvar` on `x1`, `x2`, and `x3`, typing `test x1+x2=x3` tests the restriction that the coefficients on `x1` and `x2` sum to the coefficient on `x3`. The expressions can be arbitrarily complicated; for instance, typing `test x1+2*(x2+x3)=x2+3*x3` is the same as typing `test x1+x2=x3`.

As a convenient shorthand, `test` also allows you to specify equality for multiple expressions; for example, `test x1+x2 = x3+x4 = x5+x6` tests that the three specified pairwise sums of coefficients are equal.

`test` understands that when you type `x1`, you are referring to the coefficient on `x1`. You could also more explicitly type `test _b[x1]+_b[x2]=_b[x3]`; or you could `test _coef[x1]+_coef[x2]=_coef[x3]`, or `test [#1]x1+[#1]x2=[#1]x3`, or many other things because there is more than one way to refer to an estimated coefficient; see [\[U\] 13.5 Accessing coefficients and standard errors](#). The shorthand involves less typing. On the other hand, you must be more explicit after estimation of multiple-equation models because there may be more than one coefficient associated with an independent variable. You might type, for instance, `test [#2]x1+[#2]x2=[#2]x3` to test the constraint in equation 2 or, more readably, `test [ford]x1+[ford]x2=[ford]x3`, meaning that Stata will test the constraint on the equation corresponding to `ford`, which might be equation 2. `ford` would be an equation name after, say, `sureg`, or, after `mlogit`, `ford` would be one of the outcomes. For `mlogit`, you could also type `test [2]x1+[2]x2=[2]x3`—note the lack of the `#`—meaning not equation 2, but the equation corresponding to the numeric outcome 2. You can even test constraints across equations: `test [ford]x1+[ford]x2=[buick]x3`.

The syntax

`test coeflist`

is available after all estimation commands and is a convenient way to test that multiple coefficients are zero following estimation. A *coeflist* can simply be a list of variable names,

`test varname [varname ...]`

and it is most often specified that way. After you have fit a model of `depvar` on `x1`, `x2`, and `x3`, typing `test x1 x3` tests that the coefficients on `x1` and `x3` are jointly zero. After multiple-equation estimation, this would test that the coefficients on `x1` and `x3` are zero in all equations that contain them. You can also be more explicit and type, for instance, `test [ford]x1 [ford]x3` to test that the coefficients on `x1` and `x3` are zero in the equation for `ford`.

In the multiple-equation case, there are more alternatives. You could also test that the coefficients on `x1` and `x3` are zero in the equation for `ford` by typing `test [ford]: x1 x3`. You could test that all coefficients except the coefficient on the constant are zero in the equation for `ford` by typing `test [ford]`. You could test that the coefficients on `x1` and `x3` in the equation for `ford` are equal to the corresponding coefficients in the equation corresponding to `buick` by typing `test [ford=buick]: x1 x3`. You could test that all the corresponding coefficients except the constant in three equations are equal by typing `test [ford=buick=volvo]`.

`testparm` is much like the first syntax of `test`. Its usefulness will be demonstrated below.

The examples below use `regress`, but what is said applies equally after any single-equation estimation command (such as `logistic`). It also applies after multiple-equation estimation commands as long as references to coefficients are qualified with an equation name or number in square brackets placed before them. The convenient syntaxes for dealing with tests of many coefficients in multiple-equation models are demonstrated in [Special syntaxes after multiple-equation estimation](#) below.

► Example 1: Testing for a single coefficient against zero

We have 1980 census data on the 50 states recording the birth rate in each state (`brate`), the median age (`medage`), and the region of the country in which each state is located.

The `region` variable is 1 if the state is in the Northeast, 2 if the state is in the North Central, 3 if the state is in the South, and 4 if the state is in the West. We estimate the following regression:

```
. use https://www.stata-press.com/data/r19/census3
(1980 Census data by state)
```

```
. regress brate medage c.medage#c.medage i.region
```

Source	SS	df	MS	Number of obs	=	50
Model	38803.4208	5	7760.68416	F(5, 44)	=	100.63
Residual	3393.39921	44	77.1227094	Prob > F	=	0.0000
				R-squared	=	0.9196
				Adj R-squared	=	0.9104
Total	42196.82	49	861.159592	Root MSE	=	8.782

brate	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
medage	-109.0958	13.52452	-8.07	0.000	-136.3527	-81.83892
c.medage# c.medage	1.635209	.2290536	7.14	0.000	1.173582	2.096836
region						
NCentral	15.00283	4.252067	3.53	0.001	6.433353	23.57231
South	7.366445	3.953335	1.86	0.069	-.6009775	15.33387
West	21.39679	4.650601	4.60	0.000	12.02412	30.76946
_cons	1947.611	199.8405	9.75	0.000	1544.859	2350.363

`test` can now be used to perform a variety of statistical tests. Specify the `coeflegend` option with your estimation command to see a legend of the coefficients and how to specify them; see [\[R\] Estimation options](#). We can test the hypothesis that the coefficient on `3.region` is zero by typing

```
. test 3.region=0
( 1) 3.region = 0
      F( 1, 44) = 3.47
      Prob > F = 0.0691
```

The F statistic with 1 numerator and 44 denominator degrees of freedom is 3.47. The significance level of the test is 6.91%—we can reject the hypothesis at the 10% level but not at the 5% level.

This result from `test` is identical to one presented in the output from `regress`, which indicates that the t statistic on the `3.region` coefficient is 1.863 and that its significance level is 0.069. The t statistic presented in the output can be used to test the hypothesis that the corresponding coefficient is zero, although it states the test in slightly different terms. The F distribution with 1 numerator degree of freedom is, however, identical to the t^2 distribution. We note that $1.863^2 \approx 3.47$ and that the significance levels in each test agree, although one extra digit is presented by the `test` command.

□ Technical note

After all estimation commands, including those that use the maximum likelihood method, the test that one variable is zero is identical to that reported by the command's output. The tests are performed in the same way—using the estimated covariance matrix—and are known as Wald tests. If the estimation command reports significance levels and confidence intervals using z rather than t statistics, test reports results using the χ^2 rather than the F statistic.

▷ Example 2: Testing the value of a single coefficient

If that were all test could do, it would be useless. We can use test, however, to perform other tests. For instance, we can test the hypothesis that the coefficient on 2.region is 21 by typing

```
. test 2.region=21
( 1) 2.region = 21
      F( 1, 44) = 1.99
      Prob > F = 0.1654
```

We find that we cannot reject that hypothesis, or at least we cannot reject it at any significance level below 16.5%.

▷ Example 3: Testing the equality of two coefficients

The previous test is useful, but we could almost as easily perform it by hand using the results presented in the regression output if we were well read on our statistics. We could type

```
. display Ftail(1,44,((_coef[2.region]-21)/4.252068)^2)
.16544873
```

So, now let's test something a bit more difficult: whether the coefficient on 2.region is the same as the coefficient on 4.region:

```
. test 2.region=4.region
( 1) 2.region - 4.region = 0
      F( 1, 44) = 2.84
      Prob > F = 0.0989
```

We find that we cannot reject the equality hypothesis at the 5% level, but we can at the 10% level.

► Example 4

When we tested the equality of the `2.region` and `4.region` coefficients, Stata rearranged our algebra. When Stata displayed its interpretation of the specified test, it indicated that we were testing whether `2.region minus 4.region` is zero. The rearrangement is innocuous and, in fact, allows Stata to perform much more complicated algebra, for instance,

```
. test 2*(2.region-3*(3.region-4.region))=3.region+2.region+6*(4.region-3.region)
( 1) 2.region - 3.region = 0
      F( 1, 44) = 5.06
      Prob > F = 0.0295
```

Although we requested what appeared to be a lengthy hypothesis, once Stata simplified the algebra, it realized that all we wanted to do was test whether the coefficient on `2.region` is the same as the coefficient on `3.region`.

□ Technical note

Stata's ability to simplify and test complex hypotheses is limited to *linear* hypotheses. If you attempt to test a nonlinear hypothesis, you will be told that it is not possible:

```
. test 2.region/3.region=2.region+3.region
not possible with test
r(131);
```

To test a nonlinear hypothesis, see [R] [testnl](#).

► Example 5: Testing joint hypotheses

The real power of `test` is demonstrated when we test *joint* hypotheses. Perhaps we wish to test whether the region variables, taken as a whole, are significant by testing whether the coefficients on `2.region`, `3.region`, and `4.region` are simultaneously zero. `test` allows us to specify multiple conditions to be tested, each embedded within parentheses.

```
. test (2.region=0) (3.region=0) (4.region=0)
( 1) 2.region = 0
( 2) 3.region = 0
( 3) 4.region = 0
      F( 3, 44) = 8.85
      Prob > F = 0.0001
```

`test` displays the set of conditions and reports an F statistic of 8.85. `test` also reports the degrees of freedom of the test to be 3, the “dimension” of the hypothesis, and the residual degrees of freedom, 44. The significance level of the test is close to 0, so we can strongly reject the hypothesis of no difference between the regions.

An alternative method to specify simultaneous hypotheses uses the convenient shorthand of conditions with multiple equality operators.

```
. test 2.region=3.region=4.region=0
( 1) 2.region - 3.region = 0
( 2) 2.region - 4.region = 0
( 3) 2.region = 0
      F( 3, 44) = 8.85
      Prob > F = 0.0001
```

□ Technical note

Another method to test simultaneous hypotheses is to specify a test for each constraint and accumulate it with the previous constraints:

```
. test 2.region=0
( 1) 2.region = 0
      F( 1, 44) = 12.45
      Prob > F = 0.0010

. test 3.region=0, accumulate
( 1) 2.region = 0
( 2) 3.region = 0
      F( 2, 44) = 6.42
      Prob > F = 0.0036

. test 4.region=0, accumulate
( 1) 2.region = 0
( 2) 3.region = 0
( 3) 4.region = 0
      F( 3, 44) = 8.85
      Prob > F = 0.0001
```

We tested the hypothesis that the coefficient on `2.region` was zero by typing `test 2.region=0`. We then tested whether the coefficient on `3.region` was also zero by typing `test 3.region=0, accumulate`. The `accumulate` option told Stata that this was not the start of a new test but a continuation of a previous one. Stata responded by showing us the two equations and reporting an F statistic of 6.42. The significance level associated with those two coefficients being zero is 0.36%.

When we added the last constraint `test 4.region=0, accumulate`, we discovered that the three region variables are significant. If all we wanted was the overall significance and we did not want to bother seeing the interim results, we could have used the `notest` option:

```
. test 2.region=0, notest
( 1) 2.region = 0

. test 3.region=0, accumulate notest
( 1) 2.region = 0
( 2) 3.region = 0

. test 4.region=0, accumulate
( 1) 2.region = 0
( 2) 3.region = 0
( 3) 4.region = 0
      F( 3, 44) = 8.85
      Prob > F = 0.0001
```

► Example 6: Quickly testing coefficients against zero

Because tests that coefficients are zero are so common in applied statistics, the `test` command has a more convenient syntax to accommodate this case:

```
. test 2.region 3.region 4.region
( 1) 2.region = 0
( 2) 3.region = 0
( 3) 4.region = 0
      F( 3, 44) = 8.85
      Prob > F = 0.0001
```

► Example 7: Specifying varlists

We will now show how to use `testparm`. In its first syntax, `test` accepts a list of variable names but not *varlist*.

```
. test i(2/4).region
i not found
r(111);
```

In the varlist, `i(2/4).region` means all the level variables from `2.region` through `4.region`, yet we received an error. `test` does not actually understand varlists, but `testparm` does. In fact, it understands only varlists.

```
. testparm i(2/4).region
( 1) 2.region = 0
( 2) 3.region = 0
( 3) 4.region = 0
      F( 3, 44) = 8.85
      Prob > F = 0.0001
```

Another way to test all the `region` variables is to type `testparm i.region`.

That `testparm` accepts varlists has other advantages that do not involve factor variables. Suppose that we have a dataset that has dummy variables `reg2`, `reg3`, and `reg4`, rather than the categorical variable `region`.

```
. use https://www.stata-press.com/data/r19/census4
(Census data on birthrate, median age)
. regress brate medage c.medage#c.medage reg2 reg3 reg4
(output omitted)
. test reg2-reg4
- not found
r(111);
```

In a varlist, `reg2-reg4` means variables `reg2` and `reg4` and all the variables between, yet we received an error. `test` is confused because the `-` has two meanings: it means subtraction in an expression and “through” in *varlist*. Similarly, `*` means “any set of characters” in *varlist* and multiplication in an expression. `testparm` avoids this confusion—it allows only *varlist*.

```
. testparm reg2-reg4
( 1)  reg2 = 0
( 2)  reg3 = 0
( 3)  reg4 = 0
      F( 3,    44) =    8.85
      Prob > F =    0.0001
```

testparm has another advantage. We have five variables in our dataset that start with the characters reg: region, reg1, reg2, reg3, and reg4. reg* thus means those five variables:

```
. describe reg*
```

Variable name	Storage type	Display format	Value label	Variable label
region	byte	%8.0g	region	Census region
reg1	byte	%9.0g		Region: NE
reg2	byte	%9.0g		Region: N Cntrl
reg3	byte	%9.0g		Region: South
reg4	byte	%9.0g		Region: West

We cannot type test reg* because, in an expression, '*' means multiplication, but here is what would happen if we attempted to test all the variables that begin with reg:

```
. test region reg1 reg2 reg3 reg4
region not found
r(111);
```

The variable region was not included in our model, so it was not found. However, with testparm,

```
. testparm reg*
( 1)  reg2 = 0
( 2)  reg3 = 0
( 3)  reg4 = 0
      F( 3,    44) =    8.85
      Prob > F =    0.0001
```

That is, testparm took reg* to mean all variables that start with reg that were in our model.

□ Technical note

Actually, reg* means what it always does—all variables in our dataset that begin with reg—in this case, region reg1 reg2 reg3 reg4. testparm just ignores any variables you specify that are not in the model.

► Example 8: Replaying the previous test

We just used `test` (`testparm`, actually, but it does not matter) to test the hypothesis that `reg2`, `reg3`, and `reg4` are jointly zero. We can review the results of our last test by typing `test` without arguments:

```
. test
( 1)  reg2 = 0
( 2)  reg3 = 0
( 3)  reg4 = 0
      F( 3, 44) = 8.85
      Prob > F = 0.0001
```

◀

□ Technical note

`test` does not care how we build joint hypotheses; we may freely mix different forms of syntax. (We can even start with `testparm`, but we cannot use it thereafter because it does not have an `accumulate` option.)

Say that we type `test reg2 reg3 reg4` to test that the coefficients on our region dummies are jointly zero. We could then add a fourth constraint, say, that `medage = 100`, by typing `test medage=100, accumulate`. Or, if we had introduced the `medage` constraint first (our first `test` command had been `test medage=100`), we could then add the region dummy test by typing `test reg2 reg3 reg4, accumulate` or `test (reg2=0) (reg3=0) (reg4=0), accumulate`.

Remember that all previous tests are cleared when we do not specify the `accumulate` option. No matter what tests we performed in the past, if we type `test medage c.medage#c.medage`, omitting the `accumulate` option, we would test that `medage` and `c.medage#c.medage` are jointly zero.

□

► Example 9: Testing the equality of multiple coefficients

Let's return to our `census3.dta` dataset and test the hypothesis that all the included regions have the same coefficient—that the Northeast is significantly different from the rest of the nation:

```
. use https://www.stata-press.com/data/r19/census3
(1980 Census data by state)
. regress brate medage c.medage#c.medage i.region
(output omitted)
. test 2.region=3.region=4.region
( 1)  2.region - 3.region = 0
( 2)  2.region - 4.region = 0
      F( 2, 44) = 8.23
      Prob > F = 0.0009
```

We find that they are not all the same. The syntax `2.region=3.region=4.region` with multiple `=` operators is just a convenient shorthand for typing that the first expression equals the second expression and that the first expression equals the third expression,

```
. test (2.region=3.region) (2.region=4.region)
```

We performed the test for equality of the three regions by imposing two constraints: region 2 has the same coefficient as region 3, and region 2 has the same coefficient as region 4. Alternatively, we could have tested that the coefficients on regions 2 and 3 are the same and that the coefficients on regions 3 and 4 are the same. We would obtain the same results in either case.

To test for equality of the three regions, we might, likely by mistake, type equality constraints for *all* pairs of regions:

```
. test (2.region=3.region) (2.region=4.region) (3.region=4.region)
( 1)  2.region - 3.region = 0
( 2)  2.region - 4.region = 0
( 3)  3.region - 4.region = 0
      Constraint 3 dropped
      F( 2,    44) =    8.23
      Prob > F =    0.0009
```

Equality of regions 2 and 3 and of regions 2 and 4, however, implies equality of regions 3 and 4. `test` recognized that the last constraint is implied by the other constraints and hence dropped it.

□ Technical note

Generally, Stata uses `=` for assignment, as in `gen newvar = exp`, and `==` as the operator for testing equality in expressions. For your convenience, `test` allows both `=` and `==` to be used.

▷ Example 10

The test for the equality of the regions is also possible with the `testparm` command. When we include the `equal` option, `testparm` tests that the coefficients of all the variables specified are equal:

```
. testparm i(2/4).region, equal
( 1)  - 2.region + 3.region = 0
( 2)  - 2.region + 4.region = 0
      F( 2,    44) =    8.23
      Prob > F =    0.0009
```

We can also obtain the equality test by accumulating single equality tests.

```
. test 2.region=3.region, notest
( 1)  2.region - 3.region = 0
. test 2.region=4.region, accum
( 1)  2.region - 3.region = 0
( 2)  2.region - 4.region = 0
      F( 2,    44) =    8.23
      Prob > F =    0.0009
```

□ Technical note

If we specify a set of inconsistent constraints, test will tell us by dropping the constraint or constraints that led to the inconsistency. For instance, let's test that the coefficients on region 2 and region 4 are the same, add the test that the coefficient on region 2 is 20, and finally add the test that the coefficient on region 4 is 21:

```
. test (2.region=4.region) (2.region=20) (4.region=21)
( 1)  2.region - 4.region = 0
( 2)  2.region = 20
( 3)  4.region = 21
      Constraint 2 dropped
      F(  2,    44) =    1.82
      Prob > F =    0.1737
```

test informed us that it was dropping constraint 2. All three equations cannot be simultaneously true, so test drops whatever it takes to get back to something that makes sense.

Special syntaxes after multiple-equation estimation

Everything said above about tests after single-equation estimation applies to tests after multiple-equation estimation, as long as you remember to specify the equation name. To demonstrate, let's estimate a seemingly unrelated regression by using sureg; see [R] [sureg](#).

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
. sureg (price foreign mpg displ) (weight foreign length)
Seemingly unrelated regression
```

Equation	Obs	Params	RMSE	"R-squared"	chi2	P>chi2
price	74	3	2165.321	0.4537	49.64	0.0000
weight	74	2	245.2916	0.8990	661.84	0.0000

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
price						
foreign	3058.25	685.7357	4.46	0.000	1714.233	4402.267
mpg	-104.9591	58.47209	-1.80	0.073	-219.5623	9.644042
displacement	18.18098	4.286372	4.24	0.000	9.779842	26.58211
_cons	3904.336	1966.521	1.99	0.047	50.0263	7758.645
weight						
foreign	-147.3481	75.44314	-1.95	0.051	-295.2139	.517755
length	30.94905	1.539895	20.10	0.000	27.93091	33.96718
_cons	-2753.064	303.9336	-9.06	0.000	-3348.763	-2157.365

To test the significance of `foreign` in the price equation, we could type

```
. test [price]foreign
( 1)  [price]foreign = 0
      chi2( 1) =    19.89
      Prob > chi2 =    0.0000
```

which is the same result reported by `sureg`: $4.460^2 \approx 19.89$. To test `foreign` in both equations, we could type

```
. test [price]foreign [weight]foreign
( 1)  [price]foreign = 0
( 2)  [weight]foreign = 0
      chi2( 2) =    31.61
      Prob > chi2 =    0.0000
```

or

```
. test foreign
( 1)  [price]foreign = 0
( 2)  [weight]foreign = 0
      chi2( 2) =    31.61
      Prob > chi2 =    0.0000
```

This last syntax—typing the variable name by itself—tests the coefficients in all equations in which they appear. The variable `length` appears in only the `weight` equation, so typing

```
. test length
( 1)  [weight]length = 0
      chi2( 1) =   403.94
      Prob > chi2 =    0.0000
```

yields the same result as typing `test [weight]length`. We may also specify a linear expression rather than a list of coefficients:

```
. test mpg=displ
( 1)  [price]mpg - [price]displacement = 0
      chi2( 1) =     4.85
      Prob > chi2 =    0.0277
```

or

```
. test [price]mpg = [price]displ
( 1)  [price]mpg - [price]displacement = 0
      chi2( 1) =     4.85
      Prob > chi2 =    0.0277
```

A variation on this syntax can be used to test cross-equation constraints:

```
. test [price]foreign = [weight]foreign
( 1)  [price]foreign - [weight]foreign = 0
      chi2( 1) =    23.07
      Prob > chi2 =    0.0000
```

Typing an equation name in square brackets by itself tests all the coefficients except the intercept in that equation:

```
. test [price]
( 1) [price]foreign = 0
( 2) [price]mpg = 0
( 3) [price]displacement = 0
      chi2( 3) =    49.64
      Prob > chi2 =    0.0000
```

Typing an equation name in square brackets, a colon, and a list of variable names tests those variables in the specified equation:

```
. test [price]: foreign displ
( 1) [price]foreign = 0
( 2) [price]displacement = 0
      chi2( 2) =    25.19
      Prob > chi2 =    0.0000
```

`test [eqname1=eqname2]` tests that all the coefficients in the two equations are equal. We cannot use that syntax here because there are different variables in the model:

```
. test [price=weight]
variables differ between equations
(to test equality of coefficients in common, specify option common)
r(111);
```

The common option specifies a test of the equality coefficients common to the equations price and weight,

```
. test [price=weight], common
( 1) [price]foreign - [weight]foreign = 0
      chi2( 1) =    23.07
      Prob > chi2 =    0.0000
```

By default, `test` does not include the constant, the coefficient of the constant variable `_cons`, in the test. The `cons` option specifies that the constant be included.

```
. test [price=weight], common cons
( 1) [price]foreign - [weight]foreign = 0
( 2) [price]_cons - [weight]_cons = 0
      chi2( 2) =    51.23
      Prob > chi2 =    0.0000
```

We can also use a modification of this syntax with the model if we also type a colon and the names of the variables we want to test:

```
. test [price=weight]: foreign
( 1) [price]foreign - [weight]foreign = 0
      chi2( 1) =    23.07
      Prob > chi2 =    0.0000
```

We have only one variable in common between the two equations, but if there had been more, we could have listed them.

Finally, a simultaneous test of multiple constraints may be specified just as after single-equation estimation.

```
. test ([price]: foreign) ([weight]: foreign)
( 1) [price]foreign = 0
( 2) [weight]foreign = 0
      chi2( 2) =    31.61
Prob > chi2 =    0.0000
```

`test` can also test for equality of coefficients across more than two equations. For instance, `test [eq1=eq2=eq3]` specifies a test that the coefficients in the three equations `eq1`, `eq2`, and `eq3` are equal. This requires that the same variables be included in the three equations. If some variables are entered only in some of the equations, you can type `test [eq1=eq2=eq3], common` to test that the coefficients of the variables common to all three equations are equal. Alternatively, you can explicitly list the variables for which equality of coefficients across the equations is to be tested. For instance, `test [eq1=eq2=eq3]: time money` tests that the coefficients of the variables `time` and `money` do not differ between the equations.

□ Technical note

`test [eq1=eq2=eq3], common` tests the equality of the coefficients common to all equations, but it does *not* test the equality of all common coefficients. Consider the case where

<code>eq1</code>	contains the variables <code>var1 var2 var3</code>
<code>eq2</code>	contains the variables <code>var1 var2 var4</code>
<code>eq3</code>	contains the variables <code>var1 var3 var4</code>

Obviously, only `var1` is common to all three equations. Thus `test [eq1=eq2=eq3], common` tests that the coefficients of `var1` do not vary across the equations, so it is equivalent to `test [eq1=eq2=eq3]: var1`. To perform a test of the coefficients of variables common to two equations, you could explicitly list the constraints to be tested,

```
. test ([eq1=eq2=eq3]:var1) ([eq1=eq2]:var2) ([eq1=eq3]:var3) ([eq2=eq3]:var4)
```

or use `test` with the `accumulate` option, and maybe also with the `notest` option, to form the appropriate joint hypothesis:

```
. test [eq1=eq2], common notest
. test [eq1=eq3], common accumulate notest
. test [eq2=eq3], common accumulate
```

Constrained coefficients

If the test indicates that the data do not allow you to conclude that the constraints are not satisfied, you may want to inspect the constrained coefficients. The `coef` option specified that the constrained results, estimated by GLS, are shown.

```
. test [price=weight], common coef
( 1)  [price]foreign - [weight]foreign = 0
      chi2( 1) =    23.07
      Prob > chi2 =    0.0000
```

Constrained coefficients

	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
price						
foreign	-216.4015	74.06083	-2.92	0.003	-361.558	-71.2449
mpg	-121.5717	58.36972	-2.08	0.037	-235.9742	-7.169116
displacement	7.632566	3.681114	2.07	0.038	.4177148	14.84742
_cons	7312.856	1834.034	3.99	0.000	3718.215	10907.5
weight						
foreign	-216.4015	74.06083	-2.92	0.003	-361.558	-71.2449
length	30.34875	1.534815	19.77	0.000	27.34057	33.35693
_cons	-2619.719	302.6632	-8.66	0.000	-3212.928	-2026.51

The constrained coefficient of `foreign` is -216.40 with standard error 74.06 in equations `price` and `weight`. The other coefficients and their standard errors are affected by imposing the equality constraint of the two coefficients of `foreign` because the unconstrained estimates of these two coefficients were correlated with the estimates of the other coefficients.

□ Technical note

The two-step constrained coefficients b_c displayed by `test`, `coef` are asymptotically equivalent to the one-stage constrained estimates that are computed by specifying the constraints during estimation using the `constraint()` option of estimation commands (Gouriéroux and Monfort 1995, chap. 10). Generally, one-step constrained estimates have better small-sample properties. For inspection and interpretation, however, two-step constrained estimates are a convenient alternative. Moreover, some estimation commands (for example, `stcox`, many `xt` estimators) do not have a `constraint()` option.

□

Multiple testing

When performing the test of a joint hypothesis, you might want to inspect the underlying 1-degree-of-freedom hypotheses. Which constraint “is to blame”? `test` displays the univariate as well as the simultaneous test if the `mtest` option is specified. For example,

```
. test [price=weight], common cons mtest
( 1)  [price]foreign - [weight]foreign = 0
( 2)  [price]_cons - [weight]_cons = 0
```

	chi2	df	p > chi2
(1)	23.07	1	0.0000*
(2)	11.17	1	0.0008*
All	51.23	2	0.0000

* Unadjusted p-values

Both coefficients seem to contribute to the highly significant result. The 1-degree-of-freedom test shown here is identical to those if `test` had been invoked to test just this simple hypotheses. There is, of course, a real risk in inspecting these simple hypotheses. Especially in high-dimensional hypotheses, you may easily find one hypothesis that happens to be significant. Multiple testing procedures are designed to provide some safeguard against this risk. *p*-values of the univariate hypotheses are modified so that the probability of falsely rejecting one of the null hypotheses is bounded. `test` provides the methods based on Bonferroni, Šidák, and Holm.

```
. test [price=weight], common cons mtest(b)
( 1)  [price]foreign - [weight]foreign = 0
( 2)  [price]_cons - [weight]_cons = 0
```

	chi2	df	p > chi2
(1)	23.07	1	0.0000*
(2)	11.17	1	0.0017*
All	51.23	2	0.0000

* Bonferroni-adjusted p-values

Stored results

`test` and `testparm` store the following in `r()`:

Scalars

<code>r(p)</code>	two-sided <i>p</i> -value	<code>r(chi2)</code>	χ^2
<code>r(F)</code>	<i>F</i> statistic	<code>r(ss)</code>	sum of squares (test)
<code>r(df)</code>	test constraints degrees of freedom	<code>r(rss)</code>	residual sum of squares
<code>r(df_r)</code>	residual degrees of freedom	<code>r(drop)</code>	1 if constraints were dropped, 0 otherwise
<code>r(dropped_i)</code>	index of <i>i</i> th constraint dropped		

Macros

<code>r(mtmetho)</code>	method of adjustment for multiple testing
-------------------------	---

Matrices

<code>r(mtest)</code>	multiple test results
-----------------------	-----------------------

`r(ss)` and `r(rss)` are defined only when `test` is used for testing effects after anova.

Methods and formulas

`test` and `testparm` perform Wald tests. Let the estimated coefficient vector be \mathbf{b} and the estimated variance–covariance matrix be \mathbf{V} . Let $\mathbf{Rb} = \mathbf{r}$ denote the set of q linear hypotheses to be tested jointly.

The Wald test statistic is (Judge et al. 1985, 20–28)

$$W = (\mathbf{Rb} - \mathbf{r})'(\mathbf{RVR}')^{-1}(\mathbf{Rb} - \mathbf{r})$$

If the estimation command reports its significance levels using Z statistics, a χ^2 distribution with q degrees of freedom,

$$W \sim \chi_q^2$$

is used for computation of the significance level of the hypothesis test.

If the estimation command reports its significance levels using t statistics with d degrees of freedom, an F statistic,

$$F = \frac{1}{q}W$$

is computed, and an F distribution with q numerator degrees of freedom and d denominator degrees of freedom computes the significance level of the hypothesis test.

The two-step constrained estimates b_c displayed by `test` with the `coef` option are the GLS estimates of the unconstrained estimates b subject to the specified constraints $Rb = c$ (Gouriéroux and Monfort 1995, chap. 10),

$$\mathbf{b}_c = \mathbf{b} - \mathbf{VR}'(\mathbf{RVR}')^{-1}(\mathbf{Rb} - \mathbf{r})$$

with variance–covariance matrix

$$\mathbf{V}_c = \mathbf{V} - \mathbf{VR}'(\mathbf{RVR}')^{-1}\mathbf{RV}$$

If `test` displays a Wald test for joint (simultaneous) hypotheses, it can also display all 1-degree-of-freedom tests, with p -values adjusted for multiple testing. Let p_1, p_2, \dots, p_k be the unadjusted p -values of these 1-degree-of-freedom tests. The Bonferroni-adjusted p -values are defined as $p_i^b = \min(1, kp_i)$. The Šidák-adjusted p -values are $p_i^s = 1 - (1 - p_i)^k$. Let $p_{(1)}, p_{(2)}, \dots, p_{(k)}$ be the ordered unadjusted p -values. The Holm's method adjusted p -values are then defined by

$$p_{(i)}^h = \max_{j \leq i} [\min\{1, (k - j + 1)p_{(j)}\}]$$

If `test` is used after a `svy` command, it carries out an adjusted Wald test—this adjustment should not be confused with the adjustment for multiple testing. Both adjustments may actually be combined. Specifically, the survey adjustment uses an approximate F statistic $(d - k + 1)W/(kd)$, where W is the Wald test statistic, k is the dimension of the hypothesis test, and d = the total number of sampled PSUs minus the total number of strata. Under the null hypothesis, $(d - k + 1)F/(kd) \sim F(k, d - k + 1)$, where $F(k, d - k + 1)$ is an F distribution with k numerator degrees of freedom and $d - k + 1$ denominator degrees of freedom. If `nosvyadjust` is specified, the p -value is computed using $W/k \sim F(k, d)$.

See Korn and Graubard (1990) for a detailed description of the Bonferroni adjustment technique and for a discussion of the relative merits of it and of the adjusted and unadjusted Wald tests.

Acknowledgment

The svy adjustment code was adopted from another command developed in collaboration with John L. Eltinge of the United States Census Bureau.

Description

`testnl` tests (linear or nonlinear) hypotheses about the estimated parameters from the most recently fit model.

`testnl` produces Wald-type tests of smooth nonlinear (or linear) hypotheses about the estimated parameters from the most recently fit model. The p -values are based on the delta method, an approximation appropriate in large samples.

`testnl` can be used with `svy` estimation results; see [\[SVY\] svy postestimation](#).

The format $(exp_1 = exp_2 = exp_3 \dots)$ for a simultaneous-equality hypothesis is just a convenient shorthand for a list $(exp_1 = exp_2) \ (exp_1 = exp_3)$, etc.

`testnl` may also be used to test linear hypotheses. `test` is faster if you want to test only linear hypotheses; see [\[R\] test](#). `testnl` is the only option for testing linear and nonlinear hypotheses simultaneously.

Quick start

After single-equation models

Test that the product of the coefficients for `x1` and `x2` is equal to 4

```
testnl _b[x1]*_b[x2] = 4
```

Test that the ratio of the indicators for the [factor variable](#) `a = 2` and `a = 3` is 1

```
testnl _b[2.a]/_b[3.a] = 1
```

Test that an expression involving continuous [factor variable](#) syntax is equal to 16

```
testnl _b[x1]/(2*_b[c.x1#c.x1]) = 16
```

Test the equality of two expressions

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3]
```

Joint test that two products are both equal to 2

```
testnl (_b[x1]*_b[x2] = 2) (_b[x1]*_b[x3] = 2)
```

Same as above

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3] = 2
```

Same as above, but add separate tests for each expression

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3] = 2, mtest
```

Same as above, but adjust p -values for multiple comparisons using Holm's method

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3] = 2, mtest(holm)
```

Test a linear hypothesis and a nonlinear hypothesis together

```
testnl (_b[x1] = _b[x2]) (_b[x2]^2 = _b[x3])
```

After multiple-equation models

Test that the product of the coefficients for x_1 and x_2 in the equation for y_1 is equal to 1

```
testnl _b[y1:x1]*_b[y1:x2] = 1
```

Test that the product of the coefficients for x_1 and x_2 in the equation for y_2 is equal to 1

```
testnl _b[y2:x1]*_b[y2:x2] = 1
```

Test the equality of expressions involving coefficients from the equations for y_1 and y_4

```
testnl _b[y1:x1]*_b[y1:x2] = _b[y4:x1]*_b[y4:x2]
```

Statistics > Postestimation

Syntax

```
testnl exp = exp [= exp ...] [, options]  
testnl (exp = exp [= exp ...]) [(exp = exp [= exp ...]) ...] [, options]
```

<i>options</i>	Description
<u>m</u> test[(<i>opt</i>)]	test each condition separately
<u>i</u> terate(#)	use maximum # of iterations to find the optimal step size
df(#)	use <i>F</i> distribution with # denominator degrees of freedom for the reference distribution of the test statistic
<u>n</u> osvyadjust	carry out the Wald test as $W/k \sim F(k, d)$; for use with svy estimation commands when the df() option is also specified

collect is allowed; see [U] 11.1.10 Prefix commands.
df(#) and nosvyadjust do not appear in the dialog box.

The second syntax means that if more than one expression is specified, each must be surrounded by parentheses.

exp is a possibly nonlinear expression containing

```
_b[coef]  
_b[eqno:coef]  
[eqno]coef  
[eqno]_b[coef]
```

eqno is

```
##  
name
```

coef identifies a coefficient in the model. *coef* is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [U] 11.4.3 Factor variables. *coef* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

Distinguish between [], which are to be typed, and [], which indicate optional arguments.

Options

mtest(*opt*) specifies that tests be performed for each condition separately. *opt* specifies the method for adjusting *p*-values for multiple testing. Valid values for *opt* are

<u>b</u> onferroni	Bonferroni’s method
<u>h</u> olm	Holm’s method
<u>s</u> idak	Šidák’s method
<u>n</u> oadjust	no adjustment is to be made

Specifying mtest without an argument is equivalent to specifying mtest(noadjust).

`iterate(#)` specifies the maximum number of iterations used to find the optimal step size in the calculation of numerical derivatives of the test expressions. By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.

The following options are available with `testnl` but are not shown in the dialog box:

`df(#)` specifies that the F distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. With survey data, # is the design degrees of freedom unless `nosvyadjust` is specified.

`nosvyadjust` is for use with `svy` estimation commands when the `df()` option is also specified; see [SVY] [svy estimation](#). It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as $W/k \sim F(k, d)$ rather than as $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$, where k = the dimension of the test and d = the design degrees of freedom specified in the `df()` option.

Introduction

► Example 1

We have just estimated the parameters of an earnings model on cross-sectional time-series data using one of Stata's more sophisticated estimators:

```
. use https://www.stata-press.com/data/r19/earnings
(NLS women 14-24 in 1968)

. xtgee ln_w grade age c.age#c.age, corr(exchangeable) nolog

GEE population-averaged model      Number of obs   = 1,326
Group variable: idcode             Number of groups = 269
Family: Gaussian                  Obs per group:
Link: Identity                     min = 1
Correlation: exchangeable          avg = 4.9
                                   max = 9

                                   Wald chi2(3)       = 327.33
                                   Prob > chi2         = 0.0000

Scale parameter = .0976738
```

ln_wage	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
grade	.0749686	.0066111	11.34	0.000	.062011	.0879261
age	.1080806	.0235861	4.58	0.000	.0618526	.1543086
c.age#c.age	-.0016253	.0004739	-3.43	0.001	-.0025541	-.0006966
_cons	-.8788933	.2830899	-3.10	0.002	-1.433739	-.3240473

An implication of this model is that peak earnings occur at age $-_b[\text{age}]/(2*_b[\text{c.age}\#\text{c.age}])$, which here is equal to 33.2. Say that we have a theory that peak earnings should occur at age $16 + 1/_b[\text{grade}]$.

```
. testnl _b[age]/(2*_b[c.age#c.age]) = 16 + 1/_b[grade]
(1)  _b[age]/(2*_b[c.age#c.age]) = 16 + 1/_b[grade]
      chi2(1) =          1.71
      Prob > chi2 =          0.1914
```

These data do not reject our theory.

Using testnl to perform linear tests

testnl may be used to test linear constraints, but test is faster; see [R] [test](#). You could type

```
. testnl _b[x4] = _b[x1]
```

but it would take less computer time if you typed

```
. test _b[x4] = _b[x1]
```

Specifying constraints

The constraints to be tested can be formulated in many different ways. You could type

```
. testnl _b[mpg]*_b[weight] = 1
```

or

```
. testnl _b[mpg] = 1/_b[weight]
```

or you could express the constraint any other way you wished. (To say that testnl allows constraints to be specified in different ways does not mean that the test itself does not depend on the formulation. This point is briefly discussed later.) In formulating the constraints, you must, however, exercise one caution: users of test often refer to the coefficient on a variable by specifying the variable name. For example,

```
. test mpg = 0
```

More formally, they should type

```
. test _b[mpg] = 0
```

but test allows the `_b[]` surrounding the variable name to be omitted. testnl does not allow this shorthand. Typing

```
. testnl mpg=0
```

specifies the constraint that the value of variable mpg in the first observation is zero. If you make this mistake, sometimes testnl will catch it:

```
. testnl mpg=0
equation (1) contains reference to X rather than _b[X]
r(198);
```

In other cases, testnl may not catch the mistake; then, the constraint will be dropped because it does not make sense:

```
. testnl mpg=0
   Constraint (1) dropped
```

(There are reasons other than this for constraints being dropped.) The worst case, however, is

```
. testnl _b[weight]*mpg = 1
```

when what you mean is not that `_b[weight]` equals the reciprocal of the value of `mpg` in the first observation, but rather that

```
. testnl _b[weight]*_b[mpg] = 1
```

Sometimes, this mistake will be caught by the “contains reference to X rather than `_b[X]`” error, and sometimes it will not. Be careful.

`testnl`, like `test`, can be used after any Stata estimation command, including the survey estimators. When you use it after a multiple-equation command, such as `mlogit` or `heckman`, you refer to coefficients by using Stata’s standard syntax: `[eqname] _b[varname]`.

Stata’s single-equation estimation output looks like this:

	Coef	...	
weight	12.27	...	<- coefficient is <code>_b[weight]</code>
mpg	3.21	...	

Stata’s multiple-equation output looks like this:

	Coef	...	
cat1	weight	12.27	<- coefficient is <code>[cat1]_b[weight]</code>
	mpg	3.21	
8	weight	5.83	<- coefficient is <code>[8]_b[weight]</code>
	mpg	7.43	

Dropped constraints

testnl automatically drops constraints when

- They are nonbinding, for example, `_b[mpg]=_b[mpg]`. More subtle cases include

```
_b[mpg]*_b[weight] = 4
_b[weight] = 2
_b[mpg] = 2
```

In this example, the third constraint is nonbinding because it is implied by the first two.

- They are contradictory, for example, `_b[mpg]=2` and `_b[mpg]=3`. More subtle cases include

```
_b[mpg]*_b[weight] = 4
_b[weight] = 2
_b[mpg] = 3
```

The third constraint contradicts the first two.

Multiple constraints

► Example 2

We illustrate the simultaneous test of a series of constraints using simulated data on labor-market promotion in a given year. We fit a probit model with separate effects for education, experience, and experience-squared for men and women.

```
. use https://www.stata-press.com/data/r19/promotion
(Simulated data on promotions)
```

```
. probit promo male#c.(yedu yexp yexp2), nolog
```

Probit regression

```
Number of obs =    775
LR chi2(7)     = 424.42
Prob > chi2    = 0.0000
Pseudo R2     = 0.4637
```

Log likelihood = -245.42768

promo	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
male	.6489974	.203739	3.19	0.001	.2496763	1.048318
male#c.yedu						
Female	.9730237	.1056136	9.21	0.000	.7660248	1.180023
Male	1.390517	.1527288	9.10	0.000	1.091174	1.68986
male#c.yexp						
Female	.4559544	.0901169	5.06	0.000	.2793285	.6325803
Male	1.422539	.1544255	9.21	0.000	1.11987	1.725207
male#c.yexp2						
Female	-.1027149	.0573059	-1.79	0.073	-.2150325	.0096026
Male	-.3749457	.1160113	-3.23	0.001	-.6023236	-.1475677
_cons	.9872018	.1148215	8.60	0.000	.7621559	1.212248

Note: 1 failure and 2 successes completely determined.

The effects of human capital seem to differ between men and women. A formal test confirms this.

```
. test (yedu#0.male = yedu#1.male) (yexp#0.male = yexp#1.male)
> (yexp2#0.male = yexp2#1.male)
( 1)  [promo]0b.male#c.yedu - [promo]1.male#c.yedu = 0
( 2)  [promo]0b.male#c.yexp - [promo]1.male#c.yexp = 0
( 3)  [promo]0b.male#c.yexp2 - [promo]1.male#c.yexp2 = 0

      chi2( 3) =    35.43
Prob > chi2 =    0.0000
```

How do we interpret this gender difference? It has repeatedly been stressed (see, for example, [Long \[1997, 47–50\]](#); [Allison \[1999\]](#)) that comparison of groups in binary response models, and similarly in other latent-variable models, is hampered by an identification problem: with β the regression coefficients for the latent variable and σ the standard deviation of the latent residual, only the β/σ are identified. In fact, in terms of the latent regression, the probit coefficients should be interpreted as β/σ , not as the β . If we cannot claim convincingly that the residual standard deviation σ does not vary between the sexes, equality of the regression coefficients β implies that the coefficients of the probit model for men and women are *proportional* but not necessarily equal. This is a nonlinear hypothesis in terms of the probit coefficients, not a linear one.

```
. testnl _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
> = _b[yexp2#1.male]/_b[yexp2#0.male]
(1)  _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(2)  _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]

      chi2(2) =        9.21
Prob > chi2 =    0.0100
```

We conclude that we find fairly strong evidence against the proportionality of the coefficients, and hence we have to conclude that success in the labor market is produced in different ways by men and women. (But remember, these were simulated data.)

► Example 3

The syntax for specifying the equality of multiple expressions is just a convenient shorthand for specifying a series of constraints, namely, that the first expression equals the second expression, the first expression also equals the third expression, etc. The Wald test performed and the output of `testnl` are the same whether we use the shorthand or we specify the series of constraints.

```
. testnl (_b[yedu#1.male]/_b[yedu#0.male] =
>         _b[yexp#1.male]/_b[yexp#0.male])
>         (_b[yedu#1.male]/_b[yedu#0.male] =
>         _b[yexp2#1.male]/_b[yexp2#0.male])
(1)  _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(2)  _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]
      chi2(2) =          9.21
      Prob > chi2 =      0.0100
```

Having established differences between men and women, we would like to do multiple testing between the ratios. Because we did not specify hypotheses in advance, we prefer to adjust the p -values of tests using, here, Bonferroni's method.

```
. testnl _b[yedu#1.male]/_b[yedu#0.male] =
>         _b[yexp#1.male]/_b[yexp#0.male] =
>         _b[yexp2#1.male]/_b[yexp2#0.male], mtest(b)
(1)  _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(2)  _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]
```

	chi2	df	p > chi2
(1)	6.89	1	0.0173*
(2)	0.93	1	0.6713*
All	9.21	2	0.0100

* Bonferroni-adjusted p -values

Manipulability

Although `testnl` allows you to specify constraints in different ways that are mathematically equivalent, as noted above, this does not mean that the tests are the same. This difference is known as the manipulability of the Wald test for nonlinear hypotheses; also see [R] [boxcox](#). The test might even be significant for one formulation but not significant for another formulation that is mathematically equivalent. Trying out different specifications to find a formulation with the desired p -value is totally inappropriate, though it may actually be fun to try. There is no variance under representation because the nonlinear Wald test is actually a standard Wald test for a linearization of the constraint, which depends on the particular specification. We note that the likelihood-ratio test is not manipulable in this sense.

From a statistical point of view, it is best to choose a specification of the constraints that is as linear as possible. Doing so usually improves the accuracy of the approximation of the null-distribution of the test by a χ^2 or an F distribution. The example above used the nonlinear Wald test to test whether the coefficients of human capital variables for men were proportional to those of women. A specification of proportionality of coefficients in terms of ratios of coefficients is fairly nonlinear if the coefficients in the denominator are close to 0. A more linear version of the test results from a bilinear formulation. Thus, instead of

```
. testnl _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(1)  _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
      chi2(1) =          6.89
      Prob > chi2 =      0.0087
```

perhaps

```
. testnl _b[yedu#1.male]*_b[yexp#0.male] = _b[yedu#0.male]*_b[yexp#1.male]
(1)  _b[yedu#1.male]*_b[yexp#0.male] = _b[yedu#0.male]*_b[yexp#1.male]
      chi2(1) =          13.95
      Prob > chi2 =      0.0002
```

is better, and in fact it has been suggested that the latter version of the test is more reliable. This assertion is confirmed by performing simulations and is in line with theoretical results of [Phillips and Park \(1988\)](#). There is strong evidence against the proportionality of human capital effects between men and women, implying for this example that differences in the residual variances between the sexes can be ruled out as the explanation of the sex differences in the analysis of labor market participation.

Stored results

`testnl` stores the following in `r()`:

Scalars

<code>r(df)</code>	degrees of freedom
<code>r(df_r)</code>	residual degrees of freedom
<code>r(chi2)</code>	χ^2
<code>r(p)</code>	p -value for Wald test
<code>r(F)</code>	F statistic

Macros

<code>r(mtmetho)</code>	method specified in <code>mtest()</code>
-------------------------	--

Matrices

<code>r(G)</code>	derivatives of $R(\mathbf{b})$ with respect to \mathbf{b} ; see Methods and formulas below
<code>r(R)</code>	$R(\mathbf{b}) - \mathbf{q}$; see Methods and formulas below
<code>r(mtest)</code>	multiple test results

Methods and formulas

After fitting a model, define \mathbf{b} as the resulting $1 \times k$ parameter vector and \mathbf{V} as the $k \times k$ covariance matrix. The (linear or nonlinear) hypothesis is given by $R(\mathbf{b}) = \mathbf{q}$, where R is a function returning a $j \times 1$ vector. The Wald test formula is (Greene 2018, 512–513)

$$W = \left\{ R(\mathbf{b}) - \mathbf{q} \right\}' \left(\mathbf{G} \mathbf{V} \mathbf{G}' \right)^{-1} \left\{ R(\mathbf{b}) - \mathbf{q} \right\}$$

where \mathbf{G} is the derivative matrix of $R(\mathbf{b})$ with respect to \mathbf{b} . W is distributed as χ^2 if \mathbf{V} is an asymptotic covariance matrix. $F = W/j$ is distributed as F for linear regression.

The adjustment methods for multiple testing are described in [R] [test](#). The adjustment for survey design effects is described in [SVY] [svy postestimation](#).

Description

`tetrachoric` computes estimates of the tetrachoric correlation coefficients of the binary variables in *varlist*. All of these variables should be 0, 1, or missing values.

Tetrachoric correlations assume a latent bivariate normal distribution (X_1, X_2) for each pair of variables (v_1, v_2) , with a threshold model for the manifest variables, $v_i = 1$ if and only if $X_i > 0$. The means and variances of the latent variables are not identified, but the correlation, r , of X_1 and X_2 can be estimated from the joint distribution of v_1 and v_2 and is called the tetrachoric correlation coefficient.

`tetrachoric` computes pairwise estimates of the tetrachoric correlations by the (iterative) maximum likelihood estimator obtained from bivariate probit without explanatory variables (see [\[R\] biprobit](#)) by using the [Edwards and Edwards \(1984\)](#) noniterative estimator as the initial value.

The pairwise correlation matrix is returned as `r(Rho)` and can be used to perform a factor analysis or a principal component analysis of binary variables by using the `factormat` or `pcamat` commands; see [\[MV\] factor](#) and [\[MV\] pca](#).

Quick start

Tetrachoric correlation of `v1` and `v2` with standard error and test of independence

```
tetrachoric v1 v2
```

Matrix of pairwise tetrachoric correlations for `v1`, `v2`, and `v3`

```
tetrachoric v1 v2 v3
```

Add standard errors and p -values

```
tetrachoric v1 v2 v3, stats(rho se p)
```

Same as above, but adjust p -values for multiple comparisons using Bonferroni's method

```
tetrachoric v1 v2 v3, stats(rho se p) bonferroni
```

Add star to correlations significant at the 5% level

```
tetrachoric v1 v2 v3, star(.05)
```

Use all available data for each pair of variables and report number of observations used

```
tetrachoric v1 v2 v3, pw stats(rho obs)
```

Adjust correlation matrix to be positive semidefinite

```
tetrachoric v1 v2 v3, posdef
```

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Tetrachoric correlations

<code>obs</code>	number of observations
<code>p</code>	exact two-sided significance level

`by` and `collect` are allowed; see [\[U\] 11.1.10 Prefix commands](#).
`fweights` are allowed; see [\[U\] 11.1.6 weight](#).

Options

Main

`stats(statlist)` specifies the statistics to be displayed in the matrix of output. `stats(rho)` is the default. Up to four statistics may be specified. `stats(rho se p obs)` would display the tetrachoric correlation coefficient, its standard error, the significance level, and the number of observations. If *varlist* contains only two variables, all statistics are shown in tabular form. `stats()`, `print()`, and `star()` have no effect unless the `matrix` option is also specified.

`edwards` specifies that the noniterative Edwards and Edwards estimator be used. The default is the maximum likelihood estimator. If you analyze many binary variables, you may want to use the fast noniterative estimator proposed by [Edwards and Edwards \(1984\)](#). However, if you have skewed variables, the approximation does not perform well.

`print(#)` specifies the maximum significance level of correlation coefficients to be printed. Correlation coefficients with larger significance levels are left blank in the matrix. Typing `tetrachoric ..., print(.10)` would list only those correlation coefficients that are significant at the 10% level or lower.

`star(#)` specifies the maximum significance level of correlation coefficients to be marked with a star. Typing `tetrachoric ..., star(.05)` would “star” all correlation coefficients significant at the 5% level or lower.

`bonferroni` makes the Bonferroni adjustment to calculated significance levels. This option affects printed significance levels and the `print()` and `star()` options. Thus, `tetrachoric ..., print(.05) bonferroni` prints coefficients with Bonferroni-adjusted significance levels of 0.05 or less.

`sidak` makes the Šidák adjustment to calculated significance levels. This option affects printed significance levels and the `print()` and `star()` options. Thus, `tetrachoric ..., print(.05) sidak` prints coefficients with Šidák-adjusted significance levels of 0.05 or less.

`pw` specifies that the tetrachoric correlation be calculated by using all available data. By default, `tetrachoric` uses casewise deletion, where observations are ignored if any of the specified variables in *varlist* are missing.

`zeroadjust` specifies that when one of the cells has a zero count, a frequency adjustment be applied in such a way as to increase the zero to one-half and maintain row and column totals.

`matrix` forces `tetrachoric` to display the statistics as a matrix, even if *varlist* contains only two variables. `matrix` is implied if more than two variables are specified.

`notable` suppresses the output.

`posdef` modifies the correlation matrix so that it is positive semidefinite, that is, a proper correlation matrix. The modified result is the correlation matrix associated with the least-squares approximation of the tetrachoric correlation matrix by a positive-semidefinite matrix. If the correlation matrix is modified, the standard errors and significance levels are not displayed and are returned in `r()`.

Remarks and examples

Remarks are presented under the following headings:

- Association in 2-by-2 tables
- Factor analysis of dichotomous variables
- Tetrachoric correlations with simulated data

Association in 2-by-2 tables

Although a wide variety of measures of association in cross tabulations have been proposed, such measures are essentially equivalent (monotonically related) in the special case of 2×2 tables—there is only 1 degree of freedom for nonindependence. Still, some measures have more desirable properties than others. Here we compare two measures: the standard Pearson correlation coefficient and the tetrachoric correlation coefficient. Given asymmetric row or column margins, Pearson correlations are limited to a range smaller than -1 to 1 , although tetrachoric correlations can still span the range from -1 to 1 . To illustrate, consider the following set of tables for two binary variables, X and Z:

	Z = 0	Z = 1	
X = 0	20 − a	10 + a	30
X = 1	a	10 − a	10
	20	20	40

For a equal to 0, 1, 2, 5, 8, 9, and 10, the Pearson and tetrachoric correlations for the above table are

a	0	1	2	5	8	9	10
Pearson	0.577	0.462	0.346	0	−0.346	−0.462	−0.577
Tetrachoric	1.000	0.792	0.607	0	−0.607	−0.792	−1.000

The restricted range for the Pearson correlation is especially unfortunate when you try to analyze the association between binary variables by using models developed for continuous data, such as factor analysis and principal component analysis.

The tetrachoric correlation of two variables (Y_1, Y_2) can be thought of as the Pearson correlation of two latent bivariate normal distributed variables (Y_1^*, Y_2^*) with threshold measurement models $Y_i = (Y_i^* > c_i)$ for unknown cutpoints c_i . Or equivalently, $Y_i = (Y_i^{**} > 0)$ where the latent bivariate normal (Y_1^{**}, Y_2^{**}) are shifted versions of (Y_1^*, Y_2^*) so that the cutpoints are zero. Obviously, you must judge whether assuming underlying latent variables is meaningful for the data. If this assumption is justified, tetrachoric correlations have two advantages. First, you have an intuitive understanding of the size of correlations that are substantively interesting in your field of research, and this intuition is based on correlations that range from -1 to 1 . Second, because the tetrachoric correlation for binary variables estimates the Pearson correlation of the latent continuous variables (assumed multivariate normal distributed), you can use the tetrachoric correlations to analyze multivariate relationships between the dichotomous variables. When doing so, remember that you must interpret the model in terms of the underlying continuous variables.

► Example 1

To illustrate tetrachoric correlations, we examine three binary variables from the familyvalues dataset (described in [example 2](#)).

```
. use https://www.stata-press.com/data/r19/familyvalues
(Attitudes on gender, relationships and family)

. tabulate RS075 RS076

  Fam att:   Fam att: trad
  women in   division of labor
  charge bad          0          1      Total
-----
      0      1,564      979      2,543
      1       119      632       751
-----
  Total      1,683      1,611      3,294

. correlate RS074 RS075 RS076
(obs=3,291)
```

	RS074	RS075	RS076
RS074	1.0000		
RS075	0.0396	1.0000	
RS076	0.1595	0.3830	1.0000

```
. tetrachoric RS074 RS075 RS076
(obs=3,291)
```

	RS074	RS075	RS076
RS074	1.0000		
RS075	0.0689	1.0000	
RS076	0.2480	0.6427	1.0000

As usual, the tetrachoric correlation coefficients are larger (in absolute value) and more dispersed than the Pearson correlations.

Factor analysis of dichotomous variables

➤ Example 2

Factor analysis is a popular model for measuring latent continuous traits. The standard estimators are appropriate only for continuous unimodal data. Because of the skewness implied by Bernoulli-distributed variables (especially when the probability is distributed unevenly), a factor analysis of a Pearson correlation matrix can be rather misleading when used in this context. A factor analysis of a matrix of tetrachoric correlations is more appropriate under these conditions (Uebersax 2000). We illustrate this with data on gender, relationship, and family attitudes of spouses using the Households in The Netherlands survey 1995 (Weesie et al. 1995). For attitude variables, it seems reasonable to assume that agreement or disagreement is just a coarse measurement of more nuanced underlying attitudes.

To demonstrate, we examine a few of the variables from the familyvalues dataset.

```
. use https://www.stata-press.com/data/r19/familyvalues

	RS063						
RS063	1.0000						

Again, we see that the tetrachoric correlations are generally larger in absolute value than the Pearson correlations. The bivariate probit and Edwards and Edwards estimators (the `edwards` option) implemented in `tetrachoric` may return a correlation matrix that is not positive semidefinite—a mathematical property of any real correlation matrix. Positive definiteness is required by commands for analyses of correlation matrices, such as `factormat` and `pcamat`; see [\[MV\] factor](#) and [\[MV\] pca](#). The `posdef` option of `tetrachoric` tests for positive definiteness and projects the estimated correlation matrix to a positive-semidefinite matrix if needed.

```
. tetrachoric RS056-RS063, notable posdef
. matrix C = r(Rho)
```

This time, we suppressed the display of the correlations with the `notable` option and requested that the correlation matrix be positive semidefinite with the `posdef` option. Had the correlation matrix not been positive definite, `tetrachoric` would have displayed a warning message and then adjusted the matrix to be positive semidefinite. We placed the resulting tetrachoric correlation matrix into a matrix, `C`, so that we can perform a factor analysis upon it.

`tetrachoric` with the `posdef` option asserted that `C` was positive definite because no warning message was displayed. We can verify this by using a familiar characterization of symmetric positive-definite matrices: all eigenvalues are real and positive.

```
. matrix symeigen eigenvectors eigenvalues = C
. matrix list eigenvalues
eigenvalues[1,8]
      e1      e2      e3      e4      e5      e6      e7
r1  2.5974789  1.3544664  1.0532476  .77980391  .73462018  .57984565  .54754512
      e8
r1  .35299228
```

We can proceed with a factor analysis on the matrix C. We use `factormat` and select iterated principal factors as the estimation method; see [\[MV\] factor](#).

```
. factormat C, n(3221) ipf factor(2)
(obs=3,221)
```

Factor analysis/correlation	Number of obs	=	3,221

► Example 3

We noted in [example 2](#) that the matrix of estimates of the tetrachoric correlation coefficients need not be positive definite. Here is an example:

```
. use https://www.stata-press.com/data/r19/familyvalues
(Attitudes on gender, relationships and family)

. tetrachoric RS056-RS063 in 1/20, posdef
(obs=18)

matrix with tetrachoric correlations is not positive semidefinite;
it has 2 negative eigenvalues
maxdiff(corr,adj-corr) = 0.2346
(adj-corr: tetrachoric correlations adjusted to be positive semidefinite)
```

adj-corr	RS056	RS057	RS058	RS059	RS060	RS061	RS062

RS063	1.0000						

```
. mata:
_____ mata (type end to exit) _____

: C2 = st_matrix("r(Rho)")
: eigenvecs = .
: eigenvals = .
: symeigensystem(C2, eigenvecs, eigenvals)
: eigenvals
```

	1	2	3	4
1	3.156592567	2.065279398	1.324911199	.7554904485
	5	6	7	8
1	.4845368741	.2131895139	-1.11022e-16	-2.27918e-16

```
: end
_____
```

The estimated tetrachoric correlation matrix is rank-2 deficient. With this C2 matrix, we can only use models of correlation that allow for singular cases.

Tetrachoric correlations with simulated data

► Example 4

We use `drawnorm` (see [D] [drawnorm](#)) to generate a sample of 1,000 observations from a bivariate normal distribution with means -1 and 1 , unit variances, and correlation 0.4 .

```
. clear
. set seed 11000
. matrix m = (1, -1)
. matrix V = (1, 0.4 \ 0.4, 1)
. drawnorm c1 c2, n(1000) means(m) cov(V)
(obs 1,000)
```

Now, consider the measurement model assumed by the tetrachoric correlations. We observe only whether c_1 and c_2 are greater than zero,

```
. generate d1 = (c1 > 0)
. generate d2 = (c2 > 0)
. tabulate d1 d2
```

d1	d2		Total
	0	1	
0	141	6	147
1	706	147	853
Total	847	153	1,000

We want to estimate the correlation of c_1 and c_2 from the binary variables d_1 and d_2 . Pearson’s correlation of the binary variables d_1 and d_2 is 0.129 —a seriously biased estimate of the underlying correlation $\rho = 0.4$.

```
. correlate d1 d2
(obs=1,000)
```

	d1	d2
d1	1.0000	
d2	0.1294	1.0000

The tetrachoric correlation coefficient of d_1 and d_2 estimates the Pearson correlation of the latent continuous variables, c_1 and c_2 .

```
. tetrachoric d1 d2
Number of obs =      1,000
Tetrachoric rho =    0.3875
Std error =      0.0787
Test of H0: d1 and d2 are independent
2-sided exact P =      0.0000
```

The estimate of the tetrachoric correlation of d_1 and d_2 , 0.3875 , is much closer to the underlying correlation, 0.4 , between c_1 and c_2 .

Stored results

`tetrachoric` stores the following in `r()`:

Scalars

<code>r(rho)</code>	tetrachoric correlation coefficient between variables 1 and 2
<code>r(N)</code>	number of observations
<code>r(nneg)</code>	number of negative eigenvalues (posdef only)
<code>r(se_rho)</code>	standard error of <code>r(rho)</code>
<code>r(p)</code>	p -value for two-sided Fisher's exact test (for the first two variables)

Macros

<code>r(method)</code>	estimator used
------------------------	----------------

Matrices

<code>r(Rho)</code>	tetrachoric correlation matrix
<code>r(Se_Rho)</code>	standard errors of <code>r(Rho)</code>
<code>r(Nobs)</code>	number of observations used in computing correlation
<code>r(P)</code>	matrix of p -values for two-sided Fisher's exact test

Methods and formulas

`tetrachoric` provides two estimators for the tetrachoric correlation ρ of two binary variables with the frequencies n_{ij} , $i, j = 0, 1$. `tetrachoric` defaults to the slower (iterative) maximum likelihood estimator obtained from bivariate probit without explanatory variables (see [R] [biprobit](#)) by using the Edwards and Edwards noniterative estimator as the initial value. A fast (noniterative) estimator is also available by specifying the `edwards` option (Edwards and Edwards 1984; Digby 1983)

$$\hat{\rho} = \frac{\alpha - 1}{\alpha + 1}$$

where

$$\alpha = \left(\frac{n_{00}n_{11}}{n_{01}n_{10}} \right)^{\pi/4} \quad (\pi = 3.14 \dots)$$

if all $n_{ij} > 0$. If $n_{00} = 0$ or $n_{11} = 0$, $\hat{\rho} = -1$; if $n_{01} = 0$ or $n_{10} = 0$, $\hat{\rho} = 1$.

The asymptotic variance of the Edwards and Edwards estimator of the tetrachoric correlation is easily obtained by the delta method,

$$\text{avar}(\hat{\rho}) = \left\{ \frac{\pi\alpha}{2(1+\alpha)^2} \right\}^2 \left(\frac{1}{n_{00}} + \frac{1}{n_{01}} + \frac{1}{n_{10}} + \frac{1}{n_{11}} \right)$$

provided all $n_{ij} > 0$, otherwise it is left undefined (missing). The Edwards and Edwards estimator is fast, but may be inaccurate if the margins are very skewed.

`tetrachoric` reports exact p -values for statistical independence, computed by the `exact` option of [R] [tabulate twoway](#).

Description

`tnbreg` estimates the parameters of a truncated negative binomial model by maximum likelihood. The dependent variable *devar* is regressed on *indepsvars*, where *devar* is a positive count variable whose values are all above the truncation point.

Quick start

Truncated negative binomial regression of *y* on *x* with truncation at 0

```
tnbreg y x
```

Report incidence-rate ratios

```
tnbreg y x, irr
```

Add categorical variable *a* using [factor variable](#) syntax

```
tnbreg y x i.a
```

Same as above, but specify a constant truncation point of 2

```
tnbreg y x i.a, ll(2)
```

With exposure variable *exp*

```
tnbreg y x i.a, exposure(exp)
```

Same as above, but specifying a variable truncation point stored in variable *min*

```
tnbreg y x i.a, exposure(exp) ll(min)
```

With cluster-robust standard errors clustering by the levels of *cvar*

```
tnbreg y x i.a, exposure(exp) ll(min) vce(cluster cvar)
```

Menu

Statistics > Count outcomes > Truncated negative binomial regression

Syntax

```
tnbreg depvar [indepvars] [if] [in] [weight] [, options]
```

<i>options</i>	Description
Model	
<code>noconstant</code>	suppress constant term
<code>ll(# <i>varname</i>)</code>	truncation point; default value is <code>ll(0)</code> , zero truncation
<code>dispersion(mean)</code>	parameterization of dispersion; the default
<code>dispersion(constant)</code>	constant dispersion for all observations
<code>exposure(<i>varname</i>_e)</code>	include <code>ln(<i>varname</i>_e)</code> in model with coefficient constrained to 1
<code>offset(<i>varname</i>_o)</code>	include <code><i>varname</i>_o</code> in model with coefficient constrained to 1
<code>constraints(<i>constraints</i>)</code>	apply specified linear constraints
SE/Robust	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>opg</code> , <code>bootstrap</code> , or <code>jackknife</code>
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>nolrttest</code>	suppress likelihood-ratio test
<code>irr</code>	report incidence-rate ratios
<code>nocnsreport</code>	do not display constraints
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<code>maximize_options</code>	control the maximization process; seldom used
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics

indepvars may contain factor variables; see [U] 11.4.3 Factor variables.

depvar and *indepvars* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes`, `bayesboot`, `bootstrap`, `by`, `collect`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: tnbreg.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] svy.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

Model
<code>noconstant</code> ; see [R] Estimation options.
<code>ll(# <i>varname</i>)</code> specifies the truncation point, which is a nonnegative integer. The default is zero truncation, <code>ll(0)</code> .

`dispersion(mean | constant)` specifies the parameterization of the model. `dispersion(mean)`, the default, yields a model with dispersion equal to $1 + \alpha \exp(\mathbf{x}_j\beta + \text{offset}_j)$; that is, the dispersion is a function of the expected mean: $\exp(\mathbf{x}_j\beta + \text{offset}_j)$. `dispersion(constant)` has dispersion equal to $1 + \delta$; that is, it is a constant for all observations.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] [Estimation options](#).

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce_option](#).

Reporting

`level(#)`; see [R] [Estimation options](#).

`no1rtest` suppresses fitting the Poisson model. Without this option, a comparison Poisson model is fit, and the likelihood is used in a likelihood-ratio test of the null hypothesis that the dispersion parameter is zero.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is, e^{β_i} rather than β_i . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `novlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `tnbreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

Remarks and examples

Grogger and Carson (1991) showed that overdispersion causes inconsistent estimation of the mean in the truncated Poisson model. To solve this problem, they proposed using the truncated negative binomial model as an alternative. If data are truncated but do not exhibit overdispersion, the truncated Poisson model is more appropriate; see [R] [tpoisson](#). For an introduction to negative binomial regression, see Cameron and Trivedi (2005, 2022) and Long and Freese (2014). For an introduction to truncated negative binomial models, see Cameron and Trivedi (2013) and Long (1997, chap. 8).

tnbreg fits the mean-dispersion and the constant-dispersion parameterizations of truncated negative binomial models. These parameterizations extend those implemented in nbreg; see [R] nbreg.

► Example 1

We illustrate the truncated negative binomial model using the 1997 MedPar dataset (Hilbe 1999). The data are from 1,495 patients in Arizona who were assigned to a diagnostic-related group (DRG) of patients having a ventilator. Length of stay (los), the dependent variable, is a positive integer; it cannot have zero values. The data are truncated because there are no observations on individuals who stayed for zero days.

The objective of this example is to determine whether the length of stay was related to the binary variables: died, hmo, type1, type2, and type3.

The died variable was recorded as a 0 unless the patient died, in which case, it was recorded as a 1. The other variables also adopted this encoding. The hmo variable was set to 1 if the patient belonged to a health maintenance organization (HMO).

The type1–type3 variables indicated the type of admission used for the patient. The type1 variable indicated an emergency admit. The type2 variable indicated an urgent admit—that is, the first available bed. The type3 variable indicated an elective admission. Because type1–type3 were mutually exclusive, only two of the three could be used in the truncated negative binomial regression shown below.

```
. use https://www.stata-press.com/data/r19/medpar
(Arizona ventilator data)

. tnbreg los died hmo type2-type3, vce(cluster provnum) nolog

Truncated negative binomial regression      Number of obs = 1,495
Truncation point = 0                      Wald chi2(4) = 36.01
Dispersion: mean                          Prob > chi2 = 0.0000
Log pseudolikelihood = -4737.535          Pseudo R2 = 0.0139

                                (Std. err. adjusted for 54 clusters in provnum)
```

los	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
died	-.2521884	.061533	-4.10	0.000	-.3727908	-.1315859
hmo	-.0754173	.0533132	-1.41	0.157	-.1799091	.0290746
type2	.2685095	.0666474	4.03	0.000	.137883	.3991359
type3	.7668101	.2183505	3.51	0.000	.338851	1.194769
_cons	2.224028	.034727	64.04	0.000	2.155964	2.292091
/lnalpha	-.630108	.0764019			-.779853	-.480363
alpha	.5325343	.0406866			.4584734	.6185588

Because observations within the same hospital (provnum) are likely to be correlated, we specified the vce(cluster provnum) option. The results show that whether the patient died in the hospital and the type of admission have significant effects on the patient's length of stay.

► Example 2

To illustrate truncated negative binomial regression with more complex data than the previous example, similar data were created from 100 hospitals. Each hospital had its own way of tracking patient data. In particular, hospitals only recorded data from patients with a minimum length of stay, denoted by the variable `minstay`.

Definitions for minimum length of stay varied among hospitals, typically, from 5 to 18 days. The objective of this example is the same as before: to determine whether the length of stay, recorded in `los`, was related to the binary variables: `died`, `hmo`, `type1`, `type2`, and `type3`.

The binary variables encode the same information as in [example 1](#) above. The `minstay` variable was used to allow for varying truncation points.

```
. use https://www.stata-press.com/data/r19/medproviders
. tnbreg los died hmo type2-type3, ll(minstay) vce(cluster hospital) nolog

Truncated negative binomial regression      Number of obs = 2,144
Truncation points: minstay                  Wald chi2(4) = 15.22
Dispersion: mean                           Prob > chi2 = 0.0043
Log pseudolikelihood = -7864.0928          Pseudo R2 = 0.0007

                                   (Std. err. adjusted for 100 clusters in hospital)
```

los	Coefficient	Robust std. err.	z	P> z	[95% conf. interval]	
died	.078104	.0303598	2.57	0.010	.0185998	.1376081
hmo	-.0731132	.0368897	-1.98	0.047	-.1454158	-.0008107
type2	.0294132	.0390166	0.75	0.451	-.047058	.1058845
type3	.0626348	.0540123	1.16	0.246	-.0432273	.168497
_cons	3.014964	.0290895	103.64	0.000	2.95795	3.071978
/lnalpha	-.996512	.0828691			-1.158932	-.8340916
alpha	.3691649	.0305923			.313821	.4342688

In this analysis, two variables have a statistically significant relationship with length of stay. On average, patients who died in the hospital had longer lengths of stay ($p = 0.01$). Because the coefficient for HMO is negative, that is, $b_{\text{HMO}} = -0.073$, on average, patients who were insured by an HMO had shorter lengths of stay ($p = 0.047$). The type of admission was not statistically significant ($p > 0.05$).

Stored results

tnbreg stores the following in `e()`:

Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(r2_p)</code>	pseudo- R^2
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(ll_c)</code>	log likelihood, comparison model
<code>e(alpha)</code>	value of alpha
<code>e(delta)</code>	value of delta
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	χ^2
<code>e(chi2_c)</code>	χ^2 for comparison test
<code>e(p)</code>	p -value for model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(rank0)</code>	rank of <code>e(V)</code> for constant-only model
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

Macros

<code>e(cmd)</code>	tnbreg
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(llopt)</code>	contents of <code>ll()</code> , or 0 if not specified
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset)</code>	linear offset variable
<code>e(chi2type)</code>	Wald or LR; type of model χ^2 test
<code>e(chi2_ct)</code>	Wald or LR; type of model χ^2 test corresponding to <code>e(chi2_c)</code>
<code>e(dispers)</code>	mean or constant
<code>e(vce)</code>	<i>vce</i> type specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	b V
<code>e(predict)</code>	program used to implement predict
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as asbalanced
<code>e(asobserved)</code>	factor variables <code>fvset</code> as asobserved

Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

Functions

e(sample)

marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices

r(table)

matrix containing the coefficients with their standard errors, test statistics, p -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

Methods and formulas are presented under the following headings:

Mean-dispersion model

Constant-dispersion model

Mean-dispersion model

A negative binomial distribution can be regarded as a gamma mixture of Poisson random variables. The number of times an event occurs, y_j , is distributed as $\text{Poisson}(\nu_j \mu_j)$. That is, its conditional likelihood is

$$f(y_j | \nu_j) = \frac{(\nu_j \mu_j)^{y_j} e^{-\nu_j \mu_j}}{\Gamma(y_j + 1)}$$

where $\mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$ and ν_j is an unobserved parameter with a $\text{Gamma}(1/\alpha, \alpha)$ density:

$$g(\nu) = \frac{\nu^{(1-\alpha)/\alpha} e^{-\nu/\alpha}}{\alpha^{1/\alpha} \Gamma(1/\alpha)}$$

This gamma distribution has a mean of 1 and a variance of α , where α is our ancillary parameter.

The unconditional likelihood for the j th observation is therefore

$$f(y_j) = \int_0^\infty f(y_j | \nu) g(\nu) d\nu = \frac{\Gamma(m + y_j)}{\Gamma(y_j + 1) \Gamma(m)} p_j^m (1 - p_j)^{y_j}$$

where $p_j = 1/(1 + \alpha \mu_j)$ and $m = 1/\alpha$. Solutions for α are handled by searching for $\ln \alpha$ because α must be greater than zero. The conditional probability of observing y_j events given that y_j is greater than the truncation point τ_j is

$$\Pr(Y = y_j | y_j > \tau_j, \mathbf{x}_j) = \frac{f(y_j)}{\Pr(Y > \tau_j | \mathbf{x}_j)}$$

The log likelihood (with weights w_j and offsets) is given by

$$m = 1/\alpha \quad p_j = 1/(1 + \alpha \mu_j) \quad \mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$$

$$\begin{aligned} \ln L = \sum_{j=1}^n w_j & \left[\ln \{ \Gamma(m + y_j) \} - \ln \{ \Gamma(y_j + 1) \} \right. \\ & \left. - \ln \{ \Gamma(m) \} + m \ln(p_j) + y_j \ln(1 - p_j) - \ln \{ \Pr(Y > \tau_j | p_j, m) \} \right] \end{aligned}$$

Constant-dispersion model

The constant-dispersion model assumes that y_j is conditionally distributed as $\text{Poisson}(\mu_j^*)$, where $\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$ for some dispersion parameter δ [by contrast, the mean-dispersion model assumes that $\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha\mu_j)$]. The log likelihood is given by

$$m_j = \mu_j/\delta \quad p = 1/(1 + \delta)$$

$$\ln L = \sum_{j=1}^n w_j \left[\ln\{\Gamma(m_j + y_j)\} - \ln\{\Gamma(y_j + 1)\} \right. \\ \left. - \ln\{\Gamma(m_j)\} + m_j \ln(p) + y_j \ln(1 - p) - \ln\{\Pr(Y > \tau_j | p, m_j)\} \right]$$

with everything else defined as shown above in the calculations for the mean-dispersion model.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

tnbreg also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

Postestimation commands

The following postestimation commands are available after `tnbreg`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	number of events, incidence rates, probabilities, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

predict

Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset ]
```

```
predict [type] stub* [if] [in] , scores
```

statistic	Description
Main	
n	number of events; the default
ir	incidence rate
cm	conditional mean, $E(y_j y_j > \tau_j)$
pr(n)	probability $\Pr(y_j = n)$
pr(a,b)	probability $\Pr(a \leq y_j \leq b)$
cpr(n)	conditional probability $\Pr(y_j = n y_j > \tau_j)$
cpr(a,b)	conditional probability $\Pr(a \leq y_j \leq b y_j > \tau_j)$
xb	linear prediction
stdp	standard error of the linear prediction

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

Main

n, the default, calculates the predicted number of events, which is $\exp(\mathbf{x}_j\beta)$ if neither `offset()` nor `exposure()` was specified when the model was fit; $\exp(\mathbf{x}_j\beta + \text{offset}_j)$ if `offset()` was specified; or $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$ if `exposure()` was specified.

ir calculates the incidence rate $\exp(\mathbf{x}_j\beta)$, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the n and the nooffset options.

cm calculates the conditional mean,

$$E(y_j | y_j > \tau_j) = \frac{E(y_j, y_j > \tau_j)}{\Pr(y_j > \tau_j)}$$

where τ_j is the truncation point found in `e(11opt)`.

`pr(n)` calculates the probability $\Pr(y_j = n)$, where *n* is a nonnegative integer that may be specified as a number or a variable.

`pr(a,b)` calculates the probability $\Pr(a \leq y_j \leq b)$, where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

b missing (*b* ≥ .) means $+\infty$;

`pr(20, .)` calculates $\Pr(y_j \geq 20)$;

`pr(20,b)` calculates $\Pr(y_j \geq 20)$ in observations for which *b* ≥ . and calculates

$\Pr(20 \leq y_j \leq b)$ elsewhere.

`pr(.,b)` produces a syntax error. A missing value in an observation of the variable *a* causes a missing value in that observation for `pr(a,b)`.

`cpr(n)` calculates the conditional probability $\Pr(y_j = n \mid y_j > \tau_j)$, where τ_j is the truncation point found in `e(11opt)`. *n* is an integer greater than the truncation point that may be specified as a number or a variable.

`cpr(a,b)` calculates the conditional probability $\Pr(a \leq y_j \leq b \mid y_j > \tau_j)$, where τ_j is the truncation point found in `e(11opt)`. The syntax for this option is analogous to that used for `pr(a,b)` except that *a* must be greater than the truncation point.

`xb` calculates the linear prediction, which is $\mathbf{x}_j\beta$ if neither `offset()` nor `exposure()` was specified when the model was fit; $\mathbf{x}_j\beta + \text{offset}_j$ if `offset()` was specified; or $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as $\mathbf{x}_j\beta$ rather than as $\mathbf{x}_j\beta + \text{offset}_j$ or $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$. Specifying `predict ..., nooffset` is equivalent to specifying `predict ..., ir`.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (\mathbf{x}_j\beta)$.

The second new variable will contain $\partial \ln L / \partial (\ln \alpha)$ for `dispersion(mean)`.

The second new variable will contain $\partial \ln L / \partial (\ln \delta)$ for `dispersion(constant)`.

margins

Description for margins

margins estimates margins of response for numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

statistic	Description
n	number of events; the default
ir	incidence rate
cm	conditional mean, $E(y_j y_j > \tau_j)$
pr(n)	probability $\Pr(y_j = n)$
pr(a,b)	probability $\Pr(a \leq y_j \leq b)$
cpr(n)	conditional probability $\Pr(y_j = n y_j > \tau_j)$
cpr(a,b)	conditional probability $\Pr(a \leq y_j \leq b y_j > \tau_j)$
xb	linear prediction
stdp	not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

Methods and formulas

In the following formulas, we use the same notation as in [R] tnbreg.

Methods and formulas are presented under the following headings:

- Mean-dispersion model
- Constant-dispersion model

Mean-dispersion model

The equation-level scores are given by

$$\begin{aligned}\text{score}(\mathbf{x}\beta)_j &= p_j(y_j - \mu_j) - \frac{p_j^{(m+1)}\mu_j}{\Pr(Y > \tau_j | p_j, m)} \\ \text{score}(\omega)_j &= -m \left\{ \frac{\alpha(\mu_j - y_j)}{1 + \alpha\mu_j} - \ln(1 + \alpha\mu_j) + \psi(y_j + m) - \psi(m) \right\} \\ &\quad - \frac{p_j^m}{\Pr(Y > \tau_j | p_j, m)} \{m \ln(p_j) + \mu_j p_j\}\end{aligned}$$

where $\omega_j = \ln\alpha_j$, $\psi(z)$ is the digamma function, and τ_j is the truncation point found in `e(11opt)`.

Constant-dispersion model

The equation-level scores are given by

$$\begin{aligned}\text{score}(\mathbf{x}\beta)_j &= m_j \left\{ \psi(y_j + m_j) - \psi(m_j) + \ln(p) + \frac{p^{m_j} \ln(p)}{\Pr(Y > \tau_j | p, m_j)} \right\} \\ \text{score}(\omega)_j &= y_j - (y_j + m_j)(1 - p) - \text{score}(\mathbf{x}\beta)_j - \frac{\mu_j p}{\Pr(Y > \tau_j | p, m_j)}\end{aligned}$$

where $\omega_j = \ln\delta_j$ and τ_j is the truncation point found in `e(11opt)`.

Description

`tobit` fits models for continuous responses where the outcome variable is censored. Censoring limits may be fixed for all observations or vary across observations.

Quick start

Tobit regression of `y` on `x1` and `x2`, specifying that `y` is censored at the minimum of `y`

```
tobit y x1 x2, ll
```

Same as above, but where the lower-censoring limit is zero

```
tobit y x1 x2, ll(0)
```

Same as above, but specify the lower- and upper-censoring limits

```
tobit y x1 x2, ll(17) ul(34)
```

Same as above, but where `lower` and `upper` are variables containing the censoring limits

```
tobit y x1 x2, ll(lower) ul(upper)
```

Menu

Statistics > Linear models and related > Censored regression > Tobit regression

Syntax

```
tobit depvar [indepvars] [if] [in] [weight] [, options]
```

<i>options</i>	Description
Model	
<code>noconstant</code>	suppress constant term
<code>ll[(<i>varname</i> #)]</code>	left-censoring variable or limit
<code>ul[(<i>varname</i> #)]</code>	right-censoring variable or limit
<code>offset(<i>varname</i>)</code>	include <i>varname</i> in model with coefficient constrained to 1
<code>constraints(<i>constraints</i>)</code>	apply specified linear constraints
SE/Robust	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>opg</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>bootstrap</code> , or <code>jackknife</code>
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>nocnsreport</code>	do not display constraints
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<code>maximize_options</code>	control the maximization process; seldom used
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics
<p><i>indepvars</i> may contain factor variables; see [U] 11.4.3 Factor variables.</p> <p><i>depvar</i> and <i>indepvars</i> may contain time-series operators; see [U] 11.4.4 Time-series varlists.</p> <p><code>bayes</code>, <code>bayesboot</code>, <code>bootstrap</code>, <code>by</code>, <code>collect</code>, <code>fmm</code>, <code>fp</code>, <code>jackknife</code>, <code>nestreg</code>, <code>rolling</code>, <code>statsby</code>, <code>stepwise</code>, and <code>svy</code> are allowed; see [U] 11.1.10 Prefix commands. Options

Model

`noconstant`; see [R] **Estimation options**.

`ll[(varname | #)]` and `ul[(varname | #)]` indicate the lower and upper limits for censoring, respectively. Observations with `depvar` \leq `ll()` are left-censored; observations with `depvar` \geq `ul()` are right-censored; and remaining observations are not censored. You do not have to specify the censoring values. If you specify `ll`, the lower limit is the minimum of *depvar*. If you specify `ul`, the upper limit is the maximum of *depvar*.

`offset(varname)`, `constraints(constraints)`; see [R] **Estimation options**.

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce_option](#).

Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `novalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `tobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

Remarks and examples

`tobit` fits a linear regression model for a censored continuous outcome. Censoring occurs when the dependent variable is observed only within a certain range of values. When it is not, we know only that it is either above (right-censoring) or below (left-censoring) the censoring value. Censoring differs from truncation. When the data are truncated, we do not observe either the dependent variable or the covariates; see [R] [truncreg](#).

Censoring may result from study design or may be a result of how the outcome is measured. Right-censoring of data may occur, for example, in income surveys that top code the highest income category. Any respondent that earns the censoring limit or more reports only the value at the limit, and we do not know the respondent's true income. Left-censoring arises naturally when measurements are obtained from an instrument or a laboratory procedure that has a limit of detection. If we observe a value at the measurement limit, we know the true value is at the limit or below it. `tobit` allows the censoring limits to be the same for all observations or to vary from observation to observation.

[Tobin \(1958\)](#) originally conceived the tobit model as one of consumption of consumer durables where purchases were left-censored at zero. Contemporary literature treats this and similar cases as a corner solution model. See [Wooldridge \(2020, sec. 17.2\)](#), [Long \(1997, 196–210\)](#), and [Maddala and Lahiri \(2006, 333–336\)](#) for an introduction to the tobit model. [Wooldridge \(2010, chap. 17 and 19\)](#) provides an advanced treatment of censored regression models. [Cameron and Trivedi \(2022, chap. 19\)](#) discuss the tobit model using Stata examples.

The tobit model can be written as the latent regression model $\mathbf{y} = \mathbf{x}\beta + \epsilon$ with a continuous outcome that is either observed or unobserved. Following Cong (2000), the observed outcome for observation i is defined as

$$y_i^* = \begin{cases} y_i & \text{if } a < y_i < b \\ a & \text{if } y_i \leq a \\ b & \text{if } y_i \geq b \end{cases}$$

where a is the lower-censoring limit and b is the upper-censoring limit. The tobit model assumes that the error term is normally distributed; $\epsilon \sim N(\mathbf{0}, \sigma^2 \mathbf{I})$. Depending on the problem at hand, the quantity of interest in a tobit model may be the censored outcome, y_i^* , or the uncensored outcome, y_i . In the measurement instrument scenario above, we may wish to predict the values that fall below the measurement threshold. By contrast, in the consumption of consumer durables scenario above, the latent variable is an artificial construct and the variable of interest is the observed consumer expenditure.

▷ Example 1: Constant-censoring limit

University administrators want to know the relationship between high school grade point average (GPA) and students’ performance in college. `gpa.dta` contains fictional data on a cohort of 4,000 college students. College GPA (`gpa2`) and high school GPA (`hsgpa`) are measured on a continuous scale between zero and four. The outcome of interest is the student’s college GPA. But, for reasons of confidentiality, GPAs below 2.0 are reported as 2.0. In other words, the outcome is censored on the left.

We believe that GPA is also a function of the logarithm of income of the student’s parents (`pincome`) and whether or not the student participated in a study-skills program while in college (`program`).

```

tobit reports the coefficients for the latent regression model. Thus, we can interpret the coefficients just as we would the coefficients from OLS. For example, participation in a study-skills program increases the expected uncensored GPA by 0.56 points.

► Example 2: Tobit model for a corner solution

Suppose that we are interested in the number of hours married women spend working for wages, and we treat observations recording zero hours as observed, per the corner-solution approach discussed [Wooldridge \(2010, chap. 16\)](#). We use the labor supply data extracted by [Mroz \(1987\)](#) from the 1975 PSID for 753 married women. The variable `whrs75` records the annual number of hours worked. Forty-three percent of the surveyed women worked zero hours, and the remaining women worked on average 1,303 hours a year.

We regress hours worked on household income excluding wife's income (`nwinc`), years of schooling (`wedyrs`), years of labor market experience (`wexper`) and its square, age (`wifeage`), an indicator for the presence of children under 6 years of age at home (`k16`), and an indicator for the presence of children from 6 to 18 years old at home (`k618`).

Unlike in [example 1](#), we are interested in the marginal effect of the covariates on the observed outcome. We can use [margins](#) to estimate, for example, the average marginal effect of years of education on the expected value of the actual hours worked.

```
. margins, dydx(wedyrs) predict(ystar(0,.))
Average marginal effects                                Number of obs = 753
Model VCE: OIM
Expression: E(whrs75*|whrs75>0), predict(ystar(0,.))
dy/dx wrt:  wedyrs
```

	Delta-method		z	P> z	[95% conf. interval]	
	dy/dx	std. err.				
wedyrs	47.47306	12.6214	3.76	0.000	22.73558	72.21054

The average marginal effect of years of education on the actual hours worked is 47.47. See [\[R\] tobit postestimation](#) for more examples using margins.

[James Tobin](#) (1918–2002) was an American economist who after education and research at Harvard moved to Yale, where he was on the faculty from 1950 to 1988. He made many outstanding contributions to economics and was awarded the Nobel Prize in 1981 “for his analysis of financial markets and their relations to expenditure decisions, employment, production and prices”. He trained in the US Navy with the writer, Herman Wouk, who later fashioned a character after Tobin in the novel *The Caine Mutiny* (1951): “A mandarin-like midshipman named Tobit, with a domed forehead, measured quiet speech, and a mind like a sponge, was ahead of the field by a spacious percentage.”

Stored results

tobit stores the following in `e()`:

Scalars	
<code>e(N)</code>	number of observations
<code>e(N_unc)</code>	number of uncensored observations
<code>e(N_lfc)</code>	number of left-censored observations
<code>e(N_rfc)</code>	number of right-censored observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(df_r)</code>	residual degrees of freedom
<code>e(r2_p)</code>	pseudo- R^2
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	χ^2
<code>e(F)</code>	F statistic
<code>e(p)</code>	p -value for model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations

<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise
Macros	
<code>e(cmd)</code>	tobit
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(llopt)</code>	minimum of <i>depvar</i> or contents of <code>ll()</code>
<code>e(ulopt)</code>	maximum of <i>depvar</i> or contents of <code>ul()</code>
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(covariates)</code>	list of covariates
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset)</code>	linear offset variable
<code>e(chi2type)</code>	type of model χ^2 test
<code>e(vce)</code>	<i>vcetype</i> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(method)</code>	estimation method: ml
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	b V
<code>e(predict)</code>	program used to implement predict
<code>e(marginsok)</code>	predictions allowed by margins
<code>e(asbalanced)</code>	factor variables <i>fvset</i> as asbalanced
<code>e(asobserved)</code>	factor variables <i>fvset</i> as asobserved
Matrices	
<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance
Functions	
<code>e(sample)</code>	marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices	
<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

Methods and formulas

See [Methods and formulas](#) in [\[R\] intreg](#).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [\[P\] _robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`tobit` also supports estimation with survey data. For details on VCEs with survey data, see [\[SVY\] Variance estimation](#).

Postestimation commands

The following postestimation commands are available after `tobit`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
<code>linktest</code>	link test for model specification
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	linear, censored, and truncated predictions
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset ]
predict [type] stub* [if] [in] , scores
```

statistic	Description
Main	
xb	linear prediction; the default
stdp	standard error of the linear prediction
stdf	standard error of the forecast
pr(a,b)	$\Pr(a < y_j < b)$
e(a,b)	$E(y_j a < y_j < b)$
ystar(a,b)	$E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

stdf is not allowed with svy estimation results.

where *a* and *b* may be numbers or variables; *a* missing (*a* ≥ .) means $-\infty$, and *b* missing (*b* ≥ .) means $+\infty$; see [U] 12.2.1 Missing values.

Options for predict

Main

xb, the default, calculates the linear prediction.

stdp calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

stdf calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by stdf are always larger than those produced by stdp; see *Methods and formulas* in [R] regress postestimation.

`pr(a,b)` calculates $\Pr(a < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b) .

a and b may be specified as numbers or variable names; lb and ub are variable names;

`pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$;

`pr(lb,ub)` calculates $\Pr(lb < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < ub)$; and

`pr(20,ub)` calculates $\Pr(20 < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < ub)$.

a missing ($a \geq .$) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$;

`pr(lb,30)` calculates $\Pr(-\infty < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$ in observations for which $lb \geq .$

and calculates $\Pr(lb < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < 30)$ elsewhere.

b missing ($b \geq .$) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j > 20)$;

`pr(20,ub)` calculates $\Pr(+\infty > \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j > 20)$ in observations for which $ub \geq .$

and calculates $\Pr(20 < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < ub)$ elsewhere.

`e(a,b)` calculates $E(\mathbf{x}_j\boldsymbol{\beta} + \epsilon_j \mid a < \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j < b)$, the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (a, b) , meaning that $y_j|\mathbf{x}_j$ is truncated.

a and b are specified as they are for `pr()`.

`ystar(a,b)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\mathbf{x}_j\boldsymbol{\beta} + \epsilon_j \leq a$, $y_j^* = b$ if $\mathbf{x}_j\boldsymbol{\beta} + \epsilon_j \geq b$, and $y_j^* = \mathbf{x}_j\boldsymbol{\beta} + \epsilon_j$ otherwise, meaning that y_j^* is censored. a and b are specified as they are for `pr()`.

`nooffset` is relevant only if you specified `offset(varname)`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\boldsymbol{\beta}$ rather than as $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L / \partial \sigma$.

margins

Description for margins

margins estimates margins of response for linear predictions, probabilities, and expected values.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]  
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

statistic	Description
xb	linear prediction; the default
pr(a,b)	$\Pr(a < y_j < b)$
e(a,b)	$E(y_j a < y_j < b)$
ystar(a,b)	$E(y_j^*, y_j^* = \max\{a, \min(y_j, b)\})$
stdp	not allowed with margins
stdf	not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

Remarks and examples

▷ Example 1: Marginal predictions

In [example 2](#) of [\[R\] tobit](#), we fit a tobit model of annual number of hours that married women spend working and then obtained estimated average marginal effect of 47.47 for years of education on observed hours worked.

```
. use https://www.stata-press.com/data/r19/mroz87
(1975 PSID data from Mroz, 1987)

. tobit whrs75 nwinc wedyrs wexper c.wexper#c.wexper wifeage kl6 k618, ll(0)
(output omitted)

. margins, dydx(wedyrs) predict(ystar(0,.))
(output omitted)
```

However, we may not want this overall effect. To obtain marginal effects for specific alternative scenarios, we use `margins` with the `at()` option. For example, continuing with [example 2](#) of [\[R\] tobit](#) to estimate the means of the marginal effects on the expected value of the censored outcome conditional on education ranging from 8 years to 17 years, we type

```
. margins, dydx(wedyrs) predict(ystar(0,.)) at(wedyrs=(8(1)17))

Average marginal effects                                Number of obs = 753
Model VCE: OIM

Description

`total` produces estimates of totals, along with standard errors.

Quick start

Total of continuous variable `v1`

```
total v1
```

Same as above, but restrict estimation to observations where `catvar = 1`

```
total v1 if catvar==1
```

Same as above, but using `svyset` data

```
svy, subpop(if catvar==1): total v1
```

Total of `v1` for each level of `catvar`

```
total v1, over(catvar)
```

With jackknife standard errors

```
total v1, vce(jackknife)
```

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Totals

Syntax

total <i>varlist</i> [<i>if</i>] [<i>in</i>] [<i>weight</i>] [, <i>options</i>]	
<i>options</i>	Description
if/in/over	
over(<i>varlist</i> _o)	group over subpopulations defined by <i>varlist</i> _o
SE/Cluster	
vce(<i>vcetype</i>)	<i>vcetype</i> may be <i>analytic</i> , <i>cluster</i> <i>clustvar</i> , <i>bootstrap</i> , or <i>jackknife</i>
Reporting	
level(#)	set confidence level; default is level(95)
noheader	suppress table header
display_options	control column formats, line width, display of omitted variables and base and empty cells, and factor-variable labeling
coeflegend	display legend instead of statistics
<i>varlist</i> may contain factor variables; see [U] 11.4.3 Factor variables.	
bayesboot, bootstrap, collect, jackknife, mi estimate, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.	
vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix.	
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.	
vce() and weights are not allowed with the svy prefix; see [SVY] svy.	
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.	
coeflegend does not appear in the dialog box.	
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.	

Options

if/in/over
over(<i>varlist</i> _o) specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in <i>varlist</i> _o . Only numeric, nonnegative, integer-valued variables are allowed in over(<i>varlist</i> _o).
SE/Cluster
vce(<i>vcetype</i>) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (<i>analytic</i>), that allow for intragroup correlation (<i>cluster</i> <i>clustvar</i>), and that use bootstrap or jackknife methods (<i>bootstrap</i> , <i>jackknife</i>); see [R] <i>vce_option</i> .
vce(<i>analytic</i>), the default, uses the analytically derived variance estimator associated with the sample total.

Reporting

`level(#)`; see [R] [Estimation options](#).

`noheader` prevents the table header from being displayed.

display_options: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

The following option is available with `total` but is not shown in the dialog box:

`coeflegend`; see [R] [Estimation options](#).

Remarks and examples

➤ Example 1

Suppose that we collected data on incidence of heart attacks. The variable `heartatk` indicates whether a person ever had a heart attack (1 means yes; 0 means no). We can then estimate the total number of persons who have had heart attacks for each sex in the population represented by the data we collected.

```
. use https://www.stata-press.com/data/r19/total
(Fictional incidence of heart-attack data)
. total heartatk [pw=swgt], over(sex)

Total estimation                                Number of obs = 4,946
```

	Total	Std. err.	[95% conf. interval]	
c.heartatk@sex				
Male	944559	104372.3	739943	1149175
Female	581590	82855.59	419156.3	744023.7

Stored results

`total` stores the following in `e()`:

Scalars

<code>e(N)</code>	number of observations
<code>e(N_over)</code>	number of subpopulations
<code>e(N_clust)</code>	number of clusters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(df_r)</code>	sample degrees of freedom
<code>e(rank)</code>	rank of <code>e(V)</code>

Macros

<code>e(cmd)</code>	<code>total</code>
<code>e(cmdline)</code>	command as typed
<code>e(varlist)</code>	<i>varlist</i>
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(over)</code>	<i>varlist</i> from <code>over()</code>
<code>e(vce)</code>	<i>vcetype</i> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(properties)</code>	<code>b V</code>
<code>e(estat_cmd)</code>	program used to implement <code>estat</code>
<code>e(marginsnotok)</code>	predictions disallowed by margins

Matrices

<code>e(b)</code>	vector of total estimates
<code>e(V)</code>	(co)variance estimates
<code>e(_N)</code>	vector of numbers of nonmissing observations
<code>e(error)</code>	error code corresponding to <code>e(b)</code>

Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals
-----------------------	--

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

Methods and formulas are presented under the following headings:

The total estimator
Survey data
The survey total estimator
The poststratified total estimator
Subpopulation estimation

The total estimator

Let y denote the variable on which to calculate the total and $y_j, j = 1, \dots, n$, denote an individual observation on y . Let w_j be the frequency weight (or `iweight` or `pweight`), and if no weight is specified, define $w_j = 1$ for all j . The sum of the weights is an estimate of the population size:

$$\widehat{N} = \sum_{j=1}^n w_j$$

If the population values of y are denoted by $Y_j, j = 1, \dots, N$, the associated population total is

$$Y = \sum_{j=1}^N Y_j = N\bar{y}$$

where \bar{y} is the population mean. The total is estimated as

$$\hat{Y} = \widehat{N}\bar{y}$$

The variance estimator for the total is

$$\widehat{V}(\hat{Y}) = \widehat{N}^2 \widehat{V}(\bar{y})$$

where $\widehat{V}(\bar{y})$ is the variance estimator for the mean; see [\[R\] mean](#). The standard error of the total is the square root of the variance.

If x, x_j, \bar{x} , and \widehat{X} are similarly defined for another variable (observed jointly with y), the covariance estimator between \widehat{X} and \hat{Y} is

$$\widehat{\text{Cov}}(\widehat{X}, \hat{Y}) = \widehat{N}^2 \widehat{\text{Cov}}(\bar{x}, \bar{y})$$

where $\widehat{\text{Cov}}(\bar{x}, \bar{y})$ is the covariance estimator between two means; see [\[R\] mean](#).

Survey data

See [\[SVY\] Variance estimation](#) and [\[SVY\] Poststratification](#) for discussions that provide background information for the following formulas.

The survey total estimator

Let Y_j be a survey item for the j th individual in the population, where $j = 1, \dots, M$ and M is the size of the population. The associated population total for the item of interest is

$$Y = \sum_{j=1}^M Y_j$$

Let y_j be the survey item for the j th sampled individual from the population, where $j = 1, \dots, m$ and m is the number of observations in the sample.

The estimator \hat{Y} for the population total Y is

$$\hat{Y} = \sum_{j=1}^m w_j y_j$$

where w_j is a sampling weight. The estimator for the number of individuals in the population is

$$\hat{M} = \sum_{j=1}^m w_j$$

The score variable for the total estimator is the variable itself,

$$z_j(\hat{Y}) = y_j$$

The poststratified total estimator

Let P_k denote the set of sampled observations that belong to poststratum k , and define $I_{P_k}(j)$ to indicate if the j th observation is a member of poststratum k , where $k = 1, \dots, L_P$ and L_P is the number of poststrata. Also, let M_k denote the population size for poststratum k . P_k and M_k are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [\[SVY\] svyset](#).

The estimator for the poststratified total is

$$\hat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) w_j y_j$$

where

$$\widehat{M}_k = \sum_{j=1}^m I_{P_k}(j) w_j$$

The score variable for the poststratified total is

$$z_j(\hat{Y}^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left(y_j - \frac{\hat{Y}_k}{\widehat{M}_k} \right)$$

Subpopulation estimation

Let S denote the set of sampled observations that belong to the subpopulation of interest, and define $I_S(j)$ to indicate if the j th observation falls within the subpopulation.

The estimator for the subpopulation total is

$$\hat{Y}^S = \sum_{j=1}^m I_S(j) w_j y_j$$

and its score variable is

$$z_j(\hat{Y}^S) = I_S(j) y_j$$

The estimator for the poststratified subpopulation total is

$$\hat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \hat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^{m_k} I_{P_k}(j) I_S(j) w_j y_j$$

and its score variable is

$$z_j(\hat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j) y_j - \frac{\hat{Y}_k^S}{\widehat{M}_k} \right\}$$

Postestimation commands

The following postestimation commands are available after `total`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
<code>marginsplot</code>	graph the results from <code>total</code>
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>pwcompare</code>	pairwise comparisons of parameters
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

Remarks and examples

► Example 1

Continuing with our data on incidence of heart attacks from [example 1](#) in [\[R\] total](#), we want to test whether there are twice as many heart attacks among men than women in the population.

```
. use https://www.stata-press.com/data/r19/total
(Fictional incidence of heart-attack data)

. total heartatk [pw=swgt], over(sex)
(output omitted)

. test heartatk@1.sex = 2 * heartatk@2.sex
( 1)  c.heartatk@1bn.sex - 2*c.heartatk@2.sex = 0
      F( 1, 4945) = 1.25
      Prob > F = 0.2643
```

Thus we do not reject our hypothesis that the total number of heart attacks for men is twice that for women in the population.

Description

`tpoisson` fits a truncated Poisson regression model when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. Truncated Poisson models are appropriate when neither the dependent variable nor the covariates are observed in the truncated part of the distribution. By default, `tpoisson` assumes left-truncation occurs at zero, but truncation may be specified at other fixed points or at values that vary across observations.

Quick start

Truncated Poisson regression of `y` on `x1` and `x2` with left-truncation at 0

```
tpoisson y x1 x2
```

Add categorical variable `a` using [factor-variable](#) syntax

```
tpoisson y x1 x2 i.a
```

Same as above, but report incidence-rate ratios and use a constant truncation point of 4

```
tpoisson y x1 x2 i.a, irr ll(4)
```

With offset variable `lnexp`

```
tpoisson y x1 x2 i.a, offset(lnexp)
```

Same as above, but with a variable truncation point stored in variable `min`

```
tpoisson y x1 x2 i.a, offset(lnexp) ll(min)
```

With variable left- and right-truncation points

```
tpoisson y x1 x2, ll(min) ul(max)
```

With variable right-truncation points

```
tpoisson y x1 x2, ul(max)
```

Constrain the coefficients for `2.a` and `3.a` to equality

```
constraint define 1 2.a = 3.a
tpoisson y x1 x2 i.a, constraints(1)
```

Menu

Statistics > Count outcomes > Truncated Poisson regression

Syntax

```
tpoisson depvar [indepvars] [if] [in] [weight] [, options]
```

<i>options</i>	Description
Model	
<code>noconstant</code>	suppress constant term
<code>ll(# <i>varname</i>)</code>	lower limit for truncation; default is <code>ll(0)</code> when neither <code>ll()</code> nor <code>ul()</code> is specified
<code>ul(# <i>varname</i>)</code>	upper limit for truncation
<code>exposure(<i>varname</i>_e)</code>	include $\ln(\text{varname}_e)$ in model with coefficient constrained to 1
<code>offset(<i>varname</i>_o)</code>	include <i>varname</i> _o in model with coefficient constrained to 1
<code>constraints(<i>constraints</i>)</code>	apply specified linear constraints
SE/Robust	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>opg</code> , <code>bootstrap</code> , or <code>jackknife</code>
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>irr</code>	report incidence-rate ratios
<code>nocnsreport</code>	do not display constraints
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<code>maximize_options</code>	control the maximization process; seldom used
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics

indepvars may contain factor variables; see [U] 11.4.3 Factor variables.

depvar and *indepvars* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes`, `bayesboot`, `bootstrap`, `by`, `collect`, `fmm`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] `bayes: tpoisson` and [FMM] `fmm: tpoisson`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 `weight`.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

Model

`noconstant`; see [R] [Estimation options](#).

`ll(#|varname)` and `ul(#|varname)` specify the lower and upper limits for truncation, respectively. You may specify nonnegative integer values for one or both.

When neither `ll()` nor `ul()` is specified, the default is zero truncation, `ll(0)`, equivalent to left-truncation at zero.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] [Estimation options](#).

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce_option](#).

Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is, e^{β_i} rather than β_i . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

display_options: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

Maximization

maximize_options: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `tpoisson` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

Remarks and examples

`tpoisson` fits a truncated Poisson regression model by maximum likelihood estimation when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. If the dependent variable is not truncated, standard Poisson regression may be more appropriate; see [R] [poisson](#).

When the data are truncated, we do not observe either the dependent variable or the covariates. For example, consider a study about the number of days that individuals with hyperglycemia are hospitalized after presenting to the hospital. If we select our sample only from admission records, then the sample is truncated at zero because we have data only on individuals who stayed at least one day. Now assume that we are relying on billing data and that hospitals may submit either a final bill when a patient is discharged or an interim bill every 30 days. In this case, we have no information about patients who are hospitalized fewer than 1 day or more than 30 days. Our data are left-truncated at 0 and right-truncated at 30.

A related phenomenon is censoring. For censored observations, we observe complete covariate information but only a censored value of the dependent variable. Different research designs can give rise to censored data or truncated data. See [R] [cpoisson](#) for information about censored Poisson regression.

Truncated Poisson regression was first proposed by [Grogger and Carson \(1991\)](#). For an introduction to Poisson regression, see [Cameron and Trivedi \(2005, 2022\)](#) and [Long and Freese \(2014\)](#). For an introduction to truncated Poisson models, see [Cameron and Trivedi \(2013\)](#) and [Long \(1997, chap. 8\)](#).

▷ Example 1: Left-truncation at zero

Consider the [Simonoff \(2003\)](#) dataset of running shoes for a sample of runners who registered an online running log. A running-shoe marketing executive is interested in knowing how the number of pairs of running shoes purchased relates to other factors such as gender, marital status, age, education, income, typical number of runs per week, average miles run per week, and the preferred type of running. These data are naturally truncated at zero. A truncated Poisson model is fit to the number of pairs of shoes owned on runs per week, miles run per week, gender, age, and marital status.

No options are needed because zero truncation is the default for `tpoisson`.

```
. use https://www.stata-press.com/data/r19/runshoes
(Running shoes)

. toipson shoes rpweek mpweek male age married

Iteration 0:  Log likelihood = -88.328151
Iteration 1:  Log likelihood = -86.272639
Iteration 2:  Log likelihood = -86.257999
Iteration 3:  Log likelihood = -86.257994

Truncated Poisson regression               Number of obs   =           60
Limits: lower =           0               LR chi2(5)      =          22.75
        upper =          +inf             Prob > chi2     =          0.0004
Log likelihood = -86.257994               Pseudo R2      =          0.1165
```

shoes	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
rpweek	.1575811	.1097893	1.44	0.151	-.057602	.3727641
mpweek	.0210673	.0091113	2.31	0.021	.0032094	.0389252
male	.0446134	.2444626	0.18	0.855	-.4345246	.5237513
age	.0185565	.0137786	1.35	0.178	-.008449	.045562
married	-.1283912	.2785044	-0.46	0.645	-.6742498	.4174674
_cons	-1.205844	.6619774	-1.82	0.069	-2.503296	.0916078

Using the zero-truncated Poisson regression with these data, only the coefficient on average miles per week is statistically significant at the 5% level.

► Example 2: Left-truncation with a fixed-truncation point

Semiconductor manufacturing requires that silicon wafers be coated with a layer of metal oxide. The depth of this layer is strictly controlled. In this example, a critical oxide layer is designed for 300 ± 20 angstroms (Å).

After the oxide layer is coated onto a wafer, the wafer enters a photolithography step in which the lines representing the electrical connections are printed on the oxide and later etched and filled with metal. The widths of these lines are measured. In this example, they are controlled to 90 ± 5 micrometers (μm).

After these and other steps, each wafer is electrically tested at probe. If too many failures are discovered, the wafer is rejected and sent for engineering analysis. In this example, the maximum number of probe failures tolerated for this product is 10.

A major failure at probe has been encountered—88 wafers had more than 10 failures each. The 88 wafers that failed were tested using 4 probe machines. The engineer suspects that the failures were a result of faulty probe machines, poor depth control, or poor line widths. The line widths and depths in these data are the actual measurement minus its specification target, 300 Å for the oxide depths and $90 \mu\text{m}$ for the line widths.

The following table tabulates the average failure rate for each probe using Stata's mean command; see [R] [mean](#).

```
. use https://www.stata-press.com/data/r19/probe
(Silicon wafers)
```

```
. mean failures, over(probe)
```

Mean estimation

Number of obs = 88

2	14.95833	.5912379	13.78318	16.13348
3	16.47059	.9279866	14.62611	18.31506
4	23.09677	.9451117	21.21826	24.97529

The 95% confidence intervals in this table suggest that there are about 5–11 additional failures per wafer on probe 4. These are unadjusted for varying line widths and oxide depths. Possibly, probe 4 received the wafers with larger line widths or extreme oxide depths.

Truncated Poisson regression more clearly identifies the root causes for the increased failures by estimating the differences between probes adjusted for the line widths and oxide depths. It also allows us to determine whether the deviations from specifications in line widths or oxide depths might be contributing to the problem.

```
. tpoisson failures i.probe depth width, ll(10) nolog
Truncated Poisson regression      Number of obs      =          88
Limits: lower =          10      LR chi2(5)            =          73.70
      upper =         +inf      Prob > chi2          =          0.0000
Log likelihood = -239.35746      Pseudo R2          =          0.1334
```

failures	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
probe						
2	-.1113037	.1019786	-1.09	0.275	-.3111781	.0885707
3	.0114339	.1036032	0.11	0.912	-.1916245	.2144924
4	.4254115	.0841277	5.06	0.000	.2605242	.5902989

width	.0330225	.015573	2.12	0.034	.0025001	.063545
_cons	2.714025	.0752617	36.06	0.000	2.566515	2.861536

The coefficients listed for the probes are testing the null hypothesis: $H_0 : \text{probe}_i = \text{probe}_1$, where i equals 2, 3, and 4. Because the only coefficient that is statistically significant is the one for testing for $H_0 : \text{probe}_4 = \text{probe}_1$, $p < 0.001$, and because the p -values for the other probes are not statistically significant, that is, $p \geq 0.275$, the implication is that there is a difference between probe 4 and the other machines. Because the coefficient for this test is positive, 0.425, the conclusion is that the average failure rate for probe 4, after adjusting for line widths and oxide depths, is higher than the other probes. Possibly, probe 4 needs calibration or the head used with this machine is defective.

Line-width control is statistically significant, $p = 0.034$, but variation in oxide depths is not causing the increased failure rate. The engineer concluded that the sudden increase in failures is the result of two problems. First, probe 4 is malfunctioning, and second, there is a possible lithography or etching problem.

◀

Stored results

tpoisson stores the following in `e()`:

Scalars

<code>e(N)</code>	number of observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(r2_p)</code>	pseudo- R^2
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	χ^2
<code>e(p)</code>	p -value for model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

Macros

<code>e(cmd)</code>	tpoisson
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(llopt)</code>	contents of <code>ll()</code> , or 0 if neither <code>ll()</code> nor <code>ul()</code> is specified
<code>e(ulopt)</code>	contents of <code>ul()</code> , if specified
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset)</code>	linear offset variable
<code>e(chi2type)</code>	Wald or LR; type of model χ^2 test
<code>e(vce)</code>	<i>vcetype</i> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of <code>ml</code> method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	b V
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices

`r(table)`

matrix containing the coefficients with their standard errors, test statistics, p -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

For a nonnegative count outcome Y with left-truncation point ll_j and right-truncation point ul_j , we can write the truncated Poisson model as

$$f(y_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | \xi_j)}$$

where

$$\xi_j = \mathbf{x}_j\beta + \text{offset}_j$$

$$\lambda_j = \exp(\xi_j)$$

and \mathbf{x}_j is a vector of observed covariates. The conditional probability of observing y_j events, therefore given by $ll_j < y_j < ul_j$, is

$$\Pr(Y = y_j | ll_j < y_j < ul_j, \mathbf{x}_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | \mathbf{x}_j)}$$

The log likelihood is given by

$$\ln L = \sum_{j=1}^n w_j [-\lambda_j + \xi_j y_j - \ln(y_j!) - \ln \{ \Pr(ll_j < Y < ul_j | \xi_j) \}]$$

If no weights are specified, $w_j = 1$.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`tpoisson` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

Postestimation commands

The following postestimation commands are available after tpoisson:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	number of events, incidence rates, probabilities, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

predict

Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, linear predictions, standard errors, and the equation-level score.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset ]
```

statistic	Description
Main	
n	number of events; the default
ir	incidence rate
cm	conditional mean, $E(y_j ll_j < y_j < ul_j)$
pr(n)	probability $\Pr(y_j = n)$
pr(a,b)	probability $\Pr(a \leq y_j \leq b)$
cpr(n)	conditional probability $\Pr(y_j = n ll_j < y_j < ul_j)$
cpr(a,b)	conditional probability $\Pr(a \leq y_j \leq b ll_j < y_j < ul_j)$
xb	linear prediction
stdp	standard error of the linear prediction
score	first derivative of the log likelihood with respect to $\mathbf{x}_j\beta$

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

- Main
- n, the default, calculates the predicted number of events, which is $\exp(\mathbf{x}_j\beta)$ if neither offset() nor exposure() was specified when the model was fit; $\exp(\mathbf{x}_j\beta + \text{offset}_j)$ if offset() was specified; or $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$ if exposure() was specified.
 - ir calculates the incidence rate $\exp(\mathbf{x}_j\beta)$, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the n and the nooffset options.
 - cm calculates the conditional mean,

$$E(y_j | ll_j < y_j < ul_j) = \frac{E(y_j, ll_j < y_j < ul_j)}{\Pr(ll_j < y_j < ul_j)}$$

where ll_j is the left-truncation point specified at estimation and ul_j is the right-truncation point specified at estimation.

`pr(n)` calculates the probability $\Pr(y_j = n)$, where *n* is a nonnegative integer that may be specified as a number or a variable.

`pr(a,b)` calculates the probability $\Pr(a \leq y_j \leq b)$, where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

b missing (*b* \geq .) means $+\infty$;

`pr(20,.)` calculates $\Pr(y_j \geq 20)$;

`pr(20,b)` calculates $\Pr(y_j \geq 20)$ in observations for which *b* \geq . and calculates

$\Pr(20 \leq y_j \leq b)$ elsewhere.

`pr(.,b)` produces a syntax error. A missing value in an observation of the variable *a* causes a missing value in that observation for `pr(a,b)`.

`cpr(n)` calculates the conditional probability $\Pr(y_j = n \mid ll_j < y_j < ul_j)$, where *n* is a nonnegative integer that may be specified as a number or a variable. *ll_j* and *ul_j* are as defined in `cm`.

`cpr(a,b)` calculates the conditional probability $\Pr(a \leq y_j \leq b \mid ll_j < y_j < ul_j)$, where *a* and *b* are as defined in `pr(a,b)` with the additional restrictions that *a* $>$ *ll_j* and *b* $<$ *ul_j*. *ll_j* and *ul_j* are as defined in `cm`.

`xb` calculates the linear prediction, which is $\mathbf{x}_j\beta$ if neither `offset()` nor `exposure()` was specified when the model was fit; $\mathbf{x}_j\beta + \text{offset}_j$ if `offset()` was specified; or $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`score` calculates the equation-level score, $\partial \ln L / \partial (\mathbf{x}_j\beta)$.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as $\mathbf{x}_j\beta$ rather than as $\mathbf{x}_j\beta + \text{offset}_j$ or $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$. Specifying `predict ..., nooffset` is equivalent to specifying `predict ..., ir`.

margins

Description for margins

margins estimates margins of response for numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

statistic	Description
n	number of events; the default
ir	incidence rate
cm	conditional mean, $E(y_j ll_j < y_j < ul_j)$
pr(n)	probability $\Pr(y_j = n)$
pr(a,b)	probability $\Pr(a \leq y_j \leq b)$
cpr(n)	conditional probability $\Pr(y_j = n ll_j < y_j < ul_j)$
cpr(a,b)	conditional probability $\Pr(a \leq y_j \leq b ll_j < y_j < ul_j)$
xb	linear prediction
stdp	not allowed with margins
<u>s</u> core	not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.

Remarks and examples

▷ Example 1: Obtaining margins of the conditional mean

In [example 1](#) of [\[R\] tpoisson](#), a truncated Poisson model is fit to the number of pairs of shoes owned on runs per week, miles run per week, gender, age, and marital status. We continue that example to determine the effect of miles run per week on the average number of pairs of shoes owned.

After reading in the data, we use [summarize](#) to obtain the 25th, 50th, and 75th percentiles for miles run per week.

```
. use https://www.stata-press.com/data/r19/runshoes
(Running shoes)
. summarize mpweek, detail
```

Miles per week				
Percentiles		Smallest		
1%	5	5		
5%	5	5		
10%	5	5	Obs	60
25%	12.5	5	Sum of wgt.	60
50%	27.5		Mean	24.71167
		Largest	Std. dev.	14.34934
75%	32.5	47.5		
90%	47.5	47.5	Variance	205.9034
95%	47.5	47.5	Skewness	.1948568
99%	57.5	57.5	Kurtosis	2.065304

We fit the model from [example 1](#) of [\[R\] tpoisson](#) again. We next specify these values for the percentiles to margins to estimate the conditional mean of the number of pairs of shoes at different quantiles of miles run per week. To do this, we use the `at()` option of `margins`.

```
. quietly tpoisson shoes rpweek mpweek male age married
. margins, at(mpweek=(12.5 27.5 32.5)) predict(cm)
```

Predictive margins Number of obs = 60
 Model VCE: OIM
 Expression: Conditional mean of n > ll(0), predict(cm)
 1._at: mpweek = 12.5
 2._at: mpweek = 27.5
 3._at: mpweek = 32.5

	Delta-method			z	P> z	[95% conf. interval]	
	Margin	std. err.					
_at							
1	1.942149	.2111564	9.20	0.000	1.52829	2.356008	
2	2.376253	.1714522	13.86	0.000	2.040213	2.712293	
3	2.564339	.1948129	13.16	0.000	2.182513	2.946165	

We see that people who run 12.5 miles per week are expected to own 1.94 pairs of shoes. The expected number of pairs of shoes owned increases as the average miles per week increases. We expect people who run 27.5 miles per week have 2.38 pairs of shoes and those who run 32.5 miles per week have 2.56 pairs of shoes.

Methods and formulas

Continuing from *Methods and formulas* in [R] [tpoisson](#), the equation-level score is given by

$$\text{score}(\mathbf{x}\beta)_j = y_j - \lambda_j - \frac{\{\exp(-\lambda_j)\lambda_j^{ll_j}/ll_j! - \exp(-\lambda_j)\lambda_j^{(ul_j-1)}/(ul_j-1)!\}\lambda_j}{\Pr(ll_j < Y < ul_j | \xi_j)}$$

[Description](#)[Options for translate](#)[Quick start](#)[Remarks and examples](#)[Syntax](#)[Stored results](#)[Options for print](#)[Also see](#)

Description

`print` prints log, SMCL, and text files. `translate` translates log and SMCL files from one format to another, the other typically being suitable for printing. `translate` can also translate SMCL logs to plain text.

Quick start

Translate SMCL-format log `mylog.smcl` to a text log file `mylog.log`

```
translate mylog.smcl mylog.log
```

Same as above, but translate `mylog.smcl` to PostScript file `mylog.ps`

```
translate mylog.smcl mylog.ps
```

Send output from the Results window to new `mylog.txt` when no log was started

```
translate @Results mylog.txt
```

Syntax

Print log and SMCL files

```
print filename [ , like(ext) name(windowname) override_options ]
```

Translate log files to SMCL files and vice versa

```
translate filenamein filenameout [ , translator(tname) name(windowname)  
    override_options replace ]
```

View translator parameter settings

```
translator query [tname]
```

Change translator parameter settings

```
translator set [tname setopt setval]
```

Return translator parameter settings to default values

```
translator reset tname
```

List current mappings from one extension to another

```
transmap query [ .ext ]
```

Specify that files with one extension be treated the same as files with another extension

```
transmap define .extnew .extold
```

filename in print, in addition to being a filename to be printed, may be specified as @Results to mean the Results window and @Viewer to mean the Viewer window.

*filename*_{in} in translate may be specified just as *filename* in print.

tname in translator specifies the name of a translator; see the [translator\(\)](#) option under *Options for translate*.

Options for print

`like(ext)` specifies how the file should be translated to a form suitable for printing. The default is to determine the translation method from the extension of *filename*. Thus, `mylog.smcl` is translated according to the rule for translating `smcl` files, `myfile.txt` is translated according to the rule for translating `txt` files, and so on. (These rules are, in fact, `translate`'s `smcl2prn` and `txt2prn` translators, but put that aside for the moment.)

Rules for the following extensions are predefined:

<code>.txt</code>	assume input file contains plain text
<code>.log</code>	assume input file contains Stata log text
<code>.smcl</code>	assume input file contains SMCL

To print a file that has an extension different from those listed above, you can define a new extension, but you do not have to do that. Assume that you wish to print the file `read.me`, which you know to contain plain text. If you were just to type `print read.me`, you would be told that Stata cannot translate `.me` files. (You would actually be told that the translator for `me2prn` was not found.) You could type `print read.me, like(txt)` to tell `print` to print `read.me` like a `.txt` file.

On the other hand, you could type

```
. transmap define .me .txt
```

to tell Stata that `.me` files are always to be treated like `.txt` files. If you did that, Stata would remember the new rule, even in future sessions.

When you specify the `like()` option, you override the recorded rules. So, if you were to type `print mylog.smcl, like(txt)`, the file would be printed as plain text (meaning that all the SMCL commands would show).

`name(windowname)` specifies which window to print when printing a Viewer. The default is for Stata to print the topmost Viewer [Unix(GUI) users: See the third [technical note](#) in *Printing files, Unix*]. The `name()` option is ignored when printing the Results window.

The window name is located inside the parentheses in the window title. For example, if the title for a Viewer window is `Viewer (#1) [help print]`, the name for the window is `#1`.

`override_options` refer to `translate`'s options for overriding default values. `print` uses `translate` to translate the file into a format suitable for sending to the printer, and thus `translate`'s `override_options` may also be used with `print`. The settings available vary between each translator (for example, `smcl2ps` will have different settings than `smcl2txt`) and may also differ across operating systems (for example, Windows may have different printing options than macOS). To find out what you can override when printing `.smcl` files, type

```
. translator query smcl2prn
(output omitted)
```

In the omitted output, you might learn that there is an `rmargin #` tunable value, which specifies the right margin in inches. You could specify the `override_option` `rmargin(#)` to temporarily override the default value, or you could type `translator set smcl2prn rmargin #` beforehand to permanently reset the value.

Alternatively, on some computers with some translators, you might discover that nothing can be set.

Options for translate

`translator(tname)` specifies the name of the translator to be used to translate the file. The available translators are

<i>tname</i>	Input	Output
<code>smcl2ps</code>	SMCL	PostScript
<code>log2ps</code>	Stata text log	PostScript
<code>txt2ps</code>	generic text file	PostScript
<code>Viewer2ps</code>	Viewer window	PostScript
<code>Results2ps</code>	Results window	PostScript
<code>smcl2prn</code>	SMCL	default printer format
<code>log2prn</code>	Stata text log	default printer format
<code>txt2prn</code>	generic text log	default printer format
<code>Results2prn</code>	Results window	default printer format
<code>Viewer2prn</code>	Viewer window	default printer format
<code>smcl2txt</code>	SMCL	generic text log
<code>smcl2log</code>	SMCL	Stata text log
<code>Results2txt</code>	Results window	generic text file
<code>Viewer2txt</code>	Viewer window	generic text file
<code>smcl2pdf</code>	SMCL	PDF
<code>log2pdf</code>	Stata text log	PDF
<code>txt2pdf</code>	generic text log	PDF
<code>Results2pdf</code>	Results window	PDF
<code>Viewer2pdf</code>	Viewer window	PDF

If `translator()` is not specified, `translate` determines which translator to use from extensions of the filenames specified. Typing `translate myfile.smcl myfile.ps` would use the `smcl2ps` translator. Typing `translate myfile.smcl myfile.ps, translate(smcl2prn)` would override the default and use the `smcl2prn` translator.

Actually, when you type `translate a.b c.d`, `translate` looks up `.b` in the `transmap` extension-synonym table. If `.b` is not found, the translator `b2d` is used. If `.b` is found in the table, the mapped extension is used (call it `b'`), and then the translator `b'2d` is used. For example,

Command	Translator used
<code>. translate myfile.smcl myfile.ps</code>	<code>smcl2ps</code>
<code>. translate myfile.odd myfile.ps</code>	<code>odd2ps</code> , which does not exist, so error
<code>. transmap define .odd .txt</code>	
<code>. translate myfile.odd myfile.ps</code>	<code>txt2ps</code>

You can list the mappings that `translate` uses by typing `transmap query`.

`name(windowname)` specifies which window to translate when translating a Viewer. The default is for Stata to translate the topmost Viewer. The `name()` option is ignored when translating the Results window.

The window name is located inside the parentheses in the window title. For example, if the title for a Viewer window is `Viewer (#1) [help print]`, the name for the window is `#1`.

override_options override any of the default options of the specified or implied translator. To find out what you can override for, say, `log2ps`, type

```
. translator query log2ps
```

In the omitted output, you might learn that there is an `rmargin` # tunable value, which, for `log2ps`, specifies the right margin in inches. You could specify the *override_option* `rmargin(#)` to temporarily override the default value or type `translator set log2ps rmargin #` beforehand to permanently reset the value.

`replace` specifies that *filename*_{out} be replaced if it already exists.

Remarks and examples

Remarks are presented under the following headings:

- [Overview](#)
- [Printing files](#)
- [Printing files, Mac and Windows](#)
- [Printing files, Unix](#)
- [Translating files from one format to another](#)

Overview

`print` prints log, SMCL, and text files. Although there is considerable flexibility in how `print` (and `translate`, which `print` uses) can be set to work, they have already been set up and should just work:

```
. print mylog.smcl
. print mylog.log
```

Unix users may discover that they need to do a bit of setup before `print` works; see [Printing files, Unix](#) below. International Unix users may also wish to modify the default paper size. All users can tailor `print` and `translate` to their needs.

`print` may also be used to print the current contents of the Results window or the Viewer. For instance, the current contents of the Results window could be printed by typing

```
. print @Results
```

`translate` translates log and SMCL files from one format to another, the other typically being suitable for printing. `translate` can also translate SMCL logs (logs created by typing, say, `log using mylog`) to plain text:

```
. translate mylog.smcl mylog.log
```

You can use `translate` to recover a log when you have forgotten to start one. You may type

```
. translate @Results mylog.txt
```

to capture as plain text what is currently shown in the Results window.

This entry provides a general overview of `print` and `translate` and covers in detail the printing and translation of text (nongraphic) files.

`translator query`, `translator set`, and `translator reset` show, change, and restore the default values of the settings for each translator.

`transmap define` and `transmap query` create and show mappings from one file extension to another for use with `print` and `translate`.

For example, `print myfile.txt` knows to use a translator appropriate for printing text files because of the `.txt` extension. However, it does not know what to do with `.xyz` files. If you have `.xyz` files and always wish to treat them as `.txt` files, you can type `transmap define .xyz .txt`.

Printing files

Printing should be easy; just type

```
. print mylog.smcl
. print mylog.log
```

You can use `print` to print SMCL files, plain text files, and even the contents of the Results and Viewer windows:

```
. print @Results
. print @Viewer
. print @Viewer, name(#2)
```

For information about printing and translating graph files, see [\[G-2\] graph print](#) and see [\[G-2\] graph export](#).

Printing files, Mac and Windows

When you type `print`, you are using the same facility that you would be using if you had selected **Print** from the **File** menu. If you try to print a file that Stata does not know about, Stata will complain:

```
. print read.me
translator me2prn not found
r(111);
```

Then, you could type

```
. print read.me, like(txt)
```

to indicate that you wanted `read.me` sent to the printer in the same fashion as if the file were named `readme.txt`, or you could type

```
. transmap define .me .txt
. print read.me
```

Here you are telling Stata once and for all that you want files ending in `.me` to be treated in the same way as files ending in `.txt`. Stata will remember this mapping, even across sessions. To clear the `.me` mapping, type

```
. transmap define .me
```

To see all the mappings, type

```
. transmap query
```

To print to a file, use the `translate` command, not `print`:

```
. translate mylog.smcl mylog.prn
```

`translate` prints to a file by using the Windows print driver when the new filename ends in `.prn`. Under Mac, the `prn` translators are the same as the `pdf` translators. We suggest that you simply use the `.pdf` file extension when printing to a file.

Printing files, Unix

Stata assumes that you have a PostScript printer attached to your Unix computer and that the Unix command `lpr(1)` can be used to send PostScript files to it, but you can change this. On your Unix system, typing

```
mycomputer$ lpr < filename
```

may not be sufficient to print PostScript files. For instance, perhaps on your system you would need to type

```
mycomputer$ lpr -Plexmark < filename
```

or

```
mycomputer$ lpr -Plexmark filename
```

or something else. To set the print command to be `lpr -Plexmark filename` and to state that the printer expects to receive PostScript files, type

```
. printer define prn ps "lpr -Plexmark @"
```

To set the print command to `lpr -Plexmark < filename` and to state that the printer expects to receive plain text files, type

```
. printer define prn txt "lpr -Plexmark < @"
```

That is, just type the command necessary to send files to your printer and include an `@` sign where the filename should be substituted. Two file formats are available: `ps` and `txt`. The default setting, as shipped from the factory, is

```
. printer define prn ps "lpr < @"
```

We will return to the `printer` command in the technical note that follows because it has some other capabilities you should know about.

In any case, after you redefine the default printer, the following should just work:

```
. print mylog.smcl
. print mylog.log
```

If you try to print a file that Stata does not know about, it will complain:

```
. print read.me
translator me2prn not found
r(111);
```

Here you could type

```
. print read.me, like(txt)
```

to indicate that you wanted `read.me` sent to the printer in the same fashion as if the file were named `readme.txt`, or you could type

```
. transmap define .me .txt
. print read.me
```

Here you are telling Stata once and for all that you want files ending in `.me` to be treated in the same way as files ending in `.txt`. Stata will remember this setting for `.me`, even across sessions.

If you want to clear the `.me` setting, type

```
. transmap define .me
```

If you want to see all your settings, type

```
. transmap query
```

□ Technical note

If the text you wish to print contains Unicode characters, those characters may not appear correctly in PostScript files because the PostScript fonts do not support Unicode. Stata will map as many characters as possible to characters supported by Unicode but will print a question mark (?) for any unsupported character. We recommend that you export the text to a PDF file, which has fonts with better support for Unicode characters.

□ Technical note

The syntax of the `printer` command is

```
printer define prntername [ { ps | txt } "Unix command with @" ]
printer query [prntername]
```

You may define multiple printers. By default, `print` uses the printer named `prn`, but `print` has the syntax

```
print filename [ , like(ext) printer(prntername) override_options ]
```

so, if you define multiple printers, you may route your output to them.

For instance, if you have a second printer on your system, you might type

```
. printer define lexmark ps "lpr -Plexmark < @"
```

After doing that, you could type

```
. print myfile.smcl, printer(lexmark)
```

Any printers that you set will be remembered even across sessions. You can delete printers:

```
. printer define lexmark
```

You can list all the defined printers by typing `printer query`, and you can list the definition of a particular printer, say, `prn`, by typing `printer query prn`.

The default printer `prn` we have predefined for you is

```
. printer define prn ps "lpr < @"
```

meaning that we assume that it is a PostScript printer and that the Unix command `lpr(1)`, without options, is sufficient to cause files to print. Feel free to change the default definition. If you change it, the change will be remembered across sessions.

□ Technical note

Unix(GUI) users should note that X-Windows does not have the concept of a window z-order, which prevents Stata from determining which window is the topmost window. Instead, Stata determines which window is topmost based on which window has the focus. However, some window managers will set the focus to a window without bringing the window to the top. What Stata considers the topmost window may not appear topmost visually. For this reason, you should always use the `name()` option to ensure that the correct window is printed.

□

□ Technical note

When you select the Results window to print from the **Print** menu or toolbar button, the result is the same as if you were to issue the `print` command. When you select a Viewer window to print from the **Print** menu or toolbar button, the result is the same as if you were to issue the `print` command with a `name()` option.

□

The translation to PostScript format is done by `translate` and, in particular, is performed by the translators `smcl2ps`, `log2ps`, and `txt2ps`. There are many tunable parameters in each of these translators. You can display the current values of these tunable parameters for, say, `smcl2ps` by typing

```
. translator query smcl2ps
(output omitted)
```

and you can set any of the tunable parameters (for instance, setting `smcl2ps`'s `rmargin` value to 1) by typing

```
. translator set smcl2ps rmargin 1
(output omitted)
```

Any settings you make will be remembered across sessions. You can reset `smcl2ps` to be as it was when Stata was shipped by typing

```
. translator reset smcl2ps
```

Translating files from one format to another

If you have a SMCL log, which you might have created by previously typing log using `mylog`, you can translate it to a text log by typing

```
. translate myfile.smcl myfile.log
```

and you can translate it to a PostScript file by typing

```
. translate myfile.smcl myfile.ps
```

`translate` translates files from one format to another, and, in fact, `print` uses `translate` to produce a file suitable for sending to the printer.

When you type

```
. translate a.b c.d
```

`translate` looks for the predefined translator `b2d` and uses that to perform the translation. If there is a `transmap` synonym for `b`, however, the mapped value `b'` is used: `b'2d`.

Only certain translators exist, and they are listed under the description of the `translate()` option in *Options for translate* above, or you can type

```
. translator query
```

for a complete (and perhaps more up-to-date) list.

Anyway, `translate` forms the name *b2d* or *b'2d*, and if the translator does not exist, `translate` issues an error message. With the `translator()` option, you can specify exactly which translator to use, and then it does not matter how your files are named.

The only other thing to know is that some translators have tunable parameters that affect how they perform their translation. You can type

```
. translator query translator_name
```

to find out what those parameters are. Some translators have no tunable parameters, and some have many:

```
. translator query smcl2ps
```

header	on		
headertext			
logo	on		
user			
projecttext			
cmdnumber	on		
fontsize	9	lmargin	1.00
pagesize	letter	rmargin	1.00
pagewidth	8.50	tmargin	1.00
pageheight	11.00	bmargin	1.00
scheme	monochrome		
cust1_result_color	0	0	0
cust1_standard_color	0	0	0
cust1_error_color	0	0	0
cust1_input_color	0	0	0
cust1_link_color	0	0	0
cust1_hilite_color	0	0	0
cust1_result_bold	on	cust2_result_bold	on
cust1_standard_bold	off	cust2_standard_bold	off
cust1_error_bold	on	cust2_error_bold	on
cust1_input_bold	off	cust2_input_bold	off
cust1_link_bold	off	cust2_link_bold	off
cust1_hilite_bold	on	cust2_hilite_bold	on
cust1_link_underline	on	cust2_link_underline	on
cust1_hilite_underline	off	cust2_hilite_underline	off

You can temporarily override any setting by specifying the *setopt(setval)* option on the `translate` (or `print`) command. For instance, you can type

```
. translate ..., ... cmdnumber(off)
```

or you can reset the value permanently by typing

```
. translator set smcl2ps setopt setval
```

For instance,

```
. translator set smcl2ps cmdnumber off
```

If you reset a value, Stata will remember the change, even in future sessions.

Mac and Windows users: The `smcl2ps` (and the other `*2ps` translators) are not used by `print`, even when you have a PostScript printer attached to your computer. Instead, the Mac or Windows print driver is used. Resetting `smcl2ps` values will not affect printing; instead, you change the defaults in the Printers Control Panel in Windows and by selecting **Page Setup...** from the **File** menu in Mac. You can, however, `translate` files yourself using the `smcl2ps` translator and the other `*2ps` translators.

□ Technical note: Using PDF translators (Windows and Unix)

When using `translate` to translate a log, SMCL, or text file or a Stata graph into a PDF file, some characters may not display correctly in the resulting PDF file. This happens when translating content that contains Unicode characters from different languages; one font may not be adequate to display every character used. If an appropriate font is not available for a character, that character will not display correctly in the resulting PDF file.

Specific fonts can be used to build a font chain. Those fonts are specified using *fontname* and are separated by commas. The most preferred font should be listed first, followed by the less preferred fonts. A maximum of 16 fonts can be specified. Stata will inspect each character in the original content, and if a glyph for the corresponding character is not available in the default font, then each font in the font chain will be checked until a font is found to display that character.

You can set fonts in the font chain by specifying `addfonts` for each PDF translator as follows:

```
. translator set tname addfonts fontname
```

Here *tname* is the name of a PDF translator, which can be `smcl2pdf`, `log2pdf`, `txt2pdf`, `Results2pdf`, `Viewer2pdf`, or `Graph2pdf`. See the `translator()` option under *Options for translate*.

Stata has the ability to select a font automatically if the default font and the fonts in the font chain do not contain a glyph for the character. Automatic font selection can be controlled using the following:

```
. translator set tname autofont on|off
```

By default, `autofont` is on. Unix (console) users will need to set the font directories so the fonts can be found.

PDF files accept Base 14 fonts, Type 1 fonts (.pfa or .pfb), TrueType fonts (.ttf or .ttc), and OpenType fonts (.otf). If *fontname* refers to a TrueType font, an OpenType font, or a Type 1 font, the corresponding TrueType, OpenType, or Type 1 font file will be searched for within the default font directory. Unix (console) users can type

```
. translator set iname fontdir fontdirectory
```

to set the default font directory. *fontdirectory* can contain multiple font directories separated by semi-colons. If the specified TrueType, OpenType, or Type 1 font cannot be found under the current font directory, an error message will be issued.

Stored results

`transmap query .ext` stores in macro `r(suffix)` the mapped extension (without the leading period) or stores *ext* if the *ext* is not mapped.

`translator query translatorname` stores *setval* in macro `r(setopt)` for every *setopt*, *setval* pair.

`printer query prntername` (Unix only) stores in macro `r(suffix)` the “filetype” of the input that the printer expects (currently “ps” or “txt”) and, in macro `r(command)`, the command to send output to the printer.

Description

`truncreg` fits a regression model of *depvar* on *indepvars* from a sample drawn from a restricted part of the population. Under the normality assumption for the whole population, the error terms in the truncated regression model have a truncated normal distribution, which is a normal distribution that has been scaled upward so that the distribution integrates to one over the restricted range.

Quick start

Truncated regression of `y` on `x1` and `x2` truncated below 16

```
truncreg y x1 x2, ll(16)
```

Specify that `y` is truncated above 35

```
truncreg y x1 x2, ul(35)
```

With `y` truncated below 17 and above 35

```
truncreg y x1 x2, ll(17) ul(35)
```

Specify a lower truncation point that varies across observations using the variable `trunc`

```
truncreg y x1 x2, ll(trunc)
```

Same as above, but with bootstrap standard errors using 200 replications

```
truncreg y x1 x2, ll(trunc) vce(bootstrap, reps(200))
```

See last estimates with legend of coefficient names instead of statistics

```
truncreg, coeflegend
```

Menu

Statistics > Linear models and related > Truncated regression

Syntax

```
truncreg deprvar [indeprvars] [if] [in] [weight] [, options]
```

<i>options</i>	Description
Model	
<code>noconstant</code>	suppress constant term
<code>ll(<i>varname</i> #)</code>	left-truncation variable or limit
<code>ul(<i>varname</i> #)</code>	right-truncation variable or limit
<code>offset(<i>varname</i>)</code>	include <i>varname</i> in model with coefficient constrained to 1
<code>constraints(<i>constraints</i>)</code>	apply specified linear constraints
SE/Robust	
<code>vce(<i>vcetype</i>)</code>	<i>vcetype</i> may be <code>oim</code> , <code>robust</code> , <code>cluster <i>clustvar</i></code> , <code>opg</code> , <code>bootstrap</code> , or <code>jackknife</code>
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>lrmodel</code>	perform the likelihood-ratio model test instead of the default Wald test
<code>nocnsreport</code>	do not display constraints
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<code>maximize_options</code>	control the maximization process; seldom used
<code>collinear</code>	keep collinear variables
<code>coeflegend</code>	display legend instead of statistics
<p><i>indeprvars</i> may contain factor variables; see [U] 11.4.3 Factor variables.</p> <p><i>deprvar</i> and <i>indeprvars</i> may contain time-series operators; see [U] 11.4.4 Time-series varlists.</p> <p><code>bayes</code>, <code>bootstrap</code>, <code>by</code>, <code>collect</code>, <code>fmm</code>, <code>fp</code>, <code>jackknife</code>, <code>mi estimate</code>, <code>rolling</code>, <code>statsby</code>, and <code>svy</code> are allowed; see [U] 11.1.10 Prefix commands. Options

Model

`noconstant`; see [R] [Estimation options](#).

`ll(varname | #)` and `ul(varname | #)` indicate the lower and upper limits for truncation, respectively. You may specify one or both. Observations with `depvar ≤ ll()` are left-truncated, observations with `depvar ≥ ul()` are right-truncated, and the remaining observations are not truncated. See [R] [tobit](#) for a more detailed description.

`offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce_option](#).

Reporting

`level(#)`, `lrmodel`, `nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `nopvalues`, `noomit`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used, but you may use the `ltol(#)` option to relax the convergence criterion; the default is $1e-6$ during specification searches.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `truncreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

Remarks and examples

Truncated regression fits a model of a dependent variable on independent variables from a restricted part of a population. Truncation is essentially a characteristic of the distribution from which the sample data are drawn. If x has a normal distribution with mean μ and standard deviation σ , the density of the truncated normal distribution is

$$\begin{aligned} f(x \mid a < x < b) &= \frac{f(x)}{\Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)} \\ &= \frac{\frac{1}{\sigma}\phi\left(\frac{x-\mu}{\sigma}\right)}{\Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)} \end{aligned}$$

where ϕ and Φ are the density and distribution functions of the standard normal distribution.

Compared with the mean of the untruncated variable, the mean of the truncated variable is greater if the truncation is from below, and the mean of the truncated variable is smaller if the truncation is from above. Moreover, truncation reduces the variance compared with the variance in the untruncated distribution.

► Example 1

We will demonstrate `truncreg` with part of the Mroz dataset distributed with [Berndt \(1996\)](#). This dataset contains 753 observations on women's labor supply. Our subsample is of 250 observations, with 150 market laborers and 100 nonmarket laborers.

```
. use https://www.stata-press.com/data/r19/laborsub
. describe
```

Contains data from https://www.stata-press.com/data/r19/laborsub.dta

Observations:	250	
Variables:	6	25 Sep 2024 18:36

Variable name	Storage type	Display format	Value label	Variable label
lfp	byte	%9.0g		1 if woman worked in 1975
whrs	int	%9.0g		Wife's hours of work
kl6	byte	%9.0g		# of children younger than 6
k618	byte	%9.0g		# of children between 6 and 18

□ Technical note

Whether truncated regression is more appropriate than the ordinary least-squares estimation depends on the purpose of that estimation. If we are interested in the mean of wife's working hours conditional on the subsample of market laborers, least-squares estimation is appropriate. However if we are interested in the mean of wife's working hours regardless of market or nonmarket labor status, least-squares estimates could be seriously misleading.

Truncation and censoring are different concepts. A sample has been censored if no observations have been systematically excluded but some of the information contained in them has been suppressed. In a truncated distribution, only the part of the distribution above (or below, or between) the truncation points is relevant to our computations. We need to scale it up by the probability that an observation falls in the range that interests us to make the distribution integrate to one. The censored distribution used by tobit, however, is a mixture of discrete and continuous distributions. Instead of rescaling over the observable range, we simply assign the full probability from the censored regions to the censoring points. The truncated regression model is sometimes less well behaved than the tobit model. [Davidson and MacKinnon \(1993\)](#) provide an example where truncation results in more inconsistency than censoring. □

Stored results

`truncreg` stores the following in `e()`:

Scalars

<code>e(N)</code>	number of observations
<code>e(N_bf)</code>	number of observations before truncation
<code>e(chi2)</code>	model χ^2
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(N_clust)</code>	number of clusters
<code>e(sigma)</code>	estimate of sigma
<code>e(p)</code>	p -value for model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise

Macros

<code>e(cmd)</code>	<code>truncreg</code>
<code>e(cmdline)</code>	command as typed
<code>e(llopt)</code>	contents of <code>ll()</code> , if specified
<code>e(ulopt)</code>	contents of <code>ul()</code> , if specified
<code>e(depvar)</code>	name of dependent variable
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression
<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset1)</code>	offset
<code>e(chi2type)</code>	Wald or LR; type of model χ^2 test
<code>e(vce)</code>	<code>vcetype</code> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of <code>ml</code> method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	<code>b V</code>
<code>e(predict)</code>	program used to implement <code>predict</code>
<code>e(marginsok)</code>	predictions allowed by <code>margins</code>
<code>e(asbalanced)</code>	factor variables <code>fvset</code> as <code>asbalanced</code>
<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

Matrices	
e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance
e(means)	means of independent variables
e(dummy)	indicator for dummy variables
Functions	
e(sample)	marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices	
r(table)	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

Greene (2018, 918–924) and Davidson and MacKinnon (1993, 534–537) provide introductions to the truncated regression model.

Let $\mathbf{y} = \mathbf{X}\beta + \epsilon$ be the model. \mathbf{y} represents continuous outcomes either observed or not observed. Our model assumes that $\epsilon \sim N(\mathbf{0}, \sigma^2 \mathbf{I})$.

Let a be the lower limit and b be the upper limit. The log likelihood is

$$\ln L = -\frac{n}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \sum_{j=1}^n (y_j - \mathbf{x}_j\beta)^2 - \sum_{j=1}^n \log \left\{ \Phi\left(\frac{b - \mathbf{x}_j\beta}{\sigma}\right) - \Phi\left(\frac{a - \mathbf{x}_j\beta}{\sigma}\right) \right\}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`truncreg` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

Postestimation commands

The following postestimation commands are available after `truncreg`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	linear, censored, and truncated predictions
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset ]
```

```
predict [type] stub* [if] [in] , scores
```

statistic	Description
Main	
xb	linear prediction; the default
stdp	standard error of the prediction
stdf	standard error of the forecast
pr(<i>a</i> , <i>b</i>)	$\Pr(a < y_j < b)$
e(<i>a</i> , <i>b</i>)	$E(y_j a < y_j < b)$
ystar(<i>a</i> , <i>b</i>)	$E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

stdf is not allowed with svy estimation results.

where *a* and *b* may be numbers or variables; *a* missing (*a* ≥ .) means $-\infty$, and *b* missing (*b* ≥ .) means $+\infty$; see [U] 12.2.1 Missing values.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see [Methods and formulas in \[R\] regress postestimation](#).

`pr(a,b)` calculates $\Pr(a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the probability that $y_j|\mathbf{x}_j$ would be observed in the interval (a, b) .

a and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;

`pr(20,30)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < 30)$;

`pr(lb,ub)` calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < ub)$; and

`pr(20,ub)` calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$.

a missing (*a* ≥ .) means $-\infty$; `pr(.,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$;

`pr(lb,30)` calculates $\Pr(-\infty < \mathbf{x}_j\mathbf{b} + u_j < 30)$ in observations for which *lb* ≥ .

and calculates $\Pr(lb < \mathbf{x}_j\mathbf{b} + u_j < 30)$ elsewhere.

b missing (*b* ≥ .) means $+\infty$; `pr(20,.)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$;

`pr(20,ub)` calculates $\Pr(+\infty > \mathbf{x}_j\mathbf{b} + u_j > 20)$ in observations for which *ub* ≥ .

and calculates $\Pr(20 < \mathbf{x}_j\mathbf{b} + u_j < ub)$ elsewhere.

`e(a,b)` calculates $E(\mathbf{x}_j\mathbf{b} + u_j \mid a < \mathbf{x}_j\mathbf{b} + u_j < b)$, the expected value of $y_j|\mathbf{x}_j$ conditional on $y_j|\mathbf{x}_j$ being in the interval (a, b) , meaning that $y_j|\mathbf{x}_j$ is truncated.

a and *b* are specified as they are for `pr()`.

`ystar(a,b)` calculates $E(y_j^*)$, where $y_j^* = a$ if $\mathbf{x}_j\mathbf{b} + u_j \leq a$, $y_j^* = b$ if $\mathbf{x}_j\mathbf{b} + u_j \geq b$, and $y_j^* = \mathbf{x}_j\mathbf{b} + u_j$ otherwise, meaning that y_j^* is censored. *a* and *b* are specified as they are for `pr()`.

`nooffset` is relevant only if you specified `offset(varname)`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $\mathbf{x}_j\mathbf{b}$ rather than as $\mathbf{x}_j\mathbf{b} + \text{offset}_j$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (\mathbf{x}_j\boldsymbol{\beta})$.

The second new variable will contain $\partial \ln L / \partial \sigma$.

margins

Description for margins

margins estimates margins of response for linear predictions, probabilities, and expected values.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]  
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

statistic	Description
xb	linear prediction; the default
pr(a,b)	$\Pr(a < y_j < b)$
e(a,b)	$E(y_j a < y_j < b)$
ystar(a,b)	$E(y_j^*, y_j^* = \max\{a, \min(y_j, b)\})$
stdp	not allowed with margins
stdf	not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

Description

`ttest` performs *t* tests on the equality of means. The test can be performed for one sample against a hypothesized population mean. Two-sample tests can be conducted for paired and unpaired data. The assumption of equal variances can be optionally relaxed in the unpaired two-sample case.

`ttesti` is the immediate form of `ttest`; see [\[U\] 19 Immediate commands](#).

Quick start

Test that the mean of `v1` is equal between two groups defined by `catvar`

```
ttest v1, by(catvar)
```

Same as above, but assume unequal variances

```
ttest v1, by(catvar) unequal
```

Paired *t* test of `v2` and `v3`

```
ttest v2 == v3
```

Same as above, but with unpaired data and conduct test separately for each level of `catvar`

```
by catvar: ttest v2 == v3, unpaired
```

Test that the mean of `v4` is 3 at the 90% confidence level

```
ttest v4 == 3, level(90)
```

Test $\mu_1 = \mu_2$ if $\bar{x}_1 = 3.2$, $sd_1 = 0.1$, $\bar{x}_2 = 3.4$, and $sd_2 = 0.15$ with $n_1 = n_2 = 12$

```
ttesti 12 3.2 .1 12 3.4 .15
```

Menu

`ttest`

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > t test (mean-comparison test)

`ttesti`

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > t test calculator

Syntax

One-sample *t* test

```
ttest varname == # [if] [in] [ , level(#) ]
```

Two-sample *t* test using groups

```
ttest varname [if] [in] , by(groupvar) [options1 ]
```

Two-sample *t* test using variables

```
ttest varname1 == varname2 [if] [in] , unpaired [unequal welch level(#) ]
```

Paired *t* test

```
ttest varname1 == varname2 [if] [in] [ , level(#) ]
```

Immediate form of one-sample *t* test

```
ttesti #obs #mean #sd #val [ , level(#) ]
```

Immediate form of two-sample *t* test

```
ttesti #obs1 #mean1 #sd1 #obs2 #mean2 #sd2 [ , options2 ]
```

options ₁	Description
Main	
* by(<i>groupvar</i>)	variable defining the groups
reverse	reverse group order for mean difference computation
unequal	unpaired data have unequal variances
welch	use Welch's approximation
level(#)	set confidence level; default is level(95)

*by(*groupvar*) is required.

options ₂	Description
Main	
unequal	unpaired data have unequal variances
welch	use Welch's approximation
level(#)	set confidence level; default is level(95)

by and collect are allowed with ttest and ttesti; see [U] 11.1.10 Prefix commands.

Options

Main

`by(groupvar)` specifies the *groupvar* that defines the two groups that `ttest` will use to test the hypothesis that their means are equal. Specifying `by(groupvar)` implies an unpaired (two sample) *t* test. Do not confuse the `by()` option with the `by` prefix; you can specify both.

`reverse` reverses the order of the mean difference between groups defined in `by()`. By default, the mean of the group corresponding to the largest value in the variable in `by()` is subtracted from the mean of the group with the smallest value in `by()`. `reverse` reverses this behavior and the order in which variables appear on the table.

`unpaired` specifies that the data be treated as unpaired. The `unpaired` option is used when the two sets of values to be compared are in different variables.

`unequal` specifies that the unpaired data not be assumed to have equal variances.

`welch` specifies that the approximate degrees of freedom for the test be obtained from Welch's formula (1947) rather than from Satterthwaite's approximation formula (1946), which is the default when `unequal` is specified. Specifying `welch` implies `unequal`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

Remarks and examples

Remarks are presented under the following headings:

[One-sample *t* test](#)

[Two-sample *t* test](#)

[Paired *t* test](#)

[Two-sample *t* test compared with one-way ANOVA](#)

[Immediate form](#)

[Video examples](#)

One-sample *t* test

► Example 1

In the first form, `ttest` tests whether the mean of the sample is equal to a known constant under the assumption of unknown variance. Assume that we have a sample of 74 automobiles. We know each automobile's average mileage rating and wish to test whether the overall average for the sample is 20 miles per gallon.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
```

```
. ttest mpg==20
```

```
One-sample t test
```

Variable	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
mpg	74	21.2973	.6725511	5.785503	19.9569	22.63769

```

      mean = mean(mpg)                                t = 1.9289
HO: mean = 20                                Degrees of freedom = 73
      Ha: mean < 20                                Ha: mean != 20                                Ha: mean > 20
Pr(T < t) = 0.9712                                Pr(|T| > |t|) = 0.0576                                Pr(T > t) = 0.0288

```

The test indicates that the underlying mean is not 20 with a significance level of 5.8%.

Two-sample t test

► Example 2: Two-sample *t* test using groups

We are testing the effectiveness of a new fuel additive. We run an experiment in which 12 cars are given the fuel treatment and 12 cars are not. The results of the experiment are as follows:

treated	mpg
0	20
0	23
0	21
0	25
0	18
0	17
0	18
0	24
0	20
0	24
0	23
0	19
1	24
1	25
1	21
1	22
1	23
1	18
1	17
1	28
1	24
1	27
1	21
1	23

The treated variable is coded as 1 if the car received the fuel treatment and 0 otherwise.

We can test the equality of means of the treated and untreated group by typing

```
. use https://www.stata.press.com/data/r19/fuel3
. ttest mpg, by(treated)
```

Two-sample t test with equal variances

Group	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
0	12	21	.7881701	2.730301	19.26525	22.73475
1	12	22.75	.9384465	3.250874	20.68449	24.81551
Combined	24	21.875	.6264476	3.068954	20.57909	23.17091
diff		-1.75	1.225518		-4.291568	.7915684

```
diff = mean(0) - mean(1)                                t = -1.4280
HO: diff = 0                                             Degrees of freedom = 22
Ha: diff < 0                                           Ha: diff != 0           Ha: diff > 0
Pr(T < t) = 0.0837      Pr(|T| > |t|) = 0.1673      Pr(T > t) = 0.9163
```

We do not find a statistically significant difference in the means.

If we were not willing to assume that the variances were equal and wanted to use Welch’s formula, we could type

```
. ttest mpg, by(treated) welch
Two-sample t test with unequal variances
```

Group	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
0	12	21	.7881701	2.730301	19.26525	22.73475
1	12	22.75	.9384465	3.250874	20.68449	24.81551
Combined	24	21.875	.6264476	3.068954	20.57909	23.17091
diff		-1.75	1.225518		-4.28369	.7836902

```
diff = mean(0) - mean(1)                                t = -1.4280
HO: diff = 0                                           Welch's degrees of freedom = 23.2465
Ha: diff < 0                                           Ha: diff != 0           Ha: diff > 0
Pr(T < t) = 0.0833      Pr(|T| > |t|) = 0.1666      Pr(T > t) = 0.9167
```

□ Technical note

In two-sample randomized designs, subjects will sometimes refuse the assigned treatment but still be measured for an outcome. In this case, take care to specify the group properly. You might be tempted to let *varname* contain missing where the subject refused and thus let *ttest* drop such observations from the analysis. [Zelen \(1979\)](#) argues that it would be better to specify that the subject belongs to the group in which he or she was randomized, even though such inclusion will dilute the measured effect.

► Example 3: Two-sample *t* test using variables

There is a second, inferior way to organize the data in the preceding example. We ran a test on 24 cars, 12 without the additive and 12 with. We now create two new variables, mpg1 and mpg2.

mpg1	mpg2
20	24
23	25
21	21
25	22
18	23
17	18
18	17
24	28
20	24
24	27
23	21
19	23

This method is inferior because it suggests a connection that is not there. There is no link between the car with 20 mpg and the car with 24 mpg in the first row of the data. Each column of data could be arranged in any order. Nevertheless, if our data are organized like this, ttest can accommodate us.

```
. use https://www.stata-press.com/data/r19/fuel
. ttest mpg1==mpg2, unpaired
```

Two-sample t test with equal variances

Variable	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
mpg1	12	21	.7881701	2.730301	19.26525	22.73475
mpg2	12	22.75	.9384465	3.250874	20.68449	24.81551
Combined	24	21.875	.6264476	3.068954	20.57909	23.17091
diff		-1.75	1.225518		-4.291568	.7915684

```
diff = mean(mpg1) - mean(mpg2)                                t = -1.4280
HO: diff = 0                                                    Degrees of freedom = 22
Ha: diff < 0                                                    Ha: diff != 0
Pr(T < t) = 0.0837                                              Pr(|T| > |t|) = 0.1673
                                                                Ha: diff > 0
                                                                Pr(T > t) = 0.9163
```

Paired t test

▷ Example 4

Suppose that the preceding data were actually collected by running a test on 12 cars. Each car was run once with the fuel additive and once without. Our data are stored in the same manner as in [example 3](#), but this time, there is most certainly a connection between the mpg values that appear in the same row. These come from the same car. The variables mpg1 and mpg2 represent mileage without and with the treatment, respectively.

```
. use https://www.stata-press.com/data/r19/fuel
. ttest mpg1==mpg2
Paired t test
```

Variable	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
mpg1	12	21	.7881701	2.730301	19.26525	22.73475
mpg2	12	22.75	.9384465	3.250874	20.68449	24.81551
diff	12	-1.75	.7797144	2.70101	-3.46614	-.0338602

```
mean(diff) = mean(mpg1 - mpg2) t = -2.2444
H0: mean(diff) = 0 Degrees of freedom = 11
Ha: mean(diff) < 0 Ha: mean(diff) != 0 Ha: mean(diff) > 0
Pr(T < t) = 0.0232 Pr(|T| > |t|) = 0.0463 Pr(T > t) = 0.9768
```

We find that the means are statistically different from each other at any level greater than 4.6%.

Two-sample t test compared with one-way ANOVA

▷ Example 5

In [example 2](#), we saw that ttest can be used to test the equality of a pair of means; see [\[R\] oneway](#) for an extension that allows testing the equality of more than two means.

Suppose that we have data on the 50 states. The dataset contains the median age of the population (medage) and the region of the country (region) for each state. Region 1 refers to the Northeast, region 2 to the North Central, region 3 to the South, and region 4 to the West. Using oneway, we can test the equality of all four means.

```
. use https://www.stata-press.com/data/r19/census
(1980 Census data by state)
. oneway medage region
```

Source	SS	df	MS	F	Prob > F
Between groups	46.3961903	3	15.4653968	7.56	0.0003
Within groups	94.1237947	46	2.04616945		
Total	140.519985	49	2.8677548		

```
Bartlett's equal-variances test: chi2(3) = 10.5757 Prob>chi2 = 0.014
```

We find that the means are different, but we are interested only in testing whether the means for the Northeast (region==1) and West (region==4) are different. We could use oneway:

```
. oneway medage region if region==1 | region==4
```

Source	Analysis of variance			F	Prob > F
	SS	df	MS		
Between groups	46.241247	1	46.241247	20.02	0.0002
Within groups	46.1969169	20	2.30984584		
Total	92.4381638	21	4.40181733		

Bartlett's equal-variances test: chi2(1) = 2.4679 Prob>chi2 = 0.116

We could also use ttest:

```
. ttest medage if region==1 | region==4, by(region)
```

Two-sample t test with equal variances

Group	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
NE	9	31.23333	.3411581	1.023474	30.44662	32.02005
West	13	28.28462	.4923577	1.775221	27.21186	29.35737
Combined	22	29.49091	.4473059	2.098051	28.56069	30.42113
diff		2.948718	.6590372		1.57399	4.323445

diff = mean(NE) - mean(West) t = 4.4743
H0: diff = 0 Degrees of freedom = 20
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(T < t) = 0.9999 Pr(|T| > |t|) = 0.0002 Pr(T > t) = 0.0001

The significance levels of both tests are the same.

Immediate form

➤ Example 6

ttesti is like ttest, except that we specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the mean number of sunspots per month as 62.6 with a standard deviation of 15.8. There are 24 months of data. We wish to test whether the mean is 75:

```
. ttesti 24 62.6 15.8 75
```

One-sample t test

	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
x	24	62.6	3.225161	15.8	55.92825	69.27175

mean = mean(x) t = -3.8448
H0: mean = 75 Degrees of freedom = 23
Ha: mean < 75 Ha: mean != 75 Ha: mean > 75
Pr(T < t) = 0.0004 Pr(|T| > |t|) = 0.0008 Pr(T > t) = 0.9996

► Example 7

There is no immediate form of `ttest` with paired data because the test is also a function of the covariance, a number unlikely to be reported in any published source. For unpaired data, however, we might type

```
. ttesti 20 20 5 32 15 4
Two-sample t test with equal variances
```

	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
x	20	20	1.118034	5	17.65993	22.34007
y	32	15	.7071068	4	13.55785	16.44215
Combined	52	16.92308	.6943785	5.007235	15.52905	18.3171
diff		5	1.256135		2.476979	7.523021

```
diff = mean(x) - mean(y)
H0: diff = 0
Ha: diff < 0
Pr(T < t) = 0.9999
```

`t = 3.9805`
Degrees of freedom = 50
`Ha: diff != 0`
`Pr(|T| > |t|) = 0.0002`
`Ha: diff > 0`
`Pr(T > t) = 0.0001`

If we had typed `ttesti 20 20 5 32 15 4, unequal`, the test would have assumed unequal variances. ◀

Stored results

One-sample `ttest` and `ttesti` store the following in `r()`:

Scalars	
<code>r(N_1)</code>	sample size
<code>r(mu_1)</code>	sample mean
<code>r(sd_1)</code>	standard deviation
<code>r(se)</code>	standard error
<code>r(lb_1)</code>	lower confidence bound for the mean
<code>r(ub_1)</code>	upper confidence bound for the mean
<code>r(t)</code>	<i>t</i> statistic
<code>r(df_t)</code>	degrees of freedom
<code>r(p_l)</code>	lower one-sided <i>p</i> -value
<code>r(p)</code>	two-sided <i>p</i> -value
<code>r(p_u)</code>	upper one-sided <i>p</i> -value
<code>r(level)</code>	confidence level

Two-sample `ttest` and `ttest1` store the following in `r()`:

Scalars

<code>r(N_1)</code>	sample size n_1
<code>r(N_2)</code>	sample size n_2
<code>r(N_combined)</code>	combined sample size
<code>r(mu_1)</code>	estimated mean for sample 1
<code>r(mu_2)</code>	estimated mean for sample 2
<code>r(mu_combined)</code>	combined sample mean
<code>r(mu_diff)</code>	difference of means
<code>r(sd_1)</code>	standard deviation for sample 1
<code>r(sd_2)</code>	standard deviation for sample 2
<code>r(sd)</code>	combined standard deviation
<code>r(se)</code>	standard error
<code>r(se_1)</code>	standard error of the mean for sample 1
<code>r(se_2)</code>	standard error of the mean for sample 2
<code>r(se_combined)</code>	standard error of combined sample mean
<code>r(lb_1)</code>	lower confidence bound for the mean for sample 1
<code>r(ub_1)</code>	upper confidence bound for the mean for sample 1
<code>r(lb_2)</code>	lower confidence bound for the mean for sample 2
<code>r(ub_2)</code>	upper confidence bound for the mean for sample 2
<code>r(lb_combined)</code>	lower confidence bound for combined sample mean
<code>r(ub_combined)</code>	upper confidence bound for combined sample mean
<code>r(lb_diff)</code>	lower confidence bound for the difference of means
<code>r(ub_diff)</code>	upper confidence bound for the difference of means
<code>r(t)</code>	<i>t</i> statistic
<code>r(df_t)</code>	degrees of freedom
<code>r(p_l)</code>	lower one-sided <i>p</i> -value
<code>r(p)</code>	two-sided <i>p</i> -value
<code>r(p_u)</code>	upper one-sided <i>p</i> -value
<code>r(level)</code>	confidence level

Paired-sample `ttest` stores the following in `r()`:

Scalars

<code>r(N_1)</code>	sample size n_1
<code>r(N_2)</code>	sample size n_2
<code>r(mu_1)</code>	estimated mean for first variable
<code>r(mu_2)</code>	estimated mean for second variable
<code>r(mu_diff)</code>	difference of means
<code>r(sd_1)</code>	standard deviation for first variable
<code>r(sd_2)</code>	standard deviation for second variable
<code>r(sd_diff)</code>	standard deviation of the paired differences
<code>r(se)</code>	standard error
<code>r(se_1)</code>	standard error of the mean for the first variable
<code>r(se_2)</code>	standard error of the mean for the second variable
<code>r(lb_1)</code>	lower confidence bound for the mean of the first variable
<code>r(ub_1)</code>	upper confidence bound for the mean of the first variable
<code>r(lb_2)</code>	lower confidence bound for the mean of the second variable
<code>r(ub_2)</code>	upper confidence bound for the mean of the second variable
<code>r(lb_diff)</code>	lower confidence bound for the difference of means
<code>r(ub_diff)</code>	upper confidence bound for the difference of means
<code>r(t)</code>	<i>t</i> statistic
<code>r(df_t)</code>	degrees of freedom
<code>r(p_l)</code>	lower one-sided <i>p</i> -value
<code>r(p)</code>	two-sided <i>p</i> -value
<code>r(p_u)</code>	upper one-sided <i>p</i> -value
<code>r(level)</code>	confidence level

Methods and formulas

See, for instance, [Hoel \(1984, 140–161\)](#) or [Dixon and Massey \(1983, 121–130\)](#) for an introduction and explanation of the calculation of these tests. [Accock \(2023, 165–179\)](#) and [Hamilton \(2013, 145–150\)](#) describe *t* tests using applications in Stata.

The test for $\mu = \mu_0$ for unknown σ is given by

$$t = \frac{(\bar{x} - \mu_0)\sqrt{n}}{s}$$

The statistic is distributed as Student's *t* with $n - 1$ degrees of freedom ([Gosset \[Student, pseud.\] 1908](#)).

The test for $\mu_x = \mu_y$ when σ_x and σ_y are unknown but $\sigma_x = \sigma_y$ is given by

$$t = \frac{\bar{x} - \bar{y}}{\left\{ \frac{(n_x - 1)s_x^2 + (n_y - 1)s_y^2}{n_x + n_y - 2} \right\}^{1/2} \left(\frac{1}{n_x} + \frac{1}{n_y} \right)^{1/2}}$$

The result is distributed as Student's *t* with $n_x + n_y - 2$ degrees of freedom.

You could perform `ttest` (without the `unequal` option) in a regression setting given that regression assumes a homoskedastic error model. To compare with the `ttest` command, denote the underlying observations on *x* and *y* by $x_j, j = 1, \dots, n_x$, and $y_j, j = 1, \dots, n_y$. In a regression framework, typing `ttest` without the `unequal` option is equivalent to

1. creating a new variable z_j that represents the stacked observations on *x* and *y* (so that $z_j = x_j$ for $j = 1, \dots, n_x$ and $z_{n_x+j} = y_j$ for $j = 1, \dots, n_y$)
2. and then estimating the equation $z_j = \beta_0 + \beta_1 d_j + \epsilon_j$, where $d_j = 0$ for $j = 1, \dots, n_x$ and $d_j = 1$ for $j = n_x + 1, \dots, n_x + n_y$ (that is, $d_j = 0$ when the *z* observations represent *x*, and $d_j = 1$ when the *z* observations represent *y*).

The estimated value of β_1, b_1 , will equal $\bar{y} - \bar{x}$, and the reported *t* statistic will be the same *t* statistic as given by the formula above.

The test for $\mu_x = \mu_y$ when σ_x and σ_y are unknown and $\sigma_x \neq \sigma_y$ is given by

$$t = \frac{\bar{x} - \bar{y}}{\left(s_x^2/n_x + s_y^2/n_y \right)^{1/2}}$$

The result is distributed as Student's *t* with ν degrees of freedom, where ν is given by (with Satterthwaite's [1946] formula)

$$\frac{\left(s_x^2/n_x + s_y^2/n_y \right)^2}{\frac{\left(s_x^2/n_x \right)^2}{n_x - 1} + \frac{\left(s_y^2/n_y \right)^2}{n_y - 1}}$$

With Welch’s formula (1947), the number of degrees of freedom is given by

$$-2 + \frac{\left(s_x^2/n_x + s_y^2/n_y\right)^2}{\frac{\left(s_x^2/n_x\right)^2}{n_x+1} + \frac{\left(s_y^2/n_y\right)^2}{n_y+1}}$$

The test for $\mu_x = \mu_y$ for matched observations (also known as paired observations, correlated pairs, or permanent components) is given by

$$t = \frac{\bar{d}\sqrt{n}}{s_d}$$

where \bar{d} represents the mean of $x_i - y_i$ and s_d represents the standard deviation. The test statistic t is distributed as Student’s t with $n - 1$ degrees of freedom.

You can also use `ttest` without the `unpaired` option in a regression setting because a paired comparison includes the assumption of constant variance. The `ttest` with an unequal variance assumption does not lend itself to an easy representation in regression settings and is not discussed here.

$$(x_j - y_j) = \beta_0 + \epsilon_j.$$

William Sealy Gosset (1876–1937) was born in Canterbury, England. He studied chemistry and mathematics at Oxford and worked as a chemist with the brewers Guinness in Dublin. Gosset became interested in statistical problems, which he discussed with Karl Pearson and later with Fisher and Neyman. He published several important papers under the pseudonym “Student”, and he lent that name to the t test he invented.

Stella Cunliffe (1917–2012) was an advocate for increased understanding of the role of human nature in experiments and methodological rigor in social statistics. She was born in Battersea, England. She was the first person from her local public girls’ school to attend college, obtaining a bachelor of science from the London School of Economics. Her first job was with the Danish Bacon Company during World War II, where she was in charge of bacon rations for London. After the war, she moved to Germany and again helped to ration food, this time for refugees.

She then spent a long career in quality control at the Guinness Brewing Company. Cunliffe observed that the weights of rejected casks skewed lighter. Noting that workers had to roll casks that were too light or too heavy uphill to be remade, she had the scales moved to the top of the hill. With workers able to roll rejected casks downhill, the weight of these casks began to follow a normal distribution.

After 25 years at Guinness, Cunliffe joined the British Home Office, where she would go on to become the first woman to serve as director of statistics. During her tenure at the Home Office, she emphasized applying principles of experimental design she had learned at Guinness to the study of such topics as birthrates, recidivism, and criminology. In 1975, she became the first woman to serve as president of the Royal Statistical Society.

Description

The `update` command reports on the current update level and installs official updates. Official updates are updates to Stata as it was originally shipped from StataCorp, not the additions to Stata published in, for instance, the *Stata Journal* (SJ). Those additions are installed using the `net` command and updated using the `ado update` command; see [\[R\] net](#) and [\[R\] ado update](#).

`update` without arguments reports on the update level of the currently installed Stata.

`update from` sets an update source, which may be a directory name or URL. If you are on the internet, type `update from https://www.stata.com`.

`update query` compares the update level of the currently installed Stata with that available from the update source and displays a report.

`update all` updates all necessary files. This is what you should type to check for and install updates.

`set update_query` determines if `update query` is to be automatically performed when Stata is launched. Only Mac and Windows platforms can be set for automatic updating.

`set update_interval #` sets the number of days to elapse before performing the next automatic update query. The default # is 7. The interval starts from the last time an update query was performed (automatically or manually). Only Mac and Windows platforms can be set for automatic updating.

`set update_prompt` determines whether a dialog is to be displayed before performing an automatic update query. The dialog allows you to perform an update query now, perform one the next time Stata is launched, perform one after the next interval has passed, or disable automatic update query. Only Mac and Windows platforms can be set for automatic updating.

Menu

Help > Check for updates

Syntax

Report on update level of currently installed Stata

```
update
```

Set update source

```
update from location
```

Compare update level of currently installed Stata with that of source

```
update query [ , from(location) ]
```

Perform update if necessary

```
update all [ , from(location) detail force exit ]
```

Set automatic updates (Mac and Windows only)

```
set update_query { on | off }
```

```
set update_interval #
```

```
set update_prompt { on | off }
```

Options

`from(location)` specifies the location of the update source. You can specify the `from()` option on the individual update commands or use the `update from` command. Which you do makes no difference. You typically do not need to use this option.

`detail` specifies to display verbose output during the update process.

`force` specifies to force downloading of all files even if, based on the date comparison, Stata does not think it is necessary. There is seldom a reason to specify this option.

`exit` instructs Stata to exit when the update has successfully completed. There is seldom a reason to specify this option.

Remarks and examples

`update` updates the official components of Stata from the official source: <https://www.stata.com>. If you are connected to the internet, the easy thing to do is to type

```
. update all
```

and follow the instructions. If Stata is up to date, `update all` will do nothing. Otherwise, it will download whatever is necessary and install the files. If you just want to know what updates are available, type

```
. update query
```

update query will check if any updates are available and report that information. If updates are available, it will recommend that you type `update all`.

If you want to report the current update level, type

```
. update
```

update will report the update level of the Stata installation. update will also show you the date that updates were last checked and if any updates were available at that time.

Stored results

update without a subcommand, update from, and update query store the following in `r()`:

Scalars

<code>r(inst_exe)</code>	date of executable installed (*)
<code>r(avbl_exe)</code>	date of executable available over web (*) (**)
<code>r(inst_ado)</code>	date of ado-files installed (*)
<code>r(avbl_ado)</code>	date of ado-files available over web (*) (**)
<code>r(inst_utilities)</code>	date of utilities installed (*)
<code>r(avbl_utilities)</code>	date of utilities available over web (*) (**)
<code>r(inst_docs)</code>	date of documentation installed (*)
<code>r(avbl_docs)</code>	date of documentation available over web (*) (**)

Macros

<code>r(name_exe)</code>	name of the Stata executable
<code>r(dir_exe)</code>	directory in which executable is stored
<code>r(dir_ado)</code>	directory in which ado-files are stored
<code>r(dir_utilities)</code>	directory in which utilities are stored
<code>r(dir_docs)</code>	directory in which PDF documentation is stored

Notes:

* Dates are stored as integers counting the number of days since January 1, 1960; see [\[D\] Datetime](#).

** These dates are not stored by update without a subcommand because update by itself reports information solely about the local computer and does not check what is available on the web.

Description

This entry describes the `vce()` option, which is common to most estimation commands. `vce()` specifies how to estimate the variance–covariance matrix (VCE) corresponding to the parameter estimates. The standard errors reported in the table of parameter estimates are the square root of the variances (diagonal elements) of the VCE.

Syntax

```
estimation_cmd ... [ , vce(vcetype) ... ]
```

vcetype	Description
Likelihood based	
<code>oim</code>	observed information matrix (OIM)
<code>opg</code>	outer product of the gradient (OPG) vectors
Sandwich estimators	
<code>robust</code>	Huber/White/sandwich estimator
<code>cluster clustvar</code>	clustered sandwich estimator
Replication based	
<code>bootstrap</code> [, bootstrap_options]	bootstrap estimation
<code>jackknife</code> [, jackknife_options]	jackknife estimation

Options

SE/Robust

`vce(oim)` is usually the default for models fit using maximum likelihood. `vce(oim)` uses the observed information matrix (OIM); see [\[R\] ml](#).

`vce(opg)` uses the sum of the outer product of the gradient (OPG) vectors; see [\[R\] ml](#). This is the default VCE when the `technique(bhhh)` option is specified; see [\[R\] Maximize](#).

`vce(robust)` uses the robust or sandwich estimator of variance. This estimator is robust to some types of misspecification so long as the observations are independent; see [\[U\] 20.22 Obtaining robust variance estimates](#).

If the command allows `pweights` and you specify them, `vce(robust)` is implied; see [\[U\] 20.24.3 Sampling weights](#).

`vce(cluster clustvar)` specifies that the standard errors allow for intragroup correlation, relaxing the usual requirement that the observations be independent. That is, the observations are independent across groups (clusters) but not necessarily within groups. *clustvar* specifies to which group each observation belongs, for example, `vce(cluster personid)` in data with repeated observations on individuals. `vce(cluster clustvar)` affects the standard errors and variance–covariance matrix of the estimators but not the estimated coefficients; see [U] 20.22 Obtaining robust variance estimates.

`vce(bootstrap [, bootstrap_options])` uses a bootstrap; see [R] bootstrap. After estimation with `vce(bootstrap)`, see [R] bootstrap postestimation to obtain percentile-based or bias-corrected confidence intervals.

`vce(jackknife [, jackknife_options])` uses the delete-one jackknife; see [R] jackknife.

Remarks and examples

Remarks are presented under the following headings:

- Prefix commands
- Passing options in `vce()`

Prefix commands

Specifying `vce(bootstrap)` or `vce(jackknife)` is often equivalent to using the corresponding prefix command. Here is an example using `jackknife` with `regress`.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)

. regress mpg turn trunk, vce(jackknife)
(running regress on estimation sample)

Jackknife replications (74): .....10.....20.....30.....40.....
> ..50.....60.....70.... done

Linear regression                               Number of obs =      74
Replications =      74
F(2, 73) = 66.26
Prob > F = 0.0000
R-squared = 0.5521
Adj R-squared = 0.5395
Root MSE = 3.9260
```

mpg	Coefficient	Jackknife std. err.	t	P> t	[95% conf. interval]	
turn	-.7610113	.150726	-5.05	0.000	-1.061408	-.4606147
trunk	-.3161825	.1282326	-2.47	0.016	-.5717498	-.0606152
_cons	55.82001	5.031107	11.09	0.000	45.79303	65.84699

```
. jackknife: regress mpg turn trunk
(running regress on estimation sample)
Jackknife replications (74): .....10.....20.....30.....40.....
> ..50.....60.....70.... done

Linear regression                                Number of obs =    74
                                                Replications   =    74
                                                F(2, 73)       =  66.26
                                                Prob > F       =  0.0000
                                                R-squared      =  0.5521
                                                Adj R-squared  =  0.5395
                                                Root MSE      =  3.9260
```

mpg	Jackknife		t	P> t	[95% conf. interval]	
	Coefficient	std. err.				
turn	-.7610113	.150726	-5.05	0.000	-1.061408	-.4606147
trunk	-.3161825	.1282326	-2.47	0.016	-.5717498	-.0606152
_cons	55.82001	5.031107	11.09	0.000	45.79303	65.84699

Here it does not matter whether we specify the `vce(jackknife)` option or instead use the `jackknife` prefix.

However, `vce(jackknife)` should be used in place of the `jackknife` prefix whenever available because they are not always equivalent. For example, to use the `jackknife` prefix with `clogit` properly, you must tell `jackknife` to omit whole groups rather than individual observations. Specifying `vce(jackknife)` does this automatically.

```
. use https://www.stata-press.com/data/r19/clogitid
. jackknife, cluster(id): clogit y x1 x2, group(id)
(output omitted)
```

This extra information is automatically communicated to `jackknife` by `clogit` when the `vce()` option is specified.

```
. clogit y x1 x2, group(id) vce(jackknife)
(running clogit on estimation sample)
Jackknife replications (66): .....10.....20.....30.....40.....
> ..50.....60..... done

Conditional (fixed-effects) logistic regression    Number of obs =   369
                                                Replications   =    66
                                                F(2, 65)       =   4.58
                                                Prob > F       =  0.0137
                                                Pseudo R2      =  0.0355

Log likelihood = -123.41386
(Replications based on 66 clusters in id)
```

y	Jackknife		t	P> t	[95% conf. interval]	
	Coefficient	std. err.				
x1	.653363	.3010608	2.17	0.034	.052103	1.254623
x2	.0659169	.0487858	1.35	0.181	-.0315151	.1633489

Passing options in vce()

If you wish to specify more options to the bootstrap or jackknife estimation, you can include them within the `vce()` option. Below, we request 300 bootstrap replications and save the replications in `bsreg.dta`:

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)

. regress mpg turn trunk, vce(bootstrap, nodots seed(123) rep(300) saving(bsreg))
Linear regression
```

Number of obs = 74

Replications = 300

Wald chi2(2) = 144.17

Prob > chi2 = 0.0000

R-squared = 0.5521

Adj R-squared = 0.5395

Root MSE = 3.9260

mpg	Observed coefficient	Bootstrap std. err.	z	P> z	Normal-based [95% conf. interval]	
turn	-.7610113	.1497877	-5.08	0.000	-1.05459	-.4674329
trunk	-.3161825	.1286802	-2.46	0.014	-.5683909	-.063974
_cons	55.82001	4.9221	11.34	0.000	46.17287	65.46715

```
. bstat using bsreg
Bootstrap results
```

Number of obs = 74

Replications = 300

Command: regress mpg turn trunk

	Observed coefficient	Bootstrap std. err.	z	P> z	Normal-based [95% conf. interval]	
turn	-.7610113	.1497877	-5.08	0.000	-1.05459	-.4674329
trunk	-.3161825	.1286802	-2.46	0.014	-.5683909	-.063974
_cons	55.82001	4.9221	11.34	0.000	46.17287	65.46715

Methods and formulas

By default, Stata’s maximum likelihood estimators display standard errors based on variance estimates given by the inverse of the negative Hessian (second derivative) matrix. If `vce(robust)`, `vce(cluster clustvar)`, or `pweights` is specified, standard errors are based on the robust variance estimator (see [\[U\] 20.22 Obtaining robust variance estimates](#)); likelihood-ratio tests are not appropriate here (see [\[SVY\] Survey](#)), and the model χ^2 is from a Wald test. If `vce(opg)` is specified, the standard errors are based on the outer product of the gradients; this option has no effect on likelihood-ratio tests, though it does affect Wald tests.

If `vce(bootstrap)` or `vce(jackknife)` is specified, the standard errors are based on the chosen replication method; here the model χ^2 or F statistic is from a Wald test using the respective replication-based covariance matrix. The t distribution is used in the coefficient table when the `vce(jackknife)` option is specified. `vce(bootstrap)` and `vce(jackknife)` are also available with some commands that are not maximum likelihood estimators.

Description

`view` displays file contents in the Viewer.

`view file` displays the specified file. `file` is optional, so if you had a SMCL session log created by typing `log using mylog`, you could view it by typing `view mylog.smcl`. `view file` can properly display `.smcl` files (logs and the like), `.sthlp` files, and text files. `view file`'s `asis` option specifies that the file be displayed as plain text, regardless of the *filename*'s extension.

`view browse` opens your browser pointed to *url*. Typing `view browse https://www.stata.com` would bring up your browser pointed to the website <https://www.stata.com>.

`[view] help` displays the specified topic in the Viewer. For example, to review the help for Stata's print command, you could type `help print`. See [\[R\] help](#) for more details.

`[view] search` displays the results of the `search` command in the Viewer. For instance, to search the system help for information on robust regression, you could type `search robust regression`. See [\[R\] search](#) for more details.

`view net` does the same as the `net` command—see [\[R\] net](#)—but displays the result in the Viewer. For instance, typing `view net search hausman test` would search the internet for additions to Stata related to the Hausman test. Typing `view net from https://www.stata.com` would go to the Stata additions download site at <https://www.stata.com>.

`view ado` does the same as the `ado` command—see [\[R\] net](#)—but displays the result in the Viewer. For instance, typing `view ado dir` would show a list of files you have installed.

`view update` does the same as the `update` command—see [\[R\] update](#)—but displays the result in the Viewer. Typing `view update` would show the dates of what you have installed, and from there you could click to compare those dates with the latest updates available. Typing `view update query` would skip the first step and show the comparison.

Menu

File > View...

Syntax

Display file in Viewer

```
view [file] [ " ]filename[ " ] [ , asis adopath ]
```

Bring up browser pointed to specified URL

```
view browse [ " ]url[ " ]
```

Display help results in Viewer

```
[view] help [ topic_or_command_name ]
```

Display search results in Viewer

```
[view] search keywords
```

Display net results in Viewer

```
view net [ netcmd ]
```

Display ado-results in Viewer

```
view ado [ adocmd ]
```

Display update results in Viewer

```
view update [ updatecmd ]
```

Options

asis, allowed with *view file*, specifies that the file be displayed as text, regardless of the *filename*'s extension. *view file*'s default action is to display files ending in *.smcl* and *.sthlp* as SMCL; see [P] [smcl](#).

adopath, allowed with *view file*, specifies that Stata search the S_ADO path for *filename* and display it, if found.

Remarks and examples

Most users access the Viewer by selecting **File > View...** and proceeding from there. Some commands allow you to skip that step. Some common interactive uses of commands that display their results in the Viewer are the following:

```
. view mysession.smcl
. view mysession.log
. help print
. help regress
. search hausman test
. view net
. view ado
. view update query
```

Description

`vwls` estimates a linear regression using variance-weighted least squares. It differs from ordinary least-squares (OLS) regression in that it does not assume homogeneity of variance, but requires that the conditional variance of *depvar* be estimated prior to the regression. The estimated variance need not be constant across observations. `vwls` treats the estimated variance as if it were the true variance when it computes standard errors of the coefficients.

You must supply an estimate of the conditional standard deviation of *depvar* to `vwls` by using the `sd(varname)` option, or you must have grouped data with the groups defined by the *indepvars* variables. In the latter case, `vwls` treats all *indepvars* as categorical variables, computes the mean and standard deviation of *depvar* separately for each subgroup, and computes the regression of the subgroup means on *indepvars*.

`regress` with analytic weights can be used to produce another kind of “variance-weighted least squares”; see [Remarks and examples](#) for an explanation of the difference.

Quick start

Variance-weighted least-squares regression of *y* on *x1* and *x2*, with the estimated conditional std. dev. of *y* stored in `sd`

```
vwls y1 x1 x2, sd(sd)
```

Add categorical variable *a* using [factor-variable](#) syntax

```
vwls y1 x1 x2 i.a, sd(sd)
```

Same as above, but restrict the sample to cases where *v* is greater than 1

```
vwls y1 x1 x2 i.a if v>1, sd(sd)
```

Variance-weighted least-squares regression for grouped data with subgroups defined by *a2* and *a3*

```
vwls y2 i.a2 i.a3
```

Menu

Statistics > Linear models and related > Other > Variance-weighted least squares

Syntax

vwls *depvar indepvars* [*if*] [*in*] [*weight*] [, *options*]

<i>options</i>	Description
Model	
<code>noconstant</code>	suppress constant term
<code>sd(<i>varname</i>)</code>	variable containing estimate of conditional standard deviation
Reporting	
<code>level(#)</code>	set confidence level; default is level(95)
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<code>coeflegend</code>	display legend instead of statistics
<p><i>indepvars</i> may contain factor variables; see [U] 11.4.3 Factor variables.</p> <p>bootstrap, by, collect, jackknife, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.</p> <p>Weights are not allowed with the bootstrap prefix; see [R] bootstrap.</p> <p>fweights are allowed; see [U] 11.1.6 weight.</p> <p>coeflegend does not appear in the dialog box.</p> <p>See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.</p>	

Options

Model

`noconstant`; see [R] Estimation options.

`sd(varname)` is an estimate of the conditional standard deviation of *depvar* (that is, it can vary observation by observation). All values of *varname* must be > 0. If you specify `sd()`, you cannot use `fweights`.

If `sd()` is not given, the data will be grouped by *indepvars*. Here *indepvars* are treated as categorical variables, and the means and standard deviations of *depvar* for each subgroup are calculated and used for the regression. Any subgroup for which the standard deviation is zero is dropped.

Reporting

`level(#)`; see [R] Estimation options.

`display_options`: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] Estimation options.

The following option is available with `vwls` but is not shown in the dialog box:

`coeflegend`; see [R] Estimation options.

Remarks and examples

The `vwls` command is intended for use with two special—and different—types of data. The first contains data that consist of measurements from physical science experiments in which all error is due solely to measurement errors and the sizes of the measurement errors are known.

You can also use variance-weighted least-squares linear regression for certain problems in categorical data analysis, such as when all the independent variables are categorical and the outcome variable is either continuous or a quantity that can sensibly be averaged. If each of the subgroups defined by the categorical variables contains a reasonable number of subjects, then the variance of the outcome variable can be estimated independently within each subgroup. For the purposes of estimation, `vwls` treats each subgroup as one observation, with the dependent variable being the subgroup mean of the outcome variable.

The `vwls` command fits the model

$$y_i = \mathbf{x}_i\boldsymbol{\beta} + \varepsilon_i$$

where the errors ε_i are independent normal random variables with the distribution $\varepsilon_i \sim N(0, \nu_i)$. The independent variables \mathbf{x}_i are assumed to be known without error.

As described above, `vwls` assumes that you already have estimates s_i^2 for the variances ν_i . The error variance is not estimated in the regression. The estimates s_i^2 are used to compute the standard errors of the coefficients; see [Methods and formulas](#) below.

In contrast, weighted OLS regression assumes that the errors have the distribution $\varepsilon_i \sim N(0, \sigma^2/w_i)$, where the w_i are known weights and σ^2 is an unknown parameter that is estimated in the regression. This is the difference from variance-weighted least squares: in weighted OLS, the magnitude of the error variance is estimated in the regression using all the data.

► Example 1

An artificial, but informative, example illustrates the difference between variance-weighted least squares and weighted OLS.

We measure the quantities x_i and y_i and estimate that the standard deviation of y_i is s_i . We enter the data into Stata:

```
. use https://www.stata-press.com/data/r19/vwlsxmpl
. list
```

	x	y	s
1.	1	1.2	.5
2.	2	1.9	.5
3.	3	3.2	1
4.	4	4.3	1
5.	5	4.9	1
6.	6	6.0	2
7.	7	7.2	2
8.	8	7.9	2

Because we want observations with smaller variance to carry larger weight in the regression, we compute an OLS regression with analytic weights proportional to the inverse of the squared standard deviations:

```
. regress y x [aweight=s^(-2)]
(sum of wgt is 11.75)
```

Source	SS	df	MS	Number of obs	=	8
Model	22.6310183	1	22.6310183	F(1, 6)	=	702.26
Residual	.193355117	6	.032225853	Prob > F	=	0.0000
				R-squared	=	0.9915
				Adj R-squared	=	0.9901
Total	22.8243734	7	3.26062477	Root MSE	=	.17952

y	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
x	.9824683	.0370739	26.50	0.000	.8917517	1.073185
_cons	.1138554	.1120078	1.02	0.349	-.1602179	.3879288

If we compute a variance-weighted least-squares regression by using `vwls`, we get the same results for the coefficient estimates but very different standard errors:

```
. vwls y x, sd(s)
```

```
Variance-weighted least-squares regression      Number of obs      =          8
Goodness-of-fit chi2(6)      =      0.28          Model chi2(1)      =      33.24
Prob > chi2      =      0.9996          Prob > chi2      =      0.0000
```

y	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
x	.9824683	.170409	5.77	0.000	.6484728	1.316464
_cons	.1138554	.51484	0.22	0.825	-.8952124	1.122923

Although the values of y_i were nicely linear with x_i , the `vwls` regression used the large estimates for the standard deviations to compute large standard errors for the coefficients. For weighted OLS regression, however, the scale of the analytic weights has no effect on the standard errors of the coefficients—only the relative proportions of the analytic weights affect the regression.

If we are sure of the sizes of our error estimates for y_i , using `vwls` is valid. However, if we can estimate only the relative proportions of error among the y_i , then `vwls` is not appropriate.

◀

➤ Example 2

Let's now consider an example of the use of `vwls` with categorical data. Suppose that we have blood pressure data for $n = 400$ subjects, categorized by gender and race (black or white). Here is a description of the data:

```
. use https://www.stata-press.com/data/r19/bp
. table gender race, statistic(mean bp) statistic(sd bp) statistic(freq)
> nformat(%8.1f)
```

	Race		
	White	Black	Total
Gender			
Female			
Mean	117.1	118.5	117.8
Standard deviation	10.3	11.6	10.9
Frequency	100.0	100.0	200.0
Male			
Mean	122.1	125.8	124.0
Standard deviation	10.6	15.5	13.3
Frequency	100.0	100.0	200.0
Total			
Mean	119.6	122.2	120.9
Standard deviation	10.7	14.1	12.6
Frequency	200.0	200.0	400.0

Performing a variance-weighted regression using `vwls` gives

```
. vwls bp gender race
Variance-weighted least-squares regression      Number of obs      =      400
Goodness-of-fit chi2(1)      =      0.88      Model chi2(2)      =      27.11
Prob > chi2      =      0.3486      Prob > chi2      =      0.0000
```

bp	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
gender	5.876522	1.170241	5.02	0.000	3.582892	8.170151
race	2.372818	1.191683	1.99	0.046	.0371631	4.708473
_cons	116.6486	.9296297	125.48	0.000	114.8266	118.4707

By comparison, an OLS regression gives the following result:

```
. regress bp gender race
Source      |      SS      df      MS      Number of obs      =      400
-----+-----+-----+-----+-----+-----
Model      | 4485.66639      2  2242.83319  F(2, 397)      =      15.24
Residual   | 58442.7305     397  147.210908  Prob > F      =      0.0000
-----+-----+-----+-----+-----+-----
Total      | 62928.3969     399  157.71528  R-squared      =      0.0713
                                           Adj R-squared   =      0.0666
                                           Root MSE       =      12.133
```

bp	Coefficient	Std. err.	t	P> t	[95% conf. interval]	
gender	6.1775	1.213305	5.09	0.000	3.792194	8.562806
race	2.5875	1.213305	2.13	0.034	.2021938	4.972806
_cons	116.4862	1.050753	110.86	0.000	114.4205	118.552

Note the larger value for the race coefficient (and smaller p -value) in the OLS regression. The assumption of homogeneity of variance in OLS means that the mean for black men pulls the regression line higher than in the `vwls` regression, which takes into account the larger variance for black men and reduces its effect on the regression.

Stored results

vwls stores the following in `e()`:

Scalars

<code>e(N)</code>	number of observations
<code>e(df_m)</code>	model degrees of freedom
<code>e(chi2)</code>	model χ^2
<code>e(df_gf)</code>	goodness-of-fit degrees of freedom
<code>e(chi2_gf)</code>	goodness-of-fit χ^2
<code>e(rank)</code>	rank of <code>e(V)</code>

Macros

<code>e(cmd)</code>	vwls
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(properties)</code>	b V
<code>e(predict)</code>	program used to implement predict
<code>e(asbalanced)</code>	factor variables fvset as asbalanced
<code>e(asobserved)</code>	factor variables fvset as asobserved

Matrices

<code>e(b)</code>	coefficient vector
<code>e(V)</code>	variance–covariance matrix of the estimators

Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, p -values, and confidence intervals
-----------------------	---

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

Let $\mathbf{y} = (y_1, y_2, \dots, y_n)'$ be the vector of observations of the dependent variable, where n is the number of observations. When `sd()` is specified, let s_1, s_2, \dots, s_n be the standard deviations supplied by `sd()`. For categorical data, when `sd()` is not given, the means and standard deviations of y for each subgroup are computed, and n becomes the number of subgroups, \mathbf{y} is the vector of subgroup means, and s_i are the standard deviations for the subgroups.

Let $\mathbf{V} = \text{diag}(s_1^2, s_2^2, \dots, s_n^2)$ denote the estimate of the variance of \mathbf{y} . Then the estimated regression coefficients are

$$\mathbf{b} = (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}^{-1}\mathbf{y}$$

and their estimated covariance matrix is

$$\widehat{\text{Cov}}(\mathbf{b}) = (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$$

A statistic for the goodness of fit of the model is

$$Q = (\mathbf{y} - \mathbf{Xb})' \mathbf{V}^{-1} (\mathbf{y} - \mathbf{Xb})$$

where Q has a χ^2 distribution with $n - k$ degrees of freedom (k is the number of independent variables plus the constant, if any).

Postestimation commands

The following postestimation commands are available after `vwls`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
<code>forecast</code>	dynamic forecasts and simulations
<code>hausman</code>	Hausman’s specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
<code>linktest</code>	link test for model specification
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	linear, censored, and truncated predictions
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

predict

Description for predict

`predict` creates a new variable containing predictions such as linear predictions and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , xb stdp]
```

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

margins

Description for margins

margins estimates margins of response for linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]  
margins [marginlist] , predict (statistic ...) [ options ]
```

statistic	Description
xb	linear prediction; the default
stdp	not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than $e(b)$.
For the full syntax, see [R] margins.

- [R] vwls — Variance-weighted least squares
- [U] 20 Estimation and postestimation commands

Description

`which` looks for file *fname.ftype* along the S_ADO path. If Stata finds the file, `which` displays the full path and filename, along with, if the file is text, all lines in the file that begin with “*!” in the first column. If Stata cannot find the file, `which` issues the message “file not found along ado-path” and sets the return code to 111. *ftype* must be a file type for which Stata usually looks along the ado-path to find. Allowable *ftypes* are

```
.ado, .class, .dlg, .idlg, .sthlp, .ihlp, .hlp, .jar, .key, .maint, .mata, .mlib,  
.mo, .mnu, .plugin, .png, .py, .scheme, .stbcal, and .style
```

If *ftype* is omitted, `which` assumes `.ado`. When searching for `.ado` files, if Stata cannot find the file, Stata then checks to see if *fname* is a built-in Stata command, allowing for valid abbreviations. If it is, the message “built-in command” is displayed; if not, the message “command not found as either built-in or ado-file” is displayed and the return code is set to 111.

Syntax

```
which fname[.ftype] [ , all ]
```

Option

`all` forces `which` to report the location of all files matching the *fname.ftype* found along the search path. The default is to report just the first one found.

Remarks and examples

If you write programs, you know that you make changes to the programs over time. If you are like us, you also end up with multiple versions of the program stored on your disk, perhaps in different directories. You may even have given copies of your programs to other Stata users, and you may not remember which version of a program you or your friends are using. The `which` command helps you solve this problem.

► Example 1

The `which` command displays the path for *filename.ado* and any lines in the code that begin with “*!”. For example, we might want information about the `test` command, described in [R] [test](#), which is an ado-file written by StataCorp. Here is what happens when we type `which test`:

```
. which test
C:\Program Files\Stata19\ado\base\t\test.ado
*! version 2.4.1 28jan2021
```

`which` displays the path for the `test.ado` file and also a line beginning with “*!” that indicates the version of the file.

Do not confuse “version 2.4.1” above with the [version](#) command or the version of Stata. The “*!” code indicates notes. In this case, the `*! version 2.4.1` line is merely a note to the author to identify the iteration (version) of the `test` program. It is an unfortunate coincidence that the word `version` is overloaded in this manner.

We do not need to be so formal. `which` will display anything typed after lines that begin with “*!”. For instance, we might write `myprog.ado`:

```
. which myprog
.\myprog.ado
*! first written 1/03/2025
*! bug fix on 1/05/2025 (no variance case)
*! updated 1/24/2025 to include noconstant option
*! still suspicious if variable takes on only two values
```

It does not matter where in the program the lines beginning with `*!` are—which will list them (in particular, our “still suspicious” comment was buried about 50 lines down in the code). All that is important is that the `*!` marker appear in the first two columns of a line.

► Example 2

If we type `which command`, where *command* is a built-in command rather than an ado-file, Stata responds with

```
. which summarize
built-in command: summarize
```

If *command* was neither a built-in command nor an ado-file, Stata would respond with

```
. which junk
command junk not found as either built-in or ado-file
r(111);
```

Description

wildbootstrap performs wild cluster bootstrap (WCB) inference for linear hypotheses about parameters in linear regression models. These hypotheses can be simple or composite. When the assumptions required for the consistency of the cluster-robust variance estimator (CRVE) do not hold, the WCB is a good alternative.

Quick start

Estimate the WCB *p*-value and confidence interval (CI) for the coefficient on *x1* in a linear regression of *y* on *x1* with clusters identified in *cvar*

```
wildbootstrap regress y x1, cluster(cvar)
```

Same as above, but test whether the coefficients on *x1* and *x2* are equal in a regression of *y* on *x1* and *x2*

```
wildbootstrap regress y x1 x2, cluster(cvar) test(x1 = x2)
```

Menu

Statistics > Resampling > Wild cluster bootstrap

Syntax

```
wildbootstrap estimator depvar [indepvars] [if] [in] [weight] [, options]
```

<i>estimator</i>	Description
<code>regress</code>	linear regression
<code>areg</code>	linear regression with a large indicator-variable set
<code>xtreg</code>	fixed-effects linear models
<i>options</i>	Description
Main	
<code>noconstant</code>	suppress constant term; available only with estimator <code>regress</code>
<code>hascons</code>	has user-supplied constant; available only with estimator <code>regress</code>
<code>absorb(<i>varname</i>)</code>	categorical variable to be absorbed; required by and available only with estimator <code>areg</code>
Statistics	
<code>coefficients(<i>coeflist</i>)</code>	perform inference for a subset of coefficients
<code>test(<i>testspec</i>)</code>	specify linear test parameters
Bootstrap	
<code>cluster(<i>clustvar</i>)</code>	specify variable identifying clusters; required for estimators <code>regress</code> and <code>areg</code>
<code>ptype(<i>ptype</i>)</code>	specify the <i>p</i> -value type; may be <code>equal</code> (the default) or <code>symmetric</code>
<code>errorweight(<i>wcbwtype</i>)</code>	specify WCB weight; default is <code>errorweight</code> (<code>rademacher</code>)
<code>reps(#)</code>	set number of bootstrap repetitions; default is <code>reps(1000)</code>
<code>rseed(# <i>statecode</i>)</code>	set random-number seed to <code>#</code> or <i>statecode</i>
<code>blocksize(#)</code>	set bootstrap repetition block size; default is <code>min(reps(#),1000)</code>
<code>cistop(largest first)</code>	specify stopping rule for CI computation
Reporting	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>display_options</code>	control column formats and display of CIs

indepvars and *coeflist* may contain factor variables; see [U] 11.4.3 Factor variables.

depvar, *indepvars*, and *coeflist* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`collect` is allowed; see [U] 11.1.10 Prefix commands.

Any weight that is allowed by the estimator is allowed; see [U] 11.1.6 weight.

Options

Main

`noconstant` and `hascons`; see [R] `regress`. These options may be specified only when estimator `regress` is specified.

`absorb(varname)`; see [R] `areg`. This option must be specified when estimator `areg` is specified.

Statistics

`coefficients(coeflist)` performs an inference for a subset of coefficients. It reports the bootstrap p -value for a test of the subset of coefficients, `coeflist`, equal to 0 and the bootstrap CI. The default is to perform inference for all variables specified in `indepvars`. `coefficients()` may not be specified with `test()`.

`test(testspec)` specifies a linear test. You may also specify multiple linear tests by using `test((testspec1) (testspec2) ...)`. The test specification must be consistent with specifying a linear constraint. See [R] [test](#) and [R] [constraint](#).

Bootstrap

`cluster(clustvar)` specifies the variable identifying the cluster groups. `cluster()` is required with estimators `regress` and `areg`. With estimator `xtreg`, `clustvar` defaults to the `xtset panelvar`.

`ptype(ptype)` specifies the p -value criterion: symmetric (`symmetric`) or equal tailed (`equal`). The default is `ptype(equal)`. See [Methods and formulas](#) for more details.

`errorweight(wcbwtype)` specifies the type of wild weight. `wcbwtype` may be one of the following:

<i>wcbwtype</i>	Description
<code>rademacher</code>	two-point distribution assigns values 1 and -1 with equal probability; the default
<code>mammen</code>	two-point distribution assigns value $1 - \phi$ with probability $\phi/\sqrt{5}$ and value ϕ otherwise, where $\phi = (1 + \sqrt{5})/2$
<code>webb</code>	six-point distribution assigns probability of $1/6$ to the points $\pm\sqrt{1/2}$, ± 1 , and $\pm\sqrt{3/2}$
<code>normal</code>	standard normal distribution
<code>gamma</code>	gamma distribution with shape parameter 4 and scale parameter $1/2$ centered on its mean of 2

`reps(#)` sets the number of repetitions for the bootstrap. The default is `reps(1000)`. For the `ptype(equal)` option, the values of `level()` and `reps()` should be chosen so that $\alpha/2 \times \text{reps}(\#)$ is an integer, where $\alpha = (100 - \text{level}(\#))/100$. For the `ptype(symmetric)` option, such values should be chosen so that $\alpha \times \text{reps}(\#)$ is an integer. When the product is not an integer, the number of repetitions is increased so that it is. Integer values improve the search efficiency of the wildbootstrap algorithm.

`rseed(#|statecode)` sets the random-number seed to `#` or `statecode`. See [R] [set seed](#).

`blocksize(#)` sets the bootstrap block size. This is an integer less than or equal to `reps(#)` and is used to reduce the amount of memory the bootstrap computation will consume. The default is `min(reps(#),1000)`.

`cistop(largest|first)` specifies the stopping rule for the CI computation. The bootstrap distribution is a step function, so for each bound, there is an interval of values that meet the CI level criterion. `cistop(largest)`, the default, specifies that the largest value within the interval be selected. `cistop(first)` specifies that the first value the algorithm finds within the interval be selected; therefore, specifying `cistop(first)` will result in faster CI computation. The `cistop()` option may not be combined with the `noci` option.

Reporting

`level(#)`; see [R] [Estimation options](#). The `level()` option will not work on replay because CIs are based on estimator-specific enumerations. To change the confidence level, you must refit the model.

`display_options`: `noci`, `cformat(%fmt)`, `pformat(%fmt)`, and `sformat(%fmt)`; see [R] [Estimation options](#). The `noci` option may not be combined with the `cistop()` option.

Remarks and examples

wildbootstrap implements the WCB, which was proposed by [Cameron, Gelbach, and Miller \(2008\)](#). It is an extension of the original wild bootstrap procedure proposed by [Wu \(1986\)](#), which was designed to work well for models with heteroskedasticity, to the case of cluster-level correlation. The wild bootstrap has proven to work well in cases where cluster-robust standard errors do not perform well. A good discussion of the methodology can be found in [Cameron and Miller \(2015\)](#), [MacKinnon \(2019\)](#), [MacKinnon and Webb \(2018\)](#), and [MacKinnon, Nielsen, and Webb \(2023\)](#), and the references therein. Specifically, the WCB is a good inference tool when one or more of the CRVE *t*-statistic consistency assumptions are violated. [MacKinnon and Webb](#) list the assumptions as follows:

1. The number of clusters goes to infinity.
2. The within-cluster error correlations are the same for all clusters.
3. Each cluster contains an equal number of observations.

Below, we illustrate how to use wildbootstrap; however, note that alternatives exist in the literature to address the inference problems noted above. For example, the [Bell and McCaffrey \(2002\)](#) *t*-statistic degrees-of-freedom correction is an alternative to wildbootstrap when at least one of the above assumptions is violated. The degrees-of-freedom correction is computed with option `vce(hc2 clustvar, dfadjust)` for `regress`, `areg`, and `xtreg`, `fe`.

► Example 1: Simple regression

Say we are interested in the effect of tenure on wages for a panel of individuals sampled from 2013 to 2016. We would like to use wild bootstrap CIs clustering at the `personid` level. For reproducibility, we set the seed by using option `rseed()`.

```
. use https://www.stata-press.com/data/r19/wagework
(Wages for 20 to 77 year olds, 2013–2016)
. wildbootstrap regress wage tenure, cluster(personid) rseed(12345)
Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
  Lower bound: .....10.....20. done (21)
  Upper bound: .....10..... done (17)

Wild cluster bootstrap
Linear regression
Cluster variable: personid
Error weight: Rademacher

Number of obs      = 1,928
Number of clusters =   589
Cluster size:
min = 1
avg  = 3.3
max  = 4
```

	wage	Estimate	t	p-value	[95% conf. interval]	
constraint						
	tenure = 0	.7807403	27.19	0.000	.7209754	.8368386

The iteration log indicates the number of iterations used to compute the lower and upper bound for the CIs. In *Methods and formulas* below, we discuss how these bounds are computed. Notably, there is a separate optimization procedure used to compute each one of these bounds.

The table header also tells us the error weights used for the sampling algorithm of the wild bootstrap, which, by default, are Rademacher weights. See the `errorweight()` option for more details about error weights.

The column header labeled *p*-value indicates that the *t*-statistic equal-tailed *p*-value has been computed. The `pctype(equal)` option is the default. Alternatively, the symmetric *p*-value is computed when the `pctype(symmetric)` option is specified and is identified with the column header of `P>|t|`.

```
. wildbootstrap regress wage tenure, cluster(personid) rseed(12345)
> pctype(symmetric)
Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
  Lower bound: .....10.....20.. done (22)
  Upper bound: .....10..... done (15)

Wild cluster bootstrap
Linear regression
Cluster variable: personid
Error weight: Rademacher

Number of obs      = 1,928
Number of clusters = 589
Cluster size:
min = 1
avg  = 3.3
max  = 4
```

	wage	Estimate	t	P> t	[95% conf. interval]	
constraint						
	tenure = 0	.7807403	27.19	0.000	.7240502	.8399896

We can always compare the CIs from the wild bootstrap with what we would have obtained using the underlying command, in this case, `regress`.

```
. regress
Linear regression
Number of obs      = 1,928
F(1, 588)          = 739.36
Prob > F           = 0.0000
R-squared          = 0.4212
Root MSE          = 3.5097

(Std. err. adjusted for 589 clusters in personid)
```

	wage	Coefficient	Robust std. err.	t	P> t	[95% conf. interval]	
	tenure	.7807403	.028713	27.19	0.000	.7243477	.8371328
	_cons	20.89884	.2135686	97.86	0.000	20.47939	21.31829

Note that typing this command will replace the return matrix `r(table)`. Observe that the *t* statistics are the same in both tables because `regress` and `wildbootstrap` use the same CRVE, but the *p*-values and CIs may vary between tables.

Similarly, you can redisplay the `wildbootstrap` table by typing `wildbootstrap`, which may be abbreviated as `wildboot`.

► Example 2: Small number of clusters with wildly varying cluster sizes

As in [example 1](#), we would like to see the effect of tenure on wages; in this case, however, we would like to cluster at the industry level. Here, for year 1988, we use a wage dataset with only 12 clusters, for which cluster sizes vary wildly from 4 to 817, violating the CRVE t -statistic consistency [assumptions 1 and 3](#) outlined previously.

```
. use https://www.stata-press.com/data/r19/nlsw88
(NLSW, 1988 extract)

. wildbootstrap regress wage tenure, cluster(industry) rseed(12345)
Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
  Lower bound: .....10.....20..... done (26)
  Upper bound: .....10.....20.... done (24)

Wild cluster bootstrap          Number of obs      = 2,217
Linear regression              Number of clusters =    12
                               Cluster size:
Cluster variable: industry                        min =     4
Error weight: Rademacher                        avg = 184.8
                                                max =   817
```

	wage	Estimate	t	p-value	[95% conf. interval]	
constraint	tenure = 0	.1830716	6.95	0.000	.1274023	.3258156

► Example 3: Small number of clusters with more regressors

Continuing with [example 2](#), we look at a more complex and perhaps more realistic example. We add to the model explanatory variables for total work experience, `ttl_exp`; a college graduate indicator, `collgrad`; and an indicator for union membership, `union`.

```
. wildbootstrap regress wage c.tenure#c.ttl_exp ib0.collgrad ib0.union,
> cluster(industry) rseed(12345)

Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
  Lower bound: .....10.....20.....30.... done (34)
  Upper bound: .....10.....20.... done (24)

Performing 1,000 replications for p-value for ttl_exp = 0 ...
Computing confidence interval for ttl_exp
  Lower bound: .....10.....20.... done (25)
  Upper bound: .....10..... done (19)

Performing 1,000 replications for p-value for c.tenure#c.ttl_exp = 0 ...
Computing confidence interval for c.tenure#c.ttl_exp
  Lower bound: .....10.....20... done (23)
  Upper bound: .....10.....20..... done (27)
note: upper-bound CI achieved  $1-F(-3.65e-04) = 0.0240$ , but target is  $1-F(x) = .025$ .
note: the sorted bootstrap t statistics have at least two tied values
      adjacent to the t statistic under the null; this prevents the CI bound
      from converging to the target.

Performing 1,000 replications for p-value for 1.collgrad = 0 ...
Computing confidence interval for 1.collgrad
  Lower bound: .....10.....20.....30.. done (32)
note: lower-bound CI achieved  $F(1.66) = 0.0240$ , but target is  $F(x) = .025$ .
note: at least one bootstrap t statistic matches the t statistic under the
      null; this prevents the CI bound from converging to the target.
  Upper bound: .....10.....20..... done (26)

Performing 1,000 replications for p-value for 1.union = 0 ...
Computing confidence interval for 1.union
  Lower bound: .....10.....20.....30 done (30)
  Upper bound: .....10.....20..... done (25)

Wild cluster bootstrap          Number of obs      = 1,855
Linear regression              Number of clusters =   12
                               Cluster size:
Cluster variable: industry      min =         2
Error weight: Rademacher       avg =       154.6
                               max =         717
```

	wage	Estimate	t	p-value	[95% conf. interval]

1.collgrad = 0		3.077377	7.59	0.034	1.662277	5.218396
1.union = 0		.9114564	2.31	0.040	.1060322	2.470924

We did not specify the `coefficients()` option, so `wildbootstrap` computes p -values and CIs for all coefficients in the model, with the exception of the constant term, using the default `ptype(equal)` option to compute the equal-tailed p -values.

The iteration log states that the CI-target tail values were not achieved for two of the reported constraints. This is because the sorted vector of bootstrap t statistics can have ties due to computer finite numeric precision and the finite number of draws for the Rademacher, Mammen, and Webb distributions. When ties occur with the t statistic under the null, or those adjacent to it, and the desired CI tail area cannot be achieved, wildbootstrap will choose a bound that results in a smaller tail area. This is the case when wildbootstrap searches for the `c.tenure#c.ttl_exp` CI upper bound and the `1.collgrad` CI lower bound.

Numerical computations will contain a roundoff error; wildbootstrap retains 13 digits on the mantissa of the t statistics before making comparisons.

► Example 4: Linear regression with an indicator-variable set

We would like to include an individual’s occupation code (`occupation`) as an additional control in the regression to avoid potential omitted-variable bias. We keep the other control variables we introduced in [example 3](#). For this analysis, we use the estimator `areg` with the `absorb(occupation)` option. We use the `test()` option to test linear combinations of regression estimates.

```
. wildbootstrap areg wage c.tenure#c.ttl_exp ib0.collgrad ib0.union,
> absorb(occupation) cluster(industry) rseed(12345)
> test((tenure=ttl_exp) (1.collgrad-1.union=1)) reps(1250)
note: for equal-tailed 95% CI, better performance is obtained when
      .025*reps() is an integer.
note: setting repetitions to 1,280.

Performing 1,280 replications for p-value for constraint
      tenure - ttl_exp = 0 ...
Computing confidence interval for tenure - ttl_exp
  Lower bound: .....10.....20... done (23)
  Upper bound: .....10.....20.... done (25)
note: upper-bound CI achieved 1-F(0.15) = 0.0242, but target is 1-F(x) =
      .025.
note: the sorted bootstrap t statistics have at least two tied values
      adjacent to the t statistic under the null; this prevents the CI bound
      from converging to the target.

Performing 1,280 replications for p-value for constraint
      1.collgrad - 1.union = 1 ...
Computing confidence interval for 1.collgrad - 1.union
  Lower bound: .....10.....20..... done (26)
  Upper bound: .....10.....20..... done (27)
note: upper-bound CI achieved 1-F(3.91) = 0.0242, but target is 1-F(x) =
      .025.
note: the sorted bootstrap t statistics have at least two tied values
      adjacent to the t statistic under the null; this prevents the CI bound
      from converging to the target.

Wild cluster bootstrap                                Number of obs      = 1,851
Linear regression, absorbing indicators                 Number of clusters =   12
                                                        Cluster size:
Cluster variable: industry                             min =           2
Error weight: Rademacher                             avg =        154.2
                                                        max =          717
```

	wage	Estimate	t	p-value	[95% conf. interval]	
constraints						
tenure - ttl_exp = 0		-.0391243	-0.71	0.517	-.1915527	.1495055
1.collgrad - 1.union = 1		1.356332	0.77	0.395	-.1882941	3.913359

The `test()` option allows us to specify a linear combination of the regression coefficients that we would like to test. The syntax is the same as specifying linear constraints, `constraint`, or linear hypothesis tests, `test`. In this example, we are inquiring how probable it would be for `tenure = ttl_exp` and `1.collgrad - 1.union = 1`.

The `reps()` option allows us to set the number of bootstrap repetitions. The default is 1,000. Because the Rademacher and Mammen distributions have two possible realizations, the maximum number of possible bootstrap samples is 2^G , where G is the number of clusters. The Webb distribution, on the other hand, has six outcomes and therefore 6^G possible combinations.

In this example, we intentionally specify a number of bootstrap repetitions that results in a non-integer product, `reps() × α/2`: `reps() × (100 - level())/200 = 1250 × 0.025 = 31.25`. In this case, we lose efficiency in searching for the CI bounds, so `wildbootstrap` adjusts the number of repetitions to 1,280; when we specify `reps(1250)` with `level(95)`, `wildbootstrap` chooses `reps() = ceil(1250 × α/2)/(α/2) = 32/0.025 = 1280`. If an integer alternative cannot be found, the original `reps()` specification will be used. For details, see [Methods and formulas](#) below.

Because the WCB distribution is a step function, there is a range of values for each CI bound. For example, the lower-bound interval of values for the linear combination `tenure - ttl_exp` is $-0.191586 < a_{lb} \leq -0.191553$. The reported bounds are the largest value of each interval. We obtain -0.191586 by running `wildbootstrap` specifying `level(#)` with $\# = (0.95 + 2/1280) \times 100$. We would likely report the CIs using three digits of precision, for instance, $[-0.192, 0.150]$, so this interval is negligible but significant in a numerical root search where a convergence tolerance for r_l might be 10^{-8} .

The estimate of `tenure - ttl_exp` is reported to be -0.0391 with a 95% CI of $[-0.192, 0.150]$. We therefore fail to reject the hypothesis that `tenure = ttl_exp`. Similarly, the estimate of `1.collgrad - 1.union` is 1.36 with a CI of $[-0.188, 3.91]$, and we conclude the difference of 1 is feasible.

► Example 5: Fixed-effects linear regression with panels

Our final example demonstrates the use of `wildbootstrap` with estimator `xtreg`. Continuing with the data in the [previous example](#), we use `industry` as the variable defining the panels.

We specify normal error weights, `errorweight(normal)`, thereby reducing the chance of identical draws for the error weights. Draws from the Rademacher distribution for 12 clusters have $2^{12} = 4096$ combinations.

We compute p -values and CIs on a subset of the model estimates: work tenure, work experience, and their interaction. If we replay the `xtreg` coefficient table, we will see that the fitted model includes `tenure`, `ttl_exp`, `c.tenure#c.ttl_exp`, `1.collgrad`, and `1.union`.

Finally, we use the symmetric p -value, option `ptype(symmetrict)`, instead of the default equal-tailed, `ptype(equal)`. The table identifies the symmetric p -value with the header `P>|t|`.

The command and the results are as follows:

```
. xtset industry
Panel variable: industry (unbalanced)

. wildbootstrap xtreg wage c.tenure#c.ttl_exp i.collgrad i.union,
> rseed(12345) coef(ten ttl ten#ttl) errorweight(normal)
> ptype(symmetric)
Panel variable: industry (unbalanced)
Performing 1,000 replications for p-value for constraint
tenure = 0 ...
Computing confidence interval for tenure
Lower bound: .....10.....20..... done (26)
Upper bound: .....10.....20. done (21)
Performing 1,000 replications for p-value for constraint
ttl_exp = 0 ...
Computing confidence interval for ttl_exp
Lower bound: .....10.....20..... done (26)
Upper bound: .....10..... done (18)
Performing 1,000 replications for p-value for constraint
c.tenure#c.ttl_exp = 0 ...
Computing confidence interval for c.tenure#c.ttl_exp
Lower bound: .....10.....20..... done (26)
Upper bound: .....10.....20... done (23)

Wild cluster bootstrap                Number of obs      = 1,855
Fixed-effects linear regression        Number of clusters =   12
                                      Cluster size:
Cluster variable: industry              min =      2
Error weight: Normal                   avg = 154.6
                                      max =   717
```

wage	Estimate	t	P> t	[95% conf. interval]	
constraints					
tenure = 0	.2026682	2.95	0.024	.0555676	.3753468
ttl_exp = 0	.2716375	11.59	0.000	.2227054	.3372929
c.tenure#c.ttl_exp = 0	-.0104125	-2.55	0.046	-.0201336	-.0003384

The fixed-effects model is the only `xtreg` model allowed with `wildbootstrap`, so specifying the `fe` option is not required.

Also note that the `cluster()` option is not specified. When the estimator `xtreg` is specified, the default cluster variable is the panel variable that is `xtset`. If the specified cluster variable is different from the panel variable, then the levels of the panel variable must be nested within the cluster variable levels.

Stored results

wildbootstrap stores the following in `e()`:

Scalars

<code>e(N_clust)</code>	number of clusters
<code>e(N_wbrep)</code>	number of bootstrap repetitions
<code>e(wb_block)</code>	bootstrap block size
<code>e(n_wbcns)</code>	number of bootstrap constraint restrictions
<code>e(min_c)</code>	smallest cluster size
<code>e(max_c)</code>	largest cluster size
<code>e(avg_c)</code>	average cluster size

Macros

<code>e(cmdline)</code>	command as typed
<code>e(cmd0)</code>	wildbootstrap
<code>e(wb_stat)</code>	WCB statistic, t
<code>e(wb_weight)</code>	WCB weights
<code>e(wb_ptype)</code>	WCB p -value criterion
<code>e(wb_level)</code>	WCB CI level
<code>e(wb_cistop)</code>	WCB CI interval type
<code>e(wb_rseed)</code>	random-number state
<code>e(wb_cns<i>i</i>)</code>	WCB constraint i , where $i = 1, \dots, e(n_wbcns)$
<code>e(clustvar)</code>	name of cluster variable

Matrices

<code>e(wboot)</code>	WCB table
<code>e(wb_pci)</code>	WCB CI coverage
<code>e(wb_Cns)</code>	WCB constraint matrix

wildbootstrap will also carry forward most of the results already in `e()` from *command*.

In addition to the above, the following is stored in `r()`:

Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, p -values, and confidence intervals
-----------------------	---

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

Methods and formulas are presented under the following headings:

[Introduction](#)

[CIs for linear combinations of coefficients](#)

[Constructing a CI inverting the hypothesis test](#)

Introduction

We will focus our discussion of the WCB on linear regression, which easily extends to the other fixed-effects estimators. A linear regression model with clustered errors and G clusters can be written as

$$\mathbf{y} = \begin{pmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \\ \vdots \\ \mathbf{y}_G \end{pmatrix} = \mathbf{X}\beta + \epsilon = \begin{pmatrix} \mathbf{X}_1 \\ \mathbf{X}_2 \\ \vdots \\ \mathbf{X}_G \end{pmatrix} \begin{pmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_k \end{pmatrix} + \begin{pmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_G \end{pmatrix} \quad (1)$$

where for each cluster g , N_g is the number of observations, y_g is an $N_g \times 1$ vector of outcomes, X_g is an $N_g \times k$ matrix of covariates, and ϵ_g is an $N_g \times 1$ vector of errors. The parameter of interest is the $k \times 1$ vector of coefficients β . Error terms are assumed uncorrelated between observations of different clusters but possibly correlated between observations within the same cluster.

Without loss of generality, we will first focus on testing the null hypothesis $H_0: \beta_k = 0$ using the WCB algorithm. Let $\hat{\beta}$ denote the ordinary least-squares estimator for β . We compute the t statistic for the k th coefficient as

$$t_k = \frac{\hat{\beta}_k}{\sqrt{\hat{\mathbf{V}}_{k,k}}}$$

where $\hat{\mathbf{V}}_{k,k}$ is the CRVE for $\hat{\beta}_k$. This is the k th diagonal element of the matrix

$$\hat{\mathbf{V}} = \frac{G(N-1)}{(G-1)(N-k)} (\mathbf{X}\mathbf{X}')^{-1} \left(\sum_{g=1}^G \mathbf{X}'_g \hat{\epsilon}_g \hat{\epsilon}'_g \mathbf{X}_g \right) (\mathbf{X}\mathbf{X}')^{-1} \quad (2)$$

where $\hat{\epsilon}_g$ is the $N_g \times 1$ vector of ordinary least-squares residuals for cluster g and $N = \sum_{g=1}^G N_g$ is the total number of observations.

The WCB algorithm proceeds as follows:

1. Refit model (1) subject to the restriction $\beta_k = 0$. Let $\tilde{\beta}$ denote the restricted estimates and $\tilde{\epsilon}$ denote the restricted residuals.
2. For each individual bootstrap replication b (out of a total of B replications):
 - (a) Generate random variable ν_g^b for each cluster g according to the distribution specified in the `errorweight()` option.
 - (b) For each cluster g and each observation in the cluster $i = 1, 2, \dots, N_g$, generate a new bootstrap-dependent variable y_{ig}^b using the data-generating process:

$$y_{ig}^b = X_{ig} \tilde{\beta} + \tilde{\epsilon}_{ig} \nu_g^b$$

- (c) Fit model (1) using the bootstrap variable y_{ig}^b as regressand. Calculate the t statistic for $\beta_k = 0$,

$$t_k^b = \frac{\hat{\beta}_k^b}{\sqrt{\hat{\mathbf{V}}_{k,k}^b}}$$

where $\hat{\beta}_k^b$ and $\hat{\mathbf{V}}_{k,k}^b$ are the ordinary least-squares coefficient and the CRVE for that coefficient in the bootstrap replication, respectively. In this case, the CRVE is the k th diagonal element of matrix (2) obtained when using the residuals from bootstrap replication b .

3. The p -values for the one-sided alternative hypotheses $H_1: \beta_k > 0$ and $H_2: \beta_k < 0$ are given by

$$p_1 = \frac{1}{B} \sum_{b=1}^B I(t_k^b > t_k)$$

$$p_2 = \frac{1}{B} \sum_{b=1}^B I(t_k^b < t_k)$$

For the alternative hypothesis $H_3: \beta_k \neq 0$, the p -value assuming that the distribution of the t statistic is symmetric around 0 is given by

$$p_S = \frac{1}{B} \sum_{b=1}^B I(|t_k^b| > |t_k|)$$

If the assumption of symmetry is not appropriate, then the p -value is given by the equal-tailed p -value $p_e = 2 \min(p_1, p_2)$. See [Djogbenou, MacKinnon, and Nielsen \(2019\)](#).

To increase computational speed, at the expense of computer memory usage, the `wildbootstrap` command uses the matrix algebra of [Roodman et al. \(2019\)](#). By doing this, the computational complexity (run time) of the WCB algorithm is reduced from the order $O(NB)$ to the order $O(GB)$. The WCB uses a $G \times B$ matrix of random variables. By organizing these variables in column-major order, `wildbootstrap` reduces overall memory usage with minimal extra computation by breaking up the number of bootstrap replicates into blocks (the `blocksize(#)` option).

CIs for linear combinations of coefficients

By inverting hypotheses tests, we can apply the WCB algorithm to find CIs for any linear combination of coefficients. Suppose we wanted to compute a CI for the linear combination of parameters $\mathbf{R}\beta$, where \mathbf{R} is a $1 \times k$ vector. In this case, the associated null hypothesis is $H_0: \mathbf{R}\beta = r$, where r is an arbitrary scalar. We can test this null hypothesis with the WCB algorithm described in the previous section by using the bootstrap t statistics

$$t^b(r) = \frac{\mathbf{R}\hat{\beta}^b - r}{\sqrt{\mathbf{R}\widehat{\mathbf{V}}^b\mathbf{R}'}}$$

for $b = 1, \dots, B$. For more on restricted regression with linear constraints on multiple coefficients, see [\[P\] makecons](#).

The associated one-sided alternative hypotheses are now $H_1: \mathbf{R}\beta > r$ and $H_2: \mathbf{R}\beta < r$. As before, their respective bootstrap p -values are given by

$$p_1(r) = \frac{1}{B} \sum_{b=1}^B I\{t^b(r) > t(r)\}$$

$$p_2(r) = \frac{1}{B} \sum_{b=1}^B I\{t^b(r) < t(r)\}$$

where $t(r)$ is the t statistic from the original sample:

$$t(r) = \frac{\mathbf{R}\hat{\beta} - r}{\sqrt{\mathbf{R}\widehat{\mathbf{V}}\mathbf{R}'}}$$

The associated two-sided alternative hypothesis is $H_3: \mathbf{R}\beta \neq r$, and its bootstrap p -value under the assumption of symmetry is given by

$$p_S(r) = \frac{1}{B} \sum_{b=1}^B I\{|t^{(b)}(r)| > |t(r)|\}$$

When using the equal-tailed criterion (the `pctype(equal)` option), the $100(1-\alpha)\%$ CI for $\mathbf{R}\beta$ is given by $[r_l, r_u]$, where r_l and r_u satisfy $p_1(r_l) = p_2(r_u) = \alpha/2$. On the other hand, when using the symmetric criterion (the `pctype(symmetric)` option), r_l and r_u satisfy $p_S(r_l) = p_S(r_u) = \alpha$. The parameter α can be specified with the `level()` option, that is, $\alpha = (100 - \text{level}()) / 100$.

The bootstrap p -values are step functions on r , and therefore a range of values for r_l and for r_u will solve the p -value conditions above. Because distribution functions are right continuous, `wildbootstrap` chooses the rightmost point in each range of solutions.

For the equal-tailed CIs, the starting values for the search of solutions to the p -value conditions are chosen as follows. First, the bootstrap t statistics are sorted $t^{(1)} \leq t^{(2)} \leq \dots < t^{(B)}$. Second, we define $b_l = \text{ceil}\{B(1 - \alpha/2)\}$ so that $t^{(b_l)}$ is smaller than $B(\alpha/2)$ of the t statistics. Similarly, we define $b_u = \text{floor}\{B(\alpha/2)\}$ so that $t^{(b_u)}$ is larger than $B(\alpha/2)$ of the t statistics. Third and finally, the initial lower and upper bounds of the CI are given by

$$r_l = \mathbf{R}\hat{\beta} - t^{(b_l)} \sqrt{\mathbf{R}\hat{\mathbf{V}}\mathbf{R}'}$$

$$r_u = \mathbf{R}\hat{\beta} - t^{(b_u)} \sqrt{\mathbf{R}\hat{\mathbf{V}}\mathbf{R}'}$$

where $\hat{\beta}$ and $\hat{\mathbf{V}}$ are the unrestricted estimator for β and the unrestricted CRVE in the original sample.

Constructing a CI inverting the hypothesis test

For a linear combination of coefficients $\sum R_j \beta_j$, we can construct a CI by inverting the hypothesis test $H_0: \mathbf{R}\beta = r$, where \mathbf{R} is a row vector that includes the coefficients R_j and r is an arbitrary scalar. To do this, `wildbootstrap` searches for the CI lower bound r_l such that $\Pr(\mathbf{R}\beta \leq r_l) = \alpha/2$ (equal-tailed criterion, the `pctype(equal)` option). The WCB distribution of $\mathbf{R}\beta$ is a step function with a step size of $1/\text{reps}(\#)$. When $\text{reps}(\#) \times \alpha/2$ is an integer, call it S , then we search for the r_l that produces the ordered bootstrapped t statistics

$$t^{(b)} = \frac{\mathbf{R}\hat{\beta}^{(b)} - r_l}{\sqrt{\mathbf{R}'\mathbf{V}^{(b)}\mathbf{R}}}$$

with the property $\sum_{b=1}^{\text{reps}(\#)} I(t^{(b)} > t) = S$ and therefore $\Pr(\mathbf{R}\beta \leq r_l) = S/\text{reps}(\#) = \alpha/2$.

Acknowledgments

We thank David Roodman of Open Philanthropy for his insights on the wild bootstrap computation.

We also acknowledge previous and ongoing contributions to this area from the Stata community. In particular, we acknowledge David Roodman, James G. MacKinnon, Morten Ørregaard Nielsen, and Matthew D. Webb for their command `boottest` and Mitchell Petersen, Douglas Miller, and Judson Caskey for their command `cgmwildboot`.

[Description](#)[Remarks and examples](#)[Menu](#)[Stored results](#)[Syntax](#)[Also see](#)[Options](#)

Description

`xi` expands terms containing categorical variables into indicator (also called dummy) variable sets by creating new variables and, in the second syntax (`xi : any_stata_command`), executes the specified command with the expanded terms. The dummy variables created are

<code>i.varname</code>	creates dummies for categorical variable <i>varname</i>
<code>i.varname₁*i.varname₂</code>	creates dummies for categorical variables <i>varname₁</i> and <i>varname₂</i> : all interactions and main effects
<code>i.varname₁*varname₃</code>	creates dummies for categorical variable <i>varname₁</i> and continuous variable <i>varname₃</i> : all interactions and main effects
<code>i.varname₁ varname₃</code>	creates dummies for categorical variable <i>varname₁</i> and continuous variable <i>varname₃</i> : all interactions and main effect of <i>varname₃</i> , but no main effect of <i>varname₁</i>

Menu

Data > Create or change data > Other variable-creation commands > Interaction expansion

Most commands in Stata now allow factor variables; see [\[U\] 11.4.3 Factor variables](#). To determine if a command allows factor variables, see the information printed below the options table for the command. If the command allows factor variables, it will say something like “*indepvars* may contain factor variables”.

We recommend that you use factor variables instead of `xi` if a command allows factor variables.

We include [\[R\] xi](#) in our documentation so that readers can consult it when using a Stata command that does not allow factor variables.

Syntax

```
xi [ , prefix(string) noomit ] term(s)
```

```
xi [ , prefix(string) noomit ] : any_stata_command varlist_with_terms ...
```

where a *term* has the form

<i>i.varname</i>	or	<i>I.varname</i>
<i>i.varname</i> ₁ * <i>i.varname</i> ₂		<i>I.varname</i> ₁ * <i>I.varname</i> ₂
<i>i.varname</i> ₁ * <i>varname</i> ₃		<i>I.varname</i> ₁ * <i>varname</i> ₃
<i>i.varname</i> ₁ <i>varname</i> ₃		<i>I.varname</i> ₁ <i>varname</i> ₃

varname, *varname*₁, and *varname*₂ denote numeric or string categorical variables. *varname*₃ denotes a continuous, numeric variable.

Options

`prefix(string)` allows you to choose a prefix other than `_I` for the newly created interaction variables.

The prefix cannot be longer than four characters. By default, `xi` will create interaction variables starting with `_I`. When you use `xi`, it drops all previously created interaction variables starting with the prefix specified in the `prefix(string)` option or with `_I` by default. Therefore, if you want to keep the variables with a certain prefix, specify a different prefix in the `prefix(string)` option.

`noomit` prevents `xi` from omitting groups. This option provides a way to generate an indicator variable for every category having one or more variables, which is useful when combined with the `noconstant` option of an estimation command.

Remarks and examples

Remarks are presented under the following headings:

- [Background](#)
- [Indicator variables for simple effects](#)
- [Controlling the omitted dummy](#)
- [Categorical variable interactions](#)
- [Interactions with continuous variables](#)
- [Using xi: Interpreting output](#)
- [How xi names variables](#)
- [xi as a command rather than a command prefix](#)
- [Warnings](#)

`xi` provides a convenient way to include dummy or indicator variables when fitting a model (say, with `regress` or `logistic`). For instance, assume that the categorical variable `agegrp` contains 1 for ages 20–24, 2 for ages 25–39, 3 for ages 40–44, etc. Typing

```
. xi: logistic outcome weight i.agegrp bp
```

estimates a logistic regression of `outcome` on `weight`, dummies for each `agegrp` category, and `bp`. That is, `xi` searches out and expands terms starting with “`i.`” or “`I.`” but ignores the other variables. `xi` will expand both numeric and string categorical variables, so if you had a string variable `race` containing “white”, “black”, and “other”, typing

```
. xi: logistic outcome weight bp i.agegrp i.race
```

would include indicator variables for the race group as well.

The `i.` indicator variables `xi` expands may appear anywhere in the *varlist*, so

```
. xi: logistic outcome i.agegrp weight i.race bp
```

would fit the same model.

You can also create interactions of categorical variables; typing

```
xi: logistic outcome weight bp i.agegrp*i.race
```

fits a model with indicator variables for all `agegrp` and `race` combinations, including the `agegrp` and `race` main-effect terms (that is, the terms that are created when you just type `i.agegrp i.race`).

You can interact dummy variables with continuous variables; typing

```
xi: logistic outcome bp i.agegrp*weight i.race
```

fits a model with indicator variables for all `agegrp` categories interacted with `weight`, plus the main-effect terms `weight` and `i.agegrp`.

You can get the interaction terms without the `agegrp` main effect (but with the `weight` main effect) by typing

```
xi: logistic outcome bp i.agegrp|weight i.race
```

You can also include multiple interactions:

```
xi: logistic outcome bp i.agegrp*weight i.agegrp*i.race
```

We will now back up and describe the construction of dummy variables in more detail.

Background

The terms *continuous*, *categorical*, and *indicator* or *dummy* variables are used below. Continuous variables measure something—such as height or weight—and at least conceptually can take on any real number over some range. Categorical variables, on the other hand, take on a finite number of values, each denoting membership in a subclass—for example, excellent, good, and poor, which might be coded 0, 1, 2, or 1, 2, 3, or even “Excellent”, “Good”, and “Poor”. An indicator or dummy variable—the terms are used interchangeably—is a special type of two-valued categorical variable that contains values 0, denoting false, and 1, denoting true. The information contained in any k -valued categorical variable can be equally well represented by k indicator variables. Instead of one variable recording values representing excellent, good, and poor, you can have three indicator variables, indicating the truth or falseness of “result is excellent”, “result is good”, and “result is poor”.

`xi` provides a convenient way to convert categorical variables to dummy or indicator variables when you fit a model (say, with `regress` or `logistic`).

► Example 1

For instance, assume that the categorical variable `agegrp` contains 1 for ages 20–24, 2 for ages 25–39, and 3 for ages 40–44. (There is no one over 44 in our data.) As it stands, `agegrp` would be a poor candidate for inclusion in a model even if we thought age affected the outcome. The reason is that the coding would restrict the effect of being in the second age group to be twice the effect of being in the first, and, similarly, the effect of being in the third to be three times the first. That is, if we fit the model,

$$y = \beta_0 + \beta_1 \text{agegrp} + X\beta_2$$

the effect of being in the first age group is β_1 , the second $2\beta_1$, and the third $3\beta_1$. If the coding 1, 2, and 3 is arbitrary, we could just as well have coded the age groups 1, 4, and 9, making the effects β_1 , $4\beta_1$, and $9\beta_1$.

The solution is to convert the categorical variable `agegrp` to a set of indicator variables, a_1 , a_2 , and a_3 , where a_i is 1 if the individual is a member of the i th age group and 0 otherwise. We can then fit the model

$$y = \beta_0 + \beta_{11}a_1 + \beta_{12}a_2 + \beta_{13}a_3 + X\beta_2$$

The effect of being in age group 1 is now β_{11} ; 2, β_{12} ; and 3, β_{13} ; and these results are independent of our (arbitrary) coding. The only difficulty at this point is that the model is unidentified in the sense that there are an infinite number of $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13})$ that fit the data equally well.

To see this, pretend that $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (1, 1, 3, 4)$. The predicted values of y for the various age groups are

$$y = \begin{cases} 1 + 1 + X\beta_2 = 2 + X\beta_2 & \text{(age group 1)} \\ 1 + 3 + X\beta_2 = 4 + X\beta_2 & \text{(age group 2)} \\ 1 + 4 + X\beta_2 = 5 + X\beta_2 & \text{(age group 3)} \end{cases}$$

Now, pretend that $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (2, 0, 2, 3)$. The predicted values of y are

$$y = \begin{cases} 2 + 0 + X\beta_2 = 2 + X\beta_2 & \text{(age group 1)} \\ 2 + 2 + X\beta_2 = 4 + X\beta_2 & \text{(age group 2)} \\ 2 + 3 + X\beta_2 = 5 + X\beta_2 & \text{(age group 3)} \end{cases}$$

These two sets of predictions are indistinguishable: for age group 1, $y = 2 + X\beta_2$ regardless of the coefficient vector used, and similarly for age groups 2 and 3. This arises because we have three equations and four unknowns. Any solution is as good as any other, and, for our purposes, we merely need to choose one of them. The popular selection method is to set the coefficient on the first indicator variable to 0 (as we have done in our second coefficient vector). This is equivalent to fitting the model

$$y = \beta_0 + \beta_{12}a_2 + \beta_{13}a_3 + X\beta_2$$

How we select a particular coefficient vector (identifies the model) does not matter. It does, however, affect the *interpretation* of the coefficients.

For instance, we could just as well choose to omit the second group. In our artificial example, this would yield $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (4, -2, 0, 1)$ instead of $(2, 0, 2, 3)$. These coefficient vectors are the same in the sense that

$$y = \begin{cases} 2 + 0 + X\beta_2 = 2 + X\beta_2 = 4 - 2 + X\beta_2 & \text{(age group 1)} \\ 2 + 2 + X\beta_2 = 4 + X\beta_2 = 4 + 0 + X\beta_2 & \text{(age group 2)} \\ 2 + 3 + X\beta_2 = 5 + X\beta_2 = 4 + 1 + X\beta_2 & \text{(age group 3)} \end{cases}$$

But what does it mean that β_{13} can just as well be 3 or 1? We obtain $\beta_{13} = 3$ when we set $\beta_{11} = 0$, so $\beta_{13} = \beta_{13} - \beta_{11}$ and β_{13} measures the difference between age groups 3 and 1.

In the second case, we obtain $\beta_{13} = 1$ when we set $\beta_{12} = 0$, so $\beta_{13} - \beta_{12} = 1$ and β_{13} measures the difference between age groups 3 and 2. There is no inconsistency. According to our $\beta_{12} = 0$ model, the difference between age groups 3 and 1 is $\beta_{13} - \beta_{11} = 1 - (-2) = 3$, the same result we got in the $\beta_{11} = 0$ model.

◀

► Example 2

The issue of interpretation is important because it can affect the way we discuss results. Imagine that we are studying recovery after a coronary bypass operation. Assume that the age groups are children under 13 (we have two of them), young adults under 25 (we have a handful of them), adults under 46 (of which we have even more), mature adults under 56, older adults under 65, and elderly adults. We follow the prescription of omitting the first group, so all our results are reported relative to children under 13. While there is nothing statistically wrong with this, readers will be suspicious when we make statements like “compared with young children, older and elder adults ...”. Moreover, we will probably have to end each statement with “although results are not statistically significant” because we have only two children in our comparison group. Of course, even with results reported in this way, we can do reasonable comparisons (say, with mature adults), but we will have to do extra work to perform the appropriate linear hypothesis test using Stata’s `test` command.

Here it would be better to force the omitted group to be more reasonable, such as mature adults. There is, however, a generic rule for automatic comparison group selection that, although less popular, tends to work better than the omit-the-first-group rule. That rule is to omit the most prevalent group. The most prevalent is usually a reasonable baseline.

◀

In any case, the prescription for categorical variables is

1. Convert each k -valued categorical variable to k indicator variables.
2. Drop one of the k indicator variables; any one will do, but dropping the first is popular, dropping the most prevalent is probably better in terms of having the computer guess at a reasonable interpretation, and dropping a specified one often eases interpretation the most.
3. Fit the model on the remaining $k - 1$ indicator variables.

xi automates this procedure.

We will now consider each of xi’s features in detail.

Indicator variables for simple effects

When you type `i.varname`, `xi` internally tabulates *varname* (which may be a string or a numeric variable) and creates indicator (dummy) variables for each observed value, omitting the indicator for the smallest value. For instance, say that `agegrp` takes on the values 1, 2, 3, and 4. Typing

```
xi: logistic outcome i.agegrp
```

creates indicator variables named `_Iagegrp_2`, `_Iagegrp_3`, and `_Iagegrp_4`. (`xi` chooses the names and tries to make them readable; `xi` guarantees that the names are unique.) The expanded logistic model is

```
. logistic outcome _Iagegrp_2 _Iagegrp_3 _Iagegrp_4
```

Afterward, you can drop the new variables `xi` leaves behind by typing `'drop _I*'` (note the capitalization).

`xi` provides the following features when you type `i.varname`:

- *varname* may be string or numeric.
- Dummy variables are created automatically.
- By default, the dummy-variable set is identified by dropping the dummy corresponding to the smallest value of the variable (how to specify otherwise is discussed below).
- The new dummy variables are left in your dataset. By default, the names of the new dummy variables start with `_I`; therefore, you can drop them by typing `'drop _I*'`. You do not have to do this; each time you use `xi`, any automatically generated dummies with the same prefix as the one specified in the `prefix(string)` option, or `_I` by default, are dropped and new ones are created.
- The new dummy variables have variable labels so that you can determine what they correspond to by typing `'describe'`.
- `xi` may be used with any Stata command (not just `logistic`).

Controlling the omitted dummy

By default, `i.varname` omits the dummy corresponding to the smallest value of *varname*; for a string variable, this is interpreted as dropping the first in an alphabetical, case-sensitive sort. `xi` provides two alternatives to dropping the first: `xi` will drop the dummy corresponding to the most prevalent value of *varname*, or `xi` will let you choose the particular dummy to be dropped.

To change `xi`'s behavior to dropping the most prevalent dummy, type

```
. char _dta[omit] prevalent
```

although whether you type “prevalent” or “yes” or anything else does not matter. Setting this characteristic affects the expansion of all categorical variables in the dataset. If you resave your dataset, the prevalent preference will be remembered. If you want to change the behavior back to the default drop-the-first rule, type

```
. char _dta[omit]
```

to clear the characteristic.

Once you set `_dta[omit]`, `i.varname` omits the dummy corresponding to the most prevalent value of *varname*. Thus, the coefficients on the dummies have the interpretation of change from the most prevalent group. For example,

```
. char _dta[omit] prevalent
. xi: regress y i.agegrp
```

might create `_Iagegrp_1` through `_Iagegrp_4`, resulting in `_Iagegrp_2` being omitted if `agegrp = 2` is most common (as opposed to the default dropping of `_Iagegrp_1`). The model is then

$$y = b_0 + b_1 _Iagegrp_1 + b_3 _Iagegrp_3 + b_4 _Iagegrp_4 + u$$

Then,

$$\begin{array}{ll} \text{Predicted } y \text{ for agegrp 1} = b_0 + b_1 & \text{Predicted } y \text{ for agegrp 3} = b_0 + b_3 \\ \text{Predicted } y \text{ for agegrp 2} = b_0 & \text{Predicted } y \text{ for agegrp 4} = b_0 + b_4 \end{array}$$

Thus, the model's reported *t* or *Z* statistics are for a test of whether each group is different from the most prevalent group.

Perhaps you wish to omit the dummy for agegrp 3 instead. You do this by setting the variable's omit characteristic:

```
. char agegrp[omit] 3
```

This overrides `_dta[omit]` if you have set it. Now, when you type

```
. xi: regress y i.agegrp
```

`_Iagegrp_3` will be omitted, and you will fit the model

$$y = b'_0 + b'_1 _Iagegrp_1 + b'_2 _Iagegrp_2 + b'_4 _Iagegrp_4 + u$$

Later, if you want to return to the default omission, type

```
. char agegrp[omit]
```

to clear the characteristic.

In summary, `i.varname` omits the first group by default, but if you define

```
. char _dta[omit] prevalent
```

the default behavior changes to dropping the most prevalent group. Either way, if you define a characteristic of the form

```
. char varname[omit] #
```

or, if *varname* is a string,

```
. char varname[omit] string-literal
```

the specified value will be omitted.

```
Examples: . char agegrp[omit] 1
           . char race[omit] White      (for race, a string variable)
           . char agegrp[omit]          (to restore default for agegrp)
```

Categorical variable interactions

`i.varname1*i.varname2` creates the dummy variables associated with the interaction of the categorical variables `varname1` and `varname2`. The identification rules—which categories are omitted—are the same as those for `i.varname`. For instance, assume that `agegrp` takes on four values and `race` takes on three values. Typing

```
. xi: regress y i.agegrp*i.race
```

results in

model:	dummies for:
$y = a + b_2 _Iagegrp_2 + b_3 _Iagegrp_3 + b_4 _Iagegrp_4$	(agegrp)
$+ c_2 _Irace_2 + c_3 _Irace_3$	(race)
$+ d_{22} _IageXrac_2_2 + d_{23} _IageXrac_2_3$	
$+ d_{32} _IageXrac_3_2 + d_{33} _IageXrac_3_3$	(agegrp*race)
$+ d_{42} _IageXrac_4_2 + d_{43} _IageXrac_4_3$	
$+ u$	

That is, typing

```
. xi: regress y i.agegrp*i.race
```

is the same as typing

```
. xi: regress y i.agegrp i.race i.agegrp*i.race
```

Although there are many other ways the interaction could have been parameterized, this method has the advantage that you can test the joint significance of the interactions by typing

```
. testparm _IageXrac*
```

When you perform the estimation step, whether you use `i.agegrp*i.race` or `i.race*i.agegrp` makes no difference (other than in the names given to the interaction terms; in the first case, the names will begin with `_IageXrac`; in the second, `_IracXage`). Thus,

```
. xi: regress y i.race*i.agegrp
```

fits the same model.

You may also include multiple interactions simultaneously:

```
. xi: regress y i.agegrp*i.race i.agegrp*i.sex
```

The model fit is

model:	dummies for:
$y = a + b_2 _Iagegrp_2 + b_3 _Iagegrp_3 + b_4 _Iagegrp_4$	(agegrp)
$+ c_2 _Irace_2 + c_3 _Irace_3$	(race)
$+ d_{22} _IageXrac_2_2 + d_{23} _IageXrac_2_3$	
$+ d_{32} _IageXrac_3_2 + d_{33} _IageXrac_3_3$	(agegrp*race)
$+ d_{42} _IageXrac_4_2 + d_{43} _IageXrac_4_3$	
$+ e_2 _Isex_2$	(sex)
$+ f_{22} _IageXsex_2_2 + f_{23} _IageXsex_2_3 + f_{24} _IageXsex_2_4$	(agegrp*sex)
$+ u$	

The agegrp dummies are (correctly) included only once.

Interactions with continuous variables

`i.varname1*varname2` (as distinguished from `i.varname1*i.varname2`—note the second `i.`) specifies an interaction of a categorical variable with a continuous variable. For instance,

```
. xi: regress y i.agegrp*wgt
```

results in the model

$y = a + b_2 _Iagegrp_2 + b_3 _Iagegrp_3 + b_4 _Iagegrp_4$	(agegrp dummies)
$+ c _wgt$	(continuous wgt effect)
$+ d_2 _IageXwgt_2 + d_3 _IageXwgt_3 + d_4 _IageXwgt_4$	(agegrp*wgt interactions)
$+ u$	

A variation on this notation, using `|` rather than `*`, omits the agegrp dummies. Typing

```
. xi: regress y i.agegrp|wgt
```

fits the model

$y = a' + c' _wgt$	(continuous wgt effect)
$+ d'_2 _IageXwgt_2 + d'_3 _IageXwgt_3 + d'_4 _IageXwgt_4$	(agegrp*wgt interactions)
$+ u'$	

The predicted values of y are

agegrp*wgt model	agegrp wgt model	
$y = a + c \text{ wgt}$	$a' + c' \text{ wgt}$	if agegrp = 1
$a + c \text{ wgt} + b_2 + d_2 \text{ wgt}$	$a' + c' \text{ wgt} + d'_2 \text{ wgt}$	if agegrp = 2
$a + c \text{ wgt} + b_3 + d_3 \text{ wgt}$	$a' + c' \text{ wgt} + d'_3 \text{ wgt}$	if agegrp = 3
$a + c \text{ wgt} + b_4 + d_4 \text{ wgt}$	$a' + c' \text{ wgt} + d'_4 \text{ wgt}$	if agegrp = 4

That is, typing

```
. xi: regress y i.agegrp*wgt
```

is equivalent to typing

```
. xi: regress y i.agegrp i.agegrp|wgt
```

In either case, you do not need to specify separately the continuous variable `wgt`; it is included automatically.

Using xi: Interpreting output

```
. xi: regress mpg i.rep78
i.rep78          _Irep78_1-5    (naturally coded; _Irep78_1 omitted)
(output from regress appears)
```

Interpretation: `i.rep78` expanded to the dummies `_Irep78_1`, `_Irep78_2`, ..., `_Irep78_5`. The numbers on the end are “natural” in the sense that `_Irep78_1` corresponds to `rep78 = 1`, `_Irep78_2` to `rep78 = 2`, and so on. Finally, the dummy for `rep78 = 1` was omitted.

```
. xi: regress mpg i.make
i.make          _Imake_1-74     (_Imake_1 for make==AMC Concord omitted)
(output from regress appears)
```

Interpretation: `i.make` expanded to `_Imake_1`, `_Imake_2`, ..., `_Imake_74`. The coding is not natural because `make` is a string variable. `_Imake_1` corresponds to one `make`, `_Imake_2` to another, and so on. You can find out the coding by typing `describe`. `_Imake_1` for the AMC Concord was omitted.

How xi names variables

By default, xi assigns to the dummy variables it creates names having the form

_Istub_groupid

You may subsequently refer to the entire set of variables by typing ‘*Istub**’. For example,

name	=	_I + stub	+ _ + groupid	Entire set
<i>_Iagegrp_1</i>	<i>_I</i>	<i>agegrp</i>	<i>_ 1</i>	<i>_Iagegrp*</i>
<i>_Iagegrp_2</i>	<i>_I</i>	<i>agegrp</i>	<i>_ 2</i>	<i>_Iagegrp*</i>
<i>_IageXwgt_1</i>	<i>_I</i>	<i>ageXwgt</i>	<i>_ 1</i>	<i>_IageXwgt*</i>
<i>_IageXrac_1_2</i>	<i>_I</i>	<i>ageXrac</i>	<i>_ 1_2</i>	<i>_IageXrac*</i>
<i>_IageXrac_2_1</i>	<i>_I</i>	<i>ageXrac</i>	<i>_ 2_1</i>	<i>_IageXrac*</i>

If you specify a prefix in the `prefix(string)` option, say, *_S*, then xi will name the variables starting with the prefix

_Sstub_groupid

xi as a command rather than a command prefix

xi can be used as a command prefix or as a command by itself. In the latter form, xi merely creates the indicator and interaction variables. Typing

```
. xi: regress y i.agegrp*wgt
i.agegrp          _Iagegrp_1-4   (naturally coded; _Iagegrp_1 omitted)
i.agegrp*wgt      _IageXwgt_1-4   (coded as above)
(output from regress appears)
```

is equivalent to typing

```
. xi i.agegrp*wgt
i.agegrp          _Iagegrp_1-4   (naturally coded; _Iagegrp_1 omitted)
i.agegrp*wgt      _IageXwgt_1-4   (coded as above)

. regress y _Iagegrp* _IageXwgt*
(output from regress appears)
```

Warnings

1. xi creates new variables in your dataset; most are bytes, but interactions with continuous variables will have the storage type of the underlying continuous variable. You may get the error message “no room to add more variables” or “insufficient memory”. You may need to adjust the `maxvar` setting or reset `max_memory` if it has been set too low; see [\[U\] 6 Managing memory](#).
2. When using xi with an estimation command, you may get the error message “unable to allocate matrix”. This usually occurs because you attempted to create a matrix that is too large; see [\[R\] Limits](#).

Stored results

xi stores the following characteristics:

<code>_dta[<code>__xi__Vars__Prefix__</code>]</code>	prefix names
<code>_dta[<code>__xi__Vars__To__Drop__</code>]</code>	variables created

Description

zbnb fits a zero-inflated negative binomial (ZINB) model to overdispersed count data with excess zero counts. The ZINB model assumes that the excess zero counts come from a logit or probit model and the remaining counts come from a negative binomial model.

Quick start

Zero-inflated negative binomial model of y on x1 and x2 with inflation modeled using x3

```
zbnb y x1 x2, inflate(x3)
```

And conduct likelihood-ratio test against ZIP model

```
zbnb y x1 x2, inflate(x3) zip
```

Use a probit model instead of a logit model to predict excess zeros

```
zbnb y x1 x2, inflate(x3) probit
```

Menu

Statistics > Count outcomes > Zero-inflated negative binomial regression

Syntax

```
zinf depvar [indepvars] [if] [in] [weight] ,
      inflate(varlist [ , offset(varname) ] | _cons) [options]
```

<i>options</i>	Description
Model	
* <u>inflate</u> ()	equation that determines whether the count is zero
<u>noconstant</u>	suppress constant term
<u>exposure</u> (<i>varname</i> _e)	include ln(<i>varname</i> _e) in model with coefficient constrained to 1
<u>offset</u> (<i>varname</i> _o)	include <i>varname</i> _o in model with coefficient constrained to 1
<u>constraints</u> (<i>constraints</i>)	apply specified linear constraints
<u>probit</u>	use probit model to characterize excess zeros; default is logit
SE/Robust	
<u>vce</u> (<i>vcetype</i>)	<i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>opg</u> , <u>bootstrap</u> , or <u>jackknife</u>
Reporting	
<u>level</u> (#)	set confidence level; default is <u>level</u> (95)
<u>irr</u>	report incidence-rate ratios
<u>zip</u>	perform ZIP likelihood-ratio test
<u>nocnsreport</u>	do not display constraints
<u>display_options</u>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<u>maximize_options</u>	control the maximization process; seldom used
<u>collinear</u>	keep collinear variables
<u>coeflegend</u>	display legend instead of statistics

*inflate(*varlist* [, offset(*varname*)] | _cons) is required.

indepvars and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

bayes, bayesboot, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: zinf.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce(), zip, and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

Model

`inflate(varlist [, offset(varname)] | _cons)` specifies the equation that determines whether the observed count is zero. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `nbreg`.

`inflate(varlist [, offset(varname)])` specifies the variables in the equation. You may optionally include an offset for this *varlist*.

`inflate(_cons)` specifies that the equation determining whether the count is zero contains only an intercept. To run a zero-inflated model of *depvar* with only an intercept in both equations, type `zinz depvar, inflate(_cons)`.

`noconstant`, `exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] **Estimation options**.

`probit` requests that a probit, instead of logit, model be used to characterize the excess zeros in the data.

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] *vce_option*.

Reporting

`level(#)`; see [R] **Estimation options**.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is, e^{β_i} rather than β_i . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`zip` requests that a likelihood-ratio test comparing the ZINB model with the zero-inflated Poisson model be included in the output.

`nocnsreport`; see [R] **Estimation options**.

display_options: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

Maximization

maximize_options: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `zinz` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] **Estimation options**.

Remarks and examples

Zero-inflated negative binomial (ZINB) models are used to model count data that have a higher fraction of zeros than is likely to be generated by a standard negative binomial model. To account for excess zeros, ZINB models assume that these excess zeros come from a model other than the negative binomial model. A zero that comes from this other model is known as a “degenerate zero”.

The negative binomial overdispersion parameter, α , differentiates the ZINB model from the zero-inflated Poisson (ZIP) model (see [\[R\] zip](#)). Here overdispersion refers to the fact that the negative binomial variance is greater than its mean, whereas the Poisson variance is equal to its mean. Thus, values of $\alpha > 1$ indicate overdispersion. The larger the α , the greater the negative binomial variance. See [Methods and formulas](#) in [\[R\] nbreg](#) for further discussion of negative binomial overdispersion.

The `zinb` command fits ZINB models and provides two choices for modeling the excess zeros: the default logit function or, when the `probit` option is specified, the probit function. Both functions are symmetric about zero, but the logistic function has more area under the tails.

See [Long \(1997, 242–247\)](#) and [Cameron and Trivedi \(2005, 680–681\)](#) for a discussion of zero-modified count models.

► Example 1: Fitting a ZINB model

In [example 1](#) of [\[R\] zip](#), we fit a zero-inflated Poisson model using the `zip` command to the fictional data on the number of fish caught by visitors to a national park. Let’s fit a ZINB model to these data.

Just like with `zip`, we use the required `inflate()` option to model whether a visitor fishes as a function of the number of accompanying children (`child`) and whether the visitor is camping (`camper`). Next, we assume the response variable, `count`, depends on whether the visitor used a live bait (`livebait`) and the number of persons in the party (`persons`), which includes the visitor plus other adults and children.

```
. use https://www.stata-press.com/data/r19/fish
(Fictional fishing data)
. zinb count persons livebait, inflate(child camper)

Fitting constant-only model:
Iteration 0:  Log likelihood = -519.33992
Iteration 1:  Log likelihood = -451.38662
Iteration 2:  Log likelihood = -444.49118
Iteration 3:  Log likelihood = -442.96272
Iteration 4:  Log likelihood = -442.71065
Iteration 5:  Log likelihood = -442.66718
Iteration 6:  Log likelihood = -442.6631
Iteration 7:  Log likelihood = -442.66299
Iteration 8:  Log likelihood = -442.66299

Fitting full model:
Iteration 0:  Log likelihood = -442.66299 (not concave)
Iteration 1:  Log likelihood = -432.83107 (not concave)
Iteration 2:  Log likelihood = -426.32934
Iteration 3:  Log likelihood = -413.75019
Iteration 4:  Log likelihood = -403.09586
Iteration 5:  Log likelihood = -401.56013
Iteration 6:  Log likelihood = -401.54781
Iteration 7:  Log likelihood = -401.54776
Iteration 8:  Log likelihood = -401.54776

Zero-inflated negative binomial regression      Number of obs =    250
Inflation model: logit                        Nonzero obs   =    108
                                              Zero obs      =    142
                                              LR chi2(2)    =   82.23
                                              Prob > chi2    = 0.0000

Log likelihood = -401.5478
```

count	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
count						
persons	.9742984	.1034938	9.41	0.000	.7714543	1.177142
livebait	1.557523	.4124424	3.78	0.000	.7491503	2.365895
_cons	-2.730064	.476953	-5.72	0.000	-3.664874	-1.795253
inflate						
child	3.185999	.7468551	4.27	0.000	1.72219	4.649808
camper	-2.020951	.872054	-2.32	0.020	-3.730146	-.3117567
_cons	-2.695385	.8929071	-3.02	0.003	-4.44545	-.9453189
/lnalpha	.5110429	.1816816	2.81	0.005	.1549535	.8671323
alpha	1.667029	.3028685			1.167604	2.380076

The coefficients in the first equation of the coefficient table, labeled count, correspond to the negative binomial model for individuals who fished. For instance, among visitors who fished, using a live bait increases the expected number of caught fish by a factor of $\exp(1.5575) \approx 4.7$, holding other covariates constant.

The confidence interval for alpha indicates that the ZINB model is more appropriate than the ZIP model. To confirm this, you can run `zinb` and specify the `zip` option to obtain the ZIP likelihood-ratio test.

The `inflate` equation models whether the visitor does not fish. We can use `margins` to obtain a better understanding of how the `inflate` equation affects the occurrence of the excess zero counts. We specify `margins`'s options `dydx(child camper)` and `predict(pr)`. `pr` is `predict`'s option for estimating the probability of a degenerate zero or, in our example, the probability of not fishing; see the `margins` section in [R] [zinb postestimation](#).

```
. margins, dydx(child camper) predict(pr)
Average marginal effects                      Number of obs = 250
Model VCE: OIM
Expression: Pr(count=0), predict(pr)
dy/dx wrt:  child camper
```

	Delta-method		z	P> z	[95% conf. interval]	
	dy/dx	std. err.				
child	.257531	.029941	8.60	0.000	.1988477	.3162144
camper	-.1633578	.0503938	-3.24	0.001	-.2621277	-.0645878

The `margins` output tells us that a visitor is less likely to be visiting the park to fish if accompanied by children and more likely to fish if camping.

You also may want to evaluate whether a standard negative binomial model is adequate to fit the data. This can be done using information criteria; see [example 2](#) in [R] [zip](#).

Stored results

`zinb` stores the following in `e()`:

Scalars	
<code>e(N)</code>	number of observations
<code>e(N_zero)</code>	number of zero observations
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(ll_0)</code>	log likelihood, constant-only model
<code>e(df_c)</code>	degrees of freedom for comparison test
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	χ^2
<code>e(p)</code>	<i>p</i> -value for model test
<code>e(chi2_cp)</code>	χ^2 for test of $\alpha = 0$
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code
<code>e(converged)</code>	1 if converged, 0 otherwise
Macros	
<code>e(cmd)</code>	<code>zinb</code>
<code>e(cmdline)</code>	command as typed
<code>e(depvar)</code>	name of dependent variable
<code>e(inflate)</code>	logit or probit
<code>e(wtype)</code>	weight type
<code>e(wexp)</code>	weight expression

<code>e(title)</code>	title in estimation output
<code>e(clustvar)</code>	name of cluster variable
<code>e(offset1)</code>	offset
<code>e(offset2)</code>	offset for <code>inflate()</code>
<code>e(chi2type)</code>	Wald or LR; type of model χ^2 test
<code>e(chi2_cpt)</code>	Wald or LR; type of model χ^2 test corresponding to <code>e(chi2_cp)</code>
<code>e(vce)</code>	<i>vcetype</i> specified in <code>vce()</code>
<code>e(vcetype)</code>	title used to label Std. err.
<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	b V
<code>e(predict)</code>	program used to implement predict
<code>e(asbalanced)</code>	factor variables <i>fvset</i> as asbalanced
<code>e(asobserved)</code>	factor variables <i>fvset</i> as asobserved
Matrices	
<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance
Functions	
<code>e(sample)</code>	marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices	
<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any *r*-class command is run after the estimation command.

Methods and formulas

The `zinb` command maximizes a likelihood function that is a mixture of the logistic (or probit) and negative binomial distributions. The logistic distribution models the unobserved process that creates the excess zeros, and the negative binomial distribution models the counts. Define

$$\begin{aligned}\xi_j^\beta &= \mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta \\ \xi_j^\gamma &= \mathbf{z}_j\boldsymbol{\gamma} + \text{offset}_j^\gamma \\ \mu_j &= \exp(\xi_j^\beta) \\ p_j &= 1/(1 + \alpha\mu_j) \\ m &= 1/\alpha\end{aligned}$$

Here the vector \mathbf{x}_j contains the covariates specified in *indepvars* for the *j*th observation, and \mathbf{z}_j contains the covariates specified in the `inflate()` option. Similarly, estimates for $\boldsymbol{\beta}$ are found in the first equation of the `zinb` coefficient table (labeled after *depvar*), and the estimates for $\boldsymbol{\gamma}$ are found in the second equation of the coefficient table (labeled `inflate`). The parameter α is the negative binomial

overdispersion parameter, and its estimate is the ancillary parameter labeled α in the coefficient table. Parameters p_j , m , and μ_j are parameters of a negative binomial distribution; see [Methods and formulas](#) in [R] **nbreg** for details.

The log likelihood maximized by **zbnb** is

$$\begin{aligned} \ln L = & \sum_{j \in S} w_j \ln \{F_j + (1 - F_j)p_j^m\} + \\ & \sum_{j \notin S} w_j \left\{ \ln(1 - F_j) + \ln \Gamma(m + y_j) - \ln \Gamma(y_j + 1) \right. \\ & \left. - \ln \Gamma(m) + m \ln p_j + y_j \ln(1 - p_j) \right\} \end{aligned}$$

where w_j are the weights, S is the set of observations for which the observed outcome $y_j = 0$, and F_j is the logistic distribution function

$$F_j = F(\xi_j^\gamma) = \exp(\xi_j^\gamma) / \{1 + \exp(\xi_j^\gamma)\}$$

or, if the probit option is specified, the standard normal distribution function

$$F_j = F(\xi_j^\gamma) = \Phi(\xi_j^\gamma)$$

From [Long \(1997\)](#), the variance of the mixture distribution is

$$\text{Var}(y_j | \mathbf{x}_i, \mathbf{z}_i) = \mu_j(1 - F_j)\{1 + \mu_j(F_j + \alpha)\}$$

When F_j is zero, we have the variance of the negative binomial distribution; when $F_j > 0$, the variance can exceed that of the negative binomial distribution.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **_robust**, particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

zbnb also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

Postestimation commands

The following postestimation commands are available after `zinp`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	number of events, incidence rates, probabilities, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

predict

Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset ]
```

```
predict [type] stub* [if] [in] , scores
```

<i>statistic</i>	Description
------------------	-------------

Main

<code>n</code>	number of events; the default
<code>ir</code>	incidence rate
<code>pr</code>	probability of a degenerate zero
<code>pr(<i>n</i>)</code>	probability $\Pr(y_j = n)$
<code>pr(<i>a</i>, <i>b</i>)</code>	probability $\Pr(a \leq y_j \leq b)$
<code>xb</code>	linear prediction
<code>stdp</code>	standard error of the linear prediction

These statistics are available both in and out of sample; type `predict ... if e(sample)` ... if wanted only for the estimation sample.

Options for predict

Main

`n`, the default, calculates the predicted number of events, which is $(1 - F_j) \exp(\mathbf{x}_j \boldsymbol{\beta})$ if neither `offset()` nor `exposure()` was specified when the model was fit, where F_j is the predicted probability of a zero outcome; $(1 - F_j) \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta)$ if `offset()` was specified; or $(1 - F_j) \{ \exp(\mathbf{x}_j \boldsymbol{\beta}) \times \text{exposure}_j \}$ if `exposure()` was specified.

`ir` calculates the incidence rate, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

`pr` calculates the probability of a degenerate zero, predicted from the fitted degenerate distribution $F_j = F(\mathbf{z}_j \boldsymbol{\gamma})$. If `offset()` was specified within the `inflate()` option, then $F_j = F(\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma)$ is calculated.

`pr(n)` calculates the probability $\Pr(y_j = n)$, where *n* is a nonnegative integer that may be specified as a number or a variable. Note that `pr` is not equivalent to `pr(0)`.

`pr(a, b)` calculates the probability $\Pr(a \leq y_j \leq b)$, where a and b are nonnegative integers that may be specified as numbers or variables;

b missing ($b \geq .$) means $+\infty$;

`pr(20, .)` calculates $\Pr(y_j \geq 20)$;

`pr(20, b)` calculates $\Pr(y_j \geq 20)$ in observations for which $b \geq .$ and calculates

$\Pr(20 \leq y_j \leq b)$ elsewhere.

`pr(., b)` produces a syntax error. A missing value in an observation of the variable a causes a missing value in that observation for `pr(a, b)`.

`xb` calculates the linear prediction, which is $\mathbf{x}_j\beta$ if neither `offset()` nor `exposure()` was specified;

$\mathbf{x}_j\beta + \text{offset}_j^\beta$ if `offset()` was specified; or $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as $\mathbf{x}_j\beta$ rather than as $\mathbf{x}_j\beta + \text{offset}_j^\beta$ or $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$. Specifying `predict ..., nooffset` is equivalent to specifying `predict ..., ir`.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (\mathbf{x}_j\beta)$.

The second new variable will contain $\partial \ln L / \partial (\mathbf{z}_j\gamma)$.

The third new variable will contain $\partial \ln L / \partial \ln \alpha$.

margins

Description for margins

`margins` estimates margins of response for number of events, incidence rates, probabilities, and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<i>statistic</i>	Description
<code>n</code>	number of events; the default
<code>ir</code>	incidence rate
<code>pr</code>	probability of a degenerate zero
<code>pr(<i>n</i>)</code>	probability $\Pr(y_j = n)$
<code>pr(<i>a</i>,<i>b</i>)</code>	probability $\Pr(a \leq y_j \leq b)$
<code>xb</code>	linear prediction
<code>stdp</code>	not allowed with <code>margins</code>

Statistics not allowed with `margins` are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [\[R\] margins](#).

Methods and formulas

See [Methods and formulas](#) in [\[R\] zinb](#) for the model definition and notation.

The probabilities calculated using the `pr(n)` option are the probability $\Pr(y_j = n)$. These are calculated using

$$\begin{aligned}\Pr(y_j = 0 | \mathbf{x}_j, \mathbf{z}_j) &= F_j + (1 - F_j) p_2(0 | \mathbf{x}_j) \\ \Pr(y_j = n | \mathbf{x}_j, \mathbf{z}_j) &= (1 - F_j) p_2(n | \mathbf{x}_j) \quad \text{for } n = 1, 2, \dots\end{aligned}$$

where F_j is the probability of obtaining an observation from the degenerate distribution whose mass is concentrated at zero, and $p_2(n | \mathbf{x}_j)$ is the probability of $y_j = n$ from the nondegenerate, negative binomial distribution. F_j can be obtained by using the `pr` option.

See [Cameron and Trivedi \(2013, sec. 4.6\)](#) for further details.

Description

`ziologit` fits a model for an ordinal outcome with excess zeros, a higher fraction of zeros than would be expected from a standard ordered logit model, also known as zero inflation. This model is known as a zero-inflated ordered logit (ZIOL) model. In the context of ZIOL models, zero is the lowest outcome category. The ZIOL model accounts for the zero inflation by assuming that the zero-valued outcomes come from both a logit model and an ordered logit model, allowing potentially different sets of covariates for each model.

Quick start

Zero-inflated ordered logit model of `y` on `x1` and categorical variable `a` with excess zeros modeled using `x2`

```
ziologit y x1 i.a, inflate(x2)
```

Add offset `x3` to the ordered logit model

```
ziologit y x1 i.a, inflate(x2) offset(x3)
```

Model excess zeros using only a constant

```
ziologit y x1 i.a, inflate(_cons)
```

Model excess zeros with `x2`, and offset `x5` while suppressing the constant term

```
ziologit y x1 i.a, inflate(x2, offset(x5) noconstant)
```

Account for complex sampling design using [svyset](#) data

```
svy: ziologit y x1 i.a, inflate(x2)
```

Menu

Statistics > Ordinal outcomes > Zero-inflated ordered logit regression

Syntax

```
ziologit devar [indepvars] [if] [in] [weight] ,  
         inflate(varlist [ , noconstant offset(varname) ] | _cons) [options]
```

<i>options</i>	Description
<hr/>	
Model	
* <u>inflate</u> ()	inflation equation that determines excess zero values
<u>offset</u> (<i>varname</i>)	include <i>varname</i> in model with coefficient constrained to 1
<u>constraints</u> (<i>constraints</i>)	apply specified linear constraints
SE/Robust	
<u>vce</u> (<i>vcetype</i>)	<i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>opg</u> , <u>bootstrap</u> , or <u>jackknife</u>
Reporting	
<u>level</u> (#)	set confidence level; default is <u>level</u> (95)
<u>nocnsreport</u>	do not display constraints
<u>or</u>	report odds ratios
<i>display_options</i>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<i>maximize_options</i>	control the maximization process; seldom used
<u>collinear</u>	keep collinear variables
<u>coeflegend</u>	display legend instead of statistics
<hr/>	
* <u>inflate</u> (<i>varlist</i> [, <u>noconstant</u> <u>offset</u> (<i>varname</i>)] _cons) is required.	
<i>indepvars</i> and <i>varlist</i> may contain factor variables; see [U] 11.4.3 Factor variables.	
<i>bayes</i> , <i>bayesboot</i> , <i>bootstrap</i> , <i>by</i> , <i>collect</i> , <i>fp</i> , <i>jackknife</i> , <i>rolling</i> , <i>statsby</i> , and <i>svy</i> are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: ziologit.	
Weights are not allowed with the <i>bootstrap</i> prefix; see [R] bootstrap.	
<i>vce</i> () and weights are not allowed with the <i>svy</i> prefix; see [SVY] svy.	
<i>fweights</i> , <i>iweights</i> , and <i>pweights</i> are allowed; see [U] 11.1.6 weight.	
<i>collinear</i> and <i>coeflegend</i> do not appear in the dialog box.	
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.	

Options

Model

`inflate(varlist [, noconstant offset(varname)] | _cons)` specifies the inflation equation for the logit model that determines the excess zero values; this option is required. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `ologit`; see [R] [ologit](#).

`inflate(varlist [, noconstant offset(varname)])` specifies the independent variables in the inflation equation. To suppress the constant in this equation, specify the `noconstant` suboption. You may optionally include an offset for this *varlist*; see `offset(varname)` in [R] [Estimation options](#).

`inflate(_cons)` specifies that the inflation equation contains only an intercept. To run a zero-inflated model of *depvar* with only an intercept in both equations, type `ziologit depvar, inflate(_cons)`.

`offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce_option](#).

Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

or reports the estimated coefficients transformed to odds ratios, that is, e^b rather than b . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. or may be specified at estimation or when replaying previously estimated results.

display_options: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

Maximization

maximize_options: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `ziologit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

Remarks and examples

ZIOL models (Kelley and Anderson 2008) are used when the outcome of interest is an ordinal response with a higher fraction of observations in the lowest level than would be expected from a standard ordered logit model. The observations in the lowest category are often referred to as zeros because they typically correspond to the absence of a behavior or trait. Examples include measurements of symptoms, diet, exercise, drug use, and other ordinal outcomes where the lowest level is “none” or “never”.

With ordinal outcomes, larger values of the response variable represent higher outcome levels, but the precise numeric value is irrelevant. For consistency, we will refer to the lowest category as zero regardless of whether that outcome takes the number 0 in the dataset.

The presence of a high fraction of zeros, also known as zero inflation, is driven by the fact that the lowest-level observations represent two latent (unobservable) groups: subjects with excess zeros and subjects with conditional zeros. Excess zeros are subjects who are not susceptible to the outcome, whereas conditional zeros are susceptible to higher outcomes even though they currently demonstrate zero response. For example, if the outcome is alcohol consumption, a teetotaler who completely abstains from alcohol would be an excess zero, whereas a drinker who chose not to drink on the day of the survey would be a conditional zero.

To determine susceptibility (that is, to identify excess zeros), ZIOL regression uses a logit model for the inflation equation. For the main regression that determines the ordinal outcome of susceptible subjects, ZIOL uses an ordered logit model. The equation for the main regression is sometimes referred to as the intensity equation. These two equations can have different sets of covariates and different offsets. Parameters can be reported as coefficients or odds ratios with the `or` option. See [Methods and formulas](#) for more details.

ZIOL models are similar in spirit to zero-inflated ordered probit (ZIOP) models (see [R] [zioprobit](#)), which use a probit model for the inflation equation and an ordered probit model for the intensity equation. Unlike ZIOP models, the results from ZIOL models can be presented as odds ratios. As such, ZIOL models often appeal to epidemiologists and health researchers, whereas ZIOP models are traditionally used by economists and social scientists. In general, the two types of models tend to produce similar predictions and yield similar inference.

In the context of ZIOL models, the excess-zero or “always-zero” group is often called the nonsusceptible group, and, likewise, the other group is called the susceptible group. In the context of ZIOP models, the terms “nonparticipation” and “participation” are used to refer to the groups. We will use both terminologies interchangeably depending on the context.

The ordered logit model is not nested within the ZIOL model, which means that a likelihood-ratio test cannot be used to check whether a standard ordered logit model is adequate. Instead, one can use information criteria; see [example 2](#) in [R] [zip](#).

► Example 1: Zero-inflated ordered logit model

We use the fictional data on cigarette consumption from [example 1](#) in [\[R\] zioprobit](#). In that example, we fit a ZIOP model to these data; here we fit a ZIOL model. Both models are appropriate for analyzing this zero-inflated ordinal outcome, but the ZIOP model is more likely to be used by an economist studying consumer purchasing patterns, while the ZIOL model is more likely to be used by an epidemiologist studying smoking behavior.

The outcome of interest, `tobacco`, represents daily cigarette consumption as an ordinal response with four levels: 0 indicates “no cigarettes”, and responses 1 through 3 indicate increasing cigarette consumption. More than half of the respondents reported no cigarette consumption, and we suspect that these respondents belong to one of two latent groups. Individuals in the first group are excess zeros, which is to say that they are genuine nonsmokers and thus are not susceptible to cigarette consumption. Individuals in the second group are would-be smokers with no current smoking activity but who might smoke, say, if the price of cigarettes falls or their income increases. These individuals are called conditional zeros because they demonstrate zero cigarette consumption, conditional on being susceptible to smoking. We suspect that these two types of zeros are driven by different patterns of behavior; hence, we choose the ZIOL model over the traditional ordered logit model.

Here the inflation (logit) equation corresponds to the decision to smoke. The intensity (ordered logit) equation corresponds to the level of cigarette consumption by a smoker or would-be smoker. The intensity equation includes covariates for education in years (`education`), annual income in tens of thousands of dollars (`income`), age in decades (`age`), and gender (`female`). The inflation equation includes all the covariates from the intensity equation, plus indicators for whether either of the respondent’s parents smoked (`parent`) and whether the respondent’s religion discourages smoking (`religion`). Covariates for the intensity equation are specified in the `ziologit` command statement directly after the dependent variable `tobacco`. Covariates for the inflation equation are specified in the required `inflate()` option.

The first section of the coefficient table, labeled `tobacco`, corresponds to the tobacco intensity equation and contains coefficients from the ordered logit model fit to susceptible subjects. The second section, labeled `inflate`, corresponds to the inflation equation and contains coefficients from the logit model for susceptibility. ZIOL models allow different sets of covariates in the inflation and intensity equations, but when a variable is included in both equations, it is possible for the coefficients to have opposite signs. The third section of the coefficient table contains the cutpoints from the ordered logit model. See [Remarks and examples](#) in [\[R\] ologit](#) for an explanation of cutpoints.

Compared with the ZIOP model from [example 1](#) in [R] [zioprobit](#), the coefficients here are larger in absolute value, but the z scores and p -values are similar. This is consistent with the fact that the logistic distribution used by ZIOL has heavier tails than the normal distribution used by ZIOP. Perhaps the most important difference between these two models is that the estimated coefficients from the ZIOP model are difficult to interpret, but the coefficients from the ZIOL model can be exponentiated and reported as odds ratios with the `or` option.

We replay our results specifying `or`:

Note: Estimates are transformed only in the first 2 equations to odds ratios.

Note: `_cons` estimates baseline odds.

Examining the odds ratios from the tobacco intensity equation, we see that a one-unit increase in income, which corresponds to an increase of \$10,000 in annual income, raises a smoker's odds of increased cigarette consumption by a factor of 3.63. Looking at the inflation equation, we see that a one-unit increase in income lowers the odds of being susceptible to smoking by a factor of 0.825. This suggests that wealthier individuals are less likely to smoke (consistent with income acting as a proxy for health consciousness), but if they do decide to smoke, they tend to smoke more cigarettes (perhaps because they can afford them).

<code>e(asobserved)</code>	factor variables <code>fvset</code> as <code>asobserved</code>

Matrices	
e(b)	coefficient vector
e(Cns)	constraints matrix
e(ilog)	iteration log (up to 20 iterations)
e(gradient)	gradient vector
e(cat)	category values
e(V)	variance–covariance matrix of the estimators
e(V_modelbased)	model-based variance
Functions	
e(sample)	marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices	
r(table)	matrix containing the coefficients with their standard errors, test statistics, p -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

The modern class of zero-inflated models was originally developed by [Lambert \(1992\)](#) to address the problem of excess zeros in count data (see [\[R\] zip](#)). This model framework has been extended to ordinal outcomes with the ZIOL model by [Kelley and Anderson \(2008\)](#).

The precise numeric value of an ordinal outcome is irrelevant, so without loss of generality we consider an ordinal response variable Y with levels coded as $0, 1, 2, \dots, H$. The first step in the ZIOL model is to determine susceptibility. Let $s_j = 1$ if the j th individual is susceptible to exhibiting a nonzero response, and let $s_j = 0$ if the j th individual is an excess zero. (Similarly, using alternative terminology, let individuals with $s_j = 1$ belong to the participation group and those with $s_j = 0$ belong to the nonparticipation group.) The ZIOL inflation equation uses a logit model to determine the probability of susceptibility (or participation) as

$$\Pr(s_j = 1 | \mathbf{z}_j) = F(\mathbf{z}_j \boldsymbol{\gamma}) \quad (1)$$

\mathbf{z}_j is a vector of covariates that determines susceptibility, $\boldsymbol{\gamma}$ is a vector of coefficients that have to be estimated, and $F(\cdot)$ is the logistic distribution function: $F(x) = e^x / (1 + e^x)$.

Next, conditioning on $s_j = 1$, outcome intensity levels \tilde{y}_j are modeled using an ordered logit model whose levels may also include 0. The corresponding probabilities are given by

$$\Pr(\tilde{y}_j = h | s_j = 1, \mathbf{x}_j) = F(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - F(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta}) \quad h = 0, 1, \dots, H \quad (2)$$

\mathbf{x}_j is a vector of covariates that determine intensity (which can be different from \mathbf{z}_j), $\boldsymbol{\beta}$ is a vector of coefficients to be estimated, and cutpoints κ_h are boundary parameters to be estimated (subject to $\kappa_{-1} = -\infty$, $\kappa_H = +\infty$). These cutpoints take the place of an intercept.

The observed response variable is $y_j = s_j \tilde{y}_j$. Thus, a zero outcome occurs when $s_j = 0$ (the individual is an excess zero) or when $s_j = 1$ and $\tilde{y}_j = 0$ (the individual is a conditional zero). To observe a positive y_j , there is a joint requirement that $s_j = 1$ and $\tilde{y}_j > 0$.

The distribution of Y is given by

$$\begin{aligned} \Pr(Y) &= \begin{cases} \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) \end{cases} \quad h = 1, 2, \dots, H \\ &= \begin{cases} \Pr(s_j = 0 | \mathbf{z}_j) + \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = 0 | s_j = 1, \mathbf{x}_j) \\ \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = h | s_j = 1, \mathbf{x}_j) \end{cases} \quad h = 1, 2, \dots, H \end{aligned} \quad (3)$$

The probability of zero outcome has been inflated because it is the sum of the probability of zero intensity from the ordered logit model and the probability of nonsusceptibility from the logit model.

Substituting (1) and (2) in (3), we get

$$\begin{aligned} \Pr(Y) &= \begin{cases} \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = H | \mathbf{z}_j, \mathbf{x}_j) \end{cases} \quad h = 1, 2, \dots, H - 1 \\ &= \begin{cases} \{1 - F(\mathbf{z}_j \boldsymbol{\gamma})\} + F(\mathbf{z}_j \boldsymbol{\gamma}) F(\kappa_0 - \mathbf{x}_j \boldsymbol{\beta}) \\ F(\mathbf{z}_j \boldsymbol{\gamma}) \{F(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - F(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta})\} \\ F(\mathbf{z}_j \boldsymbol{\gamma}) \{1 - F(\kappa_{H-1} - \mathbf{x}_j \boldsymbol{\beta})\} \end{cases} \quad h = 1, 2, \dots, H - 1 \end{aligned} \quad (4)$$

If the `offset()` option is specified, $\mathbf{x}_j \boldsymbol{\beta}$ in the intensity equation is replaced with $\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta$. If the `offset()` suboption is specified in the `inflate()` option, $\mathbf{z}_j \boldsymbol{\gamma}$ in the inflation equation is replaced with $\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma$.

The log-likelihood function is

$$\ln L = \sum_{j=1}^N w_j \sum_{h=0}^H I(y_j = h) \ln \{\Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j)\}$$

where w_j is an optional weight for the j th observation and

$$I(y_j = h) = \begin{cases} 1 & \text{if } y_j = h \\ 0 & \text{otherwise} \end{cases}$$

The choice between the ZIOL model and the ordered logit model cannot be made using a likelihood-ratio test because the two hypotheses are not nested in the usual sense of parameter restrictions. The inflation effect is removed, and all subjects are deemed susceptible when $\mathbf{z}_j \boldsymbol{\gamma} \rightarrow \infty$, a condition that cannot be imposed. To compare the fits of nonnested models, you can use `estat ic` to display information criteria (see [R] [estat ic](#)).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version with `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`zilogit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

Postestimation commands

The following postestimation commands are available after `ziologit`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	probabilities, linear predictions and their SEs, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [ , statistic
outcome(outcome) nooffset ]

predict [type] stub* [if] [in] , scores
```

statistic	Description
Main	
pmargin	marginal probabilities of levels, $\Pr(y_j = h)$; the default
pjoint1	joint probabilities of levels and susceptibility, $\Pr(y_j = h, s_j = 1)$
pcond1	probabilities of levels conditional on susceptibility, $\Pr(y_j = h s_j = 1)$
ps	probability of susceptibility, $\Pr(s_j = 1)$
pns	probability of nonsusceptibility, $\Pr(s_j = 0)$
xb	linear prediction
xbinfl	linear prediction for inflation equation
stdp	standard error of the linear prediction
stdpinfl	standard error of the linear prediction for inflation equation

If you do not specify outcome(), pmargin, pjoint1, and pcond1 (with one new variable specified) assume outcome(#1). You specify one or *k* new variables with pmargin, pjoint1, and pcond1, where *k* is the number of outcomes. You specify one new variable with ps, pns, xb, xbinfl, stdp, and stdpinfl. These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

Main

`pmargin`, the default, calculates the predicted marginal probabilities of outcome levels, $\Pr(y_j = h)$.

`pjoint1` calculates the predicted joint probabilities of outcome levels and susceptibility, $\Pr(y_j = h, s_j = 1)$.

`pcond1` calculates the predicted probabilities of outcome levels conditional on susceptibility, $\Pr(y_j = h | s_j = 1)$.

With `pmargin`, `pjoint1`, and `pcond1`, you can compute predicted probabilities for one or for all outcome levels. When you specify one new variable, `predict` computes probabilities for the first outcome level. You can specify the `outcome(#i)` option to obtain probabilities for the i th level. When you specify multiple new variables or a stub, `predict` computes probabilities for all outcome levels. The behavior of `predict` with one new variable is equivalent to specifying `outcome(#1)`.

`ps` and `pns` calculate the predicted marginal probability of susceptibility [$\Pr(s_j = 1)$] and of nonsusceptibility [$\Pr(s_j = 0)$], respectively.

In econometrics literature, probabilities of susceptibility and nonsusceptibility are known as probabilities of participation and nonparticipation. Similarly to `predict` after `zioprobit`, you can use options `ppar` and `pnpar` to compute these probabilities. Options `ppar` and `pnpar` produce identical results to the respective options `ps` and `pns` but label new variables as `Pr(participation)` and `Pr(nonparticipation)` instead of `Pr(susceptible)` and `Pr(nonsusceptible)`.

`xb` calculates the linear prediction for the ordered logit equation, which is $\mathbf{x}_j\beta$ if `offset()` was not specified with `ziologit` and is $\mathbf{x}_j\beta + \text{offset}_j^\beta$ if `offset()` was specified.

`xbinfl` calculates the linear prediction for the inflation equation, which is $\mathbf{z}_j\gamma$ if `offset()` was not specified in `inflate()` and is $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$ if `offset()` was specified in `inflate()`.

`stdp` calculates the standard error of the linear prediction for the ordered logit equation.

`stdpinfl` calculates the standard error of the linear prediction for the inflation equation.

`outcome(outcome)` specifies the outcome for which predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is allowed only with `pmargin`, `pjoint1`, and `pcond1`.

`nooffset` is relevant only if you specified `offset(varname)` with `ziologit` or within the `inflate()` option. It modifies the calculations made by `predict` so that they ignore the offset variable; that is, the linear prediction for the main regression equation is treated as $\mathbf{x}_j\beta$ rather than as $\mathbf{x}_j\beta + \text{offset}_j^\beta$ and the linear prediction for the inflation equation is treated as $\mathbf{z}_j\gamma$ rather than as $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (\mathbf{x}_j\beta)$. In the absence of independent variables in the main equation, this variable is not stored.

The second new variable will contain $\partial \ln L / \partial (\mathbf{z}_j\gamma)$.

When the dependent variable takes k different values, the third new variable through new variable $k + 1$ will contain $\partial \ln L / \partial (\kappa_h)$ for $h = 0, 1, \dots, k - 2$.

margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]  
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

statistic	Description
default	marginal probabilities for each outcome
<u>pmargin</u>	marginal probabilities of levels, $\Pr(y_j = h)$; the default
<u>pjoint1</u>	joint probabilities of levels and susceptibility, $\Pr(y_j = h, s_j = 1)$
<u>pcond1</u>	probabilities of levels conditional on susceptibility, $\Pr(y_j = h s_j = 1)$
<u>ps</u>	probability of susceptibility, $\Pr(s_j = 1)$
<u>pns</u>	probability of nonsusceptibility, $\Pr(s_j = 0)$
<u>xb</u>	linear prediction
<u>xbinfl</u>	linear prediction for inflation equation
<u>stdp</u>	not allowed with margins
<u>stdpinfl</u>	not allowed with margins

pmargin, pjoint1, and pcond1 default to the first outcome.
Statistics not allowed with margins are functions of stochastic quantities other than $e(b)$.
For the full syntax, see [R] margins.

Remarks and examples

The ZIOL model allows all the predictions and marginal effects available with the standard `ologit` model (see [\[R\] ologit postestimation](#)), along with additional predictions and marginal effects related to the inflation equation for susceptibility. The probabilities of susceptibility and nonsusceptibility can be calculated using options `ps` and `pns`, respectively. If you prefer an alternative terminology of probabilities of participation and nonparticipation, you can instead use options `ppar` and `pnpair`, which will produce identical numerical results but label variables as `Pr(participation)` and `Pr(nonparticipation)` instead of `Pr(susceptible)` and `Pr(nonsusceptible)`.

► Example 1: Average marginal effect of gender on probability of nonsusceptibility

In [example 1](#) of [\[R\] ziologit](#), we fit a model for levels of cigarette consumption.

```
. use https://www.stata-press.com/data/r19/tobacco
(Fictional tobacco consumption data)

. ziologit tobacco education income age i.female,
> inflate(education income age i.female i.parent i.religion)
(output omitted)
```

This model parallels the zero-inflated ordered probit (ZIOP) model that was fit in [example 1](#) of [\[R\] zio-probit](#).

To continue the comparison between the ZIOL and ZIOP models, we re-create [example 1](#) from [\[R\] zio-probit postestimation](#) by using `margins` to estimate the average marginal effect of gender on the probability of nonsusceptibility (being an excess zero) for individuals with a college degree (17 years of education) and a smoking parent.

```
. margins, predict(pns) dydx(female) at(education = 17 parent = 1)
Average marginal effects                                Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonsusceptible), predict(pns)
dy/dx wrt: 1.female
At: education = 17
    parent   = 1
```

	Delta-method		z	P> z	[95% conf. interval]	
	dy/dx	std. err.				
female	.085421	.010096	8.46	0.000	.0656333	.1052087
Female						

Note: dy/dx for factor levels is the discrete change from the base level.

Despite the differences between the ZIOL and ZIOP models, the conclusion is the same: women with a college degree and a smoking parent are expected to have an approximately 8.5% higher chance of being genuine nonsmokers (excess zeros) than comparable men.

► Example 2: Predicted probabilities of conditional zeros

Next, we consider the effect of income on the probability of zero tobacco consumption, conditional on susceptibility. These would-be smokers are known as conditional zeros. In [example 1](#) of [\[R\] ziologit](#), we saw that increasing income raises a smoker’s odds of increased tobacco consumption dramatically, so we expect to see a larger fraction of conditional zeros at the lower end of the income scale.

We examine conditional probabilities of zero consumption for incomes ranging from \$10,000 to \$60,000, and we use the `noatlegend` option to suppress the default legend because we know the values 1 to 6 correspond to income in tens of thousands of dollars.

```
. margins, predict(pcond1 outcome(0)) at(income = (1/6)) noatlegend
Predictive margins                                Number of obs = 15,000
Model VCE: OIM
Expression: Pr(tobacco=0|susceptible=1), predict(pcond1 outcome(0))
```

	Delta-method		z	P> z	[95% conf. interval]	
	Margin	std. err.				
_at						
1	.5923634	.0027586	214.73	0.000	.5869566	.5977702
2	.5393818	.0025948	207.87	0.000	.534296	.5444676
3	.4854668	.0024651	196.94	0.000	.4806354	.4902982
4	.4306299	.0023953	179.78	0.000	.4259352	.4353245
5	.3741538	.0024547	152.42	0.000	.3693427	.3789649
6	.3152985	.0026294	119.91	0.000	.3101449	.320452

The influence of income is dramatic: susceptible individuals (potential smokers) who earn \$10,000 a year are almost twice as likely to refrain from smoking as potential smokers who earn \$60,000 per year (59% versus 32%).

Methods and formulas

See *Methods and formulas* in [R] **ziologit** for the model definition and notation. Specifically, see (1) for the formula for the probability of susceptibility, $\Pr(s_j = 1|\mathbf{z}_j)$; see (2) for the formula for the probabilities of outcome levels conditional on susceptibility, $\Pr(y_j = h|s_j = 1, \mathbf{x}_j)$; and see (4) for the formula for the marginal probabilities of outcome levels, $\Pr(y_j = h|\mathbf{z}_j, \mathbf{x}_j)$.

The joint probability of susceptibility and outcome $y_j = h$ can be expressed as

$$\Pr(y_j = h, s_j = 1|\mathbf{z}_j, \mathbf{x}_j) = \Pr(s_j = 1|\mathbf{z}_j) \Pr(y_j = h|s_j = 1, \mathbf{x}_j)$$

for $h = 0, 1, \dots, H$.

Description

`zioprobit` fits a model for an ordinal outcome with excess zeros, a higher fraction of zeros than would be expected from a standard ordered probit model, also known as zero inflation. This model is known as a zero-inflated ordered probit (ZIOP) model. In the context of ZIOP models, zero is an actual 0 value or the lowest outcome category. The ZIOP model accounts for the zero inflation by assuming that the zero-valued outcomes come from both a probit model and an ordered probit model, allowing potentially different sets of covariates for each model.

Quick start

Zero-inflated ordered probit model of `y` on `x1` and categorical variable `a` with excess zeros modeled using `x2`

```
zioprobit y x1 i.a, inflate(x2)
```

Add offset `x3` to the ordered probit model

```
zioprobit y x1 i.a, inflate(x2) offset(x3)
```

Model excess zeros using only a constant

```
zioprobit y x1 i.a, inflate(_cons)
```

Model excess zeros with `x2`, and offset `x5` while suppressing the constant term

```
zioprobit y x1 i.a, inflate(x2, offset(x5) noconstant)
```

Account for complex sampling design using `svyset` data

```
svy: zioprobit y x1 i.a, inflate(x2)
```

Menu

Statistics > Ordinal outcomes > Zero-inflated ordered probit regression

Syntax

```
zioprobit depvar [indepvars] [if] [in] [weight] ,
      inflate(varlist [ , noconstant offset(varname) ] | _cons) [options]
```

<i>options</i>	Description
Model	
* <u>inflate</u> ()	inflation equation that determines excess zero values
<u>offset</u> (<i>varname</i>)	include <i>varname</i> in model with coefficient constrained to 1
<u>constraints</u> (<i>constraints</i>)	apply specified linear constraints
SE/Robust	
vce(<i>vcetype</i>)	<i>vcetype</i> may be oim, <u>robust</u> , <u>cluster</u> <i>clustvar</i> , opg, <u>bootstrap</u> , or <u>jackknife</u>
Reporting	
<u>level</u> (#)	set confidence level; default is level(95)
<u>nocnsreport</u>	do not display constraints
<u>display_options</u>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
Maximization	
<u>maximize_options</u>	control the maximization process; seldom used
<u>collinear</u>	keep collinear variables
<u>coeflegend</u>	display legend instead of statistics

*inflate(*varlist* [, noconstant offset(*varname*)] | _cons) is required.

indepvars and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

bayes, bayesboot, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: zioprobit.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

Model

`inflate(varlist [, noconstant offset(varname)] | _cons)` specifies the inflation equation for the probit model that determines the excess zero values; this option is required. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `oprobit`; see [R] [oprobit](#).

`inflate(varlist [, noconstant offset(varname)])` specifies the independent variables in the inflation equation. To suppress the constant in this equation, specify the `noconstant` suboption. You may optionally include an offset for this *varlist*; see `offset(varname)` in [R] [Estimation options](#).

`inflate(_cons)` specifies that the inflation equation contains only an intercept. To run a zero-inflated model of *depvar* with only an intercept in both equations, type `zioprobit depvar, inflate(_cons)`.

`offset(varname)`, `constraints(constraints)`; see [R] [Estimation options](#).

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce_option](#).

Reporting

`level(#)`, `nocnsreport`; see [R] [Estimation options](#).

display_options: `nocl`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `novlabeled`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `no1stretch`; see [R] [Estimation options](#).

Maximization

maximize_options: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `zioprobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

Remarks and examples

ZIOP models are used when the outcome of interest is an ordinal response variable and the data exhibit a high fraction of observations in the lowest category or what we will refer to from now on as “zero” but without quotes. Like the ordered probit model, the actual values taken by the ordinal response variable are irrelevant. While the outcome is typically coded as 0, 1, 2, ..., *H*, `zioprobit` interprets the lowest value present in the dataset as 0 to be consistent with the original derivation of the model and subsequent applications.

Like all zero-inflated models, the ZIOP model is an alternative when the data exhibit a higher fraction of zero-valued outcomes than is likely compatible with an ordered probit model. This concentration of zeros is referred to as zero inflation. Inflation is assumed to occur in the lowest value to ensure that shifting the levels of the ordinal response variable by a constant will not affect the estimated parameters in the model. This is common in ordered probit models; see [\[R\] oprobit](#).

Without loss of generality, we consider an ordinal response variable with levels 0, 1, 2, ..., H . Traditional ordered probit models treat all observations with zero-valued outcomes as a homogeneous group. By contrast, ZIOP models assume that zeros could occur in the data as members of two latent (unobservable) groups. Individuals in the “always-zero” group have outcome 0 as the only possible value. This first group is often called the nonparticipation group. The second group, in addition to 0, may also assume any of the other values, 1, 2, ..., H . This group is often called the participation group. Some disciplines, such as public health and medicine, refer to the process that determines the zeros rather than the groups. In this case, there is an incidence or occurrence process that determines whether an observation belongs to the always-zero group and a severity or intensity process that determines the level in the second group. The result of having two groups or processes is an inflation in the proportion of zero-valued observations in the data.

The ZIOP model has been used in studies of international and domestic conflicts ([Bagozzi et al. 2015](#)), sports participation ([Downward, Lera-Lopez, and Rasciute 2011](#)), and the adoption of new building technologies ([Ganguly, Koebel, and Cantrell 2010](#)), to name a few. See [Kelley and Anderson \(2008\)](#) for a discussion of zero-inflated ordinal models in the context of health.

The classic application of the ZIOP model is the study of tobacco use by [Harris and Zhao \(2007\)](#). Like the zero-inflated Poisson models in the count-data literature ([Lambert 1992](#)), [Harris and Zhao](#) derived the ZIOP model using a two-stage decision process. An individual must decide whether to participate in an activity (for example, smoking or drug consumption) and, conditional on participating, must decide on the level of participation, which also includes zero participation. The first decision is a binary choice and is modeled using a probit model, while the second is an ordered choice and is modeled using an ordered probit model. In other terms, to account for the excess of zeros, [Harris and Zhao](#) allowed for zero observations to occur in two ways: as a realization of the probit model (nonparticipants) and as a realization of the ordered probit model when the binary random variable in the probit model is 1 (participant with zero activity). See [Methods and formulas](#) for more details. For a Bayesian derivation of the ZIOP model, see [Gurmu and Dagne \(2012\)](#).

You may want to check whether a standard ordered probit model is adequate to fit the data. You can do this, for instance, using information criteria; see [example 2](#) in [\[R\] zip](#).

► Example 1: Zero-inflated ordered probit model

We have fictional data on cigarette consumption per day for 15,000 subjects between ages 14 and 84. The outcome of interest, tobacco, is an ordinal response with four levels coded as 0 for “no cigarettes”, 1 for “up to 8 cigarettes/day”, 2 for “8 to 12 cigarettes/day”, and 3 for “more than 12 cigarettes/day”. The exact number of daily consumed cigarettes is unknown.

About 63% of the respondents identified themselves as current nonsmokers. We suspect that these self-identified current nonsmokers belong to one of two groups. Individuals in the first group are genuine nonsmokers (always-zero group) who have never smoked and will never smoke. Individuals in the second group are smokers with no smoking activity who could be the corner solution of a standard consumer demand problem and who may smoke, say, if the price of tobacco falls or their income increases. It is likely that these two types of zeros are driven by different patterns of consumer behavior and a ZIOP model is a good candidate in this case.

We model tobacco consumption levels for subjects who choose to smoke as a function of years of education (education), annual income in tens of thousands of dollars (income), age in tens of years (age), and whether the respondent is a female (female). In addition to education, income, age, and female, the decision to smoke is modeled as a function of whether either of the respondent's parents smoked (parent) and whether the respondent's religion discourages smoking (religion). We list all the covariates in the required `inflate()` option.

```
. use https://www.stata-press.com/data/r19/tobacco
(Fictional tobacco consumption data)

. zioprobit tobacco education income i.female age,
> inflate(education income i.parent age i.female i.religion)

Iteration 0:  Log likelihood = -14820.211   (not concave)
Iteration 1:  Log likelihood = -12819.475   (not concave)

/cut1	2.959808	.0753035			2.812216	3.1074
/cut2	8.111228	.1648965			7.788037	8.43442
/cut3	11.20791	.2247711			10.76736	11.64845

In the output table, the first set of coefficients, labeled tobacco, corresponds to the participation (smoking) levels. These coefficients are interpreted in the same way as coefficients from an ordered probit model. The second set of coefficients, labeled inflate, corresponds to the equation for the participation decision. These are interpreted in the same way as coefficients from a binary probit model. ZIOP models do not require the variables to be the same in the participation level and decision equations. However, the same variables can appear in both. If the same variables are included, it is not uncommon for the coefficients to have opposite signs. For example, income and education in the model above have positive signs in the level equation and negative signs in the decision equation.

The estimated coefficients are not particularly informative, and as with all discrete choice models, marginal effects are better to interpret. We use `margins` to estimate the average marginal effect of having a smoking parent on the probability of being a genuine nonsmoker. Specifying `pnpar` within the `predict()` option means that we are requesting the predicted probability of nonparticipation, which in our example is equivalent to being a genuine nonsmoker.

```
. margins, predict(pnpar) dydx(parent)
Average marginal effects                               Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonparticipation), predict(pnpar)
dy/dx wrt: 1.parent
```

	Delta-method					[95% conf. interval]
	dy/dx	std. err.	z	P> z		
parent Smoking	-.1797895	.0071967	-24.98	0.000	-.1938948	-.1656843

Note: dy/dx for factor levels is the discrete change from the base level.

On average, individuals whose parents are smokers are about 18% less likely to be nonsmokers themselves than individuals whose parents did not use tobacco. See [\[R\] zioprobit postestimation](#) for more information and examples.

Stored results

zioprobit stores the following in `e()`:

Scalars

<code>e(N)</code>	number of observations
<code>e(N_zero)</code>	number of zeros or lowest-category observations
<code>e(k_cat)</code>	number of categories
<code>e(k)</code>	number of parameters
<code>e(k_eq)</code>	number of equations in <code>e(b)</code>
<code>e(k_eq_model)</code>	number of equations in overall model test
<code>e(k_aux)</code>	number of auxiliary parameters
<code>e(k_dv)</code>	number of dependent variables
<code>e(df_m)</code>	model degrees of freedom
<code>e(ll)</code>	log likelihood
<code>e(N_clust)</code>	number of clusters
<code>e(chi2)</code>	χ^2
<code>e(p)</code>	p -value for model test
<code>e(rank)</code>	rank of <code>e(V)</code>
<code>e(ic)</code>	number of iterations
<code>e(rc)</code>	return code

<code>e(V_modelbased)</code>	model-based variance

Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices

`r(table)`

matrix containing the coefficients with their standard errors, test statistics, p -values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

Consider an ordinal response variable Y with levels coded as $0, 1, 2, \dots, H$. For notational simplicity, we assume that the zeros are inflated, but the following derivation may be adapted to accommodate inflation in the lowest outcome category. Harris and Zhao (2007) derived the ZIOP model in two steps. First, the group membership (participants versus nonparticipants) can be modeled using a probit model. Let $s_j = 1$ if the j th individual belongs to the participation group or let $s_j = 0$ otherwise. With the probit model, the probability of participation is given by

$$\Pr(s_j = 1 | \mathbf{z}_j) = \Phi(\mathbf{z}_j \boldsymbol{\gamma}) \quad (1)$$

\mathbf{z}_j is a vector of covariates that determines group membership, $\boldsymbol{\gamma}$ is a vector of coefficients that have to be estimated, and $\Phi(\cdot)$ is the standard normal distribution function. Next, conditioning on $s_j = 1$, participation levels \tilde{y}_j are modeled using an ordered probit model; these levels may also include 0. The corresponding probabilities are given by

$$\Pr(\tilde{y}_j = h | s_j = 1, \mathbf{x}_j) = \Phi(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - \Phi(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta}) \quad h = 0, 1, \dots, H \quad (2)$$

where $\kappa_{-1} = -\infty$, $\kappa_H = +\infty$, and \mathbf{x}_j is a vector of covariates that could be different from \mathbf{z}_j . κ_h are boundary parameters that need to be estimated in addition to the coefficients vector $\boldsymbol{\beta}$.

The intercept β_0 is set equal to 0 in (2) for identification. Note that s_j and \tilde{y}_j are both unobservable in terms of the zeros. The observed response variable is $y_j = s_j \tilde{y}_j$. Thus, the zero outcome occurs when $s_j = 0$ (the individual is not a participant) or occurs when $s_j = 1$ and $\tilde{y}_j = 0$ (the individual is a participant with zero activity). To observe a positive y_j , it is a joint requirement that $s_j = 1$ and $\tilde{y}_j > 0$.

The distribution of Y is given by

$$\begin{aligned} \Pr(Y) &= \begin{cases} \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) \end{cases} \quad h = 1, 2, \dots, H \\ &= \begin{cases} \Pr(s_j = 0 | \mathbf{z}_j) + \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = 0 | s_j = 1, \mathbf{x}_j) \\ \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = h | s_j = 1, \mathbf{x}_j) \end{cases} \quad h = 1, 2, \dots, H \end{aligned} \quad (3)$$

The probability of zero outcome has been inflated because it is the sum of the probability of zero activity from the ordered probit model and the probability of nonparticipation from the probit model.

Substituting (1) and (2) in (3), we get

$$\Pr(Y) = \begin{cases} \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) & h = 1, 2, \dots, H-1 \\ \Pr(y_j = H | \mathbf{z}_j, \mathbf{x}_j) \end{cases}$$

$$= \begin{cases} \{1 - \Phi(\mathbf{z}_j\gamma)\} + \Phi(\mathbf{z}_j\gamma)\Phi(\kappa_0 - \mathbf{x}_j\beta) \\ \Phi(\mathbf{z}_j\gamma) \{ \Phi(\kappa_h - \mathbf{x}_j\beta) - \Phi(\kappa_{h-1} - \mathbf{x}_j\beta) \} & h = 1, 2, \dots, H-1 \\ \Phi(\mathbf{z}_j\gamma) \{1 - \Phi(\kappa_{H-1} - \mathbf{x}_j\beta)\} \end{cases}$$

If the respective `offset()` option is specified, $\mathbf{x}_j\beta$ and $\mathbf{z}_j\gamma$ are replaced with $\mathbf{x}_j\beta + \text{offset}_j^\beta$ and $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$, respectively.

The log-likelihood function is

$$\ln L = \sum_{j=1}^N w_j \sum_{h=0}^H I(y_j = h) \ln \{ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) \}$$

where w_j is an optional weight for the j th observation and

$$I(y_j = h) = \begin{cases} 1 & \text{if } y_j = h \\ 0 & \text{otherwise} \end{cases}$$

The choice between the ZIOP model and the ordered probit model cannot be made using a likelihood-ratio test because the two hypotheses are not nested in the usual sense of parameter restrictions. The restriction $\gamma = 0$ does not eliminate the inflation effect; it makes the group membership probabilities both equal to 0.5 [see (1)]. What is needed to remove the inflation effect is $\mathbf{z}_j\gamma \rightarrow \infty$, which cannot be imposed. Because ZIOP and ordered probit models are not nested, you can compare the fits of the two models using information criteria.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version with `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`zioprobit` also supports estimation with survey data. For details on VCEs with survey data, see [\[SVY\] Variance estimation](#).

Postestimation commands

Remarks and examples

predict

Methods and formulas

margins

Also see

Postestimation commands

The following postestimation commands are available after `zioprobit`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	probabilities, linear predictions and their SEs, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [ , statistic
outcome(outcome) nooffset ]
```

```
predict [type] stub* [if] [in] , scores
```

statistic	Description
Main	
pmargin	marginal probabilities of levels, $\Pr(y_j = h)$; the default
pjoint1	joint probabilities of levels and participation, $\Pr(y_j = h, s_j = 1)$
pcond1	probabilities of levels conditional on participation, $\Pr(y_j = h s_j = 1)$
ppar	probability of participation, $\Pr(s_j = 1)$
pnpar	probability of nonparticipation, $\Pr(s_j = 0)$
xb	linear prediction
xbinfl	linear prediction for inflation equation
stdp	standard error of the linear prediction
stdpinfl	standard error of the linear prediction for inflation equation

If you do not specify outcome(), pmargin, pjoint1, and pcond1 (with one new variable specified) assume outcome(#1).

You specify one or *k* new variables with pmargin, pjoint1, and pcond1, where *k* is the number of outcomes.

You specify one new variable with ppar, pnpar, xb, xbinfl, stdp, and stdpinfl.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

Main

`pmargin`, the default, calculates the predicted marginal probabilities of outcome levels, $\Pr(y_j = h)$.

`pjoint1` calculates the predicted joint probabilities of outcome levels and participation, $\Pr(y_j = h, s_j = 1)$.

`pcond1` calculates the predicted probabilities of outcome levels conditional on participation, $\Pr(y_j = h | s_j = 1)$.

With `pmargin`, `pjoint1`, and `pcond1`, you can compute predicted probabilities for one or for all outcome levels. When you specify one new variable, `predict` computes probabilities for the first outcome level. You can specify the `outcome(#i)` option to obtain probabilities for the i th level. When you specify multiple new variables or a stub, `predict` computes probabilities for all outcome levels. The behavior of `predict` with one new variable is equivalent to specifying `outcome(#1)`.

`ppar` and `pnpar` calculate the predicted marginal probability of participation [$\Pr(s_j = 1)$] and of non-participation [$\Pr(s_j = 0)$], respectively.

In health-related fields, probabilities of participation and nonparticipation are known as probabilities of susceptibility and nonsusceptibility. Similarly to `predict` after `ziologit`, you can use options `ps` and `pns` to compute these probabilities. Options `ps` and `pns` produce identical results to the respective options `ppar` and `pnpar` but label new variables as $\Pr(\text{susceptible})$ and $\Pr(\text{nonsusceptible})$ instead of $\Pr(\text{participation})$ and $\Pr(\text{nonparticipation})$.

`xb` calculates the linear prediction for the ordered probit equation, which is $\mathbf{x}_j\beta$ if `offset()` was not specified with `zioprobit` and is $\mathbf{x}_j\beta + \text{offset}_j^\beta$ if `offset()` was specified.

`xbinfl` calculates the linear prediction for the inflation equation, which is $\mathbf{z}_j\gamma$ if `offset()` was not specified in `inflate()` and is $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$ if `offset()` was specified in `inflate()`.

`stdp` calculates the standard error of the linear prediction for the ordered probit equation.

`stdpinfl` calculates the standard error of the linear prediction for the inflation equation.

`outcome(outcome)` specifies the outcome for which predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is allowed only with `pmargin`, `pjoint1`, and `pcond1`.

`nooffset` is relevant only if you specified `offset(varname)` with `zioprobit` or within the `inflate()` option. It modifies the calculations made by `predict` so that they ignore the offset variable; that is, the linear prediction for the main regression equation is treated as $\mathbf{x}_j\beta$ rather than as $\mathbf{x}_j\beta + \text{offset}_j^\beta$ and the linear prediction for the inflation equation is treated as $\mathbf{z}_j\gamma$ rather than as $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (\mathbf{x}_j\beta)$. In the absence of independent variables in the main equation, this variable is not stored.

The second new variable will contain $\partial \ln L / \partial (\mathbf{z}_j\gamma)$.

When the dependent variable takes k different values, the third new variable through new variable $k + 1$ will contain $\partial \ln L / \partial (\kappa_h)$ for $h = 0, 1, \dots, k - 2$.

margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

statistic	Description
default	marginal probabilities for each outcome
pmargin	marginal probabilities of levels, $\Pr(y_j = h)$; the default
pjoint1	joint probabilities of levels and participation, $\Pr(y_j = h, s_j = 1)$
pcond1	probabilities of levels conditional on participation, $\Pr(y_j = h s_j = 1)$
ppar	probability of participation, $\Pr(s_j = 1)$
pnpar	probability of nonparticipation, $\Pr(s_j = 0)$
xb	linear prediction
xbinfl	linear prediction for inflation equation
stdp	not allowed with margins
stdpinfl	not allowed with margins

pmargin, pjoint1, and pcond1 default to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] margins.

Remarks and examples

Various sets of predictions and marginal effects may be of interest for the ZIOP model. For instance, we may want to investigate the marginal effects of a covariate on the probability of participation, or on the probabilities for levels of consumption conditional on participation, or on the overall probabilities for different consumption levels. We explore these options in greater detail in the following examples.

► Example 1: Average marginal effects on probability of nonparticipation

In [example 1](#) of [\[R\] zioprobit](#), we fit a model for level of cigarette consumption.

```
. use https://www.stata-press.com/data/r19/tobacco
(Fictional tobacco consumption data)

. zioprobit tobacco education income i.female age,
> inflate(education income i.parent age i.female i.religion)

(output omitted)
```

We can use `margins` to estimate the expected marginal effect of gender for individuals with a college degree (17 years of education) and a smoking parent on the probability of nonparticipation (being a genuine nonsmoker). To do this, we specify `predict(pnpar)` with `margins` as follows:

```
. margins, predict(pnpar) dydx(female) at(education = 17 parent = 1)
Average marginal effects                                Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonparticipation), predict(pnpar)
dy/dx wrt:  1.female
At: education = 17
    parent   =  1
```

	Delta-method				[95% conf. interval]	
	dy/dx	std. err.	z	P> z		
female	.0855995	.0100239	8.54	0.000	.0659531	.105246
Female						

Note: dy/dx for factor levels is the discrete change from the base level.

Women with a college degree and a smoking parent are expected to have about an 8.5% higher chance of being genuine nonsmokers than do men.

► Example 2: Predicted probabilities of zero-valued outcomes

In [example 1](#) of [\[R\] zioprobit](#), we found that the coefficient on `income` was positive in the level equation but negative in the participation equation. In the case of our tobacco consumption example, economic theory offers a reasonable interpretation for this. Higher income may act as an indicator for health awareness, which accounts for its association with an increased probability of being a genuine nonsmoker. However, if cigarettes are a normal good—that is, something for which demand increases when income increases—then smokers with higher income should have a lower probability of having zero consumption at the time of the survey.

We first consider the effect of `income` at six prespecified values ranging from \$10,000 to \$60,000 on the probability of being a genuine nonsmoker (nonparticipation). Because we know the values 1 to 6 correspond to income in tens of thousands, we conserve space and suppress the default legend by using the `noatlegend` option.

```
. margins, predict(pnpar) at(income = (1/6)) noatlegend
Predictive margins                                Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonparticipation), predict(pnpar)
```

	Delta-method					[95% conf. interval]
	Margin	std. err.	z	P> z		
_at						
1	.1727928	.0056963	30.33	0.000	.1616283	.1839573
2	.1944564	.0055236	35.20	0.000	.1836304	.2052824
3	.2176787	.0052981	41.09	0.000	.2072945	.2280629
4	.2424141	.0050413	48.09	0.000	.2325333	.2522948
5	.2685948	.0047857	56.12	0.000	.259215	.2779745
6	.2961309	.0045767	64.70	0.000	.2871607	.3051011

The probability of being a genuine nonsmoker increases with income. For instance, for individuals who earn \$10,000 a year, the expected increase in the probability of being a genuine nonsmoker is about $(0.1945 - 0.1728) \times 100\% = 2.17\%$ if they earn an additional \$10,000.

We next investigate the effect of income on the joint probability of being a smoker (participation equals 1) with zero consumption. We do this by specifying `predict(pjoint1 outcome(0))` with `margins`:

```
. margins, predict(pjoint1 outcome(0)) at(income = (1/6)) noatlegend
Predictive margins                                Number of obs = 15,000
Model VCE: OIM
Expression: Pr(tobacco=0, participation=1), predict(pjoint1 outcome(0))
```

	Delta-method					[95% conf. interval]
	Margin	std. err.	z	P> z		
_at						
1	.5595131	.0040167	139.30	0.000	.5516405	.5673856
2	.5080066	.0037793	134.42	0.000	.5005993	.5154139
3	.4558656	.0035553	128.22	0.000	.4488975	.4628338
4	.4029089	.0033683	119.62	0.000	.3963072	.4095106
5	.3485692	.0032481	107.32	0.000	.3422031	.3549352
6	.2929155	.00317	92.40	0.000	.2867023	.2991287

For individuals who are smokers, the probability of zero consumption decreases as income increases, suggesting that tobacco is like a normal good for smokers. For example, for individuals who earn \$10,000 a year, earning an additional \$10,000 will decrease their probability of being a smoker with zero consumption by about $(0.5595 - 0.5080) \times 100\% = 5.15\%$.

If we wanted to compute the effect of income on the overall probability of zero consumption instead of the probability of zero consumption among smokers, we would omit `pjoint1` from within the `predict` option.

```
. margins, predict(outcome(0)) at(income = (1/6)) noatlegend
(output omitted)
```

This version of the `margins` command gives the sum of the probability of nonparticipation and the joint probability of participation with zero consumption.

Methods and formulas

The participation equation is

$$s_j = I(\mathbf{z}_j\boldsymbol{\gamma} + u_{1j} > 0) \quad j = 1, 2, \dots, n$$

where s_j is 1 if the j th subject belongs to the participation group (for example, smokers) and is 0 if the subject belongs to the nonparticipation group (for example, genuine nonsmokers), \mathbf{z}_j are the covariates used to model the group membership, $\boldsymbol{\gamma}$ is a vector of coefficients, and u_{1j} is a random-error term following a standard normal distribution.

The ordinal outcome equation is

$$\tilde{y}_j = \sum_{h=0}^H hI(\kappa_{h-1} < \mathbf{x}_j\boldsymbol{\beta} + u_{2j} \leq \kappa_h)$$

where \tilde{y}_j is the ordinal outcome conditional on participation, \mathbf{x}_j are the outcome covariates, $\boldsymbol{\beta}$ are the coefficients, and u_{2j} is a random-error term following a standard normal distribution. The observed outcome values are 0, 1, ..., H . $\kappa_0, \kappa_1, \dots, \kappa_{H-1}$ are real numbers such that $\kappa_i < \kappa_m$ for $i < m$. κ_{-1} is taken as $-\infty$ and κ_H is taken as $+\infty$. We assume that the error terms u_{1j} and u_{2j} are independent. We observe $y_j = s_j\tilde{y}_j$.

The probability of participation is

$$\Pr(s_j = 1|\mathbf{z}_j) = \Phi(\mathbf{z}_j\boldsymbol{\gamma}) \quad (1)$$

where $\Phi(\cdot)$ is the standard normal distribution function.

The probability of nonparticipation is

$$\Pr(s_j = 0|\mathbf{z}_j) = 1 - \Phi(\mathbf{z}_j\boldsymbol{\gamma}) \quad (2)$$

The probability of outcome $y_j = h$ given that the j th subject belongs to the participation group is

$$\begin{aligned} \Pr(y_j = h|s_j = 1, \mathbf{x}_j) &= \Pr(\tilde{y}_j = h|\mathbf{x}_j) \\ &= \Phi(\kappa_h - \mathbf{x}_j\boldsymbol{\beta}) - \Phi(\kappa_{h-1} - \mathbf{x}_j\boldsymbol{\beta}) \end{aligned} \quad (3)$$

for $h = 0, 1, \dots, H$, where $\Phi(\kappa_{-1} - \mathbf{x}_j\boldsymbol{\beta}) = 0$ and $\Phi(\kappa_H - \mathbf{x}_j\boldsymbol{\beta}) = 1$.

The joint probability of outcome $y_j = h$ and participation can be expressed as

$$\Pr(y_j = h, s_j = 1|\mathbf{z}_j, \mathbf{x}_j) = \Pr(s_j = 1|\mathbf{z}_j) \Pr(y_j = h|s_j = 1, \mathbf{x}_j)$$

for $h = 0, 1, \dots, H$, and computed using (1) and (3).

The marginal probabilities of the outcome y_j are

$$\begin{aligned} \Pr(y_j = 0|\mathbf{z}_j, \mathbf{x}_j) &= \Pr(s_j = 0|\mathbf{z}_j) + \Pr(s_j = 1|\mathbf{z}_j) \Pr(\tilde{y}_j = 0|\mathbf{x}_j) \\ \Pr(y_j = h|\mathbf{z}_j, \mathbf{x}_j) &= \Pr(s_j = 1|\mathbf{z}_j) \Pr(\tilde{y}_j = h|\mathbf{x}_j) \quad h = 1, 2, \dots, H-1 \\ \Pr(y_j = H|\mathbf{z}_j, \mathbf{x}_j) &= \Pr(s_j = 1|\mathbf{z}_j) \Pr(\tilde{y}_j = H|\mathbf{x}_j) \end{aligned}$$

and can be computed using (1), (2), and (3).

If the `offset()` option is specified with `zioprobit`, $\mathbf{x}_j\boldsymbol{\beta}$ is replaced with $\mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta$. If the `offset()` option is specified within the `inflate()` option, $\mathbf{z}_j\boldsymbol{\gamma}$ is replaced with $\mathbf{z}_j\boldsymbol{\gamma} + \text{offset}_j^\gamma$.

Description

`zip` fits a zero-inflated Poisson (ZIP) model to count data with excess zero counts. The ZIP model assumes that the excess zero counts come from a logit or probit model and the remaining counts come from a Poisson model.

Quick start

Zero-inflated Poisson model of `y` on `x1` and `x2` with inflation modeled using `x3`
`zip y x1 x2, inflate(x3)`

Use a probit model instead of a logit model to predict excess zeros
`zip y x1 x2, inflate(x3) probit`

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.	
vce() and weights are not allowed with the svy prefix; see [SVY] svy.	
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.	
collinear and coeflegend do not appear in the dialog box.	
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.	

Options

Model

`inflate(varlist [, offset(varname)] | _cons)` specifies the equation that determines whether the observed count is zero. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `poisson`; see [R] [poisson](#).

`inflate(varlist [, offset(varname)])` specifies the variables in the equation. You may optionally include an offset for this *varlist*.

`inflate(_cons)` specifies that the equation determining whether the count is zero contains only an intercept. To run a zero-inflated model of *depvar* with only an intercept in both equations, type `zip depvar, inflate(_cons)`.

`noconstant`, `exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] [Estimation options](#).

`probit` requests that a probit, instead of logit, model be used to characterize the excess zeros in the data.

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce_option](#).

Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is, e^b rather than b . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

display_options: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

Maximization

maximize_options: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default *vcetype* to `vce(opg)`.

The following options are available with `zip` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

Remarks and examples

Zero-inflated Poisson (ZIP) models address the case when the data contain a higher fraction of zeros than is likely to be generated from a Poisson model. Having a large proportion of zero observations, in itself, does not necessarily mean that we have the excess zeros problem. For instance, a Poisson model with a mean value of 0.2 predicts that $P(Y = 0) = \exp(-0.2) \approx 0.82$. However, the range of possible outcomes is restricted because of the small variance, 0.2 (mean and variance are equal for a Poisson model), as shown by $P(Y > 3) \approx 0.00006$. Unlike Poisson models, ZIP models allow us to have a large fraction of zeros without restricting the range of outcomes.

ZIP models assume that an observation is 0 with a probability p or is a realization of a Poisson random variable, which can also be 0, with a probability $1 - p$. For instance, you might count how many fish each visitor to a park catches. Many visitors may catch zero, because they do not fish (as opposed to being unsuccessful). Using a logit or probit model, you may model the probability p of whether a person does not fish depending on several covariates related to fishing. Using a Poisson distribution, you may model how many fish a person catches depending on several covariates having to do with the success of catching fish (type of lure or bait, time of day, temperature, season, etc.). This is the type of data for which the `zip` command is useful.

See [Long \(1997, 242–247\)](#) and [Cameron and Trivedi \(2005, 680–681\)](#) for a discussion of the ZIP model and other zero-modified count models.

► Example 1: Fitting a ZIP model

We have fictional data on the number of fish caught (count) by visitors to a national park on a particular day. Some of the visitors do not fish, but we do not have the data on whether a person fished; we merely have data on how many fish were caught together with several covariates.

Variable count exhibits an excess of zero observations (142 of 250 observations), beyond what would be expected from a Poisson model. We suspect that the number of zeros may be inflated because many visitors are not fishing. That is, a zero observation may be the result of a visitor who was unfortunate and caught no fish but may also be because the visitor did not fish. A standard Poisson model (see [\[R\] poisson](#)) treats these two types of zero observations as a homogeneous group, which typically leads to biased statistical results. We would like to distinguish between the two types of zeros and possibly draw inference for them separately (see [example 1](#) in [\[R\] zip postestimation](#)).

The `zip` command allows us to model the two types of zeros. First, using the required the `inflate()` option, we model whether a visitor fishes as a function of the number of children accompanying him or her (`child`) and whether he or she is camping (`camper`). Next, we assume the response variable, `count`, depends on whether the visitor used a live bait (`livebait`) and the number of persons (`persons`), which includes the visitor and any adults or children accompanying him. Note that `persons` is always greater than `child`.

```
. use https://www.stata-press.com/data/r19/fish
(Fictional fishing data)
. zip count persons livebait, inflate(child camper)
Fitting constant-only model:
Iteration 0: Log likelihood = -1347.807
Iteration 1: Log likelihood = -1305.3245
Iteration 2: Log likelihood = -1104.3005
Iteration 3: Log likelihood = -1103.9426
Iteration 4: Log likelihood = -1103.9425
Fitting full model:
Iteration 0: Log likelihood = -1103.9425
Iteration 1: Log likelihood = -896.2346
Iteration 2: Log likelihood = -851.61723
Iteration 3: Log likelihood = -850.70435
Iteration 4: Log likelihood = -850.70142
Iteration 5: Log likelihood = -850.70142
Zero-inflated Poisson regression
Inflation model: logit
Log likelihood = -850.7014
Number of obs = 250
Nonzero obs = 108
Zero obs = 142
LR chi2(2) = 506.48
Prob > chi2 = 0.0000
```

count	Coefficient	Std. err.	z	P> z	[95% conf. interval]	
count						
persons	.8068853	.0453288	17.80	0.000	.7180424	.8957281
livebait	1.757289	.2446082	7.18	0.000	1.277866	2.236713
_cons	-2.178472	.2860289	-7.62	0.000	-2.739078	-1.617865
inflate						
child	1.602571	.2797719	5.73	0.000	1.054228	2.150913
camper	-1.015698	.365259	-2.78	0.005	-1.731593	-.2998038
_cons	-.4922872	.3114562	-1.58	0.114	-1.10273	.1181558

Coefficients in the upper half of the table correspond to the Poisson model for individuals who fished. For instance, among visitors who fished, using a live bait increases the expected number of caught fish by a factor of $\exp(1.7572) \approx 5.8$, holding other covariates constant.

► Example 2: Comparing model fit

When you have count data, you may want to test whether a conventional count data model or a zero-inflated count data model is preferable. The classical likelihood-ratio test cannot be used here because the models are not nested. But we can use information criteria such as the AIC and BIC to check whether the standard or zero-inflated model is more appropriate.

Continuing with our fishing example, let's check whether the standard Poisson or ZIP model is more appropriate for our data. First, we store the estimation results from the previous ZIP model by typing

```
. estimates store zip
```

Next, we fit the Poisson model corresponding to the main equation of the ZIP model and store its results as `pois`:

```
. poisson count persons livebait
(output omitted)
. estimates store pois
```

We use `estimates stats` to display the AIC and BIC values for the two models.

```
. estimates stats pois zip
Akaike's information criterion and Bayesian information criterion
```

Model	N	ll(null)	ll(model)	df	AIC	BIC
pois	250	-1647.716	-1312.178	3	2630.356	2640.92
zip	250	-1103.942	-850.7014	6	1713.403	1734.532

Note: BIC uses N = number of observations. See [\[R\] IC note](#).

The ZIP model has smaller AIC and BIC values; we thus conclude that it fits our data better than the standard Poisson model.

Stored results

`zip` stores the following in `e()`:

- Scalars
- `e(N)`

`e(N_zero)`

`e(k)`

`e(k_eq)`

`e(k_eq_model)`

`e(k_dv)`

`e(df_m)`

`e(ll)`

`e(ll_0)`

`e(N_clust)`

`e(chi2)`

`e(p)`

`e(rank)`

`e(ic)`

`e(rc)`

`e(converged)`

number of observations

number of zero observations

number of parameters

number of equations in `e(b)`

number of equations in overall model test

number of dependent variables

model degrees of freedom

log likelihood

log likelihood, constant-only model

number of clusters

χ^2

p -value for model test

rank of `e(V)`

number of iterations

return code

1 if converged, 0 otherwise

- Macros
- `e(cmd)`

`e(cmdline)`

`e(depvar)`

`e(inflate)`

`e(wtype)`

`e(wexp)`

`e(title)`

`e(clustvar)`

`e(offset1)`

`e(offset2)`

`e(chi2type)`

`e(vce)`

`e(vcetype)`

zip

command as typed

name of dependent variable

logit or probit

weight type

weight expression

title in estimation output

name of cluster variable

offset

offset for `inflate()`

Wald or LR; type of model χ^2 test

`vcetype` specified in `vce()`

title used to label Std. err.

<code>e(opt)</code>	type of optimization
<code>e(which)</code>	max or min; whether optimizer is to perform maximization or minimization
<code>e(ml_method)</code>	type of ml method
<code>e(user)</code>	name of likelihood-evaluator program
<code>e(technique)</code>	maximization technique
<code>e(properties)</code>	b V
<code>e(predict)</code>	program used to implement predict
<code>e(asbalanced)</code>	factor variables fvset as asbalanced
<code>e(asobserved)</code>	factor variables fvset as asobserved

Matrices

<code>e(b)</code>	coefficient vector
<code>e(Cns)</code>	constraints matrix
<code>e(ilog)</code>	iteration log (up to 20 iterations)
<code>e(gradient)</code>	gradient vector
<code>e(V)</code>	variance–covariance matrix of the estimators
<code>e(V_modelbased)</code>	model-based variance

Functions

<code>e(sample)</code>	marks estimation sample
------------------------	-------------------------

In addition to the above, the following is stored in `r()`:

Matrices

<code>r(table)</code>	matrix containing the coefficients with their standard errors, test statistics, <i>p</i> -values, and confidence intervals
-----------------------	--

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r-class` command is run after the estimation command.

Methods and formulas

Consider the formulation of a zero-inflated model as presented in [Lambert \(1992\)](#). Define

$$\begin{aligned}\xi_j^\beta &= \mathbf{x}_j\boldsymbol{\beta} + \text{offset}_j^\beta \\ \xi_j^\gamma &= \mathbf{z}_j\boldsymbol{\gamma} + \text{offset}_j^\gamma \\ \lambda_j &= \exp(\xi_j^\beta) \\ F_j &= F(\xi_j^\gamma)\end{aligned}$$

where $F(\cdot)$ is the inverse of the logit function or, if the `probit` option was specified, the inverse of the probit function (or the standard normal cumulative distribution function). All subjects are assumed to be independent with the j th response determined as follows:

$$\begin{aligned}Y_j &= 0 && \text{with probability } F_j \\ Y_j &\sim \text{Poisson}(\lambda_j) && \text{with probability } 1 - F_j\end{aligned}$$

In other words,

$$\begin{aligned}\Pr(Y_j = 0 | \mathbf{x}_j, \mathbf{z}_j) &= F_j + (1 - F_j) \exp(-\lambda_j) \\ \Pr(Y_j = n | \mathbf{x}_j, \mathbf{z}_j) &= (1 - F_j) \exp(-\lambda_j) \frac{\lambda_j^n}{n!} \quad \text{for } n = 1, 2, \dots\end{aligned}$$

The `zip` command maximizes the log-likelihood $\ln L$, defined by

$$\begin{aligned}\ln L = & \sum_{j \in S} w_j \ln \{F_j + (1 - F_j) \exp(-\lambda_j)\} \\ & + \sum_{j \notin S} w_j \{ \ln(1 - F_j) - \lambda_j + \xi_j y_j - \ln(y_j!) \}\end{aligned}$$

where w_j are the weights and S is the set of observations for which the observed outcome $y_j = 0$.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [_robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`zip` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

Postestimation commands

The following postestimation commands are available after `zip`:

Command	Description
<code>contrast</code>	contrasts and ANOVA-style joint tests of parameters
<code>estat ic</code>	Akaike's, consistent Akaike's, corrected Akaike's, and Schwarz's Bayesian information criteria (AIC, CAIC, AICc, and BIC, respectively)
<code>estat summarize</code>	summary statistics for the estimation sample
<code>estat vce</code>	variance–covariance matrix of the estimators (VCE)
<code>estat (svy)</code>	postestimation statistics for survey data
<code>estimates</code>	cataloging estimation results
<code>etable</code>	table of estimation results
* <code>forecast</code>	dynamic forecasts and simulations
* <code>hausman</code>	Hausman's specification test
<code>lincom</code>	point estimates, standard errors, testing, and inference for linear combinations of parameters
* <code>lrtest</code>	likelihood-ratio test
<code>margins</code>	marginal means, predictive margins, marginal effects, and average marginal effects
<code>marginsplot</code>	graph the results from margins (profile plots, interaction plots, etc.)
<code>nlcom</code>	point estimates, standard errors, testing, and inference for nonlinear combinations of parameters
<code>predict</code>	number of events, incidence rates, probabilities, etc.
<code>predictnl</code>	point estimates, standard errors, testing, and inference for generalized predictions
<code>pwcompare</code>	pairwise comparisons of parameters
<code>suest</code>	seemingly unrelated estimation
<code>test</code>	Wald tests of simple and composite linear hypotheses
<code>testnl</code>	Wald tests of nonlinear hypotheses

*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

predict

Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset ]
```

```
predict [type] stub* [if] [in] , scores
```

statistic	Description
Main	
n	number of events; the default
ir	incidence rate
pr	probability of a degenerate zero
pr(<i>n</i>)	probability $\Pr(y_j = n)$
pr(<i>a</i> , <i>b</i>)	probability $\Pr(a \leq y_j \leq b)$
xb	linear prediction
stdp	standard error of the linear prediction

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

Main

n, the default, calculates the predicted number of events, which is $(1 - F_j) \exp(\mathbf{x}_j\beta)$ if neither `offset()` nor `exposure()` was specified when the model was fit, where F_j is the predicted probability of a zero outcome; $(1 - F_j) \exp(\mathbf{x}_j\beta + \text{offset}_j^\beta)$ if `offset()` was specified; or $(1 - F_j) \{ \exp(\mathbf{x}_j\beta) \times \text{exposure}_j \}$ if `exposure()` was specified.

ir calculates the incidence rate, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the **n** and the **nooffset** options.

pr calculates the probability of a degenerate zero, predicted from the fitted degenerate distribution $F_j = F(\mathbf{z}_j\gamma)$. If `offset()` was specified within the `inflate()` option, then $F_j = F(\mathbf{z}_j\gamma + \text{offset}_j^\gamma)$ is calculated.

pr(*n*) calculates the probability $\Pr(y_j = n)$, where *n* is a nonnegative integer that may be specified as a number or a variable. Note that **pr** is not equivalent to **pr(0)**.

pr(*a*, *b*) calculates the probability $\Pr(a \leq y_j \leq b)$, where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

b missing (*b* ≥ .) means $+\infty$;

pr(20, .) calculates $\Pr(y_j \geq 20)$;

pr(20, *b*) calculates $\Pr(y_j \geq 20)$ in observations for which *b* ≥ . and calculates

$\Pr(20 \leq y_j \leq b)$ elsewhere.

pr(., *b*) produces a syntax error. A missing value in an observation of the variable *a* causes a missing value in that observation for **pr(*a*, *b*)**.

xb calculates the linear prediction, which is $\mathbf{x}_j\beta$ if neither `offset()` nor `exposure()` was specified; $\mathbf{x}_j\beta + \text{offset}_j^\beta$ if `offset()` was specified; or $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ if `exposure()` was specified; see **nooffset** below.

stdp calculates the standard error of the linear prediction.

nooffset is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by **predict** so that they ignore the offset or exposure variable; the linear prediction is treated as $\mathbf{x}_j\beta$ rather than as $\mathbf{x}_j\beta + \text{offset}_j^\beta$ or $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$. Specifying **predict** ..., **nooffset** is equivalent to specifying **predict** ..., **ir**.

scores calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (\mathbf{x}_j\beta)$.

The second new variable will contain $\partial \ln L / \partial (\mathbf{z}_j\gamma)$.

margins

Description for margins

margins estimates margins of response for the numbers of events, incidence rates, probabilities, and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]  
margins [marginlist] , predict (statistic ...) [predict (statistic ...) ...] [options]
```

statistic	Description
n	number of events; the default
ir	incidence rate
pr	probability of a degenerate zero
pr (n)	probability $\Pr(y_j = n)$
pr (a,b)	probability $\Pr(a \leq y_j \leq b)$
xb	linear prediction
stdp	not allowed with margins

Statistics not allowed with margins are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] margins.

Remarks and examples

► Example 1: Obtaining predicted counts

Continuing with [example 1](#) from [\[R\] zip](#), we will use `predict` to compute the predicted number of fish captured by each individual.

```
. use https://www.stata-press.com/data/r19/fish
(Fictional fishing data)
. zip count persons livebait, inflate(child camper)
(output omitted)
. predict numfish
(option n assumed; predicted number of events)
. summarize numfish
```

Variable	Obs	Mean	Std. dev.	Min	Max
numfish	250	2.770999	3.269588	.079269	13.55015

The average predicted number of fish caught by all visitors, regardless of whether or not they fished, is 2.77 fish.

► Example 2: Obtaining predicted probabilities

`predict` with the `pr` option computes the probability that an individual does not fish.

```
. predict pr, pr
```

On the other hand, `predict` with the `pr(n)` option computes the probability of catching *n* fish; particularly, the probability of catching zero fish will be

```
. predict pr0, pr(0)
. list pr pr0 in 1
```

	pr	pr0
1.	.3793549	.8609267

Notice that `pr0` is always equal to or greater than `pr`. For example, for the first individual, the probability of not fishing is 0.38; on the other hand, the probability of catching zero fish (0.86) is equal to the sum of the probability of not fishing and the probability of fishing but not catching any fish. `pr0` can be also computed as one minus the probability of catching at least one fish, that is:

```
. predict pr_catch, pr(1,.)
. gen pr0b = 1-pr_catch
```

Methods and formulas

See [Methods and formulas](#) in [\[R\] zip](#) for the model definition and notation.

The probabilities calculated using the `pr(n)` option are the probability $\Pr(y_j = n)$. These are calculated using

$$\begin{aligned}\Pr(y_j = 0 | \mathbf{x}_j, \mathbf{z}_j) &= F_j + (1 - F_j) \exp(-\lambda_j) \\ \Pr(y_j = n | \mathbf{x}_j, \mathbf{z}_j) &= (1 - F_j) \frac{\lambda_j^n \exp(-\lambda_j)}{n!} \quad \text{for } n = 1, 2, \dots\end{aligned}$$

where F_j is the probability of obtaining an observation from the degenerate distribution whose mass is concentrated at zero. F_j can be obtained by using the `pr` option.

See [Cameron and Trivedi \(2013, sec. 4.6\)](#) for further details.

Description

`ztest` performs z tests on the equality of means, assuming known variances. The test can be performed for one sample against a hypothesized population value or for no difference in population means estimated from two samples. Two-sample tests can be conducted for paired and unpaired data. Clustered data are also supported.

`ztesti` is the immediate form of `ztest`; see [\[U\] 19 Immediate commands](#).

For the comparison of means when variances are unknown, use `ttest`; see [\[R\] ttest](#).

Quick start

One-sample test that the mean of `v1` is 3 at the 90% confidence level

```
ztest v1 == 3, level(90)
```

Same as above, and adjust for clustering with clusters defined by `cvar` and an intraclass correlation of 0.5

```
ztest v1 == 3, level(90) cluster(cvar) rho(0.5)
```

Unpaired z test that the mean of `v1` is equal between two groups defined by `catvar`

```
ztest v1, by(catvar)
```

Same as above, and adjust for clustering with clusters defined by `cvar` and an intraclass correlation of 0.5 in the two groups

```
ztest v1, by(catvar) cluster(cvar) rho(0.5)
```

Unpaired test of equality of the means of `v2` and `v3`

```
ztest v2 == v3, unpaired
```

Paired test of equality of the means of `v2` and `v3` with standard deviation of the differences between paired observations of 2.4

```
ztest v2 == v3, sddiff(2.4)
```

Same as above, specified using a common standard deviation of 2 and correlation between observations of 0.28

```
ztest v2 == v3, sd(2) corr(0.28)
```

Immediate form unpaired test of $\mu_1 = \mu_2$ if $\bar{x}_1 = 3.2$, $sd_1 = 0.1$, $\bar{x}_2 = 3.4$, and $sd_2 = 0.15$ with $n_1 = n_2 = 120$

```
ztesti 120 3.2 0.1 120 3.4 0.15
```

Syntax

One-sample z test

```
ztest varname == # [ if ] [ in ] [ , onesampleopts ]
```

Two-sample z test using groups

```
ztest varname [ if ] [ in ], by(groupvar) [ twosamplegropts ]
```

Two-sample z test using variables

```
ztest varname1 == varname2 [ if ] [ in ], unpaired [ twosamplevaropts ]
```

Paired z test

```
ztest varname1 == varname2 [ if ] [ in ], sddiff(#) [ level(#) ]  
ztest varname1 == varname2 [ if ] [ in ], corr(#) [ pairedopts ]
```

Immediate form of one-sample z test

```
ztesti #obs #mean #sd #val [ , level(#) ]
```

Immediate form of two-sample unpaired z test

```
ztesti #obs1 #mean1 #sd1 #obs2 #mean2 #sd2 [ , level(#) ]
```

<i>onesampleopts</i>	Description
<hr/>	
sd(#)	one-population standard deviation; default is sd(1)
<u>l</u> evel(#)	confidence level; default is level(95)
cluster(<i>varname</i>)	variable defining the clusters
rho(#)	intraclass correlation

<i>twosamplegrop</i> <i>ts</i>	Description
Main	
* <i>by</i> (<i>groupvar</i>)	variable defining the groups
<i>unpaired</i>	unpaired test; implied when <i>by</i> () is specified
<i>sd</i> (#)	two-population common standard deviation; default is <i>sd</i> (1)
<i>sd1</i> (#)	standard deviation of the first population; requires <i>sd2</i> () and may not be combined with <i>sd</i> ()
<i>sd2</i> (#)	standard deviation of the second population; requires <i>sd1</i> () and may not be combined with <i>sd</i> ()
<i>level</i> (#)	confidence level; default is <i>level</i> (95)
<i>cluster</i> (<i>varname</i>)	variable defining the clusters
<i>rho</i> (#)	common intraclass correlation
<i>rho1</i> (#)	intraclass correlation for group 1
<i>rho2</i> (#)	intraclass correlation for group 2

**by*(*groupvar*) is required.

<i>twosamplevaropt</i> <i>s</i>	Description
Main	
* <i>unpaired</i>	unpaired test
<i>sd</i> (#)	two-population common standard deviation; default is <i>sd</i> (1)
<i>sd1</i> (#)	standard deviation of the first population; requires <i>sd2</i> () and may not be combined with <i>sd</i> ()
<i>sd2</i> (#)	standard deviation of the second population; requires <i>sd1</i> () and may not be combined with <i>sd</i> ()
<i>level</i> (#)	confidence level; default is <i>level</i> (95)

**unpaired* is required.

<i>pairedopt</i> <i>s</i>	Description
Main	
* <i>corr</i> (#)	correlation between paired observations
<i>sd</i> (#)	two-population common standard deviation; default is <i>sd</i> (1); may not be combined with <i>sd1</i> (), <i>sd2</i> (), or <i>sddiff</i> ()
<i>sd1</i> (#)	standard deviation of the first population; requires <i>corr</i> () and <i>sd2</i> () and may not be combined with <i>sd</i> () or <i>sddiff</i> ()
<i>sd2</i> (#)	standard deviation of the second population; requires <i>corr</i> () and <i>sd1</i> () and may not be combined with <i>sd</i> () or <i>sddiff</i> ()
<i>level</i> (#)	confidence level; default is <i>level</i> (95)

**corr*(#) is required.

by and *collect* are allowed with *ztest* and *ztesti*; see [U] 11.1.10 Prefix commands.

Options

Main

`by(groupvar)` specifies the *groupvar* that defines the two groups that `ztest` will use to test the hypothesis that their means are equal. Specifying `by(groupvar)` implies an unpaired (two-sample) *z* test. Do not confuse the `by()` option with the `by prefix`; you can specify both.

`unpaired` specifies that the data be treated as unpaired. The `unpaired` option is used when the two sets of values to be compared are in different variables.

`sddiff(#)` specifies the population standard deviation of the differences between paired observations for a paired *z* test. For this kind of test, either `sddiff()` or `corr()` must be specified.

`corr(#)` specifies the correlation between paired observations for a paired *z* test. This option along with `sd1()` and `sd2()` or with `sd()` is used to compute the standard deviation of the differences between paired observations unless that standard deviation is supplied directly in the `sddiff()` option. For a paired *z* test, either `sddiff()` or `corr()` must be specified.

`sd(#)` specifies the population standard deviation for a one-sample *z* test or the common population standard deviation for a two-sample *z* test. The default is `sd(1)`. `sd()` may not be combined with `sd1()`, `sd2()`, or `sddiff()`.

`sd1(#)` specifies the standard deviation of the first population or group. When `sd1()` is specified with `by(groupvar)`, the first group is defined by the first category of the sorted *groupvar*. `sd1()` requires `sd2()` and may not be combined with `sd()` or `sddiff()`.

`sd2(#)` specifies the standard deviation of the second population or group. When `sd2()` is specified with `by(groupvar)`, the second group is defined by the second category of the sorted *groupvar*. `sd2()` requires `sd1()` and may not be combined with `sd()` or `sddiff()`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

`cluster(varname)` specifies the variable that identifies clusters. The `cluster()` option is required to adjust the computation for clustering.

`rho(#)` specifies the intraclass correlation for a one-sample test or the common intraclass correlation for a two-sample test. The `rho()` option is required to adjust the computation for clustering for a one-sample test.

`rho1(#)` specifies the intraclass correlation of the first group for a two-sample test using groups. The `rho()` option or both `rho1()` and `rho2()` options are required to adjust the computation for clustering.

`rho2(#)` specifies the intraclass correlation of the second group for a two-sample test using groups. The `rho()` option or both `rho1()` and `rho2()` options are required to adjust the computation for clustering.

When `by()` is used, `sd1()` and `sd2()` or `sd()` is used to specify the population standard deviations of the two groups defined by *groupvar* for an unpaired two-sample *z* test (using groups). By default, a common standard deviation of one, `sd(1)`, is assumed.

When `unpaired` is used, `sd1()` and `sd2()` or `sd()` is used to specify the population standard deviations of *varname*₁ and *varname*₂ for an unpaired two-sample *z* test (using variables). By default, a common standard deviation of one, `sd(1)`, is assumed.

Remarks are presented under the following headings:

- One-sample z test
- Two-sample z test
- Paired z test
- Adjust for clustering
- Immediate form

For the purpose of illustration, we assume that variances are known in all the examples below.

One-sample z test

► Example 1

In the first form, `ztest` tests whether the mean of the sample is equal to a known constant under the assumption of known variance. Assume that we have a sample of 74 automobiles. We know each automobile's average mileage rating and wish to test whether the overall average for the sample is 20 miles per gallon. We also assume that the population standard deviation is 6.

```
. use https://www.stata-press.com/data/r19/auto
(1978 automobile data)
```

```
. ztest mpg==20, sd(6)
```

One-sample z test

Variable	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
mpg	74	21.2973	.6974858	6	19.93025	22.66434

```
mean = mean(mpg)          z = 1.8600
H0: mean = 20
```

Ha: mean < 20	Ha: mean != 20	Ha: mean > 20
Pr(Z < z) = 0.9686	Pr(Z > z) = 0.0629	Pr(Z > z) = 0.0314

The p -value for the two-sided test is 0.0629, so we do not have statistical evidence to reject the null hypothesis that the mean equals 20 at a 5% significance level, but we would reject the null hypothesis at a 10% level.

Two-sample z test

► Example 2: Two-sample z test using groups

We are testing the effectiveness of a new fuel additive. We run an experiment in which 12 cars are given the fuel treatment and 12 cars are not. The results of the experiment are as follows:

treated	mpg
0	20
0	23
0	21
0	25
0	18
0	17
0	18
0	24
0	20
0	24
0	23
0	19
1	24
1	25
1	21
1	22
1	23
1	18
1	17
1	28
1	24
1	27
1	21
1	23

The treated variable is coded as 1 if the car received the fuel treatment and 0 otherwise.

We can test the equality of means of the treated and untreated group by typing

```
. use https://www.stata-press.com/data/r19/fuel13
. ztest mpg, by(treated) sd(3)
```

Two-sample z test

Group	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
0	12	21	.8660254	3	19.30262	22.69738
1	12	22.75	.8660254	3	21.05262	24.44738
diff		-1.75	1.224745		-4.150456	.6504558

```
diff = mean(0) - mean(1)                                z = -1.4289
HO: diff = 0
Ha: diff < 0                                Ha: diff != 0                                Ha: diff > 0
Pr(Z < z) = 0.0765                        Pr(|Z| > |z|) = 0.1530                        Pr(Z > z) = 0.9235
```

We do not have evidence to reject the null hypothesis that the means of the two groups are equal at a 5% significance level.

In the above, we assumed that the two groups have the same standard deviation of 3. If the standard deviations for the two groups are different, we can specify group-specific standard deviations in options `sd1()` and `sd2()`:

```
. ztest mpg, by(treated) sd1(2.7) sd2(3.2)
Two-sample z test
```

Group	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
0	12	21	.7794229	2.7	19.47236	22.52764
1	12	22.75	.9237604	3.2	20.93946	24.56054
diff		-1.75	1.208649		-4.118909	.6189093

```
diff = mean(0) - mean(1) z = -1.4479
H0: diff = 0
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0738 Pr(|Z| > |z|) = 0.1476 Pr(Z > z) = 0.9262
```

□ Technical note

In two-sample randomized designs, subjects will sometimes refuse the assigned treatment but still be measured for an outcome. In this case, take care to specify the group properly. You might be tempted to let *varname* contain missing where the subject refused and thus let `ztest` drop such observations from the analysis. [Zelen \(1979\)](#) argues that it would be better to specify that the subject belongs to the group in which he or she was randomized, even though such inclusion will dilute the measured effect.

▷ Example 3: Two-sample z test using variables

There is a second, inferior way to organize the data in the preceding example. We ran a test on 24 cars, 12 without the additive and 12 with. We now create two new variables, `mpg1` and `mpg2`.

mpg1	mpg2
20	24
23	25
21	21
25	22
18	23
17	18
18	17
24	28
20	24
24	27
23	21
19	23

This method is inferior because it suggests a connection that is not there. There is no link between the car with 20 mpg and the car with 24 mpg in the first row of the data. Each column of data could be arranged in any order. Nevertheless, if our data are organized like this, `ztest` can accommodate us.

```
. use https://www.stata-press.com/data/r19/fuel
. ztest mpg1==mpg2, unpaired sd(3)
```

Two-sample z test

Variable	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
mpg1	12	21	.8660254	3	19.30262	22.69738
mpg2	12	22.75	.8660254	3	21.05262	24.44738
diff		-1.75	1.224745		-4.150456	.6504558
diff = mean(mpg1) - mean(mpg2)					z = -1.4289	
H0: diff = 0						
Ha: diff < 0		Ha: diff != 0		Ha: diff > 0		
Pr(Z < z) = 0.0765		Pr(Z > z) = 0.1530		Pr(Z > z) = 0.9235		

Paired z test

Example 4

Suppose that the preceding data were actually collected by running a test on 12 cars. Each car was run once with the fuel additive and once without. Our data are stored in the same manner as in [example 3](#), but this time, there is most certainly a connection between the mpg values that appear in the same row. These come from the same car. The variables mpg1 and mpg2 represent mileage without and with the treatment, respectively. Suppose that the two variables have a common standard deviation of 2 and the correlation between them is 0.4.

```
. use https://www.stata-press.com/data/r19/fuel
. ztest mpg1==mpg2, sd(2) corr(0.4)
```

Paired z test

Variable	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
mpg1	12	21	.5773503	2	19.86841	22.13159
mpg2	12	22.75	.5773503	2	21.61841	23.88159
diff	12	-1.75	.6324555	2.19089	-2.98959	-.5104099
mean(diff) = mean(mpg1 - mpg2)					z = -2.7670	
H0: mean(diff) = 0						
Ha: mean(diff) < 0		Ha: mean(diff) != 0		Ha: mean(diff) > 0		
Pr(Z < z) = 0.0028		Pr(Z > z) = 0.0057		Pr(Z > z) = 0.9972		

The *p*-value for the two-sided test is 0.0057, so we reject, for example, the null hypothesis that the two means are equal at a 5% significance level.

Equivalently, we could specify directly the standard deviation of the differences between paired observations with the `sddiff()` option:

```
. ztest mpg1==mpg2, sddiff(2.191)
Paired z test
```

Variable	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
diff	12	-1.75	.6324872	2.191	-2.989652	-.5103478

```
mean(diff) = mean(mpg1 - mpg2) z = -2.7669
H0: mean(diff) = 0
Ha: mean(diff) < 0 Ha: mean(diff) != 0 Ha: mean(diff) > 0
Pr(Z < z) = 0.0028 Pr(|Z| > |z|) = 0.0057 Pr(Z > z) = 0.9972
```

Adjust for clustering

When observations are not independent and can be grouped into clusters, we need to adjust for clustering in a *z* test. For example, in a cluster randomized design, groups of individuals are randomized instead of individuals. To adjust for clustering, we need to specify the cluster identifier variable in the `cluster()` option. In the case of a one-sample *z* test, we need to also specify the intraclass correlation in the `rho()` option. In the case of a two-sample *z* test, we need to also specify the common population intraclass correlation in the `rho()` option or group-specific population intraclass correlations in the `rho1()` and `rho2()` options.

► Example 5: One-sample z test, adjusting for clusters

Consider data on the SAT score of 75 students from 15 classes, with 5 students in each class. We want to test whether the mean verbal SAT score is different from 600. We assume a known standard deviation of 132 and a known intraclass correlation of 0.7. To perform the test, we specify the options `cluster(class)`, `rho(0.7)`, and `sd(132)`:

```
. use https://www.stata-press.com/data/r19/sat
(Fictional SAT data)
. ztest score == 600, cluster(class) rho(0.7) sd(132)
```

Variable	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
score	75	504.8	29.71222	132	446.5651	563.0349

```
One-sample z test Number of clusters = 15
Cluster variable: class Cluster size = 5
Intraclass corr. = 0.7000
```

```
mean = mean(score) z = -3.2041
H0: mean = 600
Ha: mean < 600 Ha: mean != 600 Ha: mean > 600
Pr(Z < z) = 0.0007 Pr(|Z| > |z|) = 0.0014 Pr(Z > z) = 0.9993
```

We find statistical evidence to reject the null hypothesis of $H_0: \mu_{\text{SAT}} = 600$ versus a two-sided alternative $H_a: \mu_{\text{SAT}} \neq 600$ at the 5% significance level; the p -value = $0.0014 < 0.05$.

► Example 6: Two-sample z test using groups, adjusting for clusters

Consider a cluster randomized control trial that studies the effect of additional training of nurses and general practitioners in patient-centered care on the well-being and future disease risk of patients with type 2 diabetes (Kinmonth et al. [1998] and Campbell and Walters [2014]). Practices (practice) are randomly allocated to two groups—one trained to give patient-centered care (intervention group) and another trained to give routine care (comparison or control group). In our analysis, we transform the original bmi using the formula $\ln(\text{bmi} - 14.67355)$ to obtain a variable that is approximately normally distributed, lbmi. We want to test the equality of the means of lbmi for the two groups. We assume a known common standard deviation of 0.35 and a known common intraclass correlation of 0.028.

To perform the test, we need to specify the rho(0.028) and sd(0.35) options. We also need to specify the cluster identifier practice in the cluster() option and the group identifier group in the by() option.

```
. use https://www.stata-press.com/data/r19/dcfid_trial
(BMI data from Diabetes Care from Diagnosis trial (Kinmonth et al., 1998))
. ztest lbmi, by(group) cluster(practice) rho(0.028) sd(0.35)

Two-sample z test
Cluster variable: practice

Group: Control                                Group: Interv.
Number of clusters =          20              Number of clusters =          18
Avg. cluster size   =          5.10           Avg. cluster size   =          7.67
CV cluster size     =          0.5330         CV cluster size     =          0.5126
Intraclass corr.    =          0.0280         Intraclass corr.    =          0.0280
```

Group	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
Control	102	2.62954	.0372502	.35	2.556531	2.702549
Interv.	138	2.749023	.0332182	.35	2.683916	2.81413
diff		-.1194831	.0499102		-.2173054	-.0216608

```
diff = mean(Control) - mean(Interv.)              z = -2.3940
H0: diff = 0
Ha: diff < 0              Ha: diff != 0              Ha: diff > 0
Pr(Z < z) = 0.0083        Pr(|Z| > |z|) = 0.0167        Pr(Z > z) = 0.9917
```

We find statistical evidence to reject the null hypothesis of $H_0: \mu_{\text{diff}} = 0$ versus a two-sided alternative $H_a: \mu_{\text{diff}} \neq 0$ at the 5% significance level; the p -value = 0.0167 < 0.05.

Immediate form

► Example 7: One-sample z test

ztesti is like ztest, except that we specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the mean number of sunspots per month as 62.6 with a standard deviation of 15.8. We assume this standard deviation is the population standard deviation. There are 24 months of data. We wish to test whether the mean is 75:

```
. ztesti 24 62.6 15.8 75
One-sample z test
```

	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
x	24	62.6	3.225161	15.8	56.2788	68.9212

```
mean = mean(x)                                z = -3.8448
H0: mean = 75
Ha: mean < 75                                Ha: mean != 75                                Ha: mean > 75
Pr(Z < z) = 0.0001                          Pr(|Z| > |z|) = 0.0001                          Pr(Z > z) = 0.9999
```

► Example 8: Two-sample z test

There is no immediate form of `ztest` with paired data because the test is also a function of the covariance, a number unlikely to be reported in any published source. For unpaired data, however, we might type

```
. ztesti 20 20 5 32 15 4
Two-sample z test
```

	Obs	Mean	Std. err.	Std. dev.	[95% conf. interval]	
x	20	20	1.118034	5	17.80869	22.19131
y	32	15	.7071068	4	13.6141	16.3859
diff		5	1.322876		2.407211	7.592789

```
diff = mean(x) - mean(y)                                z = 3.7796
H0: diff = 0
Ha: diff < 0                                Ha: diff != 0                                Ha: diff > 0
Pr(Z < z) = 0.9999                          Pr(|Z| > |z|) = 0.0002                          Pr(Z > z) = 0.0001
```

Stored results

One-sample `ztest` and `ztesti` store the following in `r()`:

Scalars	
<code>r(N)</code>	sample size
<code>r(mu)</code>	sample mean
<code>r(sd)</code>	standard deviation
<code>r(se)</code>	standard error
<code>r(lb)</code>	lower confidence bound of one-sample mean
<code>r(ub)</code>	upper confidence bound of one-sample mean
<code>r(z)</code>	z statistic
<code>r(p_l)</code>	lower one-sided p-value
<code>r(p)</code>	two-sided p-value
<code>r(p_u)</code>	upper one-sided p-value
<code>r(level)</code>	confidence level

Cluster-adjusted one-sample `ztest` also stores the following in `r()`:

Scalars

<code>r(K)</code>	number of clusters K
<code>r(M)</code>	cluster size M
<code>r(rho)</code>	intraclass correlation
<code>r(CV_cluster)</code>	coefficient of variation for cluster sizes

Two-sample `ztest` and `ztesti` store the following in `r()`:

Scalars

<code>r(N1)</code>	sample size of population one
<code>r(N2)</code>	sample size of population two
<code>r(mu1)</code>	sample mean for population one
<code>r(mu2)</code>	sample mean for population two
<code>r(mu_diff)</code>	difference of means
<code>r(corr)</code>	correlation between paired observations; if the <code>corr()</code> option is specified
<code>r(sd)</code>	common standard deviation
<code>r(sd1)</code>	standard deviation for population one
<code>r(sd2)</code>	standard deviation for population two
<code>r(sd_diff)</code>	standard deviation of the differences between paired observations
<code>r(se1)</code>	standard error of population-one sample mean
<code>r(se2)</code>	standard error of population-two sample mean
<code>r(se_diff)</code>	standard error of the difference of means
<code>r(lb1)</code>	lower confidence bound of population-one sample mean
<code>r(ub1)</code>	upper confidence bound of population-one sample mean
<code>r(lb2)</code>	lower confidence bound of population-two sample mean
<code>r(ub2)</code>	upper confidence bound of population-two sample mean
<code>r(lb_diff)</code>	lower confidence bound of the difference of means
<code>r(ub_diff)</code>	upper confidence bound of the difference of means
<code>r(z)</code>	<i>z</i> statistic
<code>r(p_l)</code>	lower one-sided <i>p</i> -value
<code>r(p)</code>	two-sided <i>p</i> -value
<code>r(p_u)</code>	upper one-sided <i>p</i> -value
<code>r(level)</code>	confidence level

Cluster-adjusted two-sample `ztest` using the `by()` option also stores the following in `r()`:

Scalars

<code>r(K1)</code>	population-one number of clusters K_1
<code>r(K2)</code>	population-two number of clusters K_2
<code>r(M1)</code>	population-one cluster size M_1
<code>r(M2)</code>	population-two cluster size M_2
<code>r(rho)</code>	common intraclass correlation
<code>r(rho1)</code>	population-one intraclass correlation
<code>r(rho2)</code>	population-two intraclass correlation
<code>r(CV_cluster1)</code>	population-one coefficient of variation for cluster sizes
<code>r(CV_cluster2)</code>	population-two coefficient of variation for cluster sizes

Methods and formulas

Methods and formulas are presented under the following headings:

*One-sample *z* test*

*Two-sample unpaired *z* test*

*Paired *z* test*

For all the tests below, the test statistic z is distributed as standard normal, and the p -value is computed as

$$p = \begin{cases} 1 - \Phi(z) & \text{for an upper one-sided test} \\ \Phi(z) & \text{for a lower one-sided test} \\ 2\{1 - \Phi(|z|)\} & \text{for a two-sided test} \end{cases}$$

where $\Phi(\cdot)$ is the cdf of a standard normal distribution and $|z|$ is an absolute value of z .

Also see, for instance, [Hoel \(1984, 140–161\)](#), [Dixon and Massey \(1983, 100–130\)](#), and [Tamhane and Dunlop \(2000, 237–290\)](#) for more information about z tests.

One-sample z test

Suppose that we observe a random sample x_1, x_2, \dots, x_n of size n , which follows a normal distribution with mean μ and standard deviation σ . We are interested in testing the null hypothesis $H_0: \mu = \mu_0$ versus the two-sided alternative hypothesis $H_a: \mu \neq \mu_0$, the upper one-sided alternative $H_a: \mu > \mu_0$, or the lower one-sided alternative $H_a: \mu < \mu_0$. Assuming a known standard deviation σ , we use the following test statistic,

$$z = \frac{(\bar{x} - \mu_0)}{s}$$

where $\bar{x} = (\sum_{i=1}^n x_i)/n$ is the sample mean and $s = \sigma/\sqrt{n}$ is the standard error of \bar{x} .

The $100(1 - \alpha)\%$ confidence interval for \bar{x} is given by

$$\bar{x} \pm z_{1-\alpha/2} s$$

where $z_{1-\alpha/2}$ is the $(1 - \alpha/2)$ th quantile of the standard normal distribution.

With clustered data, suppose that there are K clusters. The i th cluster of size M_i contains the observations $x_{i1}, x_{i2}, \dots, x_{iM_i}$, such that $n = \sum_{i=1}^K M_i$ and $\bar{x} = \frac{1}{n} \sum_{i=1}^K \sum_{j=1}^{M_i} x_{ij}$. Let ρ be the intraclass correlation. Following [Ahn, Heo, and Zhang \(2015\)](#), we assume that the cluster sizes M_i are independent and identically distributed. Let C_{adj} be the adjustment to the standard error for clustered data,

$$C_{\text{adj}} = \sqrt{\sum_{i=1}^K M_i \{1 + \rho(M_i - 1)\} / n}$$

such that $s_{\text{cl}} = C_{\text{adj}} s$.

C_{adj} can be equivalently written as

$$C_{\text{adj}} = \sqrt{1 + \rho(\bar{M} - 1) + \rho \bar{M} \text{CV}_{\text{cl}}^2}$$

where $\bar{M} = \sum_{i=1}^K M_i / K$ is the average cluster size and CV_{cl} is the coefficient of variation for cluster sizes:

$$\text{CV}_{\text{cl}} = \frac{\sqrt{\sum_{i=1}^K (M_i - \bar{M})^2 / K}}{\bar{M}}$$

To adjust the test statistic z and the confidence interval for clustering, replace s with s_{cl} in the corresponding formulas. In the presence of clustering, the test statistic z is asymptotically normally distributed conditional on the empirical distribution of M_i 's.

Two-sample unpaired z test

Suppose that we observe a random sample $x_{11}, x_{12}, \dots, x_{1n_1}$ of size n_1 , which follows a normal distribution with mean μ_1 and standard deviation σ_1 , and another random sample $x_{21}, x_{22}, \dots, x_{2n_2}$ of size n_2 , which follows a normal distribution with mean μ_2 and standard deviation σ_2 . We are interested in testing the null hypothesis $H_0: \mu_2 = \mu_1$ versus the two-sided alternative hypothesis $H_a: \mu_2 \neq \mu_1$, the upper one-sided alternative $H_a: \mu_2 > \mu_1$, or the lower one-sided alternative $H_a: \mu_2 < \mu_1$. Assuming known standard deviations σ_1 and σ_2 , we use the following test statistic,

$$z = \frac{\bar{x}_2 - \bar{x}_1}{\sqrt{s_1^2 + s_2^2}}$$

where $\bar{x}_1 = (\sum_{i=1}^{n_1} x_{1i})/n_1$ and $\bar{x}_2 = (\sum_{i=1}^{n_2} x_{2i})/n_2$ are the two sample means and $s_1 = \sigma_1/\sqrt{n_1}$ and $s_2 = \sigma_2/\sqrt{n_2}$ are the corresponding two standard errors.

The $100(1 - \alpha)\%$ confidence intervals for \bar{x}_1 and \bar{x}_2 are given by

$$\begin{aligned} \bar{x}_1 \pm z_{1-\alpha/2} s_1 \\ \bar{x}_2 \pm z_{1-\alpha/2} s_2 \end{aligned}$$

where $z_{1-\alpha/2}$ is the $(1 - \alpha/2)$ th quantile of the standard normal distribution.

The $100(1 - \alpha)\%$ confidence interval for $\bar{x}_1 - \bar{x}_2$ is given by

$$\bar{x}_1 - \bar{x}_2 \pm z_{1-\alpha/2} \sqrt{s_1^2 + s_2^2}$$

With clustered data, similar to the discussion for the one-sample test, suppose that population one has K_1 clusters and population two has K_2 clusters. Let ρ_1 and ρ_2 be the intraclass correlations, \bar{M}_1 and \bar{M}_2 be the average cluster sizes, $\bar{x}_1 = (1/n_1) \sum_{i=1}^{K_1} \sum_{j=1}^{M_{1i}} x_{1ij}$ and $\bar{x}_2 = (1/n_2) \sum_{i=1}^{K_2} \sum_{j=1}^{M_{2i}} x_{2ij}$ be the sample means, and $\text{CV}_{\text{cl},1}$ and $\text{CV}_{\text{cl},2}$ be the coefficients of variation for cluster sizes for population one and population two. Let $s_{1,\text{cl}} = C_{\text{adj},1} s_1$ and $s_{2,\text{cl}} = C_{\text{adj},2} s_2$ be the standard errors of the population-specific sample means adjusted for clustered data, where the population-specific adjustment factors are defined as described for the one-sample test. To adjust the two-sample test statistic and the confidence intervals for clustering, replace s_1 with $s_{1,\text{cl}}$ and s_2 with $s_{2,\text{cl}}$ in the corresponding formulas.

Paired z test

Some experiments have paired observations (also known as matched observations, correlated pairs, or permanent components). Consider a sequence of n paired observations denoted by x_{ij} for subjects $i = 1, 2, \dots, n$ and groups $j = 1, 2$. An individual observation corresponds to the pair (x_{i1}, x_{i2}) , and inference is made on the differences within the pairs. Let $\mu_d = \mu_2 - \mu_1$ denote the mean difference, where μ_j is the population mean of group j , and let $D_i = x_{i2} - x_{i1}$ denote the difference between individual observations. D_i follows a normal distribution with mean $\mu_2 - \mu_1$ and standard deviation σ_d , where $\sigma_d = \sqrt{\sigma_1^2 + \sigma_2^2 - 2\rho_{\text{pair}}\sigma_1\sigma_2}$, σ_j is the population standard deviation of group j and ρ_{pair} is the correlation between paired observations.

We are interested in testing the null hypothesis $H_0: \mu_2 = \mu_1$ versus the two-sided alternative hypothesis $H_a: \mu_2 \neq \mu_1$, the upper one-sided alternative $H_a: \mu_2 > \mu_1$, or the lower one-sided alternative $H_a: \mu_2 < \mu_1$. Assuming the standard deviation of the differences σ_d is known, we use the following test statistic,

$$z = \frac{\bar{d}}{s_d}$$

where $\bar{d} = (\sum_{i=1}^n D_i)/n$ is the sample mean of the differences between paired observations and $s_d = \sigma_d/\sqrt{n}$ is the standard error of \bar{d} .

The $100(1 - \alpha)\%$ confidence interval for \bar{d} is given by

$$\bar{d} \pm z_{1-\alpha/2} s_d$$
