The program accepts three variables for log output, capital, and labor, and it accepts an \texttt{if exp} qualifier to restrict the estimation sample. All programs that you write to use with \texttt{nl} must accept an \texttt{if exp} qualifier because, when \texttt{nl} calls the program, it passes a binary variable that marks the estimation sample (the variable equals one if the observation is in the sample and zero otherwise). When calculating initial values, you will want to restrict your computations to the estimation sample, and you can do so by using \texttt{if} with any commands that accept \texttt{if exp} qualifiers. Even if your program does not calculate initial values or otherwise use the \texttt{if} qualifier, the \texttt{syntax} statement must still allow it. See \cite{[P] syntax} for more information on the \texttt{syntax} command and the use of \texttt{if}.

As in the previous example, reasonable initial values for \(\delta\) and \(\rho\) are 0.5 and 1, respectively. Conditional on those values, \eqref{eq:beta0} can be rewritten as

\[
\beta_0 = \ln Q_i + \ln(0.5K_i^{-1} + 0.5L_i^{-1}) - \epsilon_i \tag{2}
\]

so a good initial value for \(\beta_0\) is the mean of the right-hand side of \eqref{eq:beta0} ignoring \(\epsilon_i\). Lines 7–10 of the function evaluator program calculate that mean and store it in a local macro. Notice the use of \texttt{if} in the \texttt{summarize} statement so that the mean is calculated only for the estimation sample.

The final part of the program returns two macros. The macro \texttt{title} is optional and defines a short description of the model that will be displayed in the output immediately above the table of parameter estimates. The macro \texttt{eq} is required and defines the substitutable expression that \texttt{nl} will use. If the expression is short, you can define it all at once. However, because the expression used here is somewhat lengthy, defining local macros and then building up the final expression from them is easier.

To verify that there are no errors in your program, you can call it directly and then use `return` list:

```
. use https://www.stata-press.com/data/r18/production
. nlces lnoutput capital labor
     (output omitted)
. return list
macros:
   r(title) : "CES ftn., ln Q=lnoutput, K=capital, L=labor"
   r(eq) : "lnoutput = \{b0=3.711606264663641\} - \{rho=1\}*ln(\{delta> a=0.5\}*capital^(-1*\{rho\}) + (1-\{delta\})*labor^(-1*\{rho\}))"
```

The macro `r(eq)` contains the same substitutable expression that we specified at the command line in the preceding example, except for the initial value for `b0`. In short, an `nl` substitutable expression program should return in `r(eq)` the same substitutable expression you would type at the command line. The only difference is that when writing a substitutable expression program, you do not bind the entire expression inside parentheses.

Having written the program, you can use it by typing

```
. nl ces: lnoutput capital labor
```

(There is a space between `nl` and `ces`.) The output is identical to that shown in example 1, save for the title defined in the function evaluator program that appears immediately above the table of parameter estimates.

Technical note

You will want to store `nlces` as an ado-file called `nlces.ado`. The alternative is to type the code into Stata interactively or to place the code in a do-file. While those alternatives are adequate for occasional use, if you save the program as an ado-file, you can use the function anytime you use Stata without having to redefine the program. When `nl` attempts to execute `nlces`, if the program is not in Stata’s memory, Stata will search the disk(s) for an ado-file of the same name and, if found, automatically load it. All you have to do is name the file with the `.ado` suffix and then place it in a directory where Stata will find it. You should put the file in the directory Stata reserves for user-written ado-files, which, depending on your operating system, is `c:\ado\personal` (Windows), `~/ado/personal` (Unix), or `~:ado:personal` (Mac). See [U] 17 Ado-files.

Sometimes you may want to pass additional options to the substitutable expression program. You can modify the `syntax` statement of your program to accept whatever options you wish. Then when you call `nl` with the syntax

```
. nl func_prog: varlist, options
```

any `options` that are not recognized by `nl` (see the table of options at the beginning of this entry) are passed on to your function evaluator program. The only other restriction is that your program cannot accept an option named `at` because `nl` uses that option with function evaluator programs.

Built-in functions

Some functions are used so often that `nl` has them built in so that you do not need to write them yourself. `nl` automatically chooses initial values for the parameters, though you can use the `initial(…)` option to override them.
Three alternatives are provided for exponential regression with one asymptote:

\[
\text{exp3} \quad y_i = \beta_0 + \beta_1 x_i^2 + \epsilon_i
\]

\[
\text{exp2} \quad y_i = \beta_1 x_i^2 + \epsilon_i
\]

\[
\text{exp2a} \quad y_i = \beta_1 (1 - \beta_2 x_i) + \epsilon_i
\]

For instance, typing \texttt{nl exp3: ras dvl} fits the three-parameter exponential model (parameters $\beta_0$, $\beta_1$, and $\beta_2$) using $y_i = \text{ras}$ and $x_i = \text{dvl}$.

Two alternatives are provided for the logistic function (symmetric sigmoid shape; not to be confused with logistic regression):

\[
\text{log4} \quad y_i = \beta_0 + \beta_1 \left[ 1 + \exp\{-\beta_2 (x_i - \beta_3)\} \right] + \epsilon_i
\]

\[
\text{log3} \quad y_i = \beta_1 \left[ 1 + \exp\{-\beta_2 (x_i - \beta_3)\} \right] + \epsilon_i
\]

Finally, two alternatives are provided for the Gompertz function (asymmetric sigmoid shape):  

\[
\text{gom4} \quad y_i = \beta_0 + \beta_1 \exp\left\{-\exp\{-\beta_2 (x_i - \beta_3)\}\right\} + \epsilon_i
\]

\[
\text{gom3} \quad y_i = \beta_1 \exp\left\{-\exp\{-\beta_2 (x_i - \beta_3)\}\right\} + \epsilon_i
\]

**Lognormal errors**

A nonlinear model with errors that are independent and identically distributed normal may be written as

\[
y_i = f(x_i, \beta) + u_i, \quad u_i \sim N(0, \sigma^2)
\]

for $i = 1, \ldots, n$. If the $y_i$ are thought to have a $k$-shifted lognormal instead of a normal distribution—that is, $\ln(y_i - k) \sim N(\zeta_i, \tau^2)$, and the systematic part $f(x_i, \beta)$ of the original model is still thought appropriate for $y_i$—the model becomes

\[
\ln(y_i - k) = \zeta_i + v_i = \ln\{f(x_i, \beta) - k\} + v_i, \quad v_i \sim N(0, \tau^2)
\]

This model is fit if \texttt{lnlsq}(k) is specified.

If model (4) is correct, the variance of $(y_i - k)$ is proportional to $\{f(x_i, \beta) - k\}^2$. Probably the most common case is $k = 0$, sometimes called “proportional errors” because the standard error of $y_i$ is proportional to its expectation, $f(x_i, \beta)$. Assuming that the value of $k$ is known, (4) is just another nonlinear model in $\beta$, and it may be fit as usual. However, we may wish to compare the fit of (3) with that of (4) using the residual sum of squares (RSS) or the deviance $D$, $D = -2 \times \log$-likelihood, from each model. To do so, we must allow for the change in scale introduced by the log transformation.

Assuming, then, the $y_i$ to be normally distributed, Atkinson (1985, 85–87, 184), by considering the Jacobian $\prod_i |\partial \ln(y_i - k) / \partial y_i|$, showed that multiplying both sides of (4) by the geometric mean of $y_i - k$, $\bar{y}$, gives residuals on the same scale as those of $y_i$. The geometric mean is given by

\[
\bar{y} = e^{n^{-1} \sum \ln(y_i - k)}
\]

which is a constant for a given dataset. The residual deviance for (3) and for (4) may be expressed as

\[
D(\hat{\beta}) = \left\{ 1 + \ln(2\pi \sigma^2) \right\} n
\]

(5)
where \( \hat{\beta} \) is the maximum likelihood estimate (MLE) of \( \beta \) for each model and \( n \hat{\sigma}^2 \) is the RSS from (3), or that from (4) multiplied by \( \hat{y}^2 \).

Because (3) and (4) are models with different error structures but the same functional form, the arithmetic difference in their RSS or deviances is not easily tested for statistical significance. However, if the deviance difference is large (>4, say), we would naturally prefer the model with the smaller deviance. Of course, the residuals for each model should be examined for departures from assumptions (nonconstant variance, nonnormality, serial correlations, etc.) in the usual way.

Alternatively, consider modeling

\[
E(y_i) = 1/(C + Ae^{Bx_i}) \tag{6}
\]

\[
E(1/y_i) = E(y_i') = C + Ae^{Bx_i} \tag{7}
\]

where \( C, A, \) and \( B \) are parameters to be estimated. Using the data \((y, x) = (0.04, 5), (0.06, 12), (0.08, 25), (0.1, 35), (0.15, 42), (0.2, 48), (0.25, 60), (0.3, 75), \) and \((0.5, 120) (Danuso 1991)\), fitting the models yields

<table>
<thead>
<tr>
<th>Model</th>
<th>( C )</th>
<th>( A )</th>
<th>( B )</th>
<th>RSS</th>
<th>Deviance</th>
</tr>
</thead>
<tbody>
<tr>
<td>(6)</td>
<td>1.781</td>
<td>25.74</td>
<td>-0.03926</td>
<td>-0.001640</td>
<td>-51.95</td>
</tr>
<tr>
<td>(6) with lnlsq(0)</td>
<td>1.799</td>
<td>25.45</td>
<td>-0.04051</td>
<td>-0.001431</td>
<td>-53.18</td>
</tr>
<tr>
<td>(7)</td>
<td>1.781</td>
<td>25.74</td>
<td>-0.03926</td>
<td>8.197</td>
<td>24.70</td>
</tr>
<tr>
<td>(7) with lnlsq(0)</td>
<td>1.799</td>
<td>27.45</td>
<td>-0.04051</td>
<td>3.651</td>
<td>17.42</td>
</tr>
</tbody>
</table>

There is little to choose between the two versions of the logistic model (6), whereas for the exponential model (7), the fit using lnlsq(0) is much better (a deviance difference of 7.28). The reciprocal transformation has introduced heteroskedasticity into \( y_i' \), which is countered by the proportional errors property of the lognormal distribution implicit in lnlsq(0). The deviances are not comparable between the logistic and exponential models because the change of scale has not been allowed for, although in principle it could be.

**Other uses**

Even if you are fitting linear regression models, you may find that nl can save you some typing. Because you specify the parameters of your model explicitly, you can impose constraints on them directly.

**Example 2**

In example 2 of [R] cnsreg, we showed how to fit the model

\[
\text{mpg} = \beta_0 + \beta_1 \text{price} + \beta_2 \text{weight} + \beta_3 \text{displ} + \beta_4 \text{gear\_ratio} + \beta_5 \text{foreign} + \beta_6 \text{length} + u
\]

subject to the constraints

\[
\begin{align*}
\beta_1 &= \beta_2 = \beta_3 = \beta_6 \\
\beta_4 &= -\beta_5 = \beta_0/20
\end{align*}
\]
An alternative way is to use `nl`:

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. nl (mpg = {b0} + {b1}*price + {b1}*weight + {b1}*displ +
   > {b0}/20*gear_ratio - {b0}/20*foreign + {b1}*length)
```

Iteration 0: Residual SS = 1578.522
Iteration 1: Residual SS = 1578.522

```
Source | SS      df    MS
--------+---------+---------+
Model   | 34429.478  2 17214.7389
Residual| 1578.5223  72 21.9239203
Total   | 36008     74 486.594595
        | 436.4562
```

```
mpg         Coefficient Std. err.  t     P>|t|   [95% conf. interval]
/b0         26.52229    1.375178  19.29    0.000   23.78092   29.26365
/b1        -.000923    .0001534 -6.02    0.000  -.0012288  -.0006172
```

The point estimates and standard errors for $\beta_0$ and $\beta_1$ are identical to those reported in example 2 of [R] cnsreg. To get the estimate for $\beta_4$, we can use `nlcom`:

```
. nlcom _b[/b0]/20
   _nl_1: _b[/b0]/20
```

```
mpg         Coefficient Std. err.  z     P>|z|   [95% conf. interval]
_nl_1       1.326114    .0687589  19.29    0.000   1.191349   1.460879
```

The advantage to using `nl` is that we do not need to use the `constraint` command six times.

`nl` is also a useful tool when doing exploratory data analysis. For example, you may want to run a regression of $y$ on a function of $x$, though you have not decided whether to use $\sqrt{x}$ or $\ln(x)$. You can use `nl` to run both regressions without having first to generate two new variables:

```
. nl (y = {b0} + {b1}*ln(x))
. nl (y = {b0} + {b1}*sqrt(x))
```

Poi (2008) shows the advantages of using `nl` when marginal effects of transformed variables are desired as well.

### Weights

Weights are specified in the usual way—analytic and frequency weights as well as `iweights` are supported; see [U] 20.24 Weighted estimation. Use of analytic weights implies that the $y_i$ have different variances. Therefore, model (3) may be rewritten as

$$ y_i = f(x_i, \beta) + u_i, \quad u_i \sim N(0, \sigma^2/w_i) \quad (3a) $$

where $w_i$ are (positive) weights, assumed to be known and normalized such that their sum equals the number of observations. The residual deviance for (3a) is

$$ D(\hat{\beta}) = \left\{1 + \ln(2\pi\hat{\sigma}^2)\right\} n - \sum \ln(w_i) \quad (5a) $$
Defining and fitting a model equivalent to (4) when weights have been specified as in (3a) is not straightforward and has not been attempted. Thus, deviances using and not using the \texttt{lnlsq()} option may not be strictly comparable when analytic weights (other than 0 and 1) are used.

You do not need to modify your substitutable expression in any way to use weights. If, however, you write a substitutable expression program, then you should account for weights when obtaining initial values. When \texttt{nl} calls your program, it passes whatever weight expression (if any) was specified by the user. Here is an outline of a substitutable expression program that accepts weights:

```stata
program nl name, rclass
    version 18.0
    syntax varlist [aw fw iw] if
    ... // Obtain initial values allowing weights
    // Use the syntax [‘weight’‘exp’]. For example,
    summarize varname [‘weight’‘exp’] ‘if’
    regress depvar varlist [‘weight’‘exp’] ‘if’
    ... // Return substitutable expression
    return local eq "substitutable expression"
    return local title "description of estimator"
end
```

For details on how the \texttt{syntax} command processes weight expressions, see \cite{syntax}.

**Potential errors**

\texttt{nl} is reasonably robust to the inability of your nonlinear function to be evaluated at some parameter values. \texttt{nl} does assume that your function can be evaluated at the initial values of the parameters. If your function cannot be evaluated at the initial values, an error message is issued with return code 480. Recall that if you do not specify an initial value for a parameter, then \texttt{nl} initializes it to zero. Many nonlinear functions cannot be evaluated when some parameters are zero, so in those cases specifying alternative initial values is crucial.

Thereafter, as \texttt{nl} changes the parameter values, it monitors your function for unexpected missing values. If these are detected, \texttt{nl} backs up. That is, \texttt{nl} finds a point between the previous, known-to-be-good parameter vector and the new, known-to-be-bad vector at which the function can be evaluated and continues its iterations from that point.

\texttt{nl} requires that once a parameter vector is found where the predictions can be calculated, small changes to the parameter vector be made to calculate numeric derivatives. If a boundary is encountered at this point, an error message is issued with return code 481.

When specifying \texttt{lnlsq()}, an attempt to take logarithms of $y_i - k$ when $y_i \leq k$ results in an error message with return code 482.

If \texttt{iterate()} iterations are performed and estimates still have not converged, results are presented with a warning, and the return code is set to 430.

If you use the programmed substitutable expression version of \texttt{nl} with a function evaluator program, or vice versa, Stata issues an error message. Verify that you are using the syntax appropriate for the program you have.
General comments on fitting nonlinear models

Achieving convergence is often problematic. For example, a unique minimum of the sum-of-squares function may not exist. Much literature exists on different algorithms that have been used, on strategies for obtaining good initial parameter values, and on tricks for parameterizing the model to make its behavior as linear-like as possible. Selected references are Kennedy and Gentle (1980, chap. 10) for computational matters and Ross (1990) and Ratkowsky (1983) for all three aspects. Ratkowsky’s book is particularly clear and approachable, with useful discussion on the meaning and practical implications of intrinsic and parameter-effects nonlinearity. An excellent text on nonlinear estimation is Gallant (1987). Also see Davidson and MacKinnon (1993 and 2004).

To enhance the success of \texttt{nl}, pay attention to the form of the model fit, along the lines of Ratkowsky and Ross. For example, Ratkowsky (1983, 49–59) analyzes three possible three-parameter yield-density models for plant growth:

\[
E(y_i) = \begin{cases} 
(\alpha + \beta x_i)^{-1/\theta} \\
(\alpha + \beta x_i + \gamma x_i^2)^{-1} \\
(\alpha + \beta x_i^\phi)^{-1}
\end{cases}
\]

All three models give similar fits. However, he shows that the second formulation is dramatically more linear-like than the other two and therefore has better convergence properties. In addition, the parameter estimates are virtually unbiased and normally distributed, and the asymptotic approximation to the standard errors, correlations, and confidence intervals is much more accurate than for the other models. Even within a given model, the way the parameters are expressed (for example, \(\phi x_i\) or \(e^{\theta x_i}\)) affects the degree of linearity and convergence behavior.

Function evaluator programs

Occasionally, a nonlinear function may be so complex that writing a substitutable expression for it is impractical. For example, there could be many parameters in the model. Alternatively, if you are implementing a two-step estimator, writing a substitutable expression may be altogether impossible. Function evaluator programs can be used in these situations.

\texttt{nl} will pass to your function evaluator program a list of variables, a weight expression, a variable marking the estimation sample, and a vector of parameters. Your program is to replace the dependent variable, which is the first variable in the variables list, with the values of the nonlinear function evaluated at those parameters. As with substitutable expression programs, the first two letters of the name must be \texttt{nl}.

To focus on the mechanics of the function evaluator program, again let’s compare the CES production function to the previous examples. The function evaluator program is
program nlces2
  version 18.0
  syntax varlist(min=3 max=3) if, at(name)
  local logout : word 1 of 'varlist'
  local capital : word 2 of 'varlist'
  local labor : word 3 of 'varlist'
  // Retrieve parameters out of at matrix
  tempname b0 rho delta
  scalar 'b0' = 'at'[1, 1]
  scalar 'rho' = 'at'[1, 2]
  scalar 'delta' = 'at'[1, 3]
  tempvar kterm lterm
  generate double 'kterm' = 'delta'*'capital'^(-1*'rho') 'if'
  generate double 'lterm' = (1-'delta')*'labor'^(-1*'rho') 'if'
  // Fill in dependent variable
  replace 'logout' = 'b0' - 1/'rho'*ln('kterm' + 'lterm') 'if'
end

Unlike the previous nlces program, this one is not declared to be r-class. The syntax statement again accepts three variables: one for log output, one for capital, and one for labor. An if exp is again required because nl will pass a binary variable marking the estimation sample. All function evaluator programs must accept an option named at() that takes a name as an argument—that is how nl passes the parameter vector to your program.

The next part of the program retrieves the output, labor, and capital variables from the variables list. It then breaks up the temporary matrix at and retrieves the parameters b0, rho, and delta. Pay careful attention to the order in which the parameters refer to the columns of the at matrix because that will affect the syntax you use with nl. The temporary names you use inside this program are immaterial, however.

The rest of the program computes the nonlinear function, using some temporary variables to hold intermediate results. The final line of the program then replaces the dependent variable with the values of the function. Notice the use of ‘if’ to restrict attention to the estimation sample. nl makes a copy of your dependent variable so that when the command is finished your data are left unchanged.

To use the program and fit your model, you type

```
  . use https://www.stata-press.com/data/r18/production, clear
  . nl ces2 @ lnoutput capital labor, parameters(b0 rho delta)
>   initial(b0 0 rho 1 delta 0.5)
```

The output is again identical to that shown in example 1. The order in which the parameters were specified in the parameters() option is the same in which they are retrieved from the at matrix in the program. To initialize them, you simply list the parameter name, a space, the initial value, and so on.

If you use the nparameters() option instead of the parameters() option, the parameters are named b1, b2, ..., bk, where k is the number of parameters. Thus, you could have typed

```
  . nl ces2 @ lnoutput capital labor, nparameters(3) initial(b1 0 b2 1 b3 0.5)
```

With that syntax, the parameters called b0, rho, and delta in the program will be labeled b1, b2, and b3, respectively. In programming situations or if there are many parameters, instead of listing the parameter names and initial values in the initial() option, you may find it more convenient to pass a column vector. In those cases, you could type

```
  . matrix myvals = (0, 1, 0.5)
  . nl ces2 @ lnoutput capital labor, nparameters(3) initial(myvals)
```
In summary, a function evaluator program receives a list of variables, the first of which is the dependent variable that you are to replace with the values of your nonlinear function. Additionally, it must accept an `if exp`, as well as an option named `at` that will contain the vector of parameters at which `nl` wants the function evaluated. You are then free to do whatever is necessary to evaluate your function and replace the dependent variable.

If you wish to use weights, your function evaluator program’s `syntax` statement must accept them. If your program consists only of, for example, `generate` statements, you need not do anything with the weights passed to your program. However, if in calculating the nonlinear function you use commands such as `summarize` or `regress`, then you will want to use the weights with those commands.

As with substitutable expression programs, `nl` will pass to it any options specified that `nl` does not accept, providing you with a way to pass more information to your function.

### Technical note

Before version 9 of Stata, the `nl` command used a different syntax, which required you to write an `nlfcn` program, and it did not have a syntax for interactive use other than the seven functions that were built-in. The old syntax of `nl` still works, and you can still use those `nlfcn` programs. If `nl` does not see a colon, an at sign, or a set of parentheses surrounding the equation in your command, it assumes that the old syntax is being used.

The current version of `nl` uses scalars and matrices to store intermediate calculations instead of local and global macros as the old version did, so the current version produces more accurate results. In practice, however, any discrepancies are likely to be small.
Stored results

`nl` stores the following in `e()`:

**Scalars**
- `e(N)` number of observations
- `e(k)` number of parameters
- `e(k_eq_model)` number of equations in overall model test; always 0
- `e(df_m)` model degrees of freedom
- `e(df_r)` residual degrees of freedom
- `e(df_t)` total degrees of freedom
- `e(mss)` model sum of squares
- `e(ssr)` residual sum of squares
- `e(tss)` total sum of squares
- `e(mme)` model mean square
- `e(msr)` residual mean square
- `e(ll)` log likelihood assuming i.i.d. normal errors
- `e(r2)` \( R^2 \)
- `e(r2_a)` adjusted \( R^2 \)
- `e(rmse)` root mean squared error
- `e(dev)` residual deviance
- `e(N_clust)` number of clusters
- `e(lnlsq)` value of `lnlsq` if specified
- `e(log_t)` 1 if `lnlsq` specified, 0 otherwise
- `e(gm_2)` square of geometric mean of \( (y-k) \) if `lnlsq`, 1 otherwise
- `e(cj)` position of constant in `e(b)` or 0 if no constant
- `e(delta)` relative change used to compute derivatives
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(converged)` 1 if converged, 0 otherwise

**Macros**
- `e(cmd)` `nl`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(title_2)` secondary title in estimation output
- `e(clustvar)` name of cluster variable
- `e(hac_kernel)` HAC kernel
- `e(hac_lag)` HAC lag
- `e(vcexp)` `vcetype` specified in `vcexp()`
- `e(vcetype)` title used to label Std. err.
- `e(type)` 1 = interactively entered expression
  2 = substitutable expression program
  3 = function evaluator program
- `e(sexp)` substitutable expression
- `e(params)` names of parameters
- `e(funcprog)` function evaluator program
- `e(rhs)` contents of `variables()`
- `e(properties)` `b V`
- `e(predict)` program used to implement `predict`
- `e(marginsok)` predictions allowed by `margins`
- `e(marginsnotok)` predictions disallowed by `margins`

**Matrices**
- `e(b)` coefficient vector
- `e(init)` initial values vector
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance

**Functions**
- `e(sample)` marks estimation sample
In addition to the above, the following is stored in \( r() \):

- \( r(\text{table}) \): matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in \( r() \) are updated when the command is replayed and will be replaced when any \( r \)-class command is run after the estimation command.

### Methods and formulas

The derivation here is based on Davidson and MacKinnon (2004, chap. 6). Let \( \beta \) denote the \( k \times 1 \) vector of parameters, and write the regression function using matrix notation as \( y = f(x, \beta) + u \) so that the objective function can be written as

\[
SSR(\beta) = \{ y - f(x, \beta) \}' D \{ y - f(x, \beta) \}
\]

The \( D \) matrix contains the weights and is defined in \([R]\) `regress`; if no weights are specified, then \( D \) is the \( N \times N \) identity matrix. Taking a second-order Taylor series expansion centered at \( \beta_0 \) yields

\[
SSR(\beta) \approx SSR(\beta_0) + g'(\beta_0)(\beta - \beta_0) + \frac{1}{2}(\beta - \beta_0)' H(\beta_0)(\beta - \beta_0)
\]

where \( g(\beta_0) \) denotes the \( k \times 1 \) gradient of \( SSR(\beta) \) evaluated at \( \beta_0 \) and \( H(\beta_0) \) denotes the \( k \times k \) Hessian of \( SSR(\beta) \) evaluated at \( \beta_0 \). Letting \( X \) denote the \( N \times k \) matrix of derivatives of \( f(x, \beta) \) with respect to \( \beta \), the gradient \( g(\beta) \) is

\[
g(\beta) = -2X'Du
\]

\( X \) and \( u \) are obviously functions of \( \beta \), though for notational simplicity that dependence is not shown explicitly. The \((m, n)\) element of the Hessian can be written as

\[
H_{mn}(\beta) = -2 \sum_{i=1}^{N} d_{ii} \left[ \frac{\partial^2 f_i}{\partial \beta_m \partial \beta_n} u_i - X_{im} X_{in} \right]
\]

where \( d_{ii} \) is the \( i \)th diagonal element of \( D \). As discussed in Davidson and MacKinnon (2004, chap. 6), the first term inside the brackets of (10) has expectation zero, so the Hessian can be approximated as

\[
H(\beta) = 2X'DX
\]

Differentiating the Taylor series expansion of \( SSR(\beta) \) shown in (8) yields the first-order condition for a minimum

\[
g(\beta_0) + H(\beta_0)(\beta - \beta_0) = 0
\]

which suggests the iterative procedure

\[
\beta_{j+1} = \beta_j - \alpha H^{-1}(\beta_j)g(\beta_j)
\]

where \( \alpha \) is a “step size” parameter chosen at each iteration to improve convergence. Using (9) and (11), we can write (12) as

\[
\beta_{j+1} = \beta_j + \alpha(X'DX)^{-1}X'Du
\]
where $X$ and $u$ are evaluated at $\beta_j$. Apart from the scalar $\alpha$, the second term on the right-hand side of (13) can be computed via a (weighted) regression of the columns of $X$ on the errors. nl computes the derivatives numerically and then calls `regress`. At each iteration, $\alpha$ is set to one, and a candidate value $\beta_{j+1}^*$ is computed by (13). If $\text{SSR}(\beta_{j+1}^*) < \text{SSR}(\beta_j)$, then $\beta_{j+1} = \beta_{j+1}^*$ and the iteration is complete. Otherwise, $\alpha$ is halved, a new $\beta_{j+1}^*$ is calculated, and the process is repeated. Convergence is declared when $\alpha|\beta_{j+1,m}| \leq \epsilon(|\beta_m| + \tau)$ for all $m = 1, \ldots, k$. nl uses $\tau = 10^{-3}$ and, by default, $\epsilon = 10^{-5}$, though you can specify an alternative value of $\epsilon$ with the `eps()` option.

As derived, for example, in Davidson and MacKinnon (2004, chap. 6), an expedient way to obtain the covariance matrix is to compute $u$ and the columns of $X$ at the final estimate $\hat{\beta}$ and then regress that $u$ on $X$. The covariance matrix of the estimated parameters of that regression serves as an estimate of $\text{Var}(\hat{\beta})$. If that regression employs a robust covariance matrix estimator, then the covariance matrix for the parameters of the nonlinear regression will also be robust.

All other statistics are calculated analogously to those in linear regression, except that the nonlinear function $f(x_i, \beta)$ plays the role of the linear function $x_i'\beta$. See [R] `regress`.

This command supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

Acknowledgments

The original version of nl was written by Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model. Francesco Danuso’s menu-driven nonlinear regression program (1991) provided the inspiration.

* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

† You must specify the `variables()` option with `nl`. 
predict

Description for predict

predict creates a new variable containing predictions such as fitted values, residuals, probabilities, and expected values.

Menu for predict

Statistics > Postestimation

Syntax for predict

predict [type] newvar [if] [in] [, statistic]
predict [type] stub* [if] [in], scores

where \( k \) is the number of parameters in the model.

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>yhat</td>
<td>fitted values; the default</td>
</tr>
<tr>
<td>residuals</td>
<td>residuals</td>
</tr>
<tr>
<td>pr((a, b))</td>
<td>( \Pr(y_j \mid a &lt; y_j &lt; b) )</td>
</tr>
<tr>
<td>e((a, b))</td>
<td>( E(y_j \mid a &lt; y_j &lt; b) )</td>
</tr>
<tr>
<td>ystar((a, b))</td>
<td>( E(y^<em>_j), y^</em>_j = \max{a, \min(y_j, b)} )</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

yhat, the default, calculates the fitted values.
residuals calculates the residuals.
pr(\(a, b\)) calculates \( \Pr(a < x_j b + u_j < b) \), the probability that \( y_j | x_j \) would be observed in the interval \((a, b)\).

\( a \) and \( b \) may be specified as numbers or variable names; \( lb \) and \( ub \) are variable names;
pr(\(20, 30\)) calculates \( \Pr(20 < x_j b + u_j < 30) \);
pr(\(lb, ub\)) calculates \( \Pr(lb < x_j b + u_j < ub) \); and
pr(\(20, ub\)) calculates \( \Pr(20 < x_j b + u_j < ub) \).

\( a \) missing \((a \geq \cdot)\) means \(-\infty\); pr(\(., 30\)) calculates \( \Pr(-\infty < x_j b + u_j < 30) \);
pr(\(lb, 30\)) calculates \( \Pr(-\infty < x_j b + u_j < 30) \) in observations for which \( lb \geq \cdot \)
and calculates \( \Pr(lb < x_j b + u_j < 30) \) elsewhere.
missing \( (b \geq \cdot) \) means \(+\infty\); \( \text{pr}(20, .) \) calculates \( \text{Pr}(+\infty > x_j b + u_j > 20) \);
and calculates \( \text{Pr}(20 < x_j b + u_j < ub) \) elsewhere.

\( \text{e}(a, b) \) calculates \( E(x_j b + u_j \mid a < x_j b + u_j < b) \), the expected value of \( y_j \mid x_j \) conditional on \( y_j \mid x_j \) being in the interval \((a, b)\), meaning that \( y_j \mid x_j \) is truncated. \( a \) and \( b \) are specified as they are for \( \text{pr}() \).

\( \text{ystar}(a, b) \) calculates \( E(y_j^* \mid x_j b + u_j \leq a, y_j^* = b \text{ if } x_j b + u_j \geq b, \text{ and } y_j^* = x_j b + u_j \text{ otherwise} \), meaning that \( y_j^* \) is censored. \( a \) and \( b \) are specified as they are for \( \text{pr}() \).

\( \text{scores} \) calculates the scores. The \( j \)th new variable created will contain the score for the \( j \)th parameter in \( \text{e}(b) \).

**margins**

**Description for margins**

\( \text{margins} \) estimates margins of response for fitted values.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

\[
\text{margins} [\text{marginlist}] [\text{, options}]
\]

\[
\text{margins} [\text{marginlist}], \text{predict(statistic ...)} [\text{options}]
\]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{yhat} )</td>
<td>fitted values; the default</td>
</tr>
<tr>
<td>( \text{pr}(a, b) )</td>
<td>not allowed with ( \text{margins} )</td>
</tr>
<tr>
<td>( \text{e}(a, b) )</td>
<td>not allowed with ( \text{margins} )</td>
</tr>
<tr>
<td>( \text{ystar}(a, b) )</td>
<td>not allowed with ( \text{margins} )</td>
</tr>
<tr>
<td>( \text{residuals} )</td>
<td>not allowed with ( \text{margins} )</td>
</tr>
</tbody>
</table>

Statistics not allowed with \( \text{margins} \) are functions of stochastic quantities other than \( \text{e}(b) \).

For the full syntax, see [R] \textit{margins}.
Remarks and examples

Example 1

Obtaining predictions after fitting a nonlinear regression model with \texttt{nl} is no more difficult than obtaining predictions after fitting a linear regression model with \texttt{regress}. Here we fit a model of \texttt{mpg} on \texttt{weight}, allowing for a nonlinear relationship:

\begin{verbatim}
.use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
.nl (mpg = {b0} + {b1}*weight^gamma=-.5), variables(weight) nolog
\end{verbatim}

\begin{verbatim}
<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>1646.4376</td>
<td>2</td>
<td>823.218806</td>
</tr>
<tr>
<td>Residual</td>
<td>797.02185</td>
<td>71</td>
<td>11.2256598</td>
</tr>
<tr>
<td>Total</td>
<td>2443.4595</td>
<td>73</td>
<td>33.4720474</td>
</tr>
</tbody>
</table>
\end{verbatim}

\begin{verbatim}
| mpg  | Coefficient | Std. err. | t    | P>|t|    | [95% conf. interval] |
|------|-------------|-----------|------|--------|----------------------|
| /b0  | -18.17583   | 60.61762  | -0.30| 0.765  | -139.0439 102.6923  |
| /b1  | 1377.267    | 5292.379  | 0.26 | 0.795  | -9175.436 11929.97  |
| /gamma | -.4460916  | .6763641  | -0.66| 0.512  | -1.794723 .9025401 |
\end{verbatim}

Note: Parameter \texttt{b0} is used as a constant term during estimation.

Now, we obtain the predicted values of \texttt{mpg} and plot them in a graph along with the observed values:

\begin{verbatim}
.predict mpghat
(option \texttt{yhat} assumed; fitted values)
.scatter mpg weight || line mpghat weight, sort
\end{verbatim}
Suppose we wanted to know how sensitive \( \text{mpg} \) is to changes in \text{weight} for cars that weigh 3,000 pounds. We can use \text{margins} to find out:

\[
.\text{margins, eyex(weight) at(weight = 3000)}
\]

Conditional marginal effects
Model VCE: GNR
Expression: Fitted values, \text{predict()} 
\text{ey/ex wrt: weight} 
At: weight = 3000

<p>| | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ey/ex</td>
<td>std. err.</td>
<td>z</td>
<td>P&gt;</td>
<td>z</td>
</tr>
<tr>
<td>weight</td>
<td>-.8408119</td>
<td>.0804339</td>
<td>-10.45</td>
<td>0.000</td>
<td>-.9984594</td>
</tr>
</tbody>
</table>

With the \text{eyex()} option, \text{margins} reports elasticities. These results show that if we increase \text{weight} by 1\%, then \text{mpg} decreases by about 0.84\%.

\[\text{Technical note}\]

Observant readers will notice that \text{margins} issued a warning message stating that it could not perform its usual check for estimable functions. In the case of \text{nl}, as long as you do not specify the \text{predict()} option of \text{margins} or specify the default \text{predict(yhat)}, you can safely ignore that message. The predicted values that \text{nl} produces are suitable for use with \text{margins}. However, if you specify any \text{predict()} options other than \text{yhat}, then the output from \text{margins} after using \text{nl} will not be correct.

\[\text{Also see}\]

[R] \text{nl} — Nonlinear least-squares estimation

[U] 20 Estimation and postestimation commands
nlcom — Nonlinear combinations of parameters

Description

nlcom computes point estimates, standard errors, test statistics, significance levels, and confidence intervals for (possibly) nonlinear combinations of parameter estimates after any Stata estimation command, including survey estimation. Results are displayed in the usual table format used for displaying estimation results. Standard error calculations are based on the “delta method”, an approximation appropriate in large samples.

Quick start

Estimate the ratio of the coefficient of x2 to the coefficient of x1

```
nlcom _b[x2]/_b[x1]
```

Also estimate the ratio of the coefficient of x3 to coefficient of x1

```
nlcom (_b[x2]/_b[x1]) (_b[x3]/_b[x1])
```

Add labels to the ratios

```
nlcom (r21:_b[x2]/_b[x1]) (r31:_b[x3]/_b[x1])
```

Same as above, but post estimates and use the test command to test that both ratios are equal to 1

```
nlcom (r21:_b[x2]/_b[x1]) (r31:_b[x3]/_b[x1]), post
test (r21 = 1) (r31 = 1)
```

Estimate the ratio of the coefficients of factor indicators 2.a and 3.a

```
nlcom _b[2.a]/_b[3.a]
```

Estimate the ratio of the coefficients of x1 in the equations for y1 and y2 in a multiequation model

```
nlcom _b[y1:x1]/_b[y2:x1]
```

Menu

Statistics > Postestimation
Syntax

Nonlinear combination of parameters—one expression

```
nlcom [name:] exp [, options]
```

Nonlinear combinations of parameters—more than one expression

```
nlcom ([name:] exp) ([name:] exp) ... [, options]
```

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>level(#)</code></td>
<td>set confidence level; default is <code>level(95)</code></td>
</tr>
<tr>
<td><code>iterate(#)</code></td>
<td>maximum number of iterations</td>
</tr>
<tr>
<td><code>display_options</code></td>
<td>control column formats and line width</td>
</tr>
<tr>
<td><code>post</code></td>
<td>post estimation results</td>

</tr>
<tr>
<td><code>noheader</code></td>
<td>suppress output header</td>
</tr>
<tr>
<td><code>df(#)</code></td>
<td>use t distribution with # degrees of freedom for computing p-values and confidence intervals</td>
</tr>
</tbody>
</table>

Only one of `eform` or `eform()` is allowed.
`noheader` and `df(#)` do not appear in the dialog box.

The second syntax means that if more than one expression is specified, each must be surrounded by parentheses. The optional `name` is any valid Stata name and labels the transformations.

`exp` is a possibly nonlinear expression containing

```
_b[coef]
_b[eqno:coef]
`eqno`coef
`eqno`_b[coef]
```

`eqno` is

```
##
name
```

`coef` identifies a coefficient in the model. `coef` is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [U] 11.4.3 Factor variables. `coef` may contain time-series operators; see [U] 11.4.4 Time-series varlists.

Distinguish between [], which are to be typed, and [], which indicate optional arguments.
Options

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.

iterate(#) specifies the maximum number of iterations used to find the optimal step size in calculating numerical derivatives of the transformation(s) with respect to the original parameters. By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.

display_options: cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] Estimation options.

post causes nlcom to behave like a Stata estimation (eclass) command. When post is specified, nlcom will post the vector of transformed parameters and its estimated variance–covariance matrix to e(). This option, in essence, makes the transformation permanent. Thus you could, after posting, treat the transformed estimation results in the same way as you would treat results from other Stata estimation commands. For example, after posting, you could redisplay the results by typing nlcom without any arguments, or use test to perform simultaneous tests of hypotheses on linear combinations of the transformed parameters; see [R] test.

Specifying post clears out the previous estimation results, which can be recovered only by refitting the original model or by storing the estimation results before running nlcom and then restoring them; see [R] estimates store.

eform and eform(string) specify that the table of estimates be displayed in exponentiated form: for each estimate, \( e^b \) rather than \( b \) is displayed, where \( b \) is the nonlinear combination of parameters. eform labels the exponentiated results \( \exp(b) \), whereas eform(string) uses string to label them. Standard errors and confidence intervals are also transformed; see [R] eform_option.

The following options are available with nlcom but are not shown in the dialog box:

noheader suppresses the output header.

df(#) specifies that the \( t \) distribution with # degrees of freedom be used for computing \( p \)-values and confidence intervals.

Remarks and examples

Remarks are presented under the following headings:

Introduction
Basics
Using the post option
Reparameterizing ML estimates for univariate data
nlcom versus eform

Introduction

nlcom and predictnl both use the delta method. They take nonlinear transformations of the estimated parameter vector from some fitted model and apply the delta method to calculate the variance, standard error, Wald test statistic, etc., of the transformations. nlcom is designed for functions of the parameters, and predictnl is designed for functions of the parameters and of the data, that is, for predictions.

nlcom generalizes lincom (see [R] lincom) in two ways. First, nlcom allows the transformations to be nonlinear. Second, nlcom can be used to simultaneously estimate many transformations (whether linear or nonlinear) and to obtain the estimated variance–covariance matrix of these transformations.
Basics

In [R] `lincom`, the following regression was performed:

```
. use https://www.stata-press.com/data/r18/regress
. regress y x1 x2 x3
```

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>Number of obs = 148</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>3259.3561</td>
<td>3</td>
<td>1086.4520</td>
<td>F(3, 144) = 96.12</td>
</tr>
<tr>
<td>Residual</td>
<td>1627.5628</td>
<td>144</td>
<td>11.3025196</td>
<td>Prob &gt; F = 0.0000</td>
</tr>
<tr>
<td>Total</td>
<td>4886.91892</td>
<td>147</td>
<td>33.2443464</td>
<td>R-squared = 0.6670</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Adj R-squared = 0.6600</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Root MSE = 3.3619</td>
</tr>
</tbody>
</table>

| y         | Coefficient | Std. err. | t | P>|t| | [95% conf. interval] |
|-----------|-------------|-----------|---|-----|----------------------|
| x1        | 1.457113    | 1.07461   | 1.36 | 0.177 | -.666934 | 3.581161 |
| x2        | 2.221682    | .8610358  | 2.58 | 0.011 | .5197797 | 3.923583 |
| x3        | -.006139    | .0005543  | -11.08 | 0.000 | -.0072345 | -.0050435 |
| _cons     | 36.10135    | 4.382693  | 8.24 | 0.000 | 27.43863 | 44.76407 |

Then, `lincom` was used to estimate the difference between the coefficients of `x1` and `x2`:

```
. lincom _b[x2] - _b[x1]
( 1)  - x1 + x2 = 0
```

| y         | Coefficient | Std. err. | t | P>|t| | [95% conf. interval] |
|-----------|-------------|-----------|---|-----|----------------------|
| (1)       | .7645682    | .9950282  | 0.77 | 0.444 | -1.20218 | 2.731316 |

It was noted, however, that nonlinear expressions are not allowed with `lincom`:

```
. lincom _b[x2] / _b[x1]
not possible with test r(131);
```

Nonlinear transformations are instead estimated using `nlcom`:

```
. nlcom _b[x2] / _b[x1]
   _nl_1: _b[x2] / _b[x1]
```

| y         | Coefficient | Std. err. | z  | P>|z| | [95% conf. interval] |
|-----------|-------------|-----------|---|-----|----------------------|
| _nl_1     | 1.524714    | .9812848  | 1.55 | 0.120 | -.3985686 | 3.447997 |

⚠️ Technical note

The notation `_b[name]` is the standard way in Stata to refer to regression coefficients; see [U] 13.5 Accessing coefficients and standard errors. Some commands, such as `lincom` and `test`, allow you to drop the `_b` and just refer to the coefficients by `name`. `nlcom`, however, requires the full specification `_b[name]`.  

⚠️
Returning to our linear regression example, `nlcom` also allows simultaneous estimation of more than one combination:

```
. nlcom (_b[x2]/_b[x1]) (_b[x3]/_b[x1]) (_b[x3]/_b[x2])
   _nl_1: _b[x2]/_b[x1]
   _nl_2: _b[x3]/_b[x1]
   _nl_3: _b[x3]/_b[x2]
```

```
y   Coefficient Std. err.  z    P>|z|  [95% conf. interval]
_nl_1  1.524714  .9812848  1.55 0.120  -.3985686   3.447997
_nl_2 -0.0042131 .0033483 -1.26 0.208  -.0107756   .0023494
_nl_3 -0.0027632 .0010695 -2.58 0.010  -.0048594  -.000667
```

We can also label the transformations to produce more informative names in the estimation table:

```
. nlcom (ratio21:_b[x2]/_b[x1]) (ratio31:_b[x3]/_b[x1]) (ratio32:_b[x3]/_b[x2])
   ratio21: _b[x2]/_b[x1]
   ratio31: _b[x3]/_b[x1]
   ratio32: _b[x3]/_b[x2]
```

```
y   Coefficient Std. err.  z    P>|z|  [95% conf. interval]
   ratio21  1.524714  .9812848  1.55 0.120  -.3985686   3.447997
   ratio31 -0.0042131 .0033483 -1.26 0.208  -.0107756   .0023494
   ratio32 -0.0027632 .0010695 -2.58 0.010  -.0048594  -.000667
```

`nlcom` stores the vector of estimated combinations and its estimated variance–covariance matrix in \( r() \).

```
. matrix list r(b)
r(b)[1,3]
   ratio21  ratio31  ratio32
c1  1.5247143  -0.00421315  -.00276324
. matrix list r(V)
symmetric r(V)[3,3]
   ratio21  ratio31  ratio32
cratio21  .96291982
cratio31 -0.00287781  .00001121
rcratio32 -0.00014234  2.137e-06  1.144e-06
```
Using the post option

When used with the post option, nlcom stores the estimation vector and variance–covariance matrix in e(), making the transformation permanent:

```
. quietly nlcom (ratio21:_b[x2]/_b[x1]) (ratio31:_b[x3]/_b[x1])
   > (ratio32:_b[x3]/_b[x2]), post
. matrix list e(b)
```

```
e(b)[1,3]
   y1  1.5247143 -.00421315 -.00276324
```

```
. matrix list e(V)
```

```
  symmetric e(V)[3,3]
   y1  1.96291982
   ratio31 -.00287781 .00001121
   ratio32 -.00014234 2.137e-06 1.144e-06
```

After posting, we can proceed as if we had just run a Stata estimation (eclass) command. For instance, we can replay the results,

```
. nlcom
```

| y       | Coefficient | Std. err. | z   | P>|z| | [95% conf. interval] |
|---------|-------------|-----------|-----|-----|----------------------|
| ratio21 | 1.524714    | .9812848  | 1.55| 0.120| -.3985686            |
| ratio31 | -.0042131   | .0033483  | -1.26| 0.208| -.0107756            |
| ratio32 | -.0027632   | .0010695  | -2.58| 0.010| -.0048594            |

or perform other postestimation tasks in the transformed metric, this time making reference to the new “coefficients”:

```
. display _b[ratio31]
-.00421315

. estat vce, correlation
```

```
Correlation matrix of coefficients of nlcom model
  e(V)
     ratio21 ratio31 ratio32
   ratio21         1.0000
   ratio31 -0.8759 1.0000
   ratio32 -0.1356 0.5969 1.0000
```

```
. test _b[ratio21] = 1
   ( 1) _b[ratio21] = 1
   chi2( 1) = 0.29
   Prob > chi2 = 0.5928
```

We see that testing _b[ratio21]=1 in the transformed metric is equivalent to testing using testnl _b[x2]/_b[x1]=1 in the original metric:

```
. quietly regress y x1 x2 x3
. testnl _b[x2]/_b[x1] = 1
   (1) _b[x2]/_b[x1] = 1
   chi2(1) = 0.29
   Prob > chi2 = 0.5928
```

We needed to refit the regression model to recover the original parameter estimates.
Technical note

In a previous technical note, we mentioned that commands such as lincom and test permit reference to name instead of _b[name]. This is not the case when lincom and test are used after nlcom, post. In the above, we used

```
    . test _b[ratio21] = 1
```

rather than

```
    . test ratio21 = 1
```

which would have returned an error. Consider this a limitation of Stata. For the shorthand notation to work, you need a variable named name in the data. In nlcom, however, name is just a coefficient label that does not necessarily correspond to any variable in the data.

Reparameterizing ML estimates for univariate data

When run using only a response and no covariates, Stata’s maximum likelihood (ML) estimation commands will produce ML estimates of the parameters of some assumed univariate distribution for the response. The parameterization, however, is usually not one we are used to dealing with in a nonregression setting. In such cases, nlcom can be used to transform the estimation results from a regression model to those from a maximum likelihood estimation of the parameters of a univariate probability distribution in a more familiar metric.

Example 1

Consider the following univariate data on $Y = \#$ of traffic accidents at a certain intersection in a given year:

```
    . use https://www.stata-press.com/data/r18/trafint
    . summarize accidents

    Variable |      Obs  Mean   Std. dev.    Min   Max
    ---------|---------|-----------|-------------|--------|--------
    accidents |      12 13.83333 14.47778      0    41
```

A quick glance of the output from summarize leads us to quickly reject the assumption that $Y$ is distributed as Poisson because the estimated variance of $Y$ is much greater than the estimated mean of $Y$.

Instead, we choose to model the data as univariate negative binomial, of which a common parameterization is

$$
\Pr(Y = y) = \frac{\Gamma(r + y)}{\Gamma(r) \Gamma(y + 1)} p^r (1 - p)^y \quad 0 \leq p \leq 1, \; r > 0, \; y = 0, 1, \ldots
$$

with

$$
E(Y) = \frac{r(1 - p)}{p} \quad \text{Var}(Y) = \frac{r(1 - p)}{p^2}
$$

There exist no closed-form solutions for the maximum likelihood estimates of $p$ and $r$, yet they may be estimated by the iterative method of Newton–Raphson. One way to get these estimates would be to write our own Newton–Raphson program for the negative binomial. Another way would be to write our own ML evaluator; see [R] ml.
The easiest solution, however, would be to use Stata’s existing negative binomial ML regression command, \texttt{nbreg}. The only problem with this solution is that \texttt{nbreg} estimates a different parameterization of the negative binomial, but we can worry about that later.

\begin{verbatim}
. nbreg accidents

\end{verbatim}

From this output, we see that, when used with univariate data, \texttt{nbreg} estimates a regression intercept, $\beta_0$, and the logarithm of some parameter $\alpha$. This parameterization is useful in regression models: $\beta_0$ is the intercept meant to be augmented with other terms of the linear predictor, and $\alpha$ is an overdispersion parameter used for comparison with the Poisson regression model.

However, we need to transform $(\beta_0, \ln \alpha)$ to $(p, r)$. Examining \textit{Methods and formulas} of \texttt{[R] nbreg} reveals the transformation as

$$p = \left\{1 + \alpha \exp(\beta_0)\right\}^{-1} \quad r = \alpha^{-1}$$

which we apply using \texttt{nlcom}:
Given the invariance of maximum likelihood estimators and the properties of the delta method, the above parameter estimates, standard errors, etc., are precisely those we would have obtained had we instead performed the Newton–Raphson optimization in the \((p, r)\) metric.

### Technical note

Note how we referred to the estimate of \(\ln \alpha\) above as \(_b[/lnalpha]\). This is not entirely evident from the output of \texttt{nbreg}, which is why we redisplayed the results using the \texttt{coeflegend} option so that we would know how to refer to the coefficients; [U] 13.5 Accessing coefficients and standard errors.

### \texttt{nlcom} versus \texttt{eform}

Many Stata estimation commands allow you to display exponentiated regression coefficients, some by default, some optionally. Known as “\texttt{eform}” in Stata terminology, this reparameterization serves many uses: it gives odds ratios for logistic models, hazard ratios in survival models, incidence-rate ratios in Poisson models, and relative-risk ratios in multinomial logit models, to name a few.

For example, consider the following estimation taken directly from the technical note in [R] \texttt{poisson}:

```stata
use https://www.stata-press.com/data/r18/airline
generate lnN = ln(n)
poisson injuries XYZowned lnN
```

Output:

```
Iteration 0:  Log likelihood = -22.333875
Iteration 1:  Log likelihood = -22.332276
Iteration 2:  Log likelihood = -22.332276
Poisson regression
Number of obs = 9
LR chi2(2)  = 19.15
Prob > chi2 = 0.0001
Pseudo R2 = 0.3001
Log likelihood = -22.332276

|                | Coefficient | Std. err. | z    | P>|z| | [95% conf. interval] |
|----------------|-------------|-----------|------|------|----------------------|
| injuries       |             |           |      |      |                      |
| XYZowned       | .6840667    | .3895877  | 1.76 | 0.079| -.0795111           | 1.447645 |
| lnN            | 1.424169    | .3725155  | 3.82 | 0.000| .6940517            | 2.154285 |
| _cons          | 4.863891    | .7090501  | 6.86 | 0.000| 3.474178            | 6.253603 |
```
When we replay results and specify the `irr` (incidence-rate ratios) option,

```
.poison, irr
Poisson regression
Number of obs = 9
LR chi2(2) = 19.15
Prob > chi2 = 0.0001
Pseudo R2 = 0.3001
Log likelihood = -22.332276
```

| injuries     | IRR     | Std. err. | z     | P>|z|   | [95% conf. interval] |
|--------------|---------|-----------|-------|-------|----------------------|
| XYZowned     | 1.981921| .7721322  | 1.76  | 0.079 | .9235678 4.253085    |
| lnN          | 4.154402| 1.547579  | 3.82  | 0.000 | 2.00181 8.621728     |
| _cons        | 129.5272| 91.84126  | 6.86  | 0.000 | 32.2713 519.8828     |

Note: `_cons` estimates baseline incidence rate.

we obtain the exponentiated regression coefficients and their estimated standard errors.

Contrast this with what we obtain if we exponentiate the coefficients manually by using `nlcom`:

```
.nlcom (E_XYZowned: exp(_b[XYZowned])) (E_lnN: exp(_b[lnN]))
E_XYZowned: exp(_b[XYZowned])
E_lnN: exp(_b[lnN])
```

| injuries     | Coefficient | Std. err. | z     | P>|z|   | [95% conf. interval] |
|--------------|-------------|-----------|-------|-------|----------------------|
| E_XYZowned   | 1.981921    | .7721322  | 2.57  | 0.010 | .4685701 3.495273    |
| E_lnN        | 4.154402    | 1.547579  | 2.68  | 0.007 | 1.121203 7.187602    |

There are three things to note when comparing an estimation command specified with an `eform_option` with the `nlcom` command specified with coefficients that are exponentiated manually:

1. The exponentiated coefficients and standard errors are identical. This is certainly good news.
2. The Wald test statistic (z) and level of significance are different. When using `eform` or any `eform_option` with an estimation command, the Wald test does not change from what you would have obtained without the `eform` option. You can see this by comparing both versions of the `poisson` output given previously.

When you use `eform`, Stata knows that what is usually desired is a test of

\[ H_0: \exp(\beta) = 1 \]

and not the uninformative-by-comparison

\[ H_0: \exp(\beta) = 0 \]

The test of \( H_0: \exp(\beta) = 1 \) is asymptotically equivalent to a test of \( H_0: \beta = 0 \), the Wald test in the original metric, but the latter has better small-sample properties. Thus if you specify `eform`, you get a test of \( H_0: \beta = 0 \).

`nlcom`, however, is general. It does not attempt to infer the test of greatest interest for a given transformation, and so a test of

\[ H_0: \text{transformed coefficient} = 0 \]

is always given, regardless of the transformation.
3. You may be surprised to see that, even though the coefficients and standard errors are identical, the confidence intervals (both 95%) are different.

Eform confidence intervals reported by an estimation command are standard confidence intervals with the endpoints transformed. For example, the confidence interval for the coefficient on lnN is [0.694, 2.154], whereas the confidence interval for the incidence-rate ratio due to lnN is \([\exp(0.694), \exp(2.154)] = [2.002, 8.619]\), which, except for some roundoff error, is what we see from the output of `poisson, irr`. For exponentiated coefficients, confidence intervals based on transform-the-endpoints methodology generally have better small-sample properties than their asymptotically equivalent counterparts.

The transform-the-endpoints method, however, gives valid coverage only when the transformation is monotonic. `nlcom` uses a more general and asymptotically equivalent method for calculating confidence intervals, as described in Methods and formulas.

Notice that `nlcom` has an `eform` option that behaves the same way as the `eform` option of any estimation command. Thus, we could have obtained the exponentiated coefficients and confidence intervals after `poisson` by specifying the `eform` option with `nlcom`; that is, we would type

```
  . nlcom (E_XYZowned:_b[XYZowned]) (E_lnN:_b[lnN]), eform

  E_XYZowned: _b[XYZowned]
  E_lnN: _b[lnN]
```

| injuries | exp(b) | Std. err. | z   | P>|z| | [95% conf. interval] |
|----------|--------|-----------|-----|------|---------------------|
| E_XYZowned | 1.981921 | .7721322 | 1.76 | 0.079 | .9235678 4.253085 |
| E_lnN    | 4.154402 | 1.547579 | 3.82 | 0.000 | 2.00181 8.621728 |

We obtain the same results as we did using `poisson` with the `irr` option. The interpretation of the coefficients and confidence intervals follows the discussion above.

**Stored results**

`nlcom` stores the following in `r()`:

Scalars
- `r(N)`: number of observations
- `r(df_r)`: residual degrees of freedom

Matrices
- `r(b)`: vector of transformed coefficients
- `r(V)`: estimated variance–covariance matrix of the transformed coefficients
- `r(table)`: matrix containing the estimates with their standard errors, test statistics, p-values, and confidence intervals

If `post` is specified, `nlcom` also stores the following in `e()`:

 Scalars
- `e(N)`: number of observations
- `e(df_r)`: residual degrees of freedom
- `e(N_strata)`: number of strata \(L\), if used after `svy`
- `e(N_psu)`: number of sampled PSUs \(n\), if used after `svy`
- `e(rank)`: rank of `e(V)`

Macros
- `e(cmd)`: `nlcom`
- `e(predict)`: program used to implement `predict`
- `e(properties)`: `b V`
Methods and formulas

Given a \(1 \times k\) vector of parameter estimates, \(\hat{\theta} = (\hat{\theta}_1, \ldots, \hat{\theta}_k)\), consider the estimated \(p\)-dimensional transformation

\[
g(\hat{\theta}) = [g_1(\hat{\theta}), g_2(\hat{\theta}), \ldots, g_p(\hat{\theta})]
\]

The estimated variance–covariance of \(g(\hat{\theta})\) is given by

\[
\hat{\text{Var}}\{g(\hat{\theta})\} = GV G' \tag{1}
\]

where \(G\) is the \(p \times k\) matrix of derivatives for which

\[
G_{ij} = \left. \frac{\partial g_i(\theta)}{\partial \theta_j} \right|_{\theta = \hat{\theta}} \quad i = 1, \ldots, p \quad j = 1, \ldots, k
\]

and \(V\) is the estimated variance–covariance matrix of \(\hat{\theta}\). Standard errors are obtained as the square roots of the variances.

The Wald test statistic for testing

\[H_0: g_i(\theta) = 0\]

versus the two-sided alternative is given by

\[
Z_i = \frac{g_i(\hat{\theta})}{\left[\hat{\text{Var}}_{ii}\{g(\hat{\theta})\}\right]^{1/2}}
\]

When the variance–covariance matrix of \(\hat{\theta}\) is an asymptotic covariance matrix, \(Z_i\) is approximately distributed as Gaussian. For linear regression, \(Z_i\) is taken to be approximately distributed as \(t_{1,r}\) where \(r\) is the residual degrees of freedom from the original fitted model.

A \((1 - \alpha)\times 100\%\) confidence interval for \(g_i(\theta)\) is given by

\[
g_i(\hat{\theta}) \pm z_{\alpha/2} \left[\hat{\text{Var}}_{ii}\{g(\hat{\theta})\}\right]^{1/2}
\]

for those cases where \(Z_i\) is Gaussian and

\[
g_i(\hat{\theta}) \pm t_{\alpha/2,r} \left[\hat{\text{Var}}_{ii}\{g(\hat{\theta})\}\right]^{1/2}
\]
for those cases where $Z_i$ is $t$ distributed. $z_p$ is the $1 - p$ quantile of the standard normal distribution, and $t_{p,r}$ is the $1 - p$ quantile of the $t$ distribution with $r$ degrees of freedom.

**nlsur** — Estimation of nonlinear systems of equations

---

**Description**

*nlsur* fits a system of nonlinear equations by feasible generalized nonlinear least squares (FGNLS). With the interactive version of the command, you enter the system of equations on the command line or in the dialog box by using **substitutable expressions**. If you have a system that you use regularly, you can write a **substitutable expression program** and use the second syntax to avoid having to reenter the system every time. The function evaluator program version gives you the most flexibility in exchange for increased complexity; with this version, your program is given a vector of parameters and a variable list, and your program computes the system of equations.

When you write a substitutable expression program or a function evaluator program, the first five letters of the name must be *nlsur*. *sexp_prog* and *func_prog* refer to the name of the program without the first five letters. For example, if you wrote a function evaluator program named *nlsurregss*, you would type *nlsur regss @* ... to estimate the parameters.

---

**Quick start**

Two-parameter exponential model regressing *y1* on *x* using the default FGNLS estimator

nlsur (y1 = {b1}*{b2}^x)

Add the variables() option to allow for missing values of *y1* and *x*

nlsur (y1 = {b1}*{b2}^x), variables(y1 x)

Two-equation, two-parameter exponential model

nlsur (y1 = {b1}*{b2}^x) (y2 = {g1}*{g2}^x), variables(y1 y2 x)

Same as above, but use the iterative FGNLS estimator

nlsur (y1 = {b1}*{b2}^x) (y2 = {g1}*{g2}^x), variables(y1 y2 x) ifgnls

Specify starting values for parameters *b1* and *g2*

nlsur (y1 = {b1=.5}*{b2}^x) (y2 = {g1}*{g2=1}^x), variables(y1 y2 x)

Same as above

nlsur (y1 = {b1}*{b2}^x) (y2 = {g1}*{g2}^x), variables(y1 y2 x) ///
initial(b1 .5 g2 1)

Same as above, but specify starting values using the matrix *i*

matrix i = (.5,0,0,1)

nlsur (y1 = {b1}*{b2}^x) (y2 = {g1}*{g2}^x), variables(y1 y2 x) ///
initial(i)

Statistics > Linear models and related > Multiple-equation models > Nonlinear seemingly unrelated regression

Syntax

Interactive version

\texttt{nlsur (depvar\_1 = <sexp\_1>) (depvar\_2 = <sexp\_2>) \ldots [if] [in] [weight] [ , options]}

Programmed substitutable expression version

\texttt{nlsur sexp\_prog : depvar\_1 depvar\_2 \ldots [varlist] [if] [in] [weight] [ , options]}

Function evaluator program version

\texttt{nlsur func\_prog @ depvar\_1 depvar\_2 \ldots [varlist] [if] [in] [weight] ,}

\texttt{ nequations(#) { parameters(namelist) | nparameters(#)} [options]}

where

\texttt{depvar\_j} is the dependent variable for equation \textit{j};

\texttt{<sexp>\_j} is the substitutable expression for equation \textit{j};

\texttt{sexp\_prog} is a substitutable expression program; and

\texttt{func\_prog} is a function evaluator program.
**Options**

**Model**

- **fgnls**: use two-step FGNLS estimator; this is the default.
- **ifgnls**: use iterative FGNLS estimator.
- **nls**: use NLS estimator.
- **variables(varlist)**: variables in model.
- **initial(initial_values)**: initial values for parameters.
- **nequations(#)**: number of equations in model (function evaluator program version only).
- **parameters(namelist)**: parameters in model (function evaluator program version only).
- **nparameters(#)**: number of parameters in model (function evaluator program version only).
- **sexp_options**: options for substitutable expression program.
- **func_options**: options for function evaluator program.

**SE/Robust**

- **vce(vcetype)**: vcetype may be **gnr, robust, cluster clustvar, bootstrap**, or **jackknife**.

**Reporting**

- **level(#)**: set confidence level; default is **level(95)**.
- **title(string)**: display string as title above the table of parameter estimates.
- **title2(string)**: display string as subtitle.
- **display_options**: control columns and column formats and line width.

**Optimization**

- **optimization_options**: control the optimization process; seldom used.
- **coeflegend**: display legend instead of statistics.

---

You must specify **nequations(#)** and one of **parameters(namelist)** or **nparameters(#)** or both.

**bootstrap**, by, **collect**, **jackknife**, rolling, and **statsby** are allowed; see [U] 11.1.10 **Prefix commands**.

Weights are not allowed with the **bootstrap** prefix; see [R] **bootstrap**.

**aweights** are not allowed with the **jackknife** prefix; see [R] **jackknife**.

**aweights**, **fweights**, **iweights**, and **pweights** are allowed; see [U] 11.1.6 **weight**.

**coeflegend** does not appear in the dialog box.

See [U] 20 **Estimation and postestimation commands** for more capabilities of estimation commands.

---

**Options**

- **fgnls**: requests the two-step FGNLS estimator; this is the default.
- **ifgnls**: requests the iterative FGNLS estimator. For the nonlinear systems estimator, this is equivalent to maximum likelihood estimation.
- **nls**: requests the nonlinear least-squares (NLS) estimator.
- **variables(varlist)**: specifies the variables in the system. **nlsur** ignores observations for which any of these variables has missing values. If you do not specify **variables()**, **nlsur** issues an error message if the estimation sample contains any missing values.
initial(initial_values) specifies the initial values to begin the estimation. You can specify a $1 \times k$ matrix, where $k$ is the total number of parameters in the system, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize alpha to 1.23 and delta to 4.57, you would type

```
.nlsur ..., initial(alpha 1.23 delta 4.57) ...
```

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model. nlsur ignores the row and column names of the matrix.

nequations(#) specifies the number of equations in the system.

parameters(namelist) specifies the names of the parameters in the system. The names of the parameters must adhere to the naming conventions of Stata’s variables; see [U] 11.3 Naming conventions. If you specify both parameters() and nparameters(), the number of names in the former must match the number specified in the latter.

nparameters(#) specifies the number of parameters in the system. If you do not specify names with the parameters() option, nlsur names them b1, b2, ..., b#. If you specify both parameters() and nparameters(), the number of names in the former must match the number specified in the latter.

sexp_options refer to any options allowed by your sexp_prog.

func_options refer to any options allowed by your func_prog.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (gnr), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

vce(gnr), the default, uses the conventionally derived variance estimator for nonlinear models fit using Gauss–Newton regression.

level(#); see [R] Estimation options.

title(string) specifies an optional title that will be displayed just above the table of parameter estimates.

title2(string) specifies an optional subtitle that will be displayed between the title specified in title() and the table of parameter estimates. If title2() is specified but title() is not, title2() has the same effect as title().

display_options: noci, nopvalues, cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] Estimation options.
optimization_options: iterate(#), [no]log, trace, eps(#), ifgnlsiterate(#), ifgnlseps(#), delta(#), noconstants, and hasconstants(namelist).

iterate() specifies the maximum number of iterations to use for NLS at each round of FGNLS estimation. This option is different from ifgnlsiterate(), which controls the maximum rounds of FGNLS estimation to use when the ifgnls option is specified.

log and nolog specify whether to show the iteration log; see set iterlog in [R] set iter.

trace specifies that the iteration log should include the current parameter vector.

eps(#) specifies the convergence criterion for successive parameter estimates and for the residual sum of squares (RSS). The default is eps(1e-5) (0.00001). eps() also specifies the convergence criterion for successive parameter estimates between rounds of iterative FGNLS estimation when ifgnls is specified.

ifgnlsiterate(#) specifies the maximum number of FGNLS iterations to perform. The default is the number set using set maxiter, which is 300 by default. To use this option, you must also specify the ifgnls option.

ifgnlseps(#) specifies the convergence criterion for successive estimates of the error covariance matrix during iterative FGNLS estimation. The default is ifgnlseps(1e-10). To use this option, you must also specify the ifgnls option.

delta(#) specifies the relative change in a parameter, δ, to be used in computing the numeric derivatives. The derivative for parameter βᵢ is computed as

\[ \frac{f_i(x_i, β_1, β_2, ..., β_i + d, β_{i+1}, ...) - f_i(x_i, β_1, β_2, ..., β_i, β_{i+1}, ...)}{d} \]

where \( d = δ(|β_i| + δ) \). The default is delta(4e-7).

noconstants indicates that none of the equations in the system includes constant terms. This option is generally not needed, even if there are no constant terms in the system; though in rare cases without this option, nlsur may claim that there is one or more constant terms even if there are none.

hasconstants(namelist) indicates the parameters that are to be treated as constant terms in the system of equations. The number of elements of namelist must equal the number of equations in the system. The \( i \)th entry of namelist specifies the constant term in the \( i \)th equation. If an equation does not include a constant term, specify a period (.) instead of a parameter name. This option is seldom needed with the interactive and programmed substitutable expression versions, because in those cases nlsur can almost always find the constant terms automatically.

The following options are available with nlsur but are not shown in the dialog box: coeflegend; see [R] Estimation options.

Remarks and examples

Remarks are presented under the following headings:

Introduction
Substitutable expression programs
Function evaluator programs
Introduction

\texttt{nlsur} fits a system of nonlinear equations by FGNLS. It can be viewed as a nonlinear variant of Zellner's seemingly unrelated regression model (Zellner 1962; Zellner and Huang 1962; Zellner 1963) and is therefore commonly called nonlinear SUR or nonlinear SURE. The model is also discussed in textbooks such as Davidson and MacKinnon (1993) and Greene (2012, 305–306). Formally, the model fit by \texttt{nlsur} is

\begin{align*}
y_{i1} &= f_1(x_i, \beta) + u_{i1} \\
y_{i2} &= f_2(x_i, \beta) + u_{i2} \\
&\vdots \\
y_{iM} &= f_M(x_i, \beta) + u_{iM}
\end{align*}

for \( i = 1, \ldots, N \) observations and \( m = 1, \ldots, M \) equations. The errors for the \( i \)th observation, \( u_{i1}, u_{i2}, \ldots, u_{iM} \), may be correlated, so fitting the \( m \) equations jointly may lead to more efficient estimates. Moreover, fitting the equations jointly allows us to impose cross-equation restrictions on the parameters. Not all elements of the parameter vector \( \beta \) and data vector \( x_i \) must appear in all the equations, though each element of \( \beta \) must appear in at least one equation for \( \beta \) to be identified. For this model, iterative FGNLS estimation is equivalent to maximum likelihood estimation with multivariate normal disturbances.

The syntax you use with \texttt{nlsur} closely mirrors that used with \texttt{nl}. In particular, you use substitutable expressions with the interactive and programmed substitutable expression versions to define the functions in your system. See \texttt{[R] nl} for more information on substitutable expressions. Here we reiterate the three rules that you must follow:

1. Parameters of the model are bound in braces: \{b0\}, \{param\}, etc.
2. Initial values for parameters are given by including an equal sign and the initial value inside the braces: \{b0=1\}, \{param=3.571\}, etc. If you do not specify an initial value, that parameter is initialized to zero. The \texttt{initial()} option overrides initial values in substitutable expressions.
3. Linear combinations of variables can be included using the notation \{eqname: varlist\}, for example, \{xb: mpg price weight\}, \{score: w x z\}, etc. Parameters of linear combinations are initialized to zero.

\begin{itemize}
    \item \textbf{Example 1: Interactive version using two-step FGNLS estimator}
\end{itemize}

We have data from an experiment in which two closely related types of bacteria were placed in a Petri dish, and the number of each type of bacteria were recorded every hour. We suspect a two-parameter exponential growth model can be used to model each type of bacteria, but because they shared the same dish, we want to allow for correlation in the error terms. We want to fit the system of equations

\begin{align*}
p_1 &= \beta_1 \beta_2^t + u_1 \\
p_2 &= \gamma_1 \gamma_2^t + u_2
\end{align*}

where \( p_1 \) and \( p_2 \) are the two populations and \( t \) is time, and we want to allow for nonzero correlation between \( u_1 \) and \( u_2 \). We type
. use https://www.stata-press.com/data/r18/petridish
. nlsur (p1 = {b1}*{b2}^t) (p2 = {g1}*{g2}^t)
(obs = 25)

The header of the output contains a summary of each equation, including the number of observations and parameters and the root mean squared error of the residuals. nlsur checks to see whether each equation contains a constant term, and if an equation does contain a constant term, an \( R^2 \) statistic is presented. If an equation does not have a constant term, an uncentered \( R^2 \) is instead reported. The \( R^2 \) statistic for each equation measures the percentage of variance explained by the nonlinear function and may be useful for descriptive purposes, though it does not have the same formal interpretation in the context of FGNLS as it does with NLS estimation. As we would expect, \( \beta_2 \) and \( \gamma_2 \) are both greater than one, indicating the two bacterial populations increased in size over time.

The model we fit in the next three examples is in fact linear in the parameters, so it could be fit using the `sureg` command. However, we will fit the model using `nlsur` so that we can focus on the mechanics of using the command. Moreover, using `nlsur` will obviate the need to generate several variables as well as the need to use the `constraint` command to impose parameter restrictions.

Example 2: Interactive version using iterative FGNLS estimator— the translog production function

Greene (1997, sec. 15.6) discusses the transcendental logarithmic (translog) cost function and provides cost and input price data for capital, labor, energy, and materials for the U.S. economy. One way to fit the translog production function to these data is to fit the system of three equations
\[
\begin{align*}
    s_k &= \beta_k + \delta_{kk} \ln \left( \frac{p_k}{p_m} \right) + \delta_{kl} \ln \left( \frac{p_l}{p_m} \right) + \delta_{ke} \ln \left( \frac{p_e}{p_m} \right) + u_1 \\
    s_l &= \beta_l + \delta_{kl} \ln \left( \frac{p_k}{p_m} \right) + \delta_{ll} \ln \left( \frac{p_l}{p_m} \right) + \delta_{le} \ln \left( \frac{p_e}{p_m} \right) + u_2 \\
    s_e &= \beta_e + \delta_{ke} \ln \left( \frac{p_k}{p_m} \right) + \delta_{le} \ln \left( \frac{p_l}{p_m} \right) + \delta_{ee} \ln \left( \frac{p_e}{p_m} \right) + u_3
\end{align*}
\]

where \( s_k \) is capital’s cost share, \( s_l \) is labor’s cost share, and \( s_e \) is energy’s cost share; \( p_k, p_l, p_e, \) and \( p_m \) are the prices of capital, labor, energy, and materials, respectively; the \( u \)’s are regression error terms; and the \( \beta \)'s and \( \delta \)'s are parameters to be estimated. There are three cross-equation restrictions on the parameters: \( \delta_{kl}, \delta_{ke}, \) and \( \delta_{le} \) each appear in two equations. To fit this model by using the iterative FGNLS estimator, we type

```
. use https://www.stata-press.com/data/r18/mfgcost
(Manufacturing cost)
.nlsur (s_k = {bk} + {dkk}*ln(p_k/p_m) + {dkl}*ln(p_l/p_m) + {dke}*ln(p_e/p_m))
> (s_l = {bl} + {dkl}*ln(p_k/p_m) + {dll}*ln(p_l/p_m) + {dle}*ln(p_e/p_m))
> (s_e = {be} + {dke}*ln(p_k/p_m) + {dle}*ln(p_l/p_m) + {dee}*ln(p_e/p_m)),
> ifgnls
(obs = 25)
```

We draw your attention to the iteration log at the top of the output. When iterative FGNLS estimation is used, the final scaled RSS will equal the product of the number of observations in the estimation sample and the number of equations; see \textit{Methods and formulas} for details. Because the RSS
scaled by the error covariance matrix during each round of FGNLS estimation, the scaled RSS is not comparable from one FGNLS iteration to the next.

Technical note

You may have noticed that we mentioned having data for four factors of production, yet we fit only three share equations. Because the four shares sum to one, we must drop one of the equations to avoid having a singular error covariance matrix. The iterative FGNLS estimator is equivalent to maximum likelihood estimation, and thus it is invariant to which one of the four equations we choose to drop. The (linearly restricted) parameters of the fourth equation can be obtained using the \texttt{lincom} command. Nonlinear functions of the parameters, such as the elasticities of substitution, can be computed using \texttt{nlcom}.

Substitutable expression programs

If you fit the same model repeatedly or you want to share code with colleagues, you can write a substitutable expression program to define your system of equations and avoid having to retype the system every time. The first five letters of the program’s name must be \texttt{nlsur}, and the program must set the \texttt{r}-class macro \texttt{r(n_eq)} to the number of equations in your system. The first equation’s substitutable expression must be returned in \texttt{r(eq_1)}, the second equation’s in \texttt{r(eq_2)}, and so on. You may optionally set \texttt{r(title)} to label your output; that has the same effect as specifying the \texttt{title()} option.

Example 3: Programmed substitutable expression version

We return to our translog cost function, for which a substitutable expression program is

```stata
program nlsurtranslog, rclass
    version 18.0
    syntax varlist(min=7 max=7) [if]
    tokenize `varlist'
    args sk sl se pk pl pe pm
    local pkpm ln('pk'/'pm')
    local plpm ln('pl'/'pm')
    local pepm ln('pe'/'pm')
    return scalar n_eq = 3
    return local eq_1 "'sk'= {bk} + {dkk}*`pkpm' + {dkl}*`plpm' + {dke}*`pepm'"
    return local eq_2 "'sl'= {bl} + {dkl}*`pkpm' + {dll}*`plpm' + {dle}*`pepm'"
    return local eq_3 "'se'= {be} + {dke}*`pkpm' + {dle}*`plpm' + {dee}*`pepm'"
    return local title "4-factor translog cost function"
end
```

We made our program accept seven variables, for the three dependent variables $s_k$, $s_l$, and $s_e$, and the four factor prices $p_k$, $p_l$, $p_m$, and $p_e$. The \texttt{tokenize} command assigns to macros ‘1’, ‘2’, ‘3’, ‘4’, ‘5’, ‘6’, ‘7’ the seven variables stored in ‘varlist’, and the \texttt{args} command transfers those numbered macros to macros ‘sk’, ‘sl’, ‘se’, ‘pk’, ‘pl’, ‘pe’, ‘pm’. Because we knew our substitutable expressions were going to be somewhat long, we created local macros to hold the log price ratios. These are simply macros that hold strings such as $\ln(p_k/p_m)$, not variables, and they will save us some repetitious typing when we define our substitutable expressions. Our program returns the number of equations in \texttt{r(n_eq)}, and we defined our substitutable expressions in \texttt{eq_1}, \texttt{eq_2}, and \texttt{eq_3}. We do not bind the expressions in parentheses as we do with the interactive version of \texttt{nlsur}. Finally, we put a title in \texttt{r(title)} to label our output.
Our syntax command also accepts an if clause, and that is how `nlsur` indicates the estimation sample to our program. In this application, we can safely ignore it because our program does not compute initial values. However, had we used commands such as `summarize` or `regress` to obtain initial values, then we would need to restrict those commands to analyze only the estimation sample. In those cases, typically, you simply need to include ‘if’ with the commands you are using. For example, instead of the command

```
summarize 'depvar', meanonly
```

you would use

```
summarize 'depvar' 'if', meanonly
```

We can check our program by typing

```
. nlsurtranslog s_k s_l s_e pk pl pe pm
. return list
scalars:
   r(n_eq) = 3
macros:
   r(title) : "4-factor translog cost function"
   r(eq_3) : "s_e= {be} + {dke}*ln(pk/pm) + {dle}*ln(pl/pm) + {.."
   r(eq_2) : "s_l= {bl} + {dkl}*ln(pk/pm) + {dll}*ln(pl/pm) + {.."
   r(eq_1) : "s_k= {bk} + {dkk}*ln(pk/pm) + {dkl}*ln(pl/pm) + {.."
```

Now that we know that our program works, we fit our model by typing

```
. nlsur translog: s_k s_l s_e pk pl pe pm, ifgnls
   (obs = 25)
```

Because we set r(title) in our substitutable expression program, the coefficient table has a title attached to it. The estimates are identical to those we obtained in example 2.

Technical note

nlsur accepts frequency and analytic weights as well as pweights (sampling weights) and iweights (importance weights). You do not need to modify your substitutable expressions in any way to perform weighted estimation, though you must make two changes to your substitutable expression program. The general outline of a sexp_prog program is

```stata
program nlsur name, rclass
    version 18.0
    syntax varlist [fw aw pw iw] [if]
    // Obtain initial values incorporating weights. For example,
    summarize varname ['weight''exp'] 'if'
    ...
    // Return n_eqn and substitutable expressions
    return scalar n_eq = #
    return local eq_1 = ...
    ...
end
```

First, we wrote the syntax statement to accept a weight expression. Here we allow all four types of weights, but if you know that your estimator is valid, say, for only frequency weights, then you should modify the syntax line to accept only fweights. Second, if your program computes starting values, then any commands you use must incorporate the weights passed to the program; you do that by including ['weight''exp'] when calling those commands.

Function evaluator programs

Although substitutable expressions are extremely flexible, there are some problems for which the nonlinear system cannot be defined using them. You can use the function evaluator program version of nlsur in these cases. We present two examples, a simple one to illustrate the mechanics of function evaluator programs and a more complicated one to illustrate the power of nlsur.
Example 4: Function evaluator program version

Here we write a function evaluator program to fit the translog cost function used in examples 2 and 3. The function evaluator program is

```stata
program nlsurtranslog2
    version 18.0
    syntax varlist(min=7 max=7) [if], at(name)
    tokenize `varlist'
    args sk sl se pk pl pe pm
    tempname bk dkk dkl dke bl dll dle be dee
    scalar `bk' = `at'[1,1]
    scalar `dkk' = `at'[1,2]
    scalar `dkl' = `at'[1,3]
    scalar `dke' = `at'[1,4]
    scalar `bl' = `at'[1,5]
    scalar `dll' = `at'[1,6]
    scalar `dle' = `at'[1,7]
    scalar `be' = `at'[1,8]
    scalar `dee' = `at'[1,9]
    local pkpm ln(`pk'/'pm')
    local plpm ln(`pl'/'pm')
    local pepm ln(`pe'/'pm')
    quietly {
        replace `sk' = `bk' + `dkk'*`pkpm' + `dkl'*`plpm' + `dke'*`pepm' 'if'
        replace `sl' = `bl' + `dkl'*`pkpm' + `dll'*`plpm' + `dle'*`pepm' 'if'
        replace `se' = `be' + `dke'*`pkpm' + `dle'*`plpm' + `dee'*`pepm' 'if'
    }
end
```

Unlike the substitutable expression program we wrote in example 3, nlsurtranslog2 is not declared as r-class because we will not be returning any stored results. We are again expecting seven variables: three shares and four factor prices, and nlsur will again mark the estimation sample with an if expression.

Our function evaluator program also accepts an option named at(), which will receive a parameter vector at which we are to evaluate the system of equations. All function evaluator programs must accept this option. Our model has nine parameters to estimate, and we created nine temporary scalars to hold the elements of the `at' matrix.

Because our model has three equations, the first three variables passed to our program are the dependent variables that we are to fill in with the function values. We replaced only the observations in our estimation sample by including the `if' qualifier in the replace statements. Here we could have ignored the `if' qualifier because nlsur will skip over observations not in the estimation sample and we did not perform any computations requiring knowledge of the estimation sample. However, including the `if' is good practice and may result in a slight speed improvement if the functions of your model are complicated and the estimation sample is much smaller than the dataset in memory.

We could have avoided creating temporary scalars to hold our individual parameters by writing the replace statements as, for example,

```stata
replace `sk' = `at'[1,1] + `at'[1,2]*`pkpm' + `at'[1,3]*`plpm' + `at'[1,4]*`pepm' 'if'
```

You can use whichever method you find more appealing, though giving the parameters descriptive names reduces the chance for mistakes and makes debugging easier.
To fit our model by using the function evaluator program version of `nlsur`, we type

```
.nlsur translog2 @ s_k s_l s_e pk pl pe pm, ifgnls nequations(3)
> parameters(bk dkk dkl dke bl dll dle be dee)
> hasconstants(bk bl be)
(ops = 25)

Iteration 0: Scaled RSS = 75
When we use the function evaluator program version, \texttt{nlsur} requires us to specify the number of equations in \texttt{nequations()}, and it requires us to specify either the names for each of our parameters or the number of parameters in the model. Here we used the \texttt{parameters()} option to name our parameters; the order in which we specified them in this option is the same as the order in which we extracted them from the ‘at’ matrix in our program. Had we instead specified \texttt{nparameters(9)}, our parameters would have been labeled \texttt{/b1}, \texttt{/b2}, ..., \texttt{/b9} in the output.

\texttt{nlsur} has no way of telling how many parameters appear in each equation, so the \texttt{Parms} column in the header contains missing values. Moreover, the function evaluator program version of \texttt{nlsur} does not attempt to identify constant terms, so we used the \texttt{hasconstant} option to tell \texttt{nlsur} which parameter in each equation is a constant term.

The estimates are identical to those we obtained in examples 2 and 3.

\section*{Technical note}

As with substitutable expression programs, if you intend to do weighted estimation with a function evaluator program, you must modify your \texttt{func prog} program’s \texttt{syntax} statement to accept weights. Moreover, if you use any statistical commands when computing your nonlinear functions, then you must include the weight expression with those commands.
Example 5: Fitting the basic AIDS model using nlsur

Deaton and Muellbauer (1980) introduce the almost ideal demand system (AIDS), and Poi (2012) presents a set of commands and several extensions for fitting the AIDS automatically. Here we show how to fit the basic AIDS model, which is a common example of a nonlinear system of equations, by manually using nlsur. The dataset food.dta contains household expenditures, expenditure shares, and log prices for four broad food groups. For a four-good demand system, we need to fit the following system of three equations:

\[
\begin{align*}
w_1 &= \alpha_1 + \gamma_{11} \ln p_1 + \gamma_{12} \ln p_2 + \gamma_{13} \ln p_3 + \beta_1 \ln \left( \frac{m}{P(p)} \right) + u_1 \\
\log(P(p)) &= \alpha_0 + \sum_{i=1}^{4} \alpha_i \ln p_i + \frac{1}{2} \sum_{i=1}^{4} \sum_{j=1}^{4} \gamma_{ij} \ln p_i \ln p_j \\
\end{align*}
\]

where \( w_k \) denotes a household’s fraction of expenditures on good \( k \), \( \ln p_k \) denotes the logarithm of the price paid for good \( k \), \( m \) denotes a household’s total expenditure on all four goods, the \( u \)'s are regression error terms, and

\[
\begin{align*}
\alpha_i &= \sum_{i=1}^{4} \alpha_i \ln p_i + \frac{1}{2} \sum_{i=1}^{4} \sum_{j=1}^{4} \gamma_{ij} \ln p_i \ln p_j \\
\end{align*}
\]

The parameters for the fourth good’s share equation can be recovered from the following constraints that are imposed by economic theory:

\[
\begin{align*}
\sum_{i=1}^{4} \alpha_i &= 1 \\
\sum_{i=1}^{4} \beta_i &= 0 \\
\gamma_{ij} &= \gamma_{ji} \\
\sum_{i=1}^{4} \gamma_{ij} &= 0 \text{ for all } j
\end{align*}
\]

Our model has a total of 12 unrestricted parameters. We will not estimate \( \alpha_0 \) directly. Instead, we will set it equal to 5; see Deaton and Muellbauer (1980) for a discussion of why treating \( \alpha_0 \) as fixed is acceptable.

        'b3'*('lnm' - 'lnpindex')
}
end
```

The `syntax` statement accepts eight variables: three expenditure share variables, all four log-price variables, and a variable for log expenditures (\( \ln m \)). Most of the code simply extracts the parameters
from the ‘at’ matrix. Although we are estimating only 12 parameters, to calculate the price index term and the expenditure share equations, we need the restricted parameters as well. Notice how we impose the constraints on the parameters. We then created a temporary variable to hold ln\(P(p)\), and we filled the three dependent variables with the predicted expenditure shares.

To fit our model, we type

To get the restricted parameters for the fourth share equation, we can use \texttt{lincom}. For example, to obtain $\alpha_4$, we type
\[
. \texttt{lincom 1} - ([a1]_{\text{cons}} - [a2]_{\text{cons}} - [a3]_{\text{cons}})
\]
(1) $- ([a1]_{\text{cons}} - [a2]_{\text{cons}} - [a3]_{\text{cons}} = -1$

\[
| \text{Coefficient} | \text{Std. err.} | z | P>|z| | [95\% \text{ conf. interval}] |
|-------------------|----------------|---|--------|------------------|
| (1)               | .3083643       | .0052611 | 58.61  | 0.000 | .2980528 | .3186758 |
\]

For more information on \texttt{lincom}, see \textbf{[R] lincom}.

**Stored results**

\texttt{nlsur} stores the following in \texttt{e}():

- Scalars
  - \texttt{e(N)}: number of observations
  - \texttt{e(k)}: number of parameters
  - \texttt{e(k\_#)}: number of parameters for equation \#
  - \texttt{e(k\_eq)}: number of equation names in \texttt{e(b)}
  - \texttt{e(k\_eq\_model)}: number of equations in overall model test
  - \texttt{e(n\_eq)}: number of equations
  - \texttt{e(mss\_#)}: model sum of squares for equation \#
  - \texttt{e(rss\_#)}: RSS for equation \#
  - \texttt{e(rmse\_#)}: root mean squared error for equation \#
  - \texttt{e(r2\_#)}: $R^2$ for equation \#
  - \texttt{e(ll)}: Gaussian log likelihood (\texttt{iflgs} version only)
  - \texttt{e(N\_clust)}: number of clusters
  - \texttt{e(rank)}: rank of \texttt{e(V)}
  - \texttt{e(converged)}: 1 if converged, 0 otherwise

- Macros
  - \texttt{e(cmd)}: \texttt{nlsur}
  - \texttt{e(cmdline)}: command as typed
  - \texttt{e(method)}: \texttt{fgnls}, \texttt{ifgnls}, or \texttt{nls}
  - \texttt{e(depvar)}: names of dependent variables
  - \texttt{e(depvar\_#)}: dependent variable for equation \#
  - \texttt{e(vce)}: \texttt{vcetype} specified in \texttt{vce()}
  - \texttt{e(vctype)}: title used to label Std. err.
  - \texttt{e(type)}: 1 = interactively entered expression
  - \texttt{e(sexpprog)}: substitutable expression program
  - \texttt{e(sexp\_#)}: substitutable expression for equation \#
  - \texttt{e(params)}: names of all parameters
  - \texttt{e(params\_#)}: parameters in equation \#
  - \texttt{e(funcprog)}: function evaluator program
  - \texttt{e(rhs)}: contents of \texttt{variables()}
  - \texttt{e(constants)}: identifies constant terms
  - \texttt{e(properties)}: \texttt{b \_V}
  - \texttt{e(predict)}: program used to implement \texttt{predict}
In addition to the above, the following is stored in \( r() \):

Matrices

- \( r(table) \) : matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in \( r() \) are updated when the command is replayed and will be replaced when any \( r \)-class command is run after the estimation command.

### Methods and formulas

Write the system of equations for the \( i \)th observation as

\[
y_i = f(x_i, \beta) + u_i
\]

where \( y_i \) and \( u_i \) are \( 1 \times M \) vectors, for \( i = 1, \ldots, N \); \( f \) is a function that returns a \( 1 \times M \) vector; \( x_i \) represents all the exogenous variables in the system; and \( \beta \) is a \( 1 \times k \) vector of parameters. The generalized nonlinear least-squares system estimator is defined as

\[
\hat{\beta} \equiv \arg\min_{\beta} \sum_{i=1}^{N} \{y_i - f(x_i, \beta)\} \Sigma^{-1} \{y_i - f(x_i, \beta)\}'
\]

where \( \Sigma = E(u'_i u_i) \) is an \( M \times M \) positive-definite weight matrix. Let \( T \) be the Cholesky decomposition of \( \Sigma^{-1} \); that is, \( TT' = \Sigma^{-1} \). Postmultiply (1) by \( T \):

\[
y_i T = f(x_i, \beta) T + u_i T
\]

Because \( E(T' u'_i u_i T) = I \), we can “stack” the columns of (2) and write

\[
\begin{align*}
y_1 T_1 &= f(x_1, \beta) T_1 + \tilde{u}_{11} \\
y_1 T_2 &= f(x_1, \beta) T_2 + \tilde{u}_{12} \\
&\vdots \\
y_1 T_M &= f(x_1, \beta) T_M + \tilde{u}_{1M} \\
y_N T_1 &= f(x_N, \beta) T_1 + \tilde{u}_{N1} \\
y_N T_2 &= f(x_N, \beta) T_2 + \tilde{u}_{N2} \\
&\vdots \\
y_N T_M &= f(x_N, \beta) T_M + \tilde{u}_{NM}
\end{align*}
\]
where \( T_j \) denotes the \( j \)th column of \( T \). By construction, all \( \tilde{u}_{ij} \) are independently distributed with unit variance. As a result, by transforming the model in (1) to that shown in (3), we have reduced the multivariate generalized nonlinear least-squares system estimator to a univariate nonlinear least-squares problem; and the same parameter estimation technique used by \texttt{n1} can be used here. See [R] \texttt{nl} for the details. Moreover, because the \( \tilde{u}_{ij} \) all have variance 1, the final scaled RSS reported by \texttt{nlsur} is equal to \( NM \).

To make the estimator feasible, we require an estimate \( \hat{\Sigma} \) of \( \Sigma \). \texttt{nlsur} first sets \( \hat{\Sigma} = I \). Although not efficient, the resulting estimate, \( \hat{\beta}_{\text{NLS}} \), is consistent. If the \texttt{nls} option is specified, estimation is complete. Otherwise, the residuals

\[
\hat{u}_i = y_i - f(x_i, \hat{\beta}_{\text{NLS}})
\]

are calculated and used to compute

\[
\hat{\Sigma} = \frac{1}{N} \sum_{i=1}^{N} \hat{u}_i' \hat{u}_i
\]

With \( \hat{\Sigma} \) in hand, a new estimate \( \hat{\beta} \) is then obtained.

If the \texttt{ifgnls} option is specified, the new \( \hat{\beta} \) is used to recompute the residuals and obtain a new estimate of \( \hat{\Sigma} \), from which \( \hat{\beta} \) can then be reestimated. Iterations stop when the relative change in \( \hat{\beta} \) is less than \texttt{eps()}\), the relative change in \( \hat{\Sigma} \) is less than \texttt{ifgnleps()}\), or if \texttt{ifgnlsiterate()} iterations have been performed.

If the \texttt{vce(robust)} and \texttt{vce(cluster clustvar)} options were not specified, then

\[
V(\hat{\beta}) = \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1}
\]

where the \( M \times k \) matrix \( X_i \) has typical element \( X_{ist} \), the derivative of the \( s \)th element of \( f \) with respect to the \( t \)th element of \( \beta \), evaluated at \( x_i \) and \( \hat{\beta} \). As a practical matter, once the model is written in the form of (3), the variance–covariance matrix can be calculated via a Gauss–Newton regression; see Davidson and MacKinnon (1993, chap. 6).

If \texttt{robust} is specified, then

\[
V_R(\hat{\beta}) = \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1} \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} \hat{u}_i \hat{u}_i' \hat{\Sigma}^{-1} X_i \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1}
\]

The cluster–robust variance matrix is

\[
V_C(\hat{\beta}) = \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1} \sum_{c=1}^{NC} w_c w_c' \left( \sum_{i=1}^{N} X_i' \hat{\Sigma}^{-1} X_i \right)^{-1}
\]
where $N_C$ is the number of clusters and

$$w_c = \sum_{j \in C_k} X_j' \hat{\Sigma}^{-1} u_j'$$

with $C_k$ denoting the set of observations in the $k$th cluster. In evaluating these formulas, we use the value of $\hat{\Sigma}$ used in calculating the final estimate of $\hat{\beta}$. That is, we do not recalculate $\hat{\Sigma}$ after we obtain the final value of $\hat{\beta}$.

The RSS for the $j$th equation, $RSS_j$, is

$$RSS_j = \sum_{i=1}^{N} (\hat{y}_{ij} - y_{ij})^2$$

where $\hat{y}_{ij}$ is the predicted value of the $i$th observation on the $j$th dependent variable; the total sum of squares (TSS) for the $j$th equation, $TSS_j$, is

$$TSS_j = \sum_{i=1}^{N} (y_{ij} - \bar{y}_j)^2$$

if there is a constant term in the $j$th equation, where $\bar{y}_j$ is the sample mean of the $j$th dependent variable, and

$$TSS_j = \sum_{i=1}^{N} y_{ij}^2$$

if there is no constant term in the $j$th equation; and the model sum of squares (MSS) for the $j$th equation, $MSS_j$, is $TSS_j - RSS_j$.

The $R^2$ for the $j$th equation is $MSS_j / TSS_j$. If an equation does not have a constant term, then the reported $R^2$ for that equation is “uncentered” and based on the latter definition of $TSS_j$.

Under the assumption that the $u_i$ are independent and identically distributed $N(0, \hat{\Sigma})$, the log likelihood for the model is

$$\ln L = -\frac{MN}{2} \left\{1 + \ln(2\pi)\right\} - \frac{N}{2} \ln |\hat{\Sigma}|$$

The log likelihood is reported only when the `ifgnlse` option is specified.

*You must specify the `variables()` option with `nlsur`.*
predict

Description for predict

predict creates a new variable containing predictions such as fitted values and residuals.

Menu for predict

Statistics  >  Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, equation(#eqno) yhat residuals]
```

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

- **equation(#eqno)** specifies to which equation you are referring. equation(#1) would mean that the calculation is to be made for the first equation, equation(#2) would mean the second, and so on.
- If you do not specify equation(), results are the same as if you had specified equation(#1).
- **yhat**, the default, calculates the fitted values for the specified equation.
- **residuals** calculates the residuals for the specified equation.
margins

Description for margins

margins estimates margins of response for fitted values.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [options]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>yhat</td>
<td>fitted values; the default</td>
</tr>
<tr>
<td>residuals</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

Remarks and examples

Example 1

In example 2 of [R] nlsur, we fit a four-factor translog cost function to data for the U.S. economy. The own-price elasticity for a factor measures the percentage change in its usage as a result of a 1% increase in the factor’s price, assuming that output is held constant. For the translog production function, the own-price factor elasticities are

$$\eta_i = \frac{\delta_{ii} + s_i (s_i - 1)}{s_i}$$

Here we compute the elasticity for capital at the sample mean of capital’s factor share. First, we use summarize to get the mean of s_k and store that value in a scalar:

```
. use https://www.stata-press.com/data/r18/mfgcost
   (Manufacturing cost)
. nlsur (s_k = {bk} + {dkk}*ln(pk/pm) + {dkl}*ln(pl/pm) + {dke}*ln(pe/pm))
   > (s_l = {bl} + {dkl}*ln(pk/pm) + {dll}*ln(pl/pm) + {dle}*ln(pe/pm))
   > (s_e = {be} + {dke}*ln(pk/pm) + {dle}*ln(pl/pm) + {dee}*ln(pe/pm)),
   > ifgnls
   (output omitted)
. summarize s_k
      Variable |     Obs  Mean   Std. dev.    Min    Max
-------------|---------|---------|-----------------|--------|--------|
          s_k |    25  .053488  .0044795    .04602  .06185
. scalar kmean = r(mean)
```
Now, we can use `nlcom` to calculate the elasticity:

```
   . nlcom ([dkk]_cons + kmean*(kmean-1)) / kmean
   _nl_1: ([dkk]_cons + kmean*(kmean-1)) / kmean
```

|         | Coefficient | Std. err. | z    | P>|z| | [95% conf. interval] |
|---------|-------------|-----------|------|-----|----------------------|
| _nl_1   | -0.3952986  | 0.1083535 | -3.65| 0.000| -0.6076676 - 0.1829295 |

If the price of capital increases by 1%, its usage will decrease by about 0.4%. To maintain its current level of output, a firm would increase its usage of other inputs to compensate for the lower capital usage. The standard error reported by `nlcom` reflects the sampling variance of the estimated parameter \( \hat{\delta}_{kk} \), but `nlcom` treats the sample mean of \( s_k \) as a fixed parameter that does not contribute to the sampling variance of the estimated elasticity.

[R] `nlsur` — Estimation of nonlinear systems of equations

[U] 20 Estimation and postestimation commands
Description

Nonparametric regression models the mean of an outcome given the covariates without making assumptions about its functional form. This makes nonparametric regression estimates robust to functional form misspecification. `npregress` implements the two most common nonparametric regression estimators: series regression and kernel regression.

Nonparametric series estimation regresses the outcome on a function of the covariates. The function of the covariates is known as a basis function. A basis is a collection of terms that approximates smooth functions arbitrarily well. A basis function includes a subset of these terms. The bases used by `npregress series` are polynomials, piecewise polynomial splines, and B-splines.

Nonparametric kernel estimation computes a weighted average of the outcome. The weights are functions called kernels, which give rise to the name of the method. `npregress kernel` performs local–linear and local–constant kernel regression.

Whether we choose to approximate the mean of our outcome using series regression or kernel regression, we obtain estimates that are robust to assumptions about functional form. This robustness comes at a cost; we need many observations and perhaps a long computation time to estimate the elements of the approximating function.

This entry introduces the intuition behind the nonparametric regression estimators implemented in `npregress`. If you are familiar with these methods, you may want to skip to [R] `npregress kernel` or [R] `npregress series`.

Remarks and examples

Remarks are presented under the following headings:

Overview
Nonparametric series regression
  Runge’s phenomenon
  Piecewise polynomial splines and B-splines
Nonparametric kernel regression
  Limitations of nonparametric methods

Overview

Nonparametric regression is used when we are uncertain about the functional form of the mean of the outcome given the covariates. For example, when we estimate a linear regression, we assume that the functional form for the mean of the outcome is a linear combination of the specified covariates. Both parametric (linear) regression and nonparametric regression provide an estimate of the mean for the different values of the covariates. Consider the simulated data in figure 1. The mean of the outcome for all values of \( x \) is overlaid on these points.
Because the mean of the data in figure 1 is not linear in $x$, using a simple linear regression will not give us a correct picture about the effect of covariate $x$ on the outcome. For example, if we perform a linear regression of the outcome on $x$ for the data, we obtain the plot shown in figure 2.

The change in the predicted outcome when $x$ changes is positive and constant, yet the true mean is nonlinear. If the assumption about the functional form of the mean is incorrect, the estimates we obtain are inconsistent. If we instead fit the model using `npregress` and graph the estimates, we obtain figure 3.
npregress gives us the correct relationship between the outcome and the covariates. The nonparametric regression estimates are consistent as long as the true function is sufficiently smooth. If the linear regression assumptions are true, nonparametric regression is still consistent but less efficient.

Although nonparametric regression is a way to obtain estimates that are robust to functional form misspecification, this robustness comes at a cost. You need many observations and more time to compute the estimates. The cost increases with the number of covariates; this is referred to as the curse of dimensionality.

**Nonparametric series regression**

The basis and the basis function are concepts essential to understanding series regression. A basis is a collection of terms that can approximate a smooth function arbitrarily well. A basis function uses a subset of these terms to approximate the mean function. `npregress series` allows you to use a polynomial basis, a piecewise polynomial spline basis, or a B-spline basis. For each basis, `npregress series` selects the basis function for you.

We use an example to illustrate the use of a basis and a basis function. Suppose a researcher has data on the outcome $y$ and a covariate $x$. We plot their relationship in the figure 4 below.
In this case, a regression of $y$ on $x$ will do a good job of approximating the true function. If our data looked like the data in figure 5, however, a regression of $y$ on $x$ would be inadequate.

In each case, we include terms from a polynomial basis. In the first case, we need a constant and the linear term $x$. In the second case, we need a constant, the linear term $x$, and the quadratic term $x^2$. A more complex function would require a basis function that includes more terms from the polynomial basis.

If we want to use a polynomial basis function, \texttt{npregress} will select a degree of the polynomial for us. Additional terms reduce bias but increase the variance of the estimator. \texttt{npregress} will select the terms that optimally tradeoff bias and variance. In other words, \texttt{npregress} selects a basis function that includes the terms that minimize the mean squared error. Our example above used a polynomial basis function, but \texttt{npregress} can also select terms from a piecewise polynomial spline or B-spline basis.
Runge’s phenomenon

Polynomials are the most intuitive basis but not the preferred basis for nonparametric series estimation. The reason is that they are poor at interpolating. This problem shows up at the boundaries of the support of the covariates, where, as you increase the order of the polynomial, the polynomial approximation oscillates frequently, even when the true function does not behave this way.

Let us demonstrate. Below is an example for which we model a mean function using a third-order polynomial. We plot the data and the estimate of the mean function:

![Figure 6.](image)

Looking at the data, it appears that a higher-order polynomial would be a better fit for the data. Below is the mean function we get using a sixth-order and a tenth-order polynomial:

![Figure 7.](image)

The predictions improve at values near the middle of the range of $x$ but become more variable at the edges of the parameter space.

What we illustrated above is referred to as Runge’s phenomenon. Increasing the complexity of the polynomial order did not improve our approximation. In fact, as we increased the polynomial order, the behavior at the edges of the parameter space became more variable. The way to address this is to use a basis that does a better job of interpolating: piecewise polynomial splines or B-splines.
Piecewise polynomial splines and B-splines

Piecewise polynomial splines and B-splines are preferred to a polynomial basis because they are better at approximation. We discuss piecewise polynomial splines to provide intuition for both the piecewise polynomial spline basis and the B-spline basis.

Low-order polynomials do a great job of approximating functions in regions where the true function does not change too much. Splines continuously connect a set of low-order polynomials to create a basis to approximate a smooth function. The graph below illustrates what this definition means. We show in maroon a piecewise polynomial spline estimate of the mean function for the data in the example above.

![Graph Illustrating Piecewise Polynomial Spline Estimation](image)

Figure 8.

To see that splines are better than polynomials, note that the spline approximation of the mean function fits the data well and that there are no regions where the approximation wiggles wildly.

Now, we delve into the definition above. The vertical lines in the graph partition the support of $x$ into subregions. The piecewise polynomial spline basis allows for a different low-order polynomial in each subregion, and it forces the polynomials in neighboring regions to be continuously connected. In figure 8 above, the basis used is a third-order polynomial in each subregion. The graph illustrates that the polynomials are smoothly connected at the subregion boundaries. The subregion boundaries are known as the knot points, or just the knots, because they are where the different polynomials are tied together.

By default, npregress selects the number of knots for you. Alternatively, you may specify the number of knots yourself.

We now look at how the mean function at each region was computed. We show this mathematically and graphically.

Defining the seven knots as $t_1, \ldots, t_7$, where $t_1 < t_2 < \cdots < t_6 < t_7$, the third-order piecewise polynomial spline estimate is given by

$$\hat{E}(y_i|x_i) = \hat{\beta}_0 + \hat{\beta}_1 x_i + \hat{\beta}_2 x_i^2 + \hat{\beta}_3 x_i^3 + \sum_{j=1}^{7} \beta_{j+3} \max(x_i - t_j, 0)^3$$
Thus, for all \( x_i \) that are less than the smallest knot, \( t_1 \), the mean estimate is given by the third-order polynomial
\[
\hat{E}(y_i|x_i \leq t_1) = \hat{\beta}_0 + \hat{\beta}_1 x_i + \hat{\beta}_2 x_i^2 + \hat{\beta}_3 x_i^3
\]
Here it is graphically:

Likewise, if \( x \) is less than the second knot, \( t_2 \), then the mean estimate for that region is different if \( x_i > t_1 \) than if \( x_i \leq t_1 \), and is given by
\[
\hat{E}(y_i|x_i \leq t_2) = \hat{\beta}_0 + \hat{\beta}_1 x_i + \hat{\beta}_2 x_i^2 + \hat{\beta}_3 x_i^3 + \beta_4 (x_i - t_1)^3 \quad (x_i > t_1)
\]
Here it is graphically:
As \( x \) increases, there are additional contributions from each subregion. If we continue plotting the resulting mean estimates, the following graphs would be what we would obtain:

![Graphs illustrating nonparametric regression](image)

Figure 11.

This example illustrates how the terms in the spline basis approximate the mean function. Both the graph of the estimated function and the intuition in the example illustrate why the spline basis is better than the polynomial basis.

In the examples above, we used a piecewise polynomial spline basis. Specifically, we used a third-order piecewise polynomial spline basis function to obtain our estimates of the conditional mean. We could have also used second-order or first-order piecewise polynomial splines, where the order of the splines is defined by the order of the polynomial terms in the covariates used in each subregion.

As mentioned before, piecewise polynomial splines are preferred to a polynomial basis because they are better at approximation. However, piecewise polynomial splines also have some issues. In particular, they can be highly collinear and therefore numerically unstable. You can see this in the regions delineated in figure 11, which are defined by terms of the form \( \max(x_i - t_j, 0) \) that may overlap.

B-splines avoid this problem, so each term that goes into the conditional mean approximation is orthogonal. It is for this reason that B-splines are the default basis for `npregress series`. However, the intuition we obtain from piecewise polynomial splines and B-splines is equivalent. In fact, B-spline and piecewise polynomial spline bases can approximate the same functions. For a more detailed explanation of B-splines, see *Methods and formulas* in [R] `npregress series`.

In this section, we provided an intuitive and brief introduction to nonparametric series estimation. For detailed introductions to series estimators and the methods implemented by `npregress series`, see de Boor (2001), Schumaker (2007), Eubank (1999), Schoenberg (1969), Newey (1997), and Chen (2007).
Nonparametric kernel regression

`npregress kernel` approximates the mean by using a kernel function. In `Overview`, we plotted the following data and nonparametric estimate of the mean function:

![Data and nonparametric estimate](image)

We used kernel regression to estimate this mean function. With this method, we estimate the mean of the outcome at different values of the covariate $x$. In this section, we build our intuition for how kernel regression estimates these means, and we demonstrate this graphically.

Suppose covariate $x$ is discrete. In this case, a consistent estimator of the mean of outcome $y$ given that $x = a$ is the average of the values of $y$ for which $x$ is equal to a given value $a$. For instance, the sample average of the yearly income for married individuals is a consistent estimator for the population mean yearly income for married individuals.

Now, consider estimating the mean of $y$ given that $x = a$ when $x$ is continuous and $a$ is a value observed for $x$. Because $x$ is continuous, the probability of any observed value being exactly equal to $a$ is 0. Therefore, we cannot compute an average for the values of $y$ for which $x$ is equal to a given value $a$. We use the average of $y$ for the observations in which $x$ is close to $a$ to estimate the mean of $y$ given that $x = a$. Specifically, we use the observations for which $|x - a| < h$, where $h$ is small. The parameter $h$ is called a bandwidth. In nonparametric kernel regression, a bandwidth determines the amount of information we use to estimate the conditional mean at each point $a$. We demonstrate how this works graphically.
For the simulated data in our example, we choose $h = 0.25$ and $a = -0.19$. The vertical lines in figure 13 delimit the values of $x$ around $a$ for which we are computing the mean of $y$. The light blue square is our estimate of the conditional mean using the observations between the vertical lines.

Repeating this estimation when $a = 2.66$ produces figure 14.
Doing this estimation for each point in our data produces a nonparametric estimate of the mean for a given value of the covariates (see figure 15).

![Nonparametric mean function estimate and data](image1)

Figure 15.

The plotted blue squares in figure 15 form what is known as the conditional mean function. Because these are simulated data, we can compare our estimate with the true conditional mean function, a comparison we show in figure 16.

![Nonparametric mean function estimate and true mean](image2)

Figure 16.

We see that the estimate is a bit less smooth than the true function. The size of the bandwidth $h$ determines the shape and smoothness of the estimated conditional mean function, because the bandwidth defines how many observations around each point are used. For example, if $h$ is arbitrarily large—say, $h = 300$—then we get figure 17.
In this case, all observations are used to estimate the conditional mean at each point, and the estimate is therefore a constant. On the other hand, a too-small bandwidth produces a jagged function with high variability, as illustrated in figure 18.

The optimal bandwidth is somewhere in between. A too-large bandwidth includes too many observations, so the estimate is biased but it has a low variance. A too-small bandwidth includes too few observations, so the estimate has little bias but the variance is large. In other words, the optimal bandwidth trades off bias and variance. In the case of \texttt{npregress kernel}, the bandwidth is chosen to minimize the cost of this tradeoff by using either cross-validation, as suggested by Li and Racine (2004), or an improved Akaike information criterion proposed by Hurvich, Simonoff, and Tsai (1998).

How we average the observations around a point is also important. In the examples above, we gave the same weight to each observation for which $|x - a| < h$. However, we might weight each observation differently. The weights that observations receive are determined by functions called kernels. We could have used any of the weights in \texttt{R kdensity}. For a nice introduction to kernel weighting, see Silverman (1986).
The estimator described above uses only nearby observations and is thus a local estimator. It uses a sample average, which is a regression on a constant, and is thus a locally constant estimator. For these reasons, the estimator described above fits what is known as a local-constant regression.

The generalization that uses the prediction from a local-linear regression on covariates is known as local-linear regression. Local-linear regression estimates the derivative of the conditional mean function in addition to the function itself. Understanding how the conditional mean changes when covariates change is sometimes the research question of interest, for example, how income changes for different levels of taxes. Local-linear regression provides an estimate for these changes for continuous and discrete variables.

See Fan and Gijbels (1996) and Li and Racine (2007) for detailed introductions to the kernel estimators implemented in `npregress kernel`.

**Limitations of nonparametric methods**

As discussed above, series regression and kernel regression approximate an unknown mean function. Series regression uses least squares on the basis function. Kernel regression uses a kernel-weighted average of nearby observations.

Series estimators are considered to be global estimators because they approximate the mean function at each point using the value of one overall approximating function. Kernel regression is considered a local estimator because it only uses nearby observations to approximate the mean for a given covariate pattern.

Although piecewise polynomial splines and B-splines are considered to be global estimators, in fact, they are local estimators. They are local because they fit a polynomial in each region defined by the knots. Like kernel estimators, piecewise polynomial spline and B-spline estimators require that there are enough data in each region. Suppose our data look like the data below.
Using a method to select knots optimally at percentiles of the data will give us figure 20.

![Figure 20](image)

The vertical line denotes the point at which the knot is placed. The blue line is the B-spline estimate, and the dotted green line is the true mean function. We see that our estimate of the mean function is not good, especially for higher positive values of the covariate. The reason is that data are sparse for these values. An alternative is to place the knots uniformly over the values of \( x \). In this case, our estimate of the mean function improves. However, this does not change the fact that we have regions with insufficient data to make reliable inferences.

Thus, for kernel, piecewise polynomial spline, and B-spline estimators, we must have enough data points for all ranges of the data. In particular, piecewise polynomial spline and B-spline estimates should not be used to predict outside the support of the data.

Another important consideration is model selection. \texttt{npregress} selects the number of terms from a basis for series estimation and the bandwidth for kernel estimation. After model selection, the models are taken as given without accounting for model-selection error. You can find an in-depth discussion and references of some of the issues that arise when performing model selection in \texttt{LASSO Lasso intro}.

[R] `regress` — Linear regression
npregress kernel performs nonparametric local–linear and local–constant kernel regression. Like linear regression, nonparametric regression models the mean of the outcome conditional on the covariates, but unlike linear regression, it makes no assumptions about the functional form of the relationship between the outcome and the covariates. npregress kernel may be used to model the mean of a continuous, count, or binary outcome.

Quick start

Nonparametric regression of \( y \) on \( x \) and discrete covariate \( a \) using the Epanechnikov kernel for \( x \) and the Li–Racine kernel for \( a \)

\[
\text{npregress kernel } y \ x \ i.a
\]

Same as above, but use 500 replications and compute bootstrap standard errors and percentile confidence intervals

\[
\text{npregress kernel } y \ x \ i.a, \ reps(500)
\]

Same as above, but use a Gaussian kernel for \( x \)

\[
\text{npregress kernel } y \ x \ i.a, \ reps(500) \ kernel(gaussian)
\]

Same as above, but use the improved AIC to find the optimal bandwidth

\[
\text{npregress kernel } y \ x \ i.a, \ reps(500) \ kernel(gaussian) \ imaic
\]

Same as above, but additionally specify that only the mean of the outcome be computed

\[
\text{npregress kernel } y \ x \ i.a, \ reps(500) \ kernel(gaussian) \ imaic \ noderivatives
\]

Specify \( h \) as the vector of bandwidths

\[
\text{npregress kernel } y \ x \ i.a, \ bwidth(h)
\]

Menu

Statistics  >  Nonparametric analysis  >  Nonparametric kernel regression
Syntax

```
npregress kernel  depvar  indepvars    [if]    [in]    [ , options ]
```

**options**  Description

**Model**

- `estimator(linear | constant)` use the local-linear or local-constant kernel estimator
- `kernel(kernel)` kernel density function for continuous covariates
- `dkernel(dkernel)` kernel density function for discrete covariates
- `predict(prspec)` store predicted values of the mean and derivatives using variable names specified in `prspec`
- `noderivatives` suppress derivative computation
- `imaic` use improved AIC instead of cross-validation to compute optimal bandwidth
- `unidentsample(newvar)` specify name of variable that marks identification problems

**Bandwidth**

- `bwidth(specs)` specify kernel bandwidth for all predictions
- `meanbwidth(specs)` specify kernel bandwidth for the mean
- `derivbwidth(specs)` specify kernel bandwidth for the derivatives

**SE**

- `vce(vcetype)` `vcetype` may be `none` or `bootstrap`
- `reps(#)` equivalent to `vce(bootstrap, reps(#))`
- `seed(#)` set random-number seed to #; must also specify `reps(#)`
- `bwreplace` vary bandwidth with each bootstrap replication; seldom used

**Reporting**

- `level(#)` set confidence level; default is `level(95)`
- `display_options` control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
- `citype(citype)` method to compute bootstrap confidence intervals; default is `citype(percentile)`

**Maximization**

- `maximize_options` control the maximization process
- `coeflegend` display legend instead of statistics

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.

`bootstrap`, `by`, `collect`, and `jackknife` are allowed; see [U] 11.1.10 Prefix commands.

`vce(bootstrap)` reports percentile confidence intervals instead of the normal-based confidence intervals reported when `vce(bootstrap)` is specified with other estimation commands.

`coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

### Options

**Model**

- **estimator(linear | constant)** specifies whether the local-constant or local-linear kernel estimator should be used. The default is **estimator(linear)**.

- **kernel(kernel)** specifies the kernel density function for continuous covariates for use in calculating the local-constant or local-linear estimator. The default is **kernel(epanechikhov)**.

- **dkernel(dkernel)** specifies the kernel density function for discrete covariates for use in calculating the local-constant or local-linear estimator. The default is **dkernel(lracine)**; see *Methods and formulas* for details on the Li–Racine kernel. When **dkernel(cellmean)** is specified, discrete covariates are weighted by their cell means.

- **predict(prspec)** specifies that npregress kernel store the predicted values for the mean and derivatives of the mean with the specified names. **prspec** is the following:

  ```
  predict(varlist | stub* [, replace noderivatives])
  ```

  The option takes a variable list or a **stub**. The first variable name corresponds to the predicted outcome mean. The second name corresponds to the derivatives of the mean. There is one derivative for each **indepvar**.

  When **replace** is used, variables with the names in **varlist** or **stub** are replaced by those in the new computation. If **noderivatives** is specified, only a variable for the mean is created. This will increase computation speed but will add to the computation burden if you want to obtain marginal effects after estimation.

  **noderivatives** suppresses the computation of the derivatives. In this case, only the mean function is computed.
imaic specifies to use the improved AIC instead of cross-validation to compute optimal bandwidths. unidentsample(newvar) specifies the name of a variable that is 1 if the observation violates the model identification assumptions and is 0 otherwise. By default, this variable is a system variable (_unident_sample).

_npregress kernel_ computes a weighted regression for each observation in our data. An observation violates identification assumptions if the regression cannot be performed at that point. The regression formula, which is discussed in detail in _Methods and formulas_, is given by

\[ \hat{\gamma} = (Z'WZ)^{-1} Z'Wy \]

_npregress kernel_ verifies that the matrix \((Z'WZ)\) is full rank for each observation to determine identification. Identification problems commonly arise when the bandwidth is too small, resulting in too few observations within a bandwidth. Independent variables that are collinear within the bandwidth can also cause a problem with identification at that point.

Observations that violate identification assumptions are reported as missing for the predicted means and derivatives.

<table>
<thead>
<tr>
<th>Bandwidth</th>
</tr>
</thead>
</table>

bwidth(specs) specifies the half-width of the kernel at each point for the computation of the mean and the derivatives of the mean function. If no bandwidth is specified, one is chosen by minimizing the integrated mean squared error of the prediction.

specs specifies bandwidths for the mean and derivative for each _indepvar_ in one of three ways: by specifying the name of a vector containing the bandwidths (for example, bwidth(H), where H is a properly labeled vector); by specifying the equation and coefficient names with the corresponding values (for example, bwidth(Mean:x1=0.5 Effect:x1=0.9)); or by specifying a list of values for the means, standard errors, and derivatives for _indepvars_ given in the order of the corresponding _indepvars_ and specifying the copy suboption (for example, bwidth(0.5 0.9, copy)).

skip specifies that any parameters found in the specified vector that are not also found in the model be ignored. The default action is to issue an error message.

copy specifies that the list of values or the vector be copied into the bandwidth vector by position rather than by name.

meanbwidth(specs) specifies the half-width of the kernel at each point for the computation of the mean function. If no bandwidth is specified, one is chosen by minimizing the integrated mean squared error of the prediction. For details on how to specify the bandwidth, see the description of bwidth(), above.

derivbwidth(specs) specifies the half-width of the kernel at each point for the computation of the derivatives of the mean. If no bandwidth is specified, one is chosen by minimizing the integrated mean squared error of the prediction. For details on how to specify the bandwidth, see the description of bwidth(), above.

<table>
<thead>
<tr>
<th>SE</th>
</tr>
</thead>
</table>

vce(vcetype) specifies the type of standard error reported, which may be either that no standard errors are reported (none; the default) or that bootstrap standard errors are reported (bootstrap); see [R] vce_option.

We recommend that you select the number of replications using reps(#) instead of specifying vce(bootstrap), which defaults to 50 replications. Be aware that the number of replications needed to produce good estimates of the standard errors varies depending on the problem.
When `vce(bootstrap)` is specified, `npregress kernel` reports percentile confidence intervals as recommended by Cattaneo and Jansson (2018) instead of reporting the normal-based confidence intervals that are reported when `vce(bootstrap)` is specified with other commands. Other types of confidence intervals can be obtained by using the `ci_type(ci_type)` option.

`reps(#)` specifies the number of bootstrap replications to be performed. Specifying this option is equivalent to specifying `vce(bootstrap, reps(#))`.

`seed(#)` sets the random-number seed. You must specify `reps(#)` with `seed(#)`.

`bwreplace` computes a different bandwidth for each bootstrap replication. The default is to compute the bandwidth once and keep it fixed for each bootstrap replication. This option is seldom used.

`level(#)`; see [R] Estimation options.

`display_options`: `noci`, `nopvalues`, `nomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)` , `fvwrapon(style)`, `cformat(%)`, `pformat(%)`, `sformat(%)`, and `nolstretch`; see [R] Estimation options.

`ci_type(ci_type)` specifies the type of confidence interval to be computed. By default, bootstrap percentile confidence intervals are reported as recommended by Cattaneo and Jansson (2018). `ci_type` may be one of `percentile`, `bc`, or `normal`.

`maximize_options`: `iterate(#)`, `[no]log`, `trace`, `showstep`, `tolerance(#)`, `ltolerance(#)`, `from(init_specs)`; see [R] Maximize. These options are seldom used.

The following option is available with `npregress kernel` but is not shown in the dialog box: `coeflegend`; see [R] Estimation options.

Remarks and examples

This entry assumes that you are already familiar with nonparametric regression. For an introduction to the nonparametric kernel regression methods used in `npregress kernel`, see [R] `npregress intro`.

Remarks are presented under the following headings:

- Overview
- Estimation and effects
- Visualizing covariate effects

Overview

`npregress kernel` implements local-constant and local-linear regression. The covariates may be continuous or discrete. You can use `npregress kernel` to nonparametrically estimate a conditional mean. `npregress kernel` also allows you to estimate covariate effects after estimation and, in models with one covariate, to plot the mean function by using `npgraph` after estimation.

The word “nonparametric” refers to the fact that the parameter of interest, the mean as a function of the covariates, is given by the unknown function $g(x_i)$, which is an element of an infinite-dimensional space of functions. In contrast, in a parametric model, the mean for a given value of the covariates, $E(y_i|x_i) = f(x_i, \beta)$, is a known function that is fully characterized by the parameter of interest, $\beta$, which is a finite-dimensional real vector (Shao 2003).
The regression model of outcome $y_i$ given the $k$-dimensional vector of covariates $x_i$ is given by

$$y_i = g(x_i) + \varepsilon_i$$  \hspace{1cm} (1)

$$E(\varepsilon_i | x_i) = 0$$  \hspace{1cm} (2)

where $\varepsilon_i$ is the error term. The covariates may include discrete and continuous variables. Equations (1) and (2) imply that

$$E(y_i | x_i) = g(x_i)$$

Once we account for the information in the covariates, the error term provides no information about the mean of our outcome. The conditional mean function is therefore given by $g(x_i)$. By estimating $E(y_i | x_i = x)$ for all points $x$ in our data, we obtain an estimate of $E(y_i | x_i)$.

`npregress kernel`, by default, estimates a local-linear regression. Local-linear regression estimates a regression for a subset of observations for each point in our data. See Fan and Gijbels (1996) for a good reference on local-linear regression. Local-linear regression, for each point $x$, solves the minimization problem given by

$$\min_{\gamma} \sum_{i=1}^{n} \{y_i - \gamma_0 - \gamma_1'(x_i - x)\}^2 K(x_i, x, h)$$  \hspace{1cm} (3)

where $\gamma = (\gamma_0, \gamma_1)'$.

Equation (3) and its solution are similar to parametric ordinary least squares. The slope and the constant in (3), however, have a different interpretation. The constant in (3), $\gamma_0$, is the conditional mean at a specific point $x$. The slope parameter, $\gamma_1$, is the derivative of the mean function with respect to $x$. The solution to this least-squares problem gives us the mean function and its derivative for each one of the elements of $x$. Repeating this optimization for each point $x$ gives us the entire mean function and its derivatives.

Another difference between (3) and the minimization problem of parametric ordinary least squares is how the optimization is weighted. The weights are given by the kernel function $K(x_i, x, h)$. The kernel function assigns weights to observations $x_i$ based on how much they differ from $x$ and based on the bandwidth, $h$. The smaller $h$ is, the larger the weight assigned to points between $x_i$ and $x$.

The bandwidth also determines the bias and variance of the mean function estimator. `npregress kernel` selects the bandwidth using cross-validation, as suggested by Li and Racine (2004), or if the `imaic` option is specified, with the improved AIC proposed by Hurvich, Simonoff, and Tsai (1998). Both methods minimize the tradeoff between bias and variance.

`npregress kernel` computes a conditional mean for each observation in the data and, for each one of these computations, verifies whether identification conditions are fulfilled. The observations for which the regression identification assumptions are not satisfied are dropped from the estimation sample. Additionally, whenever there is a violation of the identification assumption, `npregress kernel` generates a system variable or a variable with a name provided in `noidsample(newvar)`. This variable is 1 for observations violating the identification assumption and is 0 otherwise. `npregress kernel` also issues a warning, letting you know the number of observations for which the identification assumption is not satisfied.
Estimation and effects

The output of \texttt{npregress kernel} reports averages of the mean function and the effects of the mean function. An average effect from nonparametric regression may be either 1) an average marginal effect, in the case of the mean of derivatives for continuous covariates or 2) the mean of contrasts for discrete covariates.

Some well-established literature estimates these average effects directly and uses an optimal bandwidth for this computation; see Powell, Stock, and Stoker (1989) and Powell and Stoker (1996). By taking averages of the local-linear estimates, \texttt{npregress kernel} is more in line with the approach in Li, Lu, and Ullah (2003). Intuitively, choosing the optimal bandwidth for the derivative produces a more efficient estimator than using the bandwidth that is optimal for the function. Both estimators are consistent for the average effect. Cattaneo and Jansson (2018) formally justify the average effect using the function-optimal bandwidth.

\texttt{npregress kernel} also reports an approximation of $n|h|$ as the expected kernel observations. This statistic rounds the product of the continuous kernel bandwidth values and the number of observations used for estimation. For instance, if the estimation sample was 500 and the bandwidth was 0.246, the expected kernel observations would be 123 ($= 500 \times 0.246$). The expected kernel observation number of 123 tells us that, on average, 123 observations are used to compute each one of the 500 regressions performed by \texttt{npregress kernel}.

Example 1: Nonparametric regression estimation and graphing

\texttt{dui.dta} contains information about the number of monthly drunk driving citations in a local jurisdiction (\texttt{citations}). Suppose we want to know the effect of increasing fines on the number of citations. Because \texttt{citations} is a count variable, we could consider fitting the model with \texttt{poisson} or \texttt{nbreg}. However, both of these estimators make assumptions about the distribution of the data. If these assumptions are not true, we will obtain inconsistent estimates.

By using \texttt{npregress kernel}, we do not have to make any assumptions about how \texttt{citations} is distributed. We use \texttt{npregress kernel} to estimate the mean of \texttt{citations} as a function of the value of the fines imposed for drunk driving (\texttt{fines}).

Note: Effect estimates are averages of derivatives.
Note: You may compute standard errors using vce(bootstrap) or reps().

The first table displays the bandwidths used to estimate the mean function and the derivative of the mean function. Each of these bandwidths is estimated by minimizing a function that trades off bias and variance; the corresponding iteration logs are displayed also. The expected number of observations used to estimate the mean function at each point is reported in E(Kernel obs) as 282.

Unlike other estimation commands, npregress kernel does not report standard errors, test statistics, and confidence intervals by default. In example 2, we demonstrate how to obtain these statistics and further discuss the output.

Example 2: Bootstrapping standard errors

We can estimate the standard errors by using the bootstrap; see Cattaneo and Jansson (2018) for formal results. We use the reps(400) option, which is equivalent to vce(bootstrap, reps(400)) and specifies that 400 bootstrap replications be used instead of the default 50 replications that are used when we specify vce(bootstrap).
Each estimation problem requires a different number of replications to produce good estimates of the standard errors. In example 3, we explain how we decided to use 400 replications. Note that nonparametric estimation and the bootstrap are computationally intensive, so running this example and others that compute bootstrap standard errors will take a while.

```
. npregress kernel citations fines, reps(400) seed(12)
              (running npregress on estimation sample)
Bootstrap replications (400): ..........10.........20.........30.........40.....
                       > ......50.........60.........70.........80.........90.........100.....
                       > ......120.........130.........140.........150.........160.........170.....
                       > ......180.........190.........200.........210.........220.........230.....
                       > ......240.........250.........260.........270.........280.........290.....
                       > ......300.........310.........320.........330.........340.........350.....
                       > ......360.........370.........380.........390.........400 done
```

Note: Effect estimates are averages of derivatives.

The coefficient table now reports the average of the predicted means and the average of the predicted derivatives of the mean function with bootstrap standard errors. The average of the observation-level predicted (citations) is 22.34. The average of the observation-level marginal effects is $-7.69$, which indicates that increasing fines reduces the mean number of citations.
We use `npgraph` to graph the estimated conditional mean function.

```
.npgraph
```

![Graph showing the negative association between fines and the number of drunk driving citations.](image)

The graph shows the negative association between fines and the number of drunk driving citations.

`npregress kernel` generates system variables for the mean function and the derivative of the mean function. To see the variables that `npregress kernel` generated for example 1, we type

```
.describe *_, fullnames
```

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Storage type</th>
<th>Display format</th>
<th>Value label</th>
<th>Variable label</th>
</tr>
</thead>
<tbody>
<tr>
<td>_Mean_citations</td>
<td>double</td>

<td>Mean function</td>
<td></td>
</tr>
<tr>
<td>_d_Mean_citations_dfines</td>
<td>double</td>
<td>%10.0g</td>
<td>derivative of mean function w.r.t fines</td>
<td></td>
</tr>
</tbody>
</table>

To specify a name for each system variable, we can use the `predict()` option.

```
.npregress kernel citations fines, predict(mean deriv)
```

```
(output omitted)
```

```
.describe mean deriv
```

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Storage type</th>
<th>Display format</th>
<th>Value label</th>
<th>Variable label</th>
</tr>
</thead>
<tbody>
<tr>
<td>mean</td>
<td>double</td>
<td>%10.0g</td>
<td>Mean function</td>
<td></td>
</tr>
<tr>
<td>deriv</td>
<td>double</td>
<td>%10.0g</td>
<td>derivative of mean function w.r.t fines</td>
<td></td>
</tr>
</tbody>
</table>

Alternatively, we can use the same `stub` for all the variable names by typing `predict(hatvar*)`, which would generate variables `hatvar1` and `hatvar2`.

You may add `noderivatives` to the option, as in `predict(hatvar*, noderivatives)`, to specify that no derivatives be generated. You save memory when you use `noderivatives`, but you add to the computational burden. As you will see below, an important feature of `npregress kernel` is the availability of the `margins` command after estimation. `margins` must compute the derivatives and their optimal bandwidth.
Example 3: Selecting the number of bootstrap replications

We start by fitting the model using 200 bootstrap replications. We want to find the number of replications for which the confidence intervals do not change much.

```
. npregress kernel citations fines, reps(200) seed(12)
(running npregress on estimation sample)
Bootstrap replications (200): .........10.........20.........30.........40.........
> .....50.........60.........70.........80.........90.........100.........110.........
> .....120.........130.........140.........150.........160.........170.........
> .....180.........190.........200 done
Bandwidth

<table>
<thead>
<tr>
<th>Mean</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.5631079</td>
<td>0.924924</td>
</tr>
</tbody>
</table>

Local-linear regression
Kernel : epanechnikov
Bandwidth: cross-validation

| citations | Observed estimate | Bootstrap std. err. | Bootstrap z | P>|z| | Percentile [95% conf. interval] |
|-----------|------------------|--------------------|-------------|--------|-----------------------------|
| Mean citations | 22.33999 | 0.4769389 | 46.84 | 0.000 | 21.49744 | 23.42156 |
| Effect fines | -7.692388 | 0.5088819 | -15.12 | 0.000 | -8.742081 | -6.77816 |

Note: Effect estimates are averages of derivatives.

For 200 replications, the confidence interval for the mean ranges from 21.50 to 23.42. For the effect of fines, this range is $-8.74$ to $-6.78$.

We repeat the estimation using 300 replications and the same seed as in the previous case.

```
. npregress kernel citations fines, reps(300) seed(12)
(running npregress on estimation sample)
Bootstrap replications (300): .........10.........20.........30.........40.........
> .....50.........60.........70.........80.........90.........100.........110.........
> .....120.........130.........140.........150.........160.........170.........
> .....180.........190.........200.........210.........220.........230.........240.
> .....250.........260.........270.........280.........290.........300 done
Bandwidth

<table>
<thead>
<tr>
<th>Mean</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.5631079</td>
<td>0.924924</td>
</tr>
</tbody>
</table>
The confidence interval for the mean ranges from 21.49 to 23.36. For the effect of fines, this range is $-8.67$ to $-6.72$. There are some differences so we try estimation with 400 replications.

```
. npregress kernel citations fines, reps(400) seed(12)
(running npregress on estimation sample)
Bootstrap replications (400): ........10.........20.........30.........40.......>
> ........50.........60.........70.........80.........90.........100.........110....>
> ........120.........130.........140.........150.........160.........170.........>
> ........180.........190.........200.........210.........220.........230.........240.>
> ........250.........260.........270.........280.........290.........300........300....>
> ........310.........320.........330.........340.........350.........360.........360.........37>
> 0.........380.........390.........400 done
```

The confidence interval for the mean ranges from 21.49 to 23.36. In the case of the effect of fines, these ranges are $-8.69$ to $-6.76$. The changes are small so we decide to use 400 replications.

```
Example 4: Estimating the effect of a percentage change in a covariate
Nonparametric estimation and the bootstrap are computationally intensive, so we use only 200 replications here.

We now extend example 2. In addition to fines, we model citations as a function of whether the jurisdiction taxes alcoholic beverages (taxes); whether the city is small, medium, or large (csize); and whether there is a college in the jurisdiction (college).
. npregress kernel citations fines i.taxes i.csizesize i.college, nolog
> reps(200) seed(12)
(running npregress on estimation sample)

Bootstrap replications (200): .........10.........20.........30.........40.........
> ....50.........60.........70.........80.........90.........100.........110.........
> ......120.........130.........140.........150.........160.........170.........
> .180.........190.........200 done

Note: Effect estimates are averages of derivatives for continuous covariates and averages of contrasts for factor covariates.

The mean number of citations predicted by the mean estimates is 22.26. The average marginal effect of fines is $-7.33$, slightly less in magnitude than the $-7.69$ that we estimated in example 2.

The average marginal effect tells us the result of an infinitesimal change in fines on citations. Instead of talking about infinitesimal changes, we want to know the effect of increasing fines by 15%. We can use margins to estimate the mean number of citations that would occur if fines were increased by 15%.

. margins, at(fines=generate(fines*1.15)) reps(200) seed(12)
(running margins on estimation sample)
The estimated mean number of citations with the new level of fines is 14.01, which is smaller than the mean 22.26 that was estimated with the observed fines. We can formally compare this estimate with the mean at the original level of fines. We use the `contrast()` option with `margins` to estimate the difference in these means.

```
. margins, at(fines=generate(fines)) at(fines=generate(fines*1.15))
> contrast(atcontrast(r) nowald) reps(200) seed(12)
(running `margins' on estimation sample)
```

We find that increasing fines by 15% reduces the average number of drunk driving citations by 8.25.
Example 5: Estimating the effect of a change in level

Now, we estimate the effect of increasing fines from $10,000 to $11,000 for fixed levels of the other covariates. The other covariate values identify a jurisdiction with a set of characteristics of interest: of medium size, with a college, and taxes alcohol.

First, we use margins to estimate the means for a jurisdiction with the characteristics of interest for the two levels of fines.

```
. margins, at(fines=10 taxes=1 csize=2 college=1)
> at(fines=11 taxes=1 csize=2 college=1) reps(200) seed(12)
```

```
Adjusted predictions
Expression: Mean function, predict()
1._at: fines = 10
taxes = 1
csize = 2
college = 1
2._at: fines = 11
taxes = 1
csize = 2
college = 1
```

<table>
<thead>
<tr>
<th>Observed</th>
<th>Bootstrap</th>
<th>Percentile</th>
</tr>
</thead>
<tbody>
<tr>
<td>margin</td>
<td>std. err.</td>
<td>[95% conf. interval]</td>
</tr>
<tr>
<td>_at</td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>23.17</td>
<td>21.95</td>
</tr>
<tr>
<td>2</td>
<td>15.90</td>
<td>13.87</td>
</tr>
</tbody>
</table>

For a medium-sized jurisdiction that taxes alcohol and has a college, the estimated mean of citations when fines are $10,000 is 23.17, and the estimated mean of citations when fines are $11,000 is 15.90.

We now use margins to estimate the difference in these means.
. margins, at(fines=10 taxes=1 csize=2 college=1)
> at(fines=11 taxes=1 csize=2 college=1)
> contrast(atcontrast(r) nowald) reps(200) seed(12)
(running margins on estimation sample)

Bootstrap replications (200): ........10.........20.........30.........40.....
> ....50........60........70.........80.........90........100.........110..
> ..........120.........130.........140.........150.........160.........170......
> .180.........190.........200 done

Contrasts of predictive margins

Number of obs = 500
Replications = 200

Expression: Mean function, predict()
1._at: fines = 10
taxes = 1
csize = 2
college = 1
2._at: fines = 11
taxes = 1
csize = 2
college = 1

<table>
<thead>
<tr>
<th></th>
<th>Observed contrast</th>
<th>Bootstrap std. err.</th>

</tr>
</thead>
<tbody>
<tr>
<td>_at (2 vs 1)</td>
<td>-7.270858</td>
<td>1.003861</td>
<td>-9.096777 -5.162513</td>
</tr>
</tbody>
</table>

In these jurisdictions, increasing fines from $10,000 to $11,000 reduces the average number of citations by 7.27.

Example 6: Population-averaged covariate effects

In example 5, we estimated the means for two values of fines for a medium-sized jurisdiction with a college and taxes on alcohol. We specified values for each covariate in our model. In this example, we will now estimate population-averaged means instead of means at specific levels of all covariates.

We first estimate the means for two levels of fines. We do not specify values for csize, college, or taxes, so the estimated means are unconditional on these covariates. We use margins to estimate means of citations when fines are $10,000 and when fines are $11,000:
The estimated mean of citations when fines are $10,000 is 20.50, and the estimated mean of citations when fines are $11,000 is 14.97. We now use `margins` to estimate the difference in these means:

```
. margins, at(fines=10) at(fines=11) reps(200) seed(12)
```

When fines increase from $10,000 to $11,000, the mean number of citations is estimated to decrease by 5.53.
Next, we consider the effect of taxing alcoholic beverages. We first estimate the population-averaged number of citations with and without such taxes.

```
. margins taxes, reps(200) seed(12)
(running margins on estimation sample)
Bootstrap replications (200): ........10 ........20 ........30 ........40 .......
> ........50 ........60 ........70 ........80 ........90 ..........100 ..........110...
> ........180 ..........190 ..........200 done
Predictive margins
Expression: Mean function, predict()

<table>
<thead>
<tr>
<th></th>
<th>Observed</th>
<th>Bootstrap</th>
<th></th>
<th></th>
<th>Percentile</th>

<td>.6445729</td>
<td>39.52</td>
<td>0.000</td>
<td>24.17515</td>
</tr>
<tr>
<td>Tax</td>
<td>20.96781</td>
<td>.4448277</td>
<td>47.14</td>
<td>0.000</td>
<td>20.17071</td>
</tr>
</tbody>
</table>
```

The estimated mean number of citations is 25.47 when there are no alcohol taxes and 20.97 when there are alcohol taxes. We again use `margins` to estimate the difference in these means.

```
. margins r.taxes, reps(200) seed(12)
(running margins on estimation sample)
Bootstrap replications (200): ........10 ........20 ........30 ........40 .......
> ........50 ........60 ........70 ........80 ........90 ..........100 ..........110...
> ........180 ..........190 ..........200 done
Contrasts of predictive margins
Expression: Mean function, predict()

<table>
<thead>
<tr>

<th>df</th>
<th>chi2</th>
<th>P&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>taxes</td>
<td>1</td>
<td>80.71</td>
<td>0.000</td>
</tr>
</tbody>
</table>
```

The mean number of citations is estimated to decrease by 4.50 when alcohol sales are taxed.

---

**Visualizing covariate effects**

**Example 7: Using margins to visualize the mean function and covariate effects**

We can also estimate the mean function for the jurisdiction with characteristics of interest over a range of observed fines. We simply add a range of fines to our `margins` specification from example 4.

```
. margins, at(fines=(8(0.5)12) taxes=1 csize=2 college=1) reps(200) seed(12)
(output omitted)
```
We graph these results using `marginsplot`.

```
marginsplot
(output omitted)
```

We estimated the mean when fines are $8,000, $8,500, and so on. From these estimated means, we can estimate the effect of a $500 increase for each of these levels of fines.

We simply reissue our `margins` command and specify a reverse adjacent contrast that subtracts the current level from the next level for each level of fines.

```
margins, at(fines=(8(0.5)12) taxes=1 csize=2 college=1)
> contrast(atcontrast(ar)) reps(200) seed(12)
(output omitted)
```

We again graph the results, adding a reference line at 0 that designates no change in citations:

```
marginplot, yline(0)
(output omitted)
```
For each level of fines between $8,500 and $11,500, the effect of a $500 increase reduces the mean number of drunk driving incidents. Between $11,500 and $12,000, the difference of a $500 increase is not statistically different from 0.

It would be easy to construct a similar graph for the population-averaged effects in example 6. Simply omit the terms that set the other covariates at fixed values.

Stored results

`npregress kernel` stores the following in `e()`:

Scalars
- `e(N)` number of observations
- `e(mean)` mean of mean function
- `e(r2)` $R^2$
- `e(nh)` expected kernel observations
- `e(converged_effect)` 1 if effect optimization converged, 0 otherwise
- `e(converged_mean)` 1 if mean optimization converged, 0 otherwise
- `e(converged)` 1 if effect and mean optimization converged, 0 otherwise

Macros
- `e(cmd)` `npregress`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(estimator)` linear or constant
- `e(kname)` name of continuous kernel
- `e(dkname)` name of discrete kernel
- `e(bselector)` criterion function for bandwidth selection
- `e(title)` title in estimation output
- `e(vce)` `vcetype` specified in `vce()`
- `e(properties)` `b` (or `b V` if `reps()` specified)
- `e(datasignaturevars)` variables used in calculation of checksum
- `e(datasignature)` the checksum
- `e(estat_cmd)` program used to implement `estat`
- `e(predict)` program used to implement `predict`
- `e(marginsok)` predictions allowed by `margins`
- `e(marginsprop)` signals to the `margins` command
Matrices
- `e(b)` - coefficient vector
- `e(bwidth)` - bandwidth for all predictions
- `e(derivbwidth)` - bandwidth for the derivative
- `e(meanbwidth)` - bandwidth for the mean
- `e(ilog_mean)` - iteration log for mean (up to 20 iterations)
- `e(ilog_effect)` - iteration log for effects (up to 20 iterations)

Functions
- `e(sample)` - marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices
- `r(table)` - matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

### Methods and formulas

The regression model of outcome $y_i$ given the $k$-dimensional vector of covariates $x_i$ was defined in (1) and (2) of Remarks and examples and repeated here:

$$y_i = g(x_i) + \varepsilon_i$$  \hspace{1cm} (1)

$$E(\varepsilon_i|x_i) = 0$$  \hspace{1cm} (2)

where $\varepsilon_i$ is the error term. The covariates may include discrete and continuous variables. Equations (1) and (2) imply that

$$E(y_i|x_i) = g(x_i)$$

`npregress kernel`, by default, estimates a local-linear regression; see Fan and Gijbels (1996) for a good reference on local-linear regression. As we discussed in Remarks and examples, local-linear regression estimates a regression for a subset of observations for each point in our data and solves the minimization problem given by

$$\min_\gamma \sum_{i=1}^{n} \{y_i - \gamma_0 - \gamma'_1 (x_i - x)\}^2 K(x_i, x; h)$$  \hspace{1cm} (3)

where $\gamma = (\gamma_0, \gamma'_1)'$ and $K(x_i, x; h)$ is the product of the kernels for each covariate.

$$K(x_i, x; h) = \prod_{j=1}^{k} K_j(x_{ij}, x_j, h_j)$$

The kernel for a continuous covariate is of the form

$$K_j(x_{ij}, x_j, h_j) = k_j \left( \frac{x_{ij} - x_j}{h_j} \right)$$
where \( k_j(\cdot) \) is one of the kernels listed in \([R]\) `kdensity`. For discrete covariates, `npregress kernel` uses the Li–Racine kernel given by

\[
K_j(x_{ij}, x_j, h_j) = \begin{cases} 
1 & \text{if } x_{ij} = x_j \\
h_j & \text{otherwise}
\end{cases}
\]

By estimating \( E(y_i|x_i = x) \) for all points \( x \) in our data, we obtain an estimate of \( E(y_i|x_i) \). For a given \( x \), the solution to the minimization problem in (3) is given by

\[
\hat{\gamma} = (Z'WZ)^{-1}Z'Wy
\]

where \( \hat{\gamma} = (\hat{\gamma}_0, \hat{\gamma}_1)' \), \( Z \) is an \( n \times (k + 1) \) matrix with an \( i \)th row given by \( \{1, (x_i - x)'/\}' \), \( W \) is an \( n \times n \) diagonal matrix with an \( i \)th diagonal given by \( K(x_i, x, h) \), and \( y \) is the \( n \times 1 \) outcome vector. \( \hat{\gamma}_0 \) is an estimate of \( g(x) \), whereas \( \hat{\gamma}_1 \) is an estimate of the derivative of \( g(x) \) with respect to \( x \). When the matrix \( (Z'WZ) \) is not full rank, the parameter \( \gamma \) is not identified. The observations for which this is true are dropped from the estimation sample.

The local-constant estimator of \( g(x) \) is a special case of (3) with \( \gamma_1 = 0 \). In this case, the solution to the optimization problem is given by

\[
\frac{\sum_{i=1}^n y_i K(x_i, x, h)}{\sum_{i=1}^n K(x_i, x, h)}
\]

This is also known as the Nadaraya–Watson kernel estimator, for Nadaraya (1965) and Watson (1964).

`npregress kernel` and `margins`, when used after `npregress kernel`, use a bootstrap estimate of the standard errors for all the estimated effects and report percentile confidence intervals by default. Cattaneo and Jansson (2018) formally justify this use of the bootstrap and provide a definitive reference for semiparametric estimation and inference using kernel-based estimators. Their work demonstrates that the percentile bootstrap provides better coverage than a normal-based confidence interval for statistics based on kernel estimates. See `Methods and formulas` in \([R]\) `bootstrap` for confidence interval formulas.

The rate of convergence of nonparametric regression estimates is given by the product of the sample size and the bandwidths \( \sqrt{n|h|} \), where \( |h| \) is the product of the bandwidths for each covariate. As the sample size increases, the bandwidth decreases. Thus, the rate of convergence of the estimator is slower than the parametric rate \( \sqrt{n} \). Another way of thinking about \( n|h| \) is that, because we are not using all our observations to estimate the mean at each point, we require more data to get more reliable estimates; the convergence rate is thus slower. The rate of convergence also decreases as the number of covariates increases, because \( |h| \) decreases. This is referred to as the curse of dimensionality; see Li and Racine (2007, chap. 2) and Stinchcombe and Drukker (2013) for details.

The convergence rate for the derivative of the mean function is different from the convergence rate of the mean function. Therefore, the bandwidth and bandwidth computation for the derivative are different. `npregress kernel` computes the bandwidth for the derivative function by using cross-validation, as suggested by Henderson et al. (2015).

predict

Description for predict

predict creates a new variable containing predictions such as conditional mean of the outcome, residuals, or derivatives of the mean function.

Menu for predict

Statistics > Postestimation

Syntax for predict

```plaintext
predict [type] newvar [if] [in] [, statistic]
predict [type] { stub* | newvarlist } [if] [in], derivatives
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>mean</strong></td>
<td>conditional mean of the outcome; the default</td>
</tr>
<tr>
<td><strong>residuals</strong></td>
<td>residuals</td>
</tr>
</tbody>
</table>

These statistics are calculated only for the estimation sample.

Options for predict

- **Main**: mean, the default, calculates the conditional mean of the outcome variable.
- **residuals** calculates the residuals.
- **derivatives** calculates the derivatives of the conditional mean.
margins

Description for margins

margins estimates margins of the conditional mean.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [options]

<table>
<thead>

</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.
Options for margins

_nose_ suppresses calculation of the VCE and standard errors. This is the default.

_vce(bootstrap)_ specifies that bootstrap standard errors are reported; see [R] _vce_option_.

We recommend that you select the number of replications using _reps(#)_ instead of specifying _vce(bootstrap)_ which defaults to 50 replications. Be aware that the number of replications needed to produce good estimates of the standard errors varies depending on the problem.

_reps(#)_ specifies the number of bootstrap replications to be performed. Specifying this option is equivalent to specifying _vce(bootstrap, reps(#))_.

_seed(#)_ sets the random-number seed. You must specify _reps(#)_ with _seed(#)_.

Reporting

_citytype(citytype)_ specifies the type of confidence interval to be computed. By default, bootstrap percentile confidence intervals are reported as recommended by Cattaneo and Jansson (2018)._citytype_ may be one of _percentile, bc, or normal._

npgraph

Description for npgraph

_npgraph_ plots the conditional mean estimated by _npregress kernel_ overlayed on a scatterplot of the data. _npgraph_ is available only after fitting models with one covariate.

Syntax for npgraph

```
_npgraph [ if ] [ in ] [ , options ]
```

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot</td>
<td></td>
</tr>
<tr>
<td><em>marker_options</em></td>
<td>change look of markers (color, size, etc.)</td>

</tr>
<tr>
<td><em>noscatter</em></td>
<td>suppress scatterplot</td>
</tr>
<tr>
<td>Smoother</td>
<td></td>
</tr>
<tr>
<td><em>lineopts(cline_options)</em></td>
<td>affect rendition of the smoothed line</td>
</tr>
<tr>
<td>Add plots</td>
<td></td>
</tr>
<tr>
<td><em>addplot(plot)</em></td>
<td>add other plots to the generated graph</td>
</tr>
<tr>
<td>Y axis, X axis, Titles, Legend, Overall</td>
<td>any options other than by() documented in [G-3] <em>twoway_options</em></td>
</tr>
</tbody>
</table>
Options for npgraph

(marker_options) affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.

(marker_label_options) specify if and how the markers are to be labeled; see [G-3] marker_label_options.

(noscatter) suppresses superimposing a scatterplot of the observed data over the smooth. This option is useful when the number of resulting points would be so large as to clutter the graph.

(lineopts(cline_options)) affects the rendition of the smoothed line; see [G-3] cline_options.

(addplot(plot)) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

(twoway_options) are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

Remarks and examples

For examples of margins after npregress kernel, see example 4, example 5, and example 6 in [R] npregress kernel.

For examples of marginsplot, see example 7 in [R] npregress kernel.

For an example of npgraph, see example 2 in [R] npregress kernel.

Methods and formulas

The formulas used by predict and margins for the conditional mean function and the mean marginal effect of a covariate are given in Methods and formulas of [R] npregress kernel.

**Description**

`npregress series` performs nonparametric series estimation using a B-spline, piecewise polynomial spline, or polynomial basis. Like linear regression, nonparametric regression models the mean of the outcome conditional on the covariates, but unlike linear regression, it makes no assumptions about the functional form of the relationship between the outcome and the covariates. `npregress series` may be used to model the mean of a continuous, count, or binary outcome.

**Quick start**

Nonparametric regression of `y` on `x` and discrete covariate `a` using the default B-spline basis

```
npregress series y x i.a
```

Same as above, but use a polynomial basis

```
npregress series y x i.a, polynomial
```

Same as above, but use a piecewise polynomial spline basis

```
npregress series y x i.a, spline
```

Same as above, but use AIC to find the optimal basis function

```
npregress series y x i.a, criterion(aic) spline
```

Interpolate using three knots

```
npregress series y x i.a, knots(3)
```

Specify values of knots in matrix `K`

```
npregress series y x i.a, knotsmat(K)
```

**Menu**

Statistics > Nonparametric analysis > Nonparametric series regression
Syntax

\texttt{npregress series depvar indepvars series [if] [in] [weight] [ , options]}

\textit{indepvars series} is the list of independent variables for which a basis function will be formed.

\textit{indepvars} and \textit{varlist} may contain factor variables; see [U] 11.4.3 Factor variables.

\texttt{bootstrap}, \texttt{by}, \texttt{collect}, and \texttt{jackknife} are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the \texttt{bootstrap} prefix; see [R] \texttt{bootstrap}.

\texttt{fweight}s and \texttt{iweight}s are allowed; see [U] 11.1.6 weight.

\texttt{coeflegend} does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
Options

bspline specifies that a third-order B-spline be selected. It is the default basis.
bspline(#) specifies that a B-spline of order # be used as the basis. The order may be 1, 2, or 3.
spline specifies that a third-order piecewise polynomial spline be selected as the basis.
spline(#) specifies that a piecewise polynomial spline of order # be used as the basis. The order may be 1, 2, or 3.
polynomial specifies that a polynomial be selected as the basis.
polynomial(#) specifies that a polynomial of order # be used as the basis. The order may be an integer between 1 and 16.
asis(varlist) specifies that variables in varlist be included as independent variables in the model without any transformation. No B-spline, piecewise polynomial spline, or polynomial basis function will be formed from these variables. Variables in varlist may not be specified in indepvars.
nointeract(seriesvarlist) specifies that the terms in the basis function formed from variables in seriesvarlist not be interacted with the terms of the basis function formed from other variables in indepvars. Covariates specified in seriesvarlist must be in indepvars.
criterion(crittype) specifies that crittype be used to select the optimal number of terms in the basis function. crittype may be one of the following: cv (cross-validation), gcv (generalized cross-validation), aic (Akaike’s information criterion), bic (Schwarz’s Bayesian information criterion), or mallows (Mallows’s $C_p$). The default is criterion(cv).
knots(#) specifies that a piecewise polynomial spline or B-spline basis function with # knots be used. The minimum number of knots must be an integer greater than or equal to 1. The maximum number of knots is either 4,096 or two-thirds of the sample size, whichever is smaller.
knotsmat(matname) specifies that the knots for each continuous covariate be the values in each row of matname. The number of knots should be the same for each covariate, and there must be as many rows as there are continuous covariates. If rows of matname are not labeled with varnames, then rows are assumed to be in the order of indepvars.
distinct(#) specifies the minimum number of distinct values allowed in continuous variables. By default, continuous variables that enter the basis through either indepvars or seriesvarlist are required to have at least 10 distinct values. Continuous variables with few distinct values provide little information for determining an appropriate basis function and may produce unreliable estimates.
basis(stub [, replace]) specifies that the elements of the basis function generated by npregress series be stored with the specified names.

The option argument stub is the prefix used to generate enumerated variables for each element of the basis.

When replace is used, existing variables named with stub are replaced by those from the new computation.

rescale(stub [, replace]) specifies that the rescaled covariates used to generate the basis function be stored with the specified names.

The option argument stub is the prefix used to generate enumerated variable names for the covariates.

When replace is used, existing covariates named with stub are replaced by those from the new computation.
vce(vcetype) specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (robust), that assume homoskedasticity (ols), and that use bootstrap methods (bootstrap); see [R] vce_option.

Reporting level(#); see [R] Estimation options.

aequations specifies that the auxiliary regression coefficients be reported. By default, only the average marginal effects of the covariates on the outcome are reported.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

Maximization maximize_options: iterate(#), [no]log, tolerance(#); see [R] Maximize. These options are seldom used.

The following option is available with npregress series but is not shown in the dialog box: coeflegend; see [R] Estimation options.

Remarks and examples

This entry assumes that you are already familiar with nonparametric regression. Below, we discuss nonparametric series estimation; see [R] npregress intro for an overview of nonparametric regression and the models fit by npregress series and npregress kernel.

Remarks are presented under the following headings:

Overview
Estimation and effects

Overview

npregress series implements nonparametric series estimation using a B-spline, piecewise polynomial spline, or polynomial basis. The covariates may be continuous or discrete. npregress series allows you to estimate covariate effects and other counterfactuals related to the unknown mean function after estimation.

The word “nonparametric” refers to the fact that the parameter of interest—the mean as a function of the covariates—is given by the unknown function $g(x_i)$, which is an element of an infinite-dimensional space of functions. In contrast, in a parametric model, the mean for a given value of the covariates, $E(y_i|x_i) = f(x_i, \beta)$, is a known function that is fully characterized by the parameter of interest, $\beta$, which is a finite-dimensional real vector (Shao 2003).

The nonparametric regression model of outcome $y_i$ given the $k$-dimensional vector of covariates $x_i$ is given by

\[ y_i = g(x_i) + \varepsilon_i \]  \hspace{1cm} (1)

\[ E(\varepsilon_i|x_i) = 0 \]  \hspace{1cm} (2)
where $\varepsilon_i$ is the error term. Equations (1) and (2) imply that

$$E(y_i|x_i) = g(x_i)$$

Once we account for the information in the covariates, the error term provides no information about the mean of our outcome. The conditional mean function is therefore given by $g(x_i)$.

The mean estimate we obtain using nonparametric series estimation has the same form of the mean function estimate we obtain using linear regression. The regressors, however, are not variables in the data but functions of the variables. An example would be a $k$th-order polynomial. Suppose we have one covariate. The elements of the polynomial in this case would be $(x_i, x_i^2, \ldots, x_i^k)$. If we define $z_i$ as a vector with elements $(x_i, x_i^2, \ldots, x_i^k)$, we may write the estimate of the mean function as $z_i^T\hat{\beta}$ where $\hat{\beta}$ has the form of an ordinary least-squares estimate.

`npregress series` allows us to specify other functional forms for $z_i$ depending on the basis we select: B-spline, piecewise polynomial spline, or polynomial. See `Methods and formulas` for the formulas for each basis.

Although the estimate of the mean function has the form of a linear regression, the individual coefficients are not easily interpretable. For instance, in our $k$th-order polynomial example, if $x_i$ is continuous, the marginal effect of $x_i$ is not a single coefficient but rather is a function of $k$ elements of $\beta$ and the covariate $x_i$.

In the example above, we had only one covariate, $x_i$. If we have more than one covariate, we approximate the mean function by using interactions of the terms in the basis function for each covariate. For instance, a polynomial of $x_i$ and $w_i$ would have terms $(x_i, w_i, x_i w_i, x_i^2, w_i^2, \ldots, w_i^k x_i^k)$. As the number of covariates increases, the number of terms in the basis function increases exponentially. This is referred to in the literature as the curse of dimensionality.

`npregress series` allows us to reduce the dimensionality by using the `nointeract()` option to request that some covariates not be interacted with others. For the example above, this is equivalent to specifying a model of the form

$$y_i = g_1(x_i) + g_2(w_i) + \varepsilon_i$$

(3)

In (3), $g_1(x_i)$ and $g_2(w_i)$ are unknown functions, but there are no interactions between $x_i$ and $w_i$. This ameliorates the curse of dimensionality but imposes more structure to the model.

You may also want to reduce the curse of dimensionality by requesting a parametric component, by using the `asis()` option, to fit models like this:

$$y_i = g(x_i) + w_i \beta + \varepsilon_i$$

(4)

In (4), $g(x_i)$ is unknown but we assume that $w_i$ enters the model linearly.

As mentioned above, the regression coefficients are not easily interpretable. We can, however, estimate marginal effects, as reported in the `npregress series` output, and use `margins` to answer specific questions about the effects of covariates on the conditional mean, $g(x_i)$. We demonstrate this in the examples below.

For detailed introductions to series estimators and the methods implemented by `npregress series`, see de Boor (2001), Schumaker (2007), Eubank (1999), Schoenberg (1969), Newey (1997), and Chen (2007).
Example 1: Nonparametric series regression estimation

dui.dta contains information about the number of monthly drunk driving citations in a local jurisdiction (citations). Suppose we want to know the effect of increasing fines on the number of citations. Because citations is a count variable, we could consider fitting the model with poisson or nbreg. However, both of these estimators make assumptions about the distribution of the data. If these assumptions are not true, we will obtain inconsistent estimates.

By using npregress series, we do not have to make any assumptions about how citations is distributed. We use npregress series to estimate the average marginal effect of drunk driving penalties (fines) on citations.

```
. use https://www.stata-press.com/data/r18/dui
   (Fictional data on monthly drunk driving citations)
   . npregress series citations fines

</table>

Note: Effect estimates are averages of derivatives.
```

The iteration log first tells us that the approximating function is being computed. At this stage, the number of knots of the cubic B-spline is selected using cross-validation. Three knots were selected.

After the approximating function is computed, average marginal effects are computed. This second step is computationally expensive. The computation time increases with the number of elements in the basis function, which in turn increases with the complexity of the mean function we are trying to compute.

The table reports that the average marginal effect of fines on the mean number of citations is −8.02. Increasing fines, on average, reduces the number of citations.
**npregress series** generates a system variable for each element of the basis function. Additionally, variables are generated with the rescaled values of the continuous covariates used to construct the basis function. To see the variables that **npregress series** generated for example 1, we type

```
. describe *.*, fullnames
```

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Storage type</th>
<th>Display format</th>
<th>Value label</th>
</tr>
</thead>
<tbody>
<tr>
<td>__x1rs</td>
<td>double</td>
<td>%10.0g</td>
<td>fines rescaled to [0,1]</td>
</tr>
<tr>

<td>Basis term 7 for fines</td>
</tr>
</tbody>
</table>

To specify a name for each of the elements of the basis function, we can use the `basis()` option with a **stub**.

```
. npregress series citations fines, basis(basis)
```

We get the following set of names for the elements of the basis function:

```
. describe basis*, fullnames
```

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Storage type</th>
<th>Display format</th>
<th>Value label</th>
</tr>
</thead>
<tbody>
<tr>
<td>basis1</td>
<td>double</td>
<td>%10.0g</td>
<td>Basis term 1 for fines</td>
</tr>
<tr>
<td>basis2</td>
<td>double</td>
<td>%10.0g</td>
<td>Basis term 2 for fines</td>
</tr>
<tr>
<td>basis3</td>
<td>double</td>
<td>%10.0g</td>
<td>Basis term 3 for fines</td>
</tr>
<tr>
<td>basis4</td>
<td>double</td>
<td>%10.0g</td>
<td>Basis term 4 for fines</td>
</tr>
<tr>

<td>%10.0g</td>
<td>Basis term 6 for fines</td>
</tr>
<tr>
<td>basis7</td>
<td>double</td>
<td>%10.0g</td>
<td>Basis term 7 for fines</td>
</tr>
</tbody>
</table>

We may also modify the name of the rescaled variable by using the `rescale()` option.

```
. npregress series citations fines, rescale(rescaled)
```

This will give us

```
. describe rescaled*, fullnames
```

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Storage type</th>
<th>Display format</th>
<th>Value label</th>
</tr>
</thead>
<tbody>
<tr>
<td>rescaled1</td>
<td>double</td>
<td>%10.0g</td>
<td>fines rescaled to [0,1]</td>
</tr>
</tbody>
</table>
Example 2: Estimation with more than one regressor

We now extend example 1. In addition to `fines`, we model `citations` as a function of whether the jurisdiction is small, medium, or large (`csize`) and whether there is a college in the jurisdiction (`college`).

```
.npregress series citations fines i.csize i.college
```

Computing approximating function

Minimizing cross-validation criterion

Iteration 0:  Cross-validation criterion = 30.26251

Computing average derivatives

Cubic B-spline estimation  Number of obs  =  500
Criterion: cross-validation  Number of knots  =  1

| Effect   | std. err. | z    | P>|z|    | [95% conf. interval] |
|----------|-----------|------|--------|----------------------|
| `fines`  | -7.787386 | .2917941 | -26.69 | 0.000 | -8.359292 | -7.215481 |
| `csize` (Medium vs Small) | 4.732592 | .5087968 | 9.30 | 0.000 | 3.735368 | 5.729815 |
| `csize` (Large vs Small) | 10.91757 | .5350892 | 20.40 | 0.000 | 9.868813 | 11.96632 |
| `college` (College vs Not coll..) | 6.514286 | .5958949 | 10.93 | 0.000 | 5.346353 | 7.682218 |

Note: Effect estimates are averages of derivatives for continuous covariates and averages of contrasts for factor covariates.

The average marginal effect of `fines` is −7.79, slightly less in magnitude than the −8.02 that we estimated in example 1. The output also shows effects for the variables `csize` and `college`. In these categorical variables, the effects are differences instead of derivatives. For example, if every jurisdiction in the population were a college town, we would expect 6.51 more citations than if none were college towns.

Example 3: Expected citations for different levels of fines

The `npregress series` command reported that the average marginal effect of `fines` on number of citations is negative. We can use `margins` to further explore the relationship between level of `fines` and expected number of citations. What would we expect if all jurisdictions set `fines` to $8,000? What if they all set `fines` to $9,000? $10,000? $11,000? We use the `at(fines=(8 9 10 11))` option with `margins` to estimate these expected values.
. margins, at(fines=(8 9 10 11))

Predictive margins  Number of obs = 500
Model VCE: Robust
Expression: Mean function, predict()
1._at: fines = 8
2._at: fines = 9
3._at: fines = 10
4._at: fines = 11

| _at  | Margin   | std. err. |  z   | P>|z|   | [95% conf. interval]       |
|------|----------|-----------|------|-------|---------------------------|
|  1   | 49.58234 | 1.47392   | 33.64| 0.000 | 46.69351–52.47117        |
|  2   | 28.35154 | 0.5730302 | 49.48| 0.000 | 27.22842–29.47466        |
|  3   | 20.40163 | 0.3320855 | 61.43| 0.000 | 19.75075–21.0525         |
|  4   | 14.78085 | 0.4297201 | 34.40| 0.000 | 13.93862–15.62309        |

There appears to be a dramatic drop in the expected number of citations as fines increase from $8,000 to $9,000. We can visualize these results if we type `marginsplot`.

![Figure 1](image)

Are there significant differences in the expected number of citations as we increase fines in increments of $1,000? If we use the reverse-adjacent contrast operator, `ar .`, with `margins`, we can estimate these differences and perform tests.
Contrasts of predictive margins

Expression: Mean function, predict()
1._at: fines = 8
2._at: fines = 9
3._at: fines = 10
4._at: fines = 11

</tr>
</tbody>
</table>

When fines are increased from $8,000 to $9,000, we expect a decrease of 21.23 in the number of citations. Smaller but still statistically significant decreases in the number of citations are expected as fines are increased from $9,000 to $10,000 and from $10,000 to $11,000.

Example 4: Estimating the effect for different levels of jurisdiction size

Now, we estimate the effect of increasing fines for different jurisdiction sizes.

<table>
<thead>

<td>-11.31067 -9.099178</td>
</tr>
</tbody>
</table>

If all jurisdictions were small but other characteristics were as they are observed, then we expect that the marginal effect of fines would be −5.99. We see that the effect is more extreme as the size of the jurisdiction increases. If all jurisdictions were large, we expect that the average marginal effect of fines would be −10.20.

We can further explore the effects of fines for different jurisdiction sizes by estimating the expected number of citations with fines at specific levels.

(output omitted)
To visualize the effect, we type `marginsplot`.

For each jurisdiction size, we see that on average higher fines result in fewer citations. We also see that the effect of changing fine levels is nonlinear and differs across the counterfactual jurisdiction size. For instance, as fines increase from $8,000 to $9,000, the expected number of citations decreases faster for small jurisdictions than for medium ones.

### Stored results

`npregress series` stores the following in `e()`:

**Scalars**
- `e(N)` number of observations
- `e(r2)` $R^2$
- `e(r2_a)` adjusted $R^2$
- `e(converged)` 1 if converged, 0 otherwise
- `e(order)` order of basis function
- `e(rank)` rank of `e(V)`

**Macros**
- `e(cmd)` `npregress`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(basis)` bsplines, splines, or polynomials
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(vcetype)` vcetype specified in `vce()`
- `e(vctype)` title used to label Std. err.
- `e(knots)` number of knots selected
- `e(datasignaturevars)` variables used in calculation of checksum
- `e(datasignature)` the checksum
- `e(estat_cmd)` program used to implement `estat`
- `e(predict)` program used to implement `predict`
- `e(properties)` `b V`
- `e(marginsok)` predictions allowed by `margins`
- `e(marginsprop)` signals to the `margins` command
- `e(marginsnotok)` predictions disallowed by `margins`
Matrices
e(b) \quad \text{coefficient vector}
e(V) \quad \text{variance–covariance matrix of estimators}
e(V_{\text{modelbased}}) \quad \text{model-based variance}
e(\text{ilog}) \quad \text{iteration log (up to 20 iterations)}

Functions
e(sample) \quad \text{marks estimation sample}

In addition to the above, the following is stored in r():

Matrices
r(table) \quad \text{matrix containing the coefficients with their standard errors, test statistics, } p \text{-values, and confidence intervals}

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

Methods and formulas

Methods and formulas are presented under the following headings:
- Overview
- Polynomials
- Piecewise polynomial splines
- B-splines
- Model selection
  - Cross-validation
  - Generalized cross-validation
  - Mallows’s $C_p$
  - AIC and BIC

Overview

The regression model of outcome $y_i$ given the $k$-dimensional vector of covariates $x_i$ was defined in (1) and (2) of Remarks and examples and is repeated here:

$$y_i = g(x_i) + \varepsilon_i \quad (1)$$
$$E(\varepsilon_i | x_i) = 0 \quad (2)$$

where $\varepsilon_i$ is the error term. The covariates may include discrete and continuous variables. Equations (1) and (2) imply that

$$E(y_i | x_i) = g(x_i)$$

As discussed in Remarks and examples, series estimators have the form of ordinary least squares. Thus, we can write the estimate of the mean function as

$$\hat{E}(y_i | x_i) = z(x_i) \hat{\beta} \quad (5)$$

where $z(x_i)$ is a known $q$-dimensional vector for which every one of the $q$ terms is a function of the $k$-dimensional vector of covariates $x_i$. Let $n$ be the sample size. If we define $Z$ as the $n \times q$ matrix formed by the $z(x_i)$ for each individual $i$, then the $q$-dimensional coefficient vector $\hat{\beta}$ is the ordinary least-squares vector that comes from regressing the $n \times 1$ outcome vector $y$ on $Z$ and has the known form

$$\hat{\beta} = (Z'Z)^{-1} (Z'y) \quad (6)$$

Each one of the series estimators has a different form for $z(x_i)$. Below, we define $z(x_i)$ for polynomials, piecewise polynomial splines, and B-splines.
Polynomials

For a polynomial of order 1 with \( k \) continuous covariates, \( x_i \equiv (x_{i1}, x_{i2}, \ldots, x_{ik}) \), \( z(x_i) \) is

\[
z(x_i) = (x_{i1}, x_{i2}, \ldots, x_{ik})
\]

For notational convenience, we will refer to the polynomial above as \( P_1 \), which also corresponds to the name we gave to the equation. More formally, we could have written \((x_{i1}, x_{i2}, \ldots, x_{ik}) \equiv P_1\). We will maintain this notational convention below.

A polynomial of order 2 with \( k \) continuous covariates includes \( P_1 \) and second-order terms:

\[
z(x_i) = (P_1, x_{i1}^2, x_{i1}x_{i2}, \ldots, x_{i1}x_{ik}, x_{i2}x_{i3}, \ldots, x_{ik}^2)
\]

A third-order polynomial with \( k \) continuous covariates includes the terms in \( P_2 \) (which already includes \( P_1 \)) and third-order terms:

\[
z(x_i) = (P_2, x_{i1}^3, x_{i1}^2x_{i2}, \ldots, x_{i1}x_{ik}, x_{i1}x_{i2}x_{i3}, \ldots, x_{ik}^3)
\]

This recursive relationship continues. Thus, fourth-order polynomials includes the terms in \( P_3 \) (which already includes \( P_1 \) and \( P_2 \)) plus fourth-order terms.

For the polynomials above and all series estimators below, discrete covariates enter the model in levels, and each level is interacted with all other covariates in the model.

Piecewise polynomial splines

Piecewise polynomial splines are formed by a polynomial and functions of the form

\[
\max(x_{ik} - t_{1k}, 0)
\]

In the expression above, \( t_{1k} \) is a constant that is called a knot. The subscript of \( t_{1k} \) indicates that it is the first knot of the continuous covariate \( x_k \). The \( \max(\cdot) \) function is 0 when \( x_{ik} < t_{1k} \) and is \( x_{ik} - t_{1k} \) otherwise. \texttt{npregress series} selects a set of knots for each one of the continuous covariates.

The regressors for \texttt{npregress series} using a piecewise polynomial spline of order 3 with one continuous covariate, \( x_1 \), and \( k \) knots, \( t_{11} < t_{21} < \cdots < t_{k1} \), are given by

\[
z(x_{i1}) = \left\{ x_{i1}, x_{i1}^2, x_{i1}^3, \max(x_{i1} - t_{11}, 0)^3, \max(x_{i1} - t_{21}, 0)^3, \ldots, \right. \\
\left. \quad \max(x_{i1} - t_{k1}, 0)^3 \right\}
\]

Equivalently, for another continuous covariate, \( x_2 \), and \( k \) knots, \( t_{12} < t_{22} < \cdots < t_{k2} \), we have

\[
z(x_{i2}) = \left\{ x_{i2}, x_{i2}^2, x_{i2}^3, \max(x_{i2} - t_{12}, 0)^3, \max(x_{i2} - t_{22}, 0)^3, \ldots, \right. \\
\left. \quad \max(x_{i2} - t_{k2}, 0)^3 \right\}
\]
To get \( z(x_{i1}, x_{i2}) \) for \( x_1 \) and \( x_2 \) and \( k \) knots, we include all terms in \( S_1 \) and \( S_2 \) as well as all the terms that result from the interaction of their terms. We write it succinctly as

\[
z(x_{i1}, x_{i2}) = \{S_1, S_2, (S_1)(S_2)\}
\]

The description above refers to the default third-order piecewise polynomial spline. Below, we describe the cases for piecewise polynomial splines of order 1 and order 2. Going back to the one covariate case, if we want a piecewise polynomial spline of order 1 with \( k \) knots, we have

\[
z(x_{i1}) = \{x_{i1}, \max(x_{i1} - t_{11}, 0), \max(x_{i1} - t_{21}, 0), \ldots, \max(x_{i1} - t_{k1}, 0)\}
\]

And for order 2 with \( k \) knots and one covariate, we have

\[
z(x_{i1}) = \{x_{i1}, x_{i1}^2, \max(x_{i1} - t_{11}, 0)^2, \max(x_{i1} - t_{21}, 0)^2, \ldots, \max(x_{i1} - t_{k1}, 0)^2\}
\]

If we have more than one covariate, the logic of interacting the expressions for each covariate is the same as the logic we used for the third-order piecewise polynomial spline in \((S12)\).

To construct \( z(x_i) \), continuous covariates are rescaled to be between 0 and 1 with the expression

\[
\{x_i - \min(x_i)\} \left\{ \frac{1}{\max(x_i) - \min(x_i)} \right\}
\]

This rescaling is used to construct the piecewise polynomial spline and B-spline bases.

**B-splines**

To construct a B-spline basis, we need to define knots that are on the interior of the range of the covariates and knots that are at the upper and lower limits of the range or outside the range. The number of knots that are not in the interior differs depending on the order of the B-spline. For a B-spline of order 1 with \( k \) interior knots, \( t_1, t_2, \ldots, t_k \), we need 4 additional knots. The set of knots for a first-order B-spline is therefore

\[
t_{-1}, t_0, t_1, \ldots, t_k, t_{k+1}, t_{k+2}
\]

We added \( t_{-1}, t_0, t_{k+1}, \) and \( t_{k+2} \) to the interior knots. By convention, \( t_{-1} = t_0 \) and \( t_{k+1} = t_{k+2} \).

For a B-spline of order 2 with \( k \) interior knots, we need 6 additional knots. The set of knots is

\[
t_{-2}, t_{-1}, t_0, t_1, \ldots, t_k, t_{k+1}, t_{k+2}, t_{k+3}
\]

For a B-spline of order 3, the set of knots is

\[
t_{-3}, t_{-2}, t_{-1}, t_0, t_1, \ldots, t_k, t_{k+1}, t_{k+2}, t_{k+3}, t_{k+4}
\]
We first define a first-order B-spline for one continuous covariate \( x \) with \( k \) interior knots. Let \( t_j \) denote an \( n \times 1 \) vector for which all elements take the value of the \( j \)th knot \( t_j \). The B-spline basis is formed by \( k + 2 \) functions of the form

\[
B_{j,1} = \frac{(x - t_j)}{t_{j+1} - t_j} 1(t_j \leq x < t_{j+1}) + \frac{(t_{j+2} - x)}{t_{j+2} - t_{j+1}} 1(t_{j+1} \leq x < t_{j+2})
\]  

\( j = -1, 0, 1, 2, \ldots, k \)

(Above, we use the indicator function \( 1(\cdot) \), which is 1 when the condition inside the parentheses is satisfied and is 0 otherwise. Also, any term for which \( t_{j+1} = t_j \) or \( t_{j+2} = t_{j+1} \) is considered to be a vector of 0s.)

The function \( z(x) \) used to estimate \( g(x) \) is given by

\[
z(x) = (B_{-1,1}, B_{0,1}, B_{1,1}, \ldots, B_{k,1})
\]

We now define a second-order B-spline for one continuous covariate \( x \) with \( k \) interior knots. The basis is constructed using the relationship given by

\[
B_{j,2} = \frac{(x - t_j)}{t_{j+2} - t_j} B_{j,1} + \frac{(t_{j+3} - x)}{t_{j+3} - t_{j+1}} B_{j+1,1}
\]

\( j = -2, -1, 0, 1, 2, \ldots, k \)

where \( B_{j,1} \) and \( B_{j+1,1} \) come from (7) above. Thus, second-order B-splines are a function of first-order B-splines, and as we will see below, third-order B-splines are a function of second-order B-splines. This recursion continues into higher orders, but \texttt{npregress series} stops at B-splines of order 3.

The function \( z(x) \) for the second-order B-spline is given by

\[
z(x) = (B_{-2,2}, B_{-1,2}, B_{0,2}, B_{1,2}, \ldots, B_{k,2})
\]

The terms of the basis for a third-order B-spline are given by

\[
B_{j,3} = \frac{(x - t_j)}{t_{j+3} - t_j} B_{j,2} + \frac{(t_{j+4} - x)}{t_{j+4} - t_{j+1}} B_{j+1,2}
\]

\( j = -3, -2, -1, 0, 1, 2, \ldots, k \)

and the function \( z(x) \) for the third-order B-spline is

\[
z(x) = (B_{-3,3}, B_{-2,3}, B_{-1,3}, B_{0,3}, B_{1,3}, \ldots, B_{k,3})
\]

(B1)

As was the case with piecewise polynomial splines, when there is more than one covariate, you include all functions of the form (B1) and their interactions to form expressions like the one in (S12).
Model selection

Below, we define the criteria used for model selection. In the case of B-splines and piecewise polynomial splines, \texttt{npregress series} selects the number of knots to be used for estimation. In the case of a polynomial basis, \texttt{npregress series} selects the order of the polynomial.

Let us first define the squared residuals, $e_i^2$, where $e_i = y_i - \hat{g}(x_i)$ and $\hat{g}(\cdot)$ is the mean function estimate defined in (5). We denote the residuals for the regressions below as $e_i(t_k)$ instead of $e_i$ to signal that the estimates we obtain are a function of the set of knots, $t_k$, used. In the case of polynomials, $t_k$ will refer to the degree of the polynomial instead of knots.

Cross-validation

The cross-validation criterion, $CV(t_k)$, is defined by

$$CV(t_k) = \frac{1}{n} \sum_{i=1}^{n} \frac{e_i(t_k)^2}{(1 - h_{ii})^2} \quad (8)$$

In (8), $h_{ii}$ are the diagonal elements of the matrix $Z(Z'Z)Z'$, where $Z$ is defined in (6) above and $n$ is the size of the estimation sample.

\texttt{npregress series} computes $CV(t_k)$ for different sets of knots, $t_1, t_2, \ldots, t_k, \ldots$, where $t_1 \subset t_2 \subset \ldots \subset t_k \subset \ldots$, and then selects the model with the smallest value for the cross-validation criterion.

Generalized cross-validation

The generalized cross-validation criterion, $GCV(t_k)$, is given by

$$GCV(t_k) = \frac{1}{n} \sum_{i=1}^{n} \frac{e_i(t_k)^2}{\left(1 - \left(\frac{K}{n}\right)\right)^2}$$

where $K$ is the number of estimated parameters and the other arguments are equivalent to those defined in (8). As with cross-validation, $GCV(t_k)$ is computed for a set of models with an increasing number of nested knots, in the case of piecewise polynomial splines and B-splines, and of polynomial order in the case of polynomials. The minimum of the sequence is the selected model.

Mallows's $C_p$

$$\text{Mallows}(t_k) = \frac{1}{n} \sum_{i=1}^{n} e_i(t_k)^2 \left(1 + \frac{2K}{n}\right)$$

As with cross-validation, Mallows $(t_k)$ is computed for a set of models with an increasing number of nested knots, and the minimum of the sequence is the selected model.

</thead>
<tbody>
<tr>
<td>mean</td>
<td>the default, calculates the conditional mean of the outcome variable.</td>
</tr>
<tr>
<td>residuals</td>
<td>calculates the residuals.</td>
</tr>
<tr>
<td>score</td>
<td>is a synonym for residuals.</td>
</tr>
<tr>
<td>atsample</td>
<td>restricts predictions to the range of covariates in the data. If requested predictions extend beyond the range of the data, atsample will compute predictions only for observations within the range of the original data and will exclude those observations that are beyond the range of the data.</td>
</tr>
<tr>
<td>tolerance(#)</td>
<td>sets the tolerance for predictions outside the range of the covariates.</td>
</tr>
</tbody>
</table>

By default, predictions will not be computed if any covariate is set to a value outside the range of the data, unless atsample or tolerance() is specified.

By default, predictions will not be computed if any covariate is set to a value outside the range of the data, unless tolerance() or atsample is specified.
margins

Description for margins

margins estimates margins of the conditional mean.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [options]

statistic Description

Main
mean conditional mean of the outcome; the default
residuals not allowed with margins
score not allowed with margins

options Description

SE
vce(vcetype) vcetype may be delta, unconditional, or bootstrap
reps(#) equivalent to vce(bootstrap, reps(#))
seed(#) set random-number seed to #; must also specify reps(#)
nose do not estimate standard errors

Reporting
citype(citype) method to compute bootstrap confidence intervals; default is
citype(_percentile)

parity

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.
Options for margins

`vce(delta), vce(unconditional), and vce(bootstrap)` specify how the VCE and, correspondingly, standard errors are calculated.

`vce(delta)` is the default. The delta method is applied to the formula for the response and the VCE of the estimation command. This method assumes that values of the covariates used to calculate the response are given or, if all covariates are not fixed using `at()`, that the data are given.

`vce(unconditional)` specifies that the covariates that are not fixed be treated in a way that accounts for their having been sampled. The VCE is estimated using the linearization method. This method allows for heteroskedasticity or other violations of distributional assumptions in the same manner as `vce(robust)`, which is the default for `npregress series`.

`vce(bootstrap)` specifies that bootstrap standard errors be reported; see [R] `vce_option`. We recommend that you select the number of replications using `reps(#)` instead of specifying `vce(bootstrap)`, which defaults to 50 replications. Be aware that the number of replications needed to produce good estimates of the standard errors varies depending on the problem.

`reps(#)` specifies the number of bootstrap replications to be performed. Specifying this option is equivalent to specifying `vce(bootstrap, reps(#))`.

`seed(#)` sets the random-number seed. You must specify `reps(#)` with `seed(#)`.

`nose` suppresses calculation of the VCE and standard errors.

`citype(citype)` specifies the type of confidence interval to be computed. By default, bootstrap percentile confidence intervals are reported as recommended by Cattaneo and Jansson (2018). `citype` may be one of `percentile`, `bc`, or `normal`.

Remarks and examples

For examples of `margins` after `npregress series`, see example 3 and example 4 in [R] `npregress series`.

For an example of `marginsplot`, see example 4 in [R] `npregress series`.

Methods and formulas

The formulas used by `predict` and `margins` for the conditional mean function and the mean marginal effect of a covariate are given in `Methods and formulas` of [R] `npregress series`.

[U] 20 Estimation and postestimation commands
**Description**

*nptrend* performs four different nonparametric tests for trend: the Cochran–Armitage test, the Jonckheere–Terpstra test, the linear-by-linear trend test, and a test using ranks developed by Cuzick.

**Quick start**

Cochran–Armitage test for the association of a binary outcome in $y$ and the ordered values of the categories of $x$

```
nptrend y, group(x) carmitage
```

Same as above, but report an exact $p$-value calculated using Monte Carlo permutations

```
nptrend y, group(x) carmitage exact
```

Same as above, but perform 100,000 Monte Carlo permutations rather than the default of 10,000, and set the random-number seed for reproducibility

```
nptrend y, group(x) carmitage exact(montecarlo, reps(100000) rseed(1234))
```

Rather than testing the trend in $y$ by the values of $x$, which are 1, 2, 3, test the trend by 1, 2, 4

```
nptrend y, group(x) carmitage scoregroup(1 2 4)
```

Jonckheere–Terpstra test for trend in $y$ across ordered categories of $catvar$

```
nptrend y, group(catvar) jterpstra
```

Same as above, but perform the linear-by-linear trend test

```
nptrend y, group(catvar) linear
```

Same as above, but perform Cuzick’s test using ranks

```
nptrend y, group(catvar) cuzick
```

**Menu**

Statistics > Nonparametric analysis > Tests of hypotheses > Trend test across ordered groups
Syntax

</table>

*group(groupvar) and one of the choices for testopt are required. collect is allowed; see [U] 11.1.10 Prefix commands. fweights are allowed, except when exact is specified; see [U] 11.1.6 weight.

Options

```
Main
```

`group(groupvar)` defines the ordered groups across which differences in the response varname are to be tested. group() is required.

When option `scoregroup()` is not specified, the values of groupvar are the group scores. When `scoregroup()` is specified, groupvar defines the ordered categories, and the scores are the values specified in `scoregroup()`. When `scoregroup()` is specified, groupvar must be a positive integer (with gaps allowed).

testopt specifies the test that is reported. It is required and must be one of carmitage, jterpstra, linear, or cuzick.

carmitage specifies that the Cochran–Armitage test for trend be reported. Typically, the response varname is a 0/1 variable, and the values of groupvar represent a set of ordered categories. It gives a test of the trend of the proportions of positive responses in the groups, with the hypothesized trend given by the values of groupvar (or the values of scoregroup() if specified). If the response varname is not 0/1, it can be valued 1/2 and mapped to 0/1 or 1/0 using scoreresponse(0 1) or scoreresponse(1 0), respectively.

Response and group specifications for carmitage can be flipped. The groupvar variable can be a 0/1 predictor, and the response varname can contain ordered outcomes. If groupvar is not 0/1, it can be valued 1/2 and mapped to 0/1 or 1/0 using scoregroup(0 1) or scoregroup(1 0), respectively.
jterpstra specifies that the Jonckheere–Terpstra test for trend be reported. The response varname contains outcomes, which can be ordered categories or continuous values, and the groupvar variable is an ordered group indicator that is believed to be a predictor of outcome. The Jonckheere–Terpstra statistic is dependent on which is the response variable and which is the group variable. If response and group variables are interchanged, the value of the statistic will be different.

Only the orderings given by the response varname and groupvar are used to calculate the Jonckheere–Terpstra statistic. Different numerical values that give the same orderings produce the same statistic. Hence, this statistic is used when a test for trend dependent only on order is desired. Typically, the options scoreresponse() and scoregroup() are not specified. However, either or both of these options can be used to change the orderings given by varname and groupvar.

linear specifies that the linear-by-linear test for trend be reported. The linear-by-linear statistic is symmetric in the response variable varname and the group indicator groupvar. Interchanging response and group variables produces the same result. Despite the name “linear”, nonlinear trends can be tested. The trend, linear or nonlinear, is based on the numerical values of the response and group variables. scoreresponse() and scoregroup() can be specified to test different trends.

cuzick specifies that ranks be used for the responses and that the test for trend across ordered groups developed by Cuzick (1985) be reported. Because ranks are used, only the ordering given by response variable varname matters. The numerical values of groupvar are used in calculation, and different values, even those that give the same ordering, will result in different values of the statistic for Cuzick’s test. scoreresponse() can be specified to change the ordering of the responses. scoregroup() can be specified to test different trends by group.

scoreresponse(numlist) specifies scores for the responses in varname. When specified, varname must contain only positive integers (with gaps allowed), and the response score for varname = i is the ith number in numlist. When scoreresponse() is not specified, the response scores are the values of the response varname.

scoregroup(numlist) specifies scores for the groups specified by groupvar. When specified, groupvar must contain only positive integers (with gaps allowed), and the group score for groupvar = i is the ith number in numlist. When scoregroup() is not specified, the group scores are the values of groupvar.

exact and exact(exact_specs) specify that an exact p-value be reported.

exact specifies that an exact p-value from a Monte Carlo permutation test be reported. exact is a synonym for exact(montecarlo).

exact(montecarlo|enumerate[, options]) specifies that an exact p-value be reported in addition to the approximate or asymptotic p-value. Specifying exact(montecarlo) does a Monte Carlo permutation test. Specifying exact(enumerate) does an enumeration of all possible permutations. Because the number of all possible permutations is typically extremely large, enumeration is feasible only for very small datasets. The number of permutations will be displayed, and you can click on Break to stop the computation. The exact p-value is computed by permute.
exact(montecarlo[, options]) allows options show, reps(#), rseed(#),
  saving(filename[, sav_options]), level(#), dots(#), nodots, and eps(#). The show
  option specifies that the table produced by permute also be displayed. By default, 10,000
  Monte Carlo permutations are done. That is, the default is the same as specifying ex-
  act(montecarlo, reps(10000)). The default for dots() is dots(100) when reps() is ≥ 10,000;
  otherwise, it is dots(1). See Options in [R] permute.

exact(enumerate[, options]) allows options show, saving(filename[, sav_options]),
  dots(#), nodots, and eps(#). The show option specifies that the table produced by per-
  mute also be displayed. The default for dots() is dots(100). See Options in [R] permute.

nolabel causes numerical values of groupvar to be displayed in the table of mean response scores
  rather than value labels.

notable suppresses the display of the table of mean response scores by group.

Remarks and examples

Remarks are presented under the following headings:

  Introduction
  Cochran–Armitage test
  Jonckheere–Terpstra test
  Linear-by-linear trend test
  Cuzick’s test

Introduction

nptrend performs four different nonparametric tests for trend: the Cochran–Armitage test, the
  Jonckheere–Terpstra test, the linear-by-linear trend test, and a test using ranks developed by Cuzick.

Data for these tests consist of two variables. The first variable, specified immediately after nptrend,
  contains responses. The second variable, specified in group(), identifies groups.

For the Cochran–Armitage test, the response is typically a 0/1 variable, and the values of the
  group variable are ordered categories. It tests the trend of the proportions of positive responses in
  the groups. The numerical values of the hypothesized trend are called “scores”. For this form of the
  test, we call the scores that specify the hypothesized trend “group scores” because it is the trend by
  group being tested. For example, group scores of 1, 2, 3 would test for a linear trend. Group scores
  of 1, 4, 9 would test for a quadratic trend.

The specification of the Cochran–Armitage test can be flipped. That is, the response variable can
  identify ordered outcome categories, and the group variable can be 0/1. In this case, we call the
  scores that specify the hypothesized trend “response scores”.

The Cochran–Armitage test requires either a 0/1 response variable or a 0/1 group variable. It
  cannot test responses with more than two levels when there are more than two groups.

The Jonckheere–Terpstra test is typically used when there are more than two groups and more than
  two response levels. The test assesses whether there is an association between the response scores
  and the group scores, but only the relative orders of the responses and groups matter. Because there
  is no need to specify a hypothesized trend, this test is in this sense “more nonparametric” than the
  other tests for trend reported by nptrend.

The linear-by-linear trend test uses response scores to specify the trend being tested. So it is
  typically used when the trend of the response scores, rather than just their ordering, is meaningful.
  The linear-by-linear statistic is asymptotically equivalent to the Pearson correlation coefficient (see
  [R] correlate).
The statistics for the Cochran–Armitage test (when the response is 0/1), the linear-by-linear trend test, and Cuzick’s test are based on the numerical values of the group scores. The linear-by-linear test requires numerical response scores as well. Different scores, even those that have the same ordering, produce different values of the statistic. For instance, group scores 1, 2, 3 would give a different result than 1, 2, 4. For the linear-by-linear test, the same holds for response scores.

The options `score(response)` and `score(group)` are provided as convenience tools to test different response scores and group scores without having to modify the underlying variables. They do, however, require that the underlying variables be valued 1, 2, 3, . . .

If your data are not grouped, you can test for trend with the `sign test` and `spearman` commands; see [R] `signrank` and [R] `spearman`. With `sign test`, you can perform the Cox and Stuart test, a sign test applied to differences between equally spaced observations of `varname`. With `spearman`, you can perform the Daniels test, a test of zero Spearman correlation between `varname` and a time index. See Conover (1999, 169–175, 323) for a discussion of these tests.

**Cochran–Armitage test**

The Cochran–Armitage test tests the trend in ordered groups of the probability of a positive response. As we stated earlier, response and group specifications can be flipped, and it can assess whether a trend based on ordered responses is associated with membership in one of two groups. In the discussion that follows we will consider only the former case: ordered groups with 0/1 responses.

The Cochran–Armitage test is based on a linear probability model for \( \theta_i \), the probability of a positive response for subjects in the \( i \)th group,

\[
\theta_i = \alpha + \beta (g_i - \bar{g})
\]

where \( \alpha \) is the intercept, \( \beta \) is the slope, \( g_i \) are the group scores, and \( \bar{g} \) is the mean of the group scores.

The estimate for \( \beta \) is the ordinary least-squares (OLS) estimate \( \hat{\beta} \), and this is the statistic for the Cochran–Armitage test.

However, the standard error of the statistic \( \hat{\beta} \) for the Cochran–Armitage test has a different formulation than that of the standard error from OLS regression—although they are the same asymptotically. The standard error \( se(\hat{\beta}) \) for the Cochran–Armitage statistic is based on decomposing the Pearson statistic for independence.

The Pearson statistic \( X_{\text{ind}}^2 \) for independence can be written as

\[
X_{\text{ind}}^2 = z^2 + X_{\text{DL}}^2
\]

where \( z = \hat{\beta}/se(\hat{\beta}) \) is the \( z \) score for the Cochran–Armitage test and \( X_{\text{DL}}^2 \) is a statistic for departure from the linear trend. Asymptotically, \( z \) has a standard normal distribution, and \( X_{\text{DL}}^2 \) has a \( \chi^2 \) distribution with \( I - 2 \) degrees of freedom, where \( I \) is the number of ordered categories. See **Cochran–Armitage test for trend** in Methods and formulas below.

This is one of the advantages of performing the Cochran–Armitage test. We get not only a test for trend but also a test for departure from this trend. Let’s be clear about what we mean when we say “departure from this trend”. The Pearson statistic for independence is decomposed into two pieces. Either piece being large means that the test for independence is rejected. The linear piece \( z^2 \) being large means there is a linear trend that rejects independence. The departure piece \( X_{\text{DL}}^2 \) being large means there are differences other than the linear trend that reject independence.
We should also be clear about what we mean when we say “linear trend”. Linear trend means whatever trend is given by the group scores $g_i$, which do not have to be 1, 2, 3, . . . . They could be, for instance, 1, 3, 10, 12, . . . . It is linear in the scores but not necessarily linear by the ordering of the groups.

When the exact option is specified, a $p$-value from the permutation test of the null hypothesis $\beta = 0$ is reported.

Example 1

We have fictional data from a clinical trial of a new drug for treating migraines. The variable dose contains the dose of the drug given to a subject. The variable relief is 0/1 with 0 indicating no relief of the migraine and 1 indicating partial or total relief. Here is a tabulation of the data:

```stata
use https://www.stata-press.com/data/r18/migraine
(tabulate dose relief, row nokey)

<table>
<thead>
<tr>
<th>Mycureit dose in mg</th>
<th>Relief of migraine after 2 hours</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>80</td>
<td>120</td>
</tr>
<tr>
<td></td>
<td>40.00</td>
<td>60.00</td>
</tr>
<tr>
<td>20</td>
<td>92</td>
<td>108</td>
</tr>
<tr>
<td></td>
<td>46.00</td>
<td>54.00</td>
</tr>
<tr>
<td>30</td>
<td>83</td>
<td>117</td>
</tr>
<tr>
<td></td>
<td>41.50</td>
<td>58.50</td>
</tr>
<tr>
<td>40</td>
<td>63</td>
<td>137</td>
</tr>
<tr>
<td></td>
<td>31.50</td>
<td>68.50</td>
</tr>
<tr>
<td>Total</td>
<td>318</td>
<td>482</td>
</tr>
<tr>
<td></td>
<td>39.75</td>
<td>60.25</td>
</tr>
</tbody>
</table>
```
There appears to be a trend of more subjects reporting relief at the higher doses. Let’s calculate the Cochran–Armitage test for trend:

```
. nptrend relief, group(dose) carmitage
```

**Cochran–Armitage test for trend**

- Number of observations = 800
- Number of groups = 4
- Number of response levels = 2

<table>
<thead>

</tr>
</tbody>
</table>

Statistic = .003
Std. err. = .0015476
z = 1.939
Prob > |z| = 0.0526

Test of departure from trend:

- chi2(2) = 5.45
- Prob > chi2 = 0.0656

The asymptotic $p$-value for the test of a linear trend is 0.0526. The $p$-value for the test of departure from linearity is 0.0656.
The $p$-value for the test of a linear trend is close to 0.05. Rather than report the asymptotic $p$-value, we may want to report an exact $p$-value. We run `nptrend` again, this time specifying the `exact` option.

```
. nptrend relief, group(dose) carmitage exact
```

Cochran-Armitage test for trend

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>chi2(2)</td>
<td></td>
</tr>
<tr>
<td>Prob &gt; chi2</td>
<td>0.0656</td>
</tr>
</tbody>
</table>

The exact $p$-value reported is 0.0576, larger than the asymptotic $p$-value of 0.0526. The exact $p$-value comes from a permutation test performed by computing 10,000 random permutations. This means that there is some random error associated with the reported exact $p$-value.

To see the Monte Carlo error in the exact $p$-value, we can use the `show` suboption of `exact`, which displays the full output of `permute`. The option we specify is

```
exact(montecarlo, show reps(100000) dots(1000) rseed(1234))
```

We increase the number of random permutations to 100,000. `dots(1000)` displays a dot after every 1,000th permutation rather than the default of every 100th. `rseed(1234)` sets the random-number seed so we can reproduce our result. We did not set the random-number seed when we ran `nptrend ... exact` earlier. If we were to run that again, we would get a different value for the exact $p$-value. Here are the results with `exact()` specified this new way:
. nptrend relief, group(dose) carmitage
> exact(montecarlo, show reps(100000) dots(1000) rseed(1234))

Monte Carlo permutation results

</tbody>
</table>

Statistic = .003
Std. err. = .0015476
z = 1.939
Prob > |z| = 0.0526
Exact prob = 0.0592 (100,000 Monte Carlo permutations)

Test of departure from trend:

chi2(2) = 5.45
Prob > chi2 = 0.0656

The reported exact p-value from this specification is 0.0592, and we see from the table reported by `permute` that the Monte Carlo 95% confidence interval for it is [0.0577, 0.0606]. Clearly, the asymptotic p-value 0.0526 is a bit anticonservative. If we were going to publish the result, we might want to run the command again with even more permutations, perhaps 1,000,000 or more, to narrow the width of the confidence level to less than 0.001. With only 800 observations in these data, the Monte Carlo permutations are computed quickly.
Example 2

We continue with the previous example to illustrate the use of the `scoregroup()` option. When we tested the linear trend of dose, we got a p-value of 0.0656 for the departure from linearity. So maybe the trend is not linear. Let’s test a quadratic trend.

To use the `scoregroup()` option, the variable in `group()` must be 1, 2, …. The variable dose is 10, 20, 30, 40. We can convert it to 1, 2, 3, 4 in several ways. Here we use the `egen group()` function because this works in general.

```stata
. egen idose = group(dose)
. tabulate idose
```

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>200</td>
<td>25.00</td>
<td>25.00</td>
</tr>
<tr>
<td>2</td>
<td>200</td>
<td>25.00</td>
<td>50.00</td>
</tr>
<tr>
<td>3</td>
<td>200</td>
<td>25.00</td>
<td>75.00</td>
</tr>
<tr>
<td>4</td>
<td>200</td>
<td>25.00</td>
<td>100.00</td>
</tr>
<tr>
<td>Total</td>
<td>800</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>

Now, we specify `scoregroup(1 4 9 16)` to test a quadratic trend.

```stata
. nptrend relief, group(idose) carmitage scoregroup(1 4 9 16)
```

Cochran-Armitage test for trend

- Number of observations = 800
- Number of groups = 4
- Number of response levels = 2

<table>
<thead>
<tr>
<th>Group</th>
<th>Group score</th>
<th>Mean response score</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>idose</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>.6</td>
<td>200</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>.54</td>
<td>200</td>
</tr>
<tr>
<td>3</td>
<td>9</td>
<td>.585</td>
<td>200</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>.685</td>
<td>200</td>
</tr>
</tbody>
</table>

Statistic = .0070543
Std. err. = .0030468
z = 2.315
Prob > |z| = 0.0206

Test of departure from trend:
- chi2(2) = 3.85
- Prob > chi2 = 0.1462

Of course, we could have just typed `generate dose2 = dose^2` and used this variable for `group()` to test the quadratic trend.

The p-value for the quadratic trend is 0.0206, and the departure p-value is 0.1462. The p-value for the linear trend was 0.0526. So it appears the relationship between dose and relief is closer to quadratic than linear. But should we be using `nptrend` to search for the trend with the smallest p-value? Surely, `logit` is the tool for that!
. generate dose2 = dose^2
. logit relief dose dose2
Iteration 0:  Log likelihood = -537.58798
Iteration 1:  Log likelihood = -532.96973
Iteration 2:  Log likelihood = -532.96346
Iteration 3:  Log likelihood = -532.96346
Logistic regression  Number of obs = 800
LR chi2(2) = 9.25
Prob > chi2 = 0.0098
Log likelihood = -532.96346  Pseudo R2 = 0.0086

relief  Coefficient Std. err.  z  P>|z|  [95% conf. interval]
dose  -.0720094  .0367396  -1.96  0.050  -.1440177   -1.19e-06
dose2  .0017005  .0007276   2.34  0.019   .0002744   .0031266
_cons  .946503  .4021702   2.35  0.019   .1582638   1.734742

To be clear, we are not recommending a model such as this for these data. There are only four doses, and this logit model fits three of the four degrees of freedom. The purpose of the Cochran–Armitage test is to test a single hypothesized trend and report an honest p-value for it. If we want to test for a trend but do not have any idea what the trend might be, we may be better off using the Jonckheere–Terpstra test.

### Jonckheere–Terpstra test

The Jonckheere–Terpstra test is useful when it is not clear what the trend might be and we simply want to test for any trend. That is, it tests whether the ordering of the groups is associated with the ordering of the responses. The test is typically used when there are many response levels and any number of groups.

Suppose there are \( J \geq 2 \) ordered groups. Let \( y_{jk} \) be the \( k \)th response in the \( j \)th group, where \( k = 1, 2, \ldots, n_j \). The responses \( y_{jk} \) are given by \( 
\text{varname} \) (the variable specified immediately after \( \text{nptrend} \)) or by \( 
\text{varname} \) mapped to the values of \( \text{scoreresponse}() \).

For groups \( j \) and \( j' \), where \( j < j' \), consider the \( n_j n_{j'} \) pairs

\[(y_{jk}, y_{j'k'})\]

Let \( C_{jj'} \) be the number of pairs such that \( y_{jk} < y_{j'k'} \) and \( D_{jj'} \) be the number of pairs such that \( y_{jk} > y_{j'k'} \). The Jonckheere–Terpstra statistic is

\[T = \sum_{j < j'} (C_{jj'} - D_{jj'})\]

In other words, count the number of response pairs, \( C_{jj'} \), where the group \( j \) response is less than the group \( j' \) response. That is, pairs in which the ordering of the responses is concordant with the ordering of the groups. Subtract from this the number of discordant pairs, \( D_{jj'} \). Then, sum over the \( J(J-1)/2 \) combinations of selecting two of the \( J \) groups, where group \( j \) is ordered before group \( j' \).

Clearly, only the ordering of responses matters relative to the ordering of the groups. There is no need to hypothesize what the trend is.
Kendall’s $\tau$ (see [R] `spearman`) also uses only relative differences, and the Jonckheere–Terpstra test can be viewed as a generalization of Kendall’s $\tau$ for groups of unequal sizes. See *Jonckheere–Terpstra test for trend* in *Methods and formulas* below.

### Example 3

The following data (Altman 1991, 217) show ocular exposure to ultraviolet radiation for 32 pairs of sunglasses classified into 3 groups according to the amount of visible light transmitted.

<table>
<thead>
<tr>
<th>Transmission of visible light</th>
<th>Ocular exposure to ultraviolet radiation</th>
</tr>
</thead>
<tbody>
<tr>
<td>$1$ &lt; 25%</td>
<td>1.4 1.4 1.4 1.6 2.3 2.5</td>
</tr>
<tr>
<td>2 25% to 35%</td>
<td>0.9 1.0 1.1 1.1 1.2 1.5 1.9 2.2 2.6 2.6</td>
</tr>
<tr>
<td>3 &gt; 35%</td>
<td>0.8 1.7 1.7 1.7 3.4 7.1 8.9 13.5</td>
</tr>
</tbody>
</table>

Entering these data into Stata, we have

```stata
use https://www.stata-press.com/data/r18/sg, clear
list, separator(6)
group exposure
1. < 25% 1.4
2. < 25% 1.4
3. < 25% 1.4
4. < 25% 1.6
5. < 25% 2.3
6. < 25% 2.5
7. 25% to 35% .9
8. 25% to 35% 1
31. > 35% 8.9
32. > 35% 13.5
```

We can now use `nptrend` to report the Jonckheere–Terpstra test results.

```stata
nptrend exposure, group(group) jterpstra
```

#### Jonckheere-Terpstra test for trend

<table>
<thead>
<tr>
<th>Mean response score</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group score</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Group</th>
<th>Group score</th>
<th>Mean response score</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 25%</td>
<td>1</td>
<td>1.766667</td>
<td>6</td>
</tr>
<tr>
<td>25% to 35%</td>
<td>2</td>
<td>2.311111</td>
<td>18</td>
</tr>
<tr>
<td>&gt; 35%</td>
<td>3</td>
<td>4.85</td>
<td>8</td>
</tr>
</tbody>
</table>

Statistic = 82
Std. err. = 54.80056
z = 1.496
Prob > |z| = 0.1346
The approximate $p$-value is 0.1346. This $p$-value is an approximation to the permutation test $p$-value. That is, it comes from a $z$ statistic that uses the exact variance of the permutation distribution. With only 32 observations, it seems better to simply compute the exact $p$-value using Monte Carlo permutations.

```plaintext
.set seed 1234
.nptrend exposure, group(group) jterpstra exact
Permutations (10,000): ..........1,000..........2,000..........3,000..........4,000
> ..........5,000..........6,000..........7,000..........8,000..........9,000.......> ..10,000 done

Jonckheere-Terpstra test for trend
Number of observations = 32
Number of groups = 3
Number of response levels = 23

<table>
<thead>
<tr>
<th>Group</th>
<th>Group score</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 25%</td>
<td>1</td>
<td>6</td>
</tr>
<tr>
<td>25% to 35%</td>
<td>2</td>
<td>18</td>
</tr>
<tr>
<td>&gt; 35%</td>
<td>3</td>
<td>8</td>
</tr>
</tbody>
</table>

Statistic = 82
Std. err. = 54.80056
z = 1.496
Prob > |z| = 0.1346
Exact prob = 0.1378 (10,000 Monte Carlo permutations)

Despite the small number of observations, the Monte Carlo exact $p$-value 0.1378 is close to the approximate $p$-value 0.1346. Because of the small number of observations, we might be tempted to try the exact(enumerate) option. We do so.

```plaintext
.nptrend exposure, group(group) jterpstra exact(enumerate, dots(1000))
(enumerating all 1.42e+12 possible permutations)
Permutations (1,415,721,106,800): ..........10,000.....—Break—
r(1);
```

`nptrend` calls `permute` to do the enumeration, and `permute` tells us there are $1.42 \times 10^{12}$ possible permutations. Because we do not want to wait years for the result, we pressed `Break`.

Let’s randomly cut the dataset in half, from 32 observations to 16.

```plaintext
.set seed 25
.generate r = runiform()
.sort r
.keep in 1/16
(16 observations deleted)
.tabulate group
```

| Transmissio |
|------------|------------|------------|
| n of      |
| visible   |
| light     |
| Freq.     | Percent    | Cum.       |
| < 25%     | 2          | 12.50      | 12.50      |
| 25% to 35%| 9          | 56.25      | 68.75      |
| > 35%     | 5          | 31.25      | 100.00     |

Total | 16         | 100.00     |
Then, let’s do the enumeration for these data:

```
.nptrend exposure, group(group) jterpstra exact(enumerate, dots(1000))
```

(enumerating all 240,240 possible permutations)

Permutations (240,240): ........10,000.........20,000.........30,000.........4
> 0,000.........50,000.........60,000.........70,000.........80,000.........90,
> 000.........100,000.........110,000.........120,000.........130,000.........1
> 40,000.........150,000.........160,000.........170,000.........180,000.....
> ....190,000.........200,000.........210,000.........220,000.........230,000....
> ....240,000. done

Jonckheere–Terpstra test for trend

<table>
<thead>
<tr>
<th>Group</th>
<th>Group score</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 25%</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>25% to 35%</td>
<td>2</td>
<td>9</td>
</tr>
<tr>
<td>&gt; 35%</td>
<td>3</td>
<td>5</td>
</tr>
</tbody>
</table>

Mean response
Number of response levels = 15

<table>
<thead>
<tr>
<th>Group</th>
<th>Group score</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 25%</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>25% to 35%</td>
<td>2</td>
<td>9</td>
</tr>
<tr>
<td>&gt; 35%</td>
<td>3</td>
<td>5</td>
</tr>
</tbody>
</table>

Statistic = 49
Std. err. = 19.57188
z = 2.504
Prob > |z| = 0.0123
Exact prob = 0.0103 (enumerated all 240,240 permutations)

There are only 240,240 possible permutations now, and the computation takes little time. Despite there being only 16 observations, the exact p-value (without any error) 0.0103 is close to the approximate p-value 0.0123. Enumeration works quite well for tiny datasets such as this.

---

**Linear-by-linear trend test**

The linear-by-linear trend test is an alternative to the Jonckheere–Terpstra test. The difference is that the linear-by-linear trend test uses response scores to specify the trend being tested. How the trend is hypothesized to vary across groups is specified by the group scores. The linear-by-linear trend test could be described as a parametric specification for trend that is tested nonparametrically!

If scores are not specified in the options, then the values of the response `varname` are used as response scores, and the values of `groupvar` are used as group scores.

The linear-by-linear statistic is

\[
T = \frac{1}{N} \sum_{i=1}^{I} \sum_{j=1}^{J} n_{ij}(g_j - \bar{g})(r_i - \bar{r})
\]

where \( N \) is the total number of observations, \( g_j \) is the group score for the \( j \)th group, \( \bar{g} \) is the mean group score over all observations, \( r_i \) is the response score for the \( i \)th ordered response, and \( \bar{r} \) is the mean response score over all observations.
The linear-by-linear statistic is equivalent to the Pearson correlation coefficient (see [R] correlate), the difference being that the Pearson correlation coefficient is standardized by the standard deviations of the scores. The $p$-values are slightly different because the $p$-value for the linear-by-linear test is based on its permutation distribution while the $p$-value for the Pearson correlation coefficient assumes normality.

Clearly, the statistic depends on the numerical values of both the response scores and the group scores. Different scores, even ones that give the same ordering, will produce different values of the statistic.

### Example 4

We again use the sunglasses data from example 3, where we did the Jonckheere–Terpstra test.

```stata
use https://www.stata-press.com/data/r18/sg, clear
(Ultraviolet radiation exposure with sunglasses)
```

We calculate the linear-by-linear trend test for these data.

```stata
.nptrend exposure, group(group) linear
```

<table>
<thead>
<tr>
<th>Group</th>
<th>Group score</th>
<th>Mean response score</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 25%</td>
<td>1</td>
<td>1.766667</td>
<td>6</td>
</tr>
<tr>
<td>25% to 35%</td>
<td>2</td>
<td>2.311111</td>
<td>18</td>
</tr>
<tr>
<td>&gt; 35%</td>
<td>3</td>
<td>4.85</td>
<td>8</td>
</tr>
</tbody>
</table>

Statistic $= .7035156$
Std. err. $= .3063377$
$z = 2.297$
Prob $> |z| = 0.0216$

The approximate $p$-value is 0.0216, which is much smaller than the Jonckheere–Terpstra test approximate $p$-value 0.1346. Such a difference is not surprising. The linear-by-linear trend test uses the actual values of the response in the statistic. The values of the response seem to follow a linear trend by group, and when this is true, one generally expects the $p$-value from the linear-by-linear trend test to be smaller than the $p$-value from the Jonckheere–Terpstra test.
Again, we might want to compute the exact $p$-value using Monte Carlo permutations.

```
. nptrend exposure, group(group) linear
> exact(montecarlo, reps(100000) dots(1000) rseed(1234))
```

Permutations (100,000): 
. . . . . 10,000 . . . . . 20,000 . . . . . 30,000 . . . . . 4
> 0,000 . . . . . 50,000 . . . . . 60,000 . . . . . 70,000 . . . . . 80,000 . . . . . 90,
> 000 . . . . . 100,000 done

Linear-by-linear test for trend

<table>
<thead>
<tr>
<th>Group</th>
<th>Number of observations</th>
<th>Number of groups</th>
<th>Number of response levels</th>
<th>Group score</th>
<th>Mean response score</th>
<th>Number of obs</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 25%</td>
<td>32</td>
<td>3</td>
<td>23</td>
<td>1</td>
<td>1.766667</td>
<td>6</td>
</tr>
<tr>
<td>25% to 35%</td>
<td>32</td>
<td>3</td>
<td>23</td>
<td>2</td>
<td>2.311111</td>
<td>18</td>
</tr>
<tr>
<td>&gt; 35%</td>
<td>32</td>
<td>3</td>
<td>23</td>
<td>3</td>
<td>4.85</td>
<td>8</td>
</tr>
</tbody>
</table>

Statistic = .7035156
Std. err. = .3063377
$z = 2.297$
Prob > $|z| = 0.0216$
Exact prob = 0.0146 (100,000 Monte Carlo permutations)

In this case, the exact $p$-value 0.0146 is smaller than the approximate $p$-value 0.0216.

**Cuzick’s test**

Cuzick’s test (Cuzick 1985) is an extension of the Kruskal–Wallis test (see [R] kwallis) for ordered groups. The response scores are ranked, the sum of the ranks is calculated for each group, and then these sums of ranks are weighted by the deviation of the group scores from their mean.

The statistic for Cuzick’s test is

$$T = \frac{1}{N} \sum_{j=1}^{J} (g_j - \bar{g})R_j$$

where $N$ is the total number of observations, $g_j$ is the group score for the $j$th group, $\bar{g}$ is the mean group score over all observations, and $R_j$ is the sum of the ranks of the response scores in the $j$th group.

The form of the statistic is similar to that of the statistic for the linear-by-linear test, but instead of using response scores being used directly, the ranks of the response scores are used. So only the ordering of the response scores matters. The numerical values of the group scores, however, are used in the calculation, so different group scores will give different values of the statistic.
Example 5

We continue with the sunglasses data from example 4. We now calculate Cuzick’s test, calculating the exact \( p \)-value as well.

```
. nptrend exposure, group(group) cuzick
  > exact(montecarlo, reps(100000) dots(1000) rseed(1234))
```

```
Permutations (100,000): ............10,000..........20,000..........30,000..........4
> 0,000..........50,000..........60,000..........70,000..........80,000..........90,
> 000..........100,000 done
```

Cuzick’s test with rank scores

<table>

Statistic = 1.65625
Std. err. = 1.090461
\( z = 1.519 \)
Prob > |z| = 0.1288
Exact prob = 0.1322 (100,000 Monte Carlo permutations)

The approximate \( p \)-value 0.1288 is close to the exact \( p \)-value 0.1322. These results are also close to the results from the Jonckheere–Terpstra test, where the approximate \( p \)-value was 0.1346. This is not surprising because using ranks of the responses in Cuzick’s test is likely to be similar to the comparisons of orderings in the Jonckheere–Terpstra test. The latter test is better known than Cuzick’s test, so for this reason alone, it may be preferable to use the Jonckheere–Terpstra test when reporting results.

Methods and formulas

Methods and formulas are presented under the following headings:

Overview
Cochran–Armitage test for trend
Jonckheere–Terpstra test for trend
Linear-by-linear test for trend
Cuzick’s test with rank scores

Overview

We will use the same notation for all the tests. Let the set of distinct responses be indexed by $i = 1, 2, \ldots, I$. Let the groups be indexed by $j = 1, 2, \ldots, J$.

We call the scores for the responses “response scores” and denote them by $r_i$.

For the Cochran–Armitage test (when the response is 0/1), linear-by-linear trend test, and Cuzick’s test the groups have scores as well. We call these scores “group scores”, and denote them by $g_j$.

All the tests for trend reported by `nptrend` are based on tests of independence between the ordering of the responses (or their scores) and the ordering of the groups (or their scores). Because these are tests of independence, there is no need to hypothesize a direction of causal inference. Responses could be outcomes predicted by group membership, or “groups” could be outcomes predicted by what we are calling “responses”.

Let $n_{ij}$ be the number of observations in the $i$th response category and $j$th group. Let $N = \sum_{ij} n_{ij}$ be the total number of observations. Let $n_{i+} = \sum_j n_{ij}$ be the row margins, and let $n_{+j} = \sum_i n_{ij}$ be the column margins.

Cochran–Armitage test for trend

When `carmitage` is specified, the Cochran–Armitage test is performed (Cochran 1954; Armitage 1955; Agresti 2013). It assesses whether the probability of a positive response is associated with a trend based on ordered groups. Or the specification can be flipped. It can be used to assess whether a trend based on ordered responses is associated with membership in one of two groups.

In these methods, we assume that the response is 0/1—that is, the response is indexed by $i = 0, 1$—and that there are $J$ ordered groups with scores $g_j$. When the specification is flipped, response and group are interchanged in the equations below.
The Cochran–Armitage test is based on a linear probability model for $\theta_j$, the probability of having response $i = 1$ for the subjects in the $j$th group,

$$\theta_j = \alpha + \beta (g_j - \bar{g})$$

where $\alpha$ is the intercept, $\beta$ is the slope, $g_j$ are the group scores, and $\bar{g}$ is the mean of the group scores.

The equation is solved using OLS,

$$\hat{\theta}_j = p + \hat{\beta} (g_j - \bar{g})$$

where $p = (\sum_j n_{1j})/N$ and $\bar{g} = (\sum_j n_{+j}g_j)/N$.

The OLS solution for $\hat{\beta}$ is

$$\hat{\beta} = \frac{\sum_j n_{+j}(p_j - p)(g_j - \bar{g})}{\sum_j n_{+j}(g_j - \bar{g})^2}$$

where $p_j = n_{1j}/n_{+j}$.

The test for independence between groups and responses can be separated into a test for the linear trend and a test for departure from the linear trend. The Pearson statistic for independence

$$X_{\text{Ind}}^2 = \frac{1}{p(1-p)} \sum_{j=1}^J n_{+j}(p_j - p)^2$$

is decomposed as

$$X_{\text{Ind}}^2 = z^2 + X_{\text{DL}}^2$$

where

$$z^2 = \frac{\hat{\beta}^2}{p(1-p)} \sum_{j=1}^J n_{+j}(g_j - \bar{g})^2$$

and

$$X_{\text{DL}}^2 = \frac{1}{p(1-p)} \sum_{j=1}^J n_{+j}(p_j - \hat{\theta}_j)^2$$

$z$ is the $z$ statistic for the linear trend, and $X_{\text{DL}}^2$ is the statistic for departure from a linear trend. Asymptotically, $z$ has a standard normal distribution, and $X_{\text{DL}}^2$ has a $\chi^2$ distribution with $J - 2$ degrees of freedom.

**Jonckheere–Terpstra test for trend**

When `jterpstra` is specified, the Jonckheere–Terpstra test is performed (Terpstra 1952; Jonckheere 1954). The Jonckheere–Terpstra test is a test of whether the hypothesized ordering of the responses is associated with the hypothesized ordering of the groups. Typically, this test is used when there are only a few groups but many response categories or even continuous responses.

Only the ordering of the responses and groups matter. The numerical values of the scores do not matter, but scores can be specified to change the ordering.
Let \( y_{jk} \) be the \( k \)th response in the \( j \)th group, where \( k = 1, 2, \ldots, n+j \). If the response falls in the \( i \)th response category, then \( y_{jk} = r_i \), the response score for the \( i \)th category.

For groups \( j \) and \( j' \), where \( j < j' \), consider the pairs \((y_{jk}, y_{j'k'})\) where \( k = 1, 2, \ldots, n+j \) and \( k' = 1, 2, \ldots, n+j' \). A total of \( n+jn+j' \) pairs are formed for these two groups.

Let \( C_{jj'} \) be the number of pairs such that \( y_{jk} < y_{j'k'} \), that is, pairs in which the response ordering is concordant with the group ordering. Let \( D_{jj'} \) be the number of discordant pairs with \( y_{jk} > y_{j'k'} \). The Jonckheere–Terpstra statistic is

\[
T = \sum_{j=1}^{J-1} \sum_{j'=j+1}^{J} (C_{jj'} - D_{jj'})
\]

The Jonckheere–Terpstra statistic is sometimes expressed as sums over \( C_{jj'} + E_{jj'}/2 \), where \( E_{jj'} \) is the number of tied pairs with \( y_{jk} = y_{j'k'} \). Because \( C_{jj'} + D_{jj'} + E_{jj'} = n+jn+j' \), the statistic \( T \) is twice the statistic based on \( C_{jj'} + E_{jj'}/2 \) minus a constant. The advantage of the formulation using \( C_{jj'} - D_{jj'} \) is that under the null hypothesis of independence between groups and responses, its expectation is zero. When \( T \) is positive, the observed trend is a positive trend between the group ordering and the response ordering, and when \( T \) is negative, it is a negative trend.

The variance of \( T \) can be computed exactly based on the permutation distribution of responses where the table margins \( n_i+j \) and \( n+1+j \) are fixed and each permutation is considered equally likely under the null hypothesis. The formula, however, is complicated when there are ties.

Let \( M \) be the number of distinct values in the responses. Let \( e_m \) be the multiplicity of the \( m \)th distinct response value. That is, the \( N \) observations \( y_{jk} \) consist of \( e_1 \) observations with value \( z_1 \), \( e_2 \) observations with value \( z_2 \), etc., with \( \sum_m e_m = N \). The variance of \( T \) under the null permutation distribution is exactly

\[
\text{Var}(T) = \frac{1}{18} \left[ N(N-1)(2N+5) - \sum_{j=1}^{J} n+j(n+_j-1)(2n+j+5) \right. \\
- \sum_{m=1}^{M} e_m(e_m-1)(2e_m+5) \\
+ \frac{1}{2N(N-1)} \left\{ \sum_{j=1}^{J} n+j(n+_j-1) \right\} \left\{ \sum_{m=1}^{M} e_m(e_m-1) \right\} \\
+ \frac{1}{9N(N-1)(N-2)} \left\{ \sum_{j=1}^{J} n+j(n+_j-1)(n+_j-2) \right\} \cdot \left\{ \sum_{m=1}^{M} e_m(e_m-1)(e_m-2) \right\}
\]

The approximate \( p \)-value is based on a normal approximation using the exact variance of \( T \).
Linear-by-linear test for trend

When linear is specified, the linear-by-linear trend test is calculated based on the statistic

\[ T = \frac{1}{N} \sum_{i=1}^{I} \sum_{j=1}^{J} n_{ij} (g_j - \bar{g})(r_i - \bar{r}) \]

where \( g_j \) is the group score for the \( j \)th group, \( \bar{g} = (\sum_j n_{+,j} g_j)/N \) is the mean group score over all observations, \( r_i \) is the response score for the \( i \)th ordered response, and \( \bar{r} = (\sum_i n_{+,i} r_i)/N \) is the mean response score over all observations.

Under the null hypothesis of independence between groups and responses, the expectation of \( T \) is zero. The variance of \( T \) is based on the permutation distribution of responses where the table margins \( n_{+,i} \) and \( n_{+,j} \) are fixed and each permutation is considered equally likely under the null hypothesis. The variance of \( T \) is exactly

\[
\text{Var}(T) = \frac{1}{N^2(N-1)} \left\{ \sum_{j=1}^{J} n_{+,j} (g_j - \bar{g})^2 \right\} \left\{ \sum_{i=1}^{I} n_{+,i} (r_i - \bar{r})^2 \right\}
\]

The approximate \( p \)-value is based on a normal approximation using the exact variance of \( T \).

Note the symmetry between the group and response scores in these equations. In the linear-by-linear test for trend, it is arbitrary as to what is a group with a group score and what is a response with a response score. The two are interchangeable.

Cuzick’s test with rank scores

When cuzick is specified, the test for trend is based on a method in Cuzick (1985), which is described in Altman (1991, 215–217).

Rank all \( N \) responses, using average ranks for ties. Let \( R_j \) be the sum of the ranks in the \( j \)th group. The statistic for Cuzick’s test \( T \) is

\[ T = \frac{1}{N} \sum_{j=1}^{J} (g_j - \bar{g}) R_j \]

where \( g_j \) is the group score for the \( j \)th group and \( \bar{g} = (\sum_j n_{+,j} g_j)/N \).

Under the null hypothesis of independence between groups and responses, the expectation of \( T \) is zero. When there are no ties, the variance of \( T \) is

\[
\text{Var}(T) = \frac{N + 1}{12N} \sum_{j=1}^{J} n_{+,j} (g_j - \bar{g})^2
\]

When there are ties, we again let \( e_m \) be the multiplicity of the \( m \)th distinct response value, \( m = 1, 2, \ldots, M \). Define

\[ a = \frac{1}{N(N^2 - 1)} \sum_{m=1}^{M} e_m (e_m^2 - 1) \]

The corrected variance of \( T \) when there are ties is

\[ \widetilde{\text{Var}}(T) = (1 - a) \text{Var}(T) \]
Exact p-values

Exact p-values are computed by `permute`. The variable permuted is that specified by `group()`, except for `carmitage` when the response variable is 0/1; in this case, the response variable is permuted. For details on the permutation computation, see [R] `permute`.

ologit — Ordered logistic regression

Description

ologit fits ordered logit models of ordinal variable depvar on the independent variables indepvars. The actual values taken on by the dependent variable are irrelevant, except that larger values are assumed to correspond to “higher” outcomes.

Quick start

Ordinal logit model of y on x1 and categorical variables a and b

ologit y x1 i.a i.b

Same as above, and include interaction between a and b and report results as odds ratios

ologit y x1 a##b, or

With bootstrap standard errors

ologit y x1 i.a i.b, vce(bootstrap)

Analysis restricted to cases where catvar = 0 using svyset data with replicate weights

svy bootstrap, subpop(if catvar==0): ologit y x1 i.a i.b

Options
- depvar may contain factor variables; see [U] 11.4.3 Factor variables.
- indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
- bayes, bootstrap, by, fmm, fp, jackknife, mfp, mi estimate, nestreg, rolling, statsby, stepwise, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: ologit and [FMM] fmm: ologit.
- vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
- Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
- vce() and weights are not allowed with the svy prefix; see [SVY] svy.
- fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
- collinear and coeflegend do not appear in the dialog box.
- See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options
- Model
  - offset(varname), constraints(constraints); see [R] Estimation options.
- SE/Robust
  - vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.
Reporting

level(#); see [R] Estimation options.

or reports the estimated coefficients transformed to odds ratios, that is, $e^b$ rather than $b$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. or may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

The following options are available with ologit but are not shown in the dialog box: collinear, coeflegend; see [R] Estimation options.

Remarks and examples

Ordered logit models are used to estimate relationships between an ordinal dependent variable and a set of independent variables. An ordinal variable is a variable that is categorical and ordered, for instance, “poor”, “good”, and “excellent”, which might indicate a person’s current health status or the repair record of a car. If there are only two outcomes, see [R] logistic, [R] logit, and [R] probit. This entry is concerned only with models in which the outcomes can be ordered.

In ordered logit, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome $i$ corresponds to the probability that the estimated linear function, plus random error, is within the range of the cutpoints estimated for the outcome:

$$\Pr(\text{outcome}_j = i) = \Pr(\kappa_{i-1} < \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + u_j \leq \kappa_i)$$

$u_j$ is assumed to be logistically distributed in ordered logit. In either case, we estimate the coefficients $\beta_1, \beta_2, \ldots, \beta_k$ together with the cutpoints $\kappa_1, \kappa_2, \ldots, \kappa_{k-1}$, where $k$ is the number of possible outcomes. $\kappa_0$ is taken as $-\infty$, and $\kappa_k$ is taken as $+\infty$. All of this is a direct generalization of the ordinary two-outcome logit model.

Example 1

We wish to analyze the 1977 repair records of 66 foreign and domestic cars. The data are a variation of the automobile dataset described in [U] 1.2.2 Example datasets. The 1977 repair records, like those in 1978, take on values “Poor”, “Fair”, “Average”, “Good”, and “Excellent”. Here is a cross-tabulation of the data:
use https://www.stata-press.com/data/r18/fullauto

Pearson chi2(4) = 13.8619 Pr = 0.008

Although it appears that foreign takes on the values Domestic and Foreign, it is actually a numeric variable taking on the values 0 and 1. Similarly, rep77 takes on the values 1, 2, 3, 4, and 5, corresponding to Poor, Fair, and so on. The more meaningful words appear because we have attached value labels to the data; see [U] 12.6.3 Value labels.

Because the χ² value is significant, we could claim that there is a relationship between foreign and rep77. Literally, however, we can only claim that the distributions are different; the χ² test is not directional. One way to model these data is to model the categorization that took place when the data were created. Cars have a true frequency of repair, which we will assume is given by \( S_j = \beta \text{foreign}_j + u_j \), and a car is categorized as “poor” if \( S_j \leq \kappa_0 \), as “fair” if \( \kappa_0 < S_j \leq \kappa_1 \), and so on:

. ologit rep77 foreign
Iteration 0: Log likelihood = -89.895098
Iteration 1: Log likelihood = -85.951765
Iteration 2: Log likelihood = -85.908227
Iteration 3: Log likelihood = -85.908161
Iteration 4: Log likelihood = -85.908161

Ordered logistic regression
Number of obs = 66
LR chi2(1) = 7.97
Prob > chi2 = 0.0047
Log likelihood = -85.908161
Pseudo R2 = 0.0444

| rep77 | Coefficient | Std. err. | z     | P>|z| | [95% conf. interval] |
|-------|-------------|-----------|-------|------|---------------------|
| foreign | 1.455878    | .5308951  | 2.74  | 0.006| 0.4153425 2.496413  |
| /cut1  | -2.765562   | .5988208  | 2.74  | 0.006| -3.939229 -1.591895 |
| /cut2  | -.9963603   | .3217706  | -1.627019 | -3.657016 |
| /cut3  | .9426153    | .3136398  | .3278925 | 1.557338  |
| /cut4  | 3.123351    | .5423257  | 2.060412 | 4.18629 |

Our model is \( S_j = 1.46 \text{foreign}_j + u_j \); the expected value for foreign cars is 1.46 and, for domestic cars, 0; foreign cars have better repair records.

The estimated cutpoints tell us how to interpret the score. For a foreign car, the probability of a poor record is the probability that \( 1.46 + u_j \leq -2.77 \), or equivalently, \( u_j \leq -4.23 \). Making this calculation requires familiarity with the logistic distribution: the probability is \( 1/(1 + e^{-4.23}) = 0.014 \). On the other hand, for domestic cars, the probability of a poor record is the probability \( u_j \leq -2.77 \), which is 0.059.
This, it seems to us, is a far more reasonable prediction than we would have made based on the table alone. The table showed that 2 of 45 domestic cars had poor records, whereas 1 of 21 foreign cars had poor records—corresponding to probabilities \( \frac{2}{45} = 0.044 \) and \( \frac{1}{21} = 0.048 \). The predictions from our model imposed a smoothness assumption—foreign cars should not, overall, have better repair records without the difference revealing itself in each category. In our data, the fractions of foreign and domestic cars in the poor category are virtually identical only because of the randomness associated with small samples.

Thus if we were asked to predict the true fractions of foreign and domestic cars that would be classified in the various categories, we would choose the numbers implied by the ordered logit model:

</table>

See [R] `ologit postestimation` for a more complete explanation of how to generate predictions from an ordered logit model.

Technical note

Here ordered logit provides an alternative to ordinary two-outcome logistic models with an arbitrary dichotomization, which might otherwise have been tempting. We could, for instance, have summarized these data by converting the five-outcome `rep77` variable to a two-outcome variable, combining cars in the average, fair, and poor categories to make one outcome and combining cars in the good and excellent categories to make the second.

Another even less appealing alternative would have been to use ordinary regression, arbitrarily labeling “excellent” as 5, “good” as 4, and so on. The problem is that with different but equally valid labelings (say, 10 for “excellent”), we would obtain different estimates. We would have no way of choosing one metric over another. That assertion is not, however, true of `ologit`. The actual values used to label the categories make no difference other than through the order they imply.

In fact, our labeling was 5 for “excellent”, 4 for “good”, and so on. The words “excellent” and “good” appear in our output because we attached a value label to the variables; see [U] 12.6.3 Value labels. If we were to now go back and type `replace rep77=10 if rep77==5`, changing all the 5s to 10s, we would still obtain the same results when we refit our model.

Example 2

In the example above, we used ordered logit as a way to model a table. We are not, however, limited to including only one explanatory variable or to including only categorical variables. We can explore the relationship of `rep77` with any of the variables in our data. We might, for instance, model `rep77` not only in terms of the origin of manufacture, but also including `length` (a proxy for size) and `mpg`: 
. ologit rep77 foreign length mpg

Iteration 0:  Log likelihood =  -89.895098
Iteration 1:  Log likelihood =  -78.775147
Iteration 2:  Log likelihood =  -78.254294
Iteration 3:  Log likelihood =  -78.250719
Iteration 4:  Log likelihood =  -78.250719

Ordered logistic regression  Number of obs = 66
LR chi2(3) = 23.29
Prob > chi2 = 0.0000
Log likelihood = -78.250719  Pseudo R2 = 0.1295

|            | Coefficient | Std. err. | z     | P>|z|  | [95% conf. interval] |

foreign still plays a role—and an even larger role than previously. We find that larger cars tend to have better repair records, as do cars with better mileage ratings.

Stored results

ologit stores the following in e():

Scalars
- e(N) number of observations
- e(N_cd) number of completely determined observations
- e(k_cat) number of categories
- e(k) number of parameters
- e(k_aux) number of auxiliary parameters
- e(k_eq) number of equations in e(b)
- e(k_eq_model) number of equations in overall model test
- e(k_dv) number of dependent variables
- e(df_m) model degrees of freedom
- e(r2_p) pseudo-R^2
- e(ll) log likelihood
- e(ll_0) log likelihood, constant-only model
- e(N clustering) number of clusters
- e(chi2) \chi^2
- e(p) p-value for model test
- e(rank) rank of e(V)
- e(ic) number of iterations
- e(rc) return code
- e(converged) 1 if converged, 0 otherwise

Macros
- e(cmd) ologit
- e(cmdline) command as typed
- e(depvar) name of dependent variable
- e(wtype) weight type
- e(wexp) weight expression
- e(title) title in estimation output
In addition to the above, the following is stored in \textit{r()}: 

Matrices
\begin{itemize}
  \item \texttt{r(table)}: matrix containing the coefficients with their standard errors, test statistics, \textit{p}-values, and confidence intervals.
\end{itemize}

Note that results stored in \textit{r()} are updated when the command is replayed and will be replaced when any \textit{r}-class command is run after the estimation command.

\section*{Methods and formulas}

See Long and Freese (2014, chap. 7) for a discussion of models for ordinal outcomes and examples that use Stata. Cameron and Trivedi (2005, chap. 15) describe multinomial models, including the model fit by \texttt{ologit}. When you have a qualitative dependent variable, several estimation procedures are available. A popular choice is multinomial logistic regression (see \texttt{mlmlogit}), but if you use this procedure when the response variable is ordinal, you are discarding information because multinomial logistic ignores the ordered aspect of the outcome. Ordered logit and probit models provide a means to exploit the ordering information.

There is more than one “ordered logit” model. The model fit by \texttt{ologit}, which we will call the ordered logit model, is also known as the proportional odds model. Another popular choice, not fit by \texttt{ologit}, is known as the stereotype model; see \texttt{slogit}. All ordered logit models have been derived by starting with a binary logit/probit model and generalizing it to allow for more than two outcomes.

The proportional-odds ordered logit model is so called because, if we consider the odds \texttt{odds}(k) = \texttt{P}(Y \leq k)/\texttt{P}(Y > k), then \texttt{odds}(k_1) and \texttt{odds}(k_2) have the same ratio for all independent variable combinations. The model is based on the principle that the only effect of combining adjoining categories in ordered categorical regression problems should be a loss of efficiency in estimating the regression parameters (McCullagh 1980). This model was also described by McKelvey and Zavoina (1975) and, previously, by Aitchison and Silvey (1957) in a different algebraic form. Brant (1990) offers a set of diagnostics for the model.
Peterson and Harrell (1990) suggest a model that allows nonproportional odds for a subset of the explanatory variables. `ologit` does not allow this, but a model similar to this was implemented by Fu (1998).

The stereotype model rejects the principle on which the ordered logit model is based. Anderson (1984) argues that there are two distinct types of ordered categorical variables: “grouped continuous”, such as income, where the “type a” model applies; and “assessed”, such as extent of pain relief, where the stereotype model applies. Greenland (1985) independently developed the same model. The stereotype model starts with a multinomial logistic regression model and imposes constraints on this model.

Goodness of fit for `ologit` can be evaluated by comparing the likelihood value with that obtained by fitting the model with `mlogit`. Let \( \ln L_1 \) be the log-likelihood value reported by `ologit`, and let \( \ln L_0 \) be the log-likelihood value reported by `mlogit`. If there are \( p \) independent variables (excluding the constant) and \( k \) categories, `mlogit` will estimate \( p(k - 1) \) additional parameters. We can then perform a “likelihood-ratio test”, that is, calculate \(-2(\ln L_1 - \ln L_0)\), and compare it with \( \chi^2\{p(k - 2)\} \). This test is suggestive only because the ordered logit model is not nested within the multinomial logit model. A large value of \(-2(\ln L_1 - \ln L_0)\) should, however, be taken as evidence of poorness of fit. Marginally large values, on the other hand, should not be taken too seriously.

The coefficients and cutpoints are estimated using maximum likelihood as described in \([R]\) \texttt{Maximize}. In our parameterization, no constant appears, because the effect is absorbed into the cutpoints.

`ologit` and `oprobit` begin by tabulating the dependent variable. Category \( i = 1 \) is defined as the minimum value of the variable, \( i = 2 \) as the next ordered value, and so on, for the empirically determined \( k \) categories.

The probability of a given observation for ordered logit is

\[
 p_{ij} = \Pr(y_j = i) = \Pr(\kappa_{i-1} < x_j \beta + u \leq \kappa_i) = \frac{1}{1 + \exp(-\kappa_i + x_j \beta)} - \frac{1}{1 + \exp(-\kappa_{i-1} + x_j \beta)}
\]

\( \kappa_0 \) is defined as \(-\infty\) and \( \kappa_k \) as \(+\infty\).

For ordered probit, the probability of a given observation is

\[
 p_{ij} = \Pr(y_j = i) = \Pr(\kappa_{i-1} < x_j \beta + u \leq \kappa_i) = \Phi(\kappa_i - x_j \beta) - \Phi(\kappa_{i-1} - x_j \beta)
\]

where \( \Phi(\cdot) \) is the standard normal cumulative distribution function.

The log likelihood is

\[
 \ln L = \sum_{j=1}^{N} w_j \sum_{i=1}^{k} I_i(y_j) \ln p_{ij}
\]

where \( w_j \) is an optional weight and

\[
 I_i(y_j) = \begin{cases} 
 1, & \text{if } y_j = i \\
 0, & \text{otherwise}
\end{cases}
\]
ologit and oprobit support the Huber/White/sandwich estimator of the variance and its clustered version using vce(robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.

These commands also support estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic outcome(outcome) nooffset]

predict [type] stub* [if] [in], scores

statistic Description

Main
pr predicted probabilities; the default
xb linear prediction
stdp standard error of the linear prediction

You specify one or k new variables with pr, where k is the number of outcomes. If you specify one new variable and you do not specify outcome(), then outcome(#1) is assumed.

You specify one new variable with xb and stdp.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

pr, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify k new variables, where k is the number of categories of the dependent variable. Alternatively, you can specify stub*; in which case, pr will store predicted probabilities in variables stub1, stub2, ..., stubk. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option outcome(); if you omit outcome(), the first outcome value, outcome(#1), is assumed.

Say that you fit a model by typing estimation cmd y x1 x2, and y takes on four values. Then, you could type predict p1 p2 p3 p4 to obtain all four predicted probabilities; alternatively, you could type predict p* to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type predict p1, outcome(#1) (or simply predict p1), predict p2, outcome(#2), and so on. See option outcome() for other ways to refer to outcome values.

xb calculates the linear prediction. You specify one new variable, for example, predict linear, xb. The linear prediction is defined, ignoring the contribution of the estimated cutpoints.
stdp calculates the standard error of the linear prediction. You specify one new variable, for example, `predict se, stdp`.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is available only with the default `pr` option.

`nooffset` is relevant only if you specified `offset(varname)` for `ologit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $x_j b$ rather than as $x_j b + offset_j$. `nooffset` is not allowed with `scores`.

`scores` calculates equation-level score variables. The number of score variables created will equal the number of outcomes in the model. If the number of outcomes in the model was $k$, then the first new variable will contain $\partial \ln L / \partial (x_j b)$; the second new variable will contain $\partial \ln L / \partial \kappa_1$; the third new variable will contain $\partial \ln L / \partial \kappa_2$; ...

and the $k$-th new variable will contain $\partial \ln L / \partial \kappa_{k-1}$, where $\kappa_i$ refers to the $i$th cutpoint.

**margins**

**Description for margins**

`margins` estimates margins of response for probabilities and linear predictions.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>probabilities for each outcome</td>
</tr>
<tr>
<td>pr</td>
<td>probability for a specified outcome</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

`pr` defaults to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] `margins`. 
Remarks and examples

See [U] 20 Estimation and postestimation commands for instructions on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests. Also see [R] lrtest for performing likelihood-ratio tests.

Example 1

In example 2 of [R] ologit, we fit the model ologit rep77 foreign length mpg. The predict command can be used to obtain the predicted probabilities.

We type predict followed by the names of the new variables to hold the predicted probabilities, ordering the names from low to high. In our data, the lowest outcome is “poor”, and the highest is “excellent”. We have five categories, so we must type five names following predict; the choice of names is up to us:

```stata
use https://www.stata-press.com/data/r18/fullauto
( Automobile models)
. ologit rep77 foreign length mpg
(output omitted)
. predict poor fair avg good exc
(option pr assumed; predicted probabilities)
. list exc good make model rep77 if rep77>=., sep(4) divider
```

<table>
<thead>
<tr>
<th></th>
<th>good</th>

</tr>
<tr>
<td>63.</td>
<td>.0294961</td>
<td>Pont.</td>
<td>Phoenix</td>
<td>.</td>
</tr>
</tbody>
</table>

The eight cars listed were introduced after 1977, so they do not have 1977 repair records in our data. We predicted what their 1977 repair records might have been using the fitted model. We see that, based on its characteristics, the Peugeot 604 had about a 41.65 + 6.53 ≈ 48.2% chance of a good or excellent repair record. The Ford Fiesta, which had only a 3% chance of a good or excellent repair record, in fact, had a good record when it was introduced in the following year.

Technical note

For ordered logit, predict, xb produces $S_j = x_{1j} \beta_1 + x_{2j} \beta_2 + \cdots + x_{kj} \beta_k$. The ordered-logit predictions are then the probability that $S_j + u_j$ lies between a pair of cutpoints, $\kappa_{i−1}$ and $\kappa_i$. Some handy formulas are

\[
\begin{align*}
\Pr(S_j + u_j < \kappa) &= 1/(1 + e^{S_j−\kappa}) \\
\Pr(S_j + u_j > \kappa) &= 1 - 1/(1 + e^{S_j−\kappa}) \\
\Pr(\kappa_1 < S_j + u_j < \kappa_2) &= 1/(1 + e^{S_j−\kappa_2}) - 1/(1 + e^{S_j−\kappa_1})
\end{align*}
\]
Rather than using `predict` directly, we could calculate the predicted probabilities by hand. If we wished to obtain the predicted probability that the repair record is excellent and the probability that it is good, we look back at `ologit`’s output to obtain the cutpoints. We find that “good” corresponds to the interval \( /\text{cut3} < S_j + u < /\text{cut4} \) and “excellent” to the interval \( S_j + u > /\text{cut4} \):

\[
\begin{align*}
\text{. predict score, xb} \\
\text{. generate probgood} &= 1/(1+\exp(score-\_b[/cut4])) - 1/(1+\exp(score-\_b[/cut3])) \\
\text{. generate probexc} &= 1 - 1/(1+\exp(score-\_b[/cut4]))
\end{align*}
\]

The results of our calculation will be the same as those produced in the previous example. We refer to the estimated cutpoints just as we would any coefficient, so \(_b[/cut3] \) refers to the value of the \( /\text{cut3} \) coefficient; see [U] 13.5 Accessing coefficients and standard errors.

[U] 20 Estimation and postestimation commands
The `oneway` command reports one-way analysis-of-variance (ANOVA) models and performs multiple-comparison tests.

If you wish to fit more complicated ANOVA layouts or wish to fit analysis-of-covariance (ANCOVA) models, see `[R] anova`.

See `[D] encode` for examples of fitting ANOVA models on string variables.

See `[R] loneway` for an alternative `oneway` command with slightly different features.

**Quick start**

One-way ANOVA model of y for factor a

```
oneway y a
```

Report the mean and std. dev. of y and number of observations for each level of a

```
oneway y a, tabulate
```

Report all pairwise comparisons of the means of y across levels of a with p-values adjusted using Bonferroni’s procedure

```
oneway y a, bonferroni
```

Same as above, but adjust p-values for multiple comparisons using Scheffé’s method

```
oneway y a, scheffe
```

by and collect are allowed; see [U] 11.1.10 Prefix commands.
aweights and fweights are allowed; see [U] 11.1.6 weight.

Options

`bonferroni` reports the results of a Bonferroni multiple-comparison test.
`scheffe` reports the results of a Scheffé multiple-comparison test.
`sidak` reports the results of a Šidák multiple-comparison test.
`tabulate` produces a table of summary statistics of the `response_var` by levels of the `factor_var`.
The table includes the mean, standard deviation, frequency, and, if the data are weighted, the number of observations. Individual elements of the table may be included or suppressed by using the `no means`, `no standard`, `no freq`, and `no obs` options. For example, typing

```
oneway response factor, tabulate means standard
```
produces a summary table that contains only the means and standard deviations. You could achieve the same result by typing

```
oneway response factor, tabulate nofreq
```
`no means` includes or suppresses only the means from the table produced by the `tabulate` option. See `tabulate` above.
`no standard` includes or suppresses only the standard deviations from the table produced by the `tabulate` option. See `tabulate` above.
`no freq` includes or suppresses only the frequencies from the table produced by the `tabulate` option. See `tabulate` above.
`no obs` includes or suppresses only the reported number of observations from the table produced by the `tabulate` option. If the data are not weighted, only the frequency is reported. If the data are weighted, the frequency refers to the sum of the weights. See `tabulate` above.
noanova suppresses the display of the ANOVA table.

nolabel causes the numeric codes to be displayed rather than the value labels in the ANOVA and multiple-comparison test tables.

wrap requests that Stata not break up wide tables to make them more readable.

missing requests that missing values of factor_var be treated as a category rather than as observations to be omitted from the analysis.

Remarks and examples

Remarks are presented under the following headings:

Introduction
Obtaining observed means
Multiple-comparison tests
Weighted data

Video example

Introduction

The oneway command reports one-way ANOVA models. To perform a one-way layout of a variable called endog on exog, type oneway endog exog.

Example 1

We run an experiment varying the amount of fertilizer used in growing apple trees. We test four concentrations, using each concentration in three groves of 12 trees each. Later in the year, we measure the average weight of the fruit.

If all had gone well, we would have had 3 observations on the average weight for each of the four concentrations. Instead, two of the groves were mistakenly leveled by a confused man on a large bulldozer. We are left with the following dataset:

. use https://www.stata-press.com/data/r18/apple
(Apple trees)
. describe
Contains data from https://www.stata-press.com/data/r18/apple.dta
Observations: 10 Apple trees
Variables: 2 16 Jan 2022 11:23

Variable name Storage type Display format Value label Variable label
--- -------- ---- ------- ------------- -------------
treatment int %8.0g Fertilizer
weight double %10.0g Average weight in grams

Sorted by:
To obtain the one-way ANOVA results, we type

```
. oneway weight treatment
```

<table>
<thead>
<tr>
<th>Source</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Bartlett’s equal-variances test: chi2(3) = 1.3900 Prob>chi2 = 0.708

We find significant (at better than the 1% level) differences among the four concentrations.

---

**Technical note**

Rather than using the `oneway` command, we could have performed this analysis by using `anova`. Example 1 in [R] `anova` repeats this same analysis. You may wish to compare the output.

You will find the `oneway` command quicker than the `anova` command, and, as you will learn, `oneway` allows you to perform multiple-comparison tests. On the other hand, `anova` will let you generate predictions, examine the covariance matrix of the estimators, and perform more general hypothesis tests.

---

**Technical note**

Although the output is a usual ANOVA table, let’s run through it anyway. The between-group sum of squares for the model is 5295.5 with 3 degrees of freedom, resulting in a mean square of 5295.5/3 ≈ 1765.2. The corresponding $F$ statistic is 21.46 and has a significance level of 0.0013. Thus, the model appears to be significant at the 0.13% level.

The second line summarizes the within-group (residual) variation. The within-group sum of squares is 493.59 with 6 degrees of freedom, resulting in a mean squared error of 82.27.

The between- and residual-group variations sum to the total sum of squares (TSS), which is reported as 5789.1 in the last line of the table. This is the TSS of weight after removal of the mean. Similarly, the between plus residual degrees of freedom sum to the total degrees of freedom, 9. Remember that there are 10 observations. Subtracting 1 for the mean, we are left with 9 total degrees of freedom.
At the bottom of the table, Bartlett’s test for equal variances is reported. The value of the statistic is 1.39. The corresponding significance level ($\chi^2$ with 3 degrees of freedom) is 0.708, so we cannot reject the assumption that the variances are homogeneous.

**Obtaining observed means**

> **Example 2**

We typed `oneway weight treatment` to obtain an ANOVA table of weight of fruit by fertilizer concentration. Although we obtained the table, we obtained no information on which fertilizer seems to work the best. If we add the `tabulate` option, we obtain that additional information:

```plaintext
. oneway weight treatment, tabulate

<table>
<thead>
<tr>
<th>Fertilizer</th>
<th>Summary of Average weight in grams</th>
<th></th>
<th></th>

Bartlett’s equal-variances test: $\chi^2(3) = 1.3900$  Prob>$\chi^2 = 0.708$

We find that the average weight was largest when we used fertilizer concentration 1.

**Multiple-comparison tests**

> **Example 3: Bonferroni multiple-comparison test**

`oneway` can also perform multiple-comparison tests using either Bonferroni, Scheffé, or Šidák normalizations. For instance, to obtain the Bonferroni multiple-comparison test, we specify the `bonferroni` option:
oneway weight treatment, bonferroni

<table>
<thead>

Bartlett’s equal-variances test: chi2(3) = 1.3900 Prob>chi2 = 0.708

Comparison of Average weight in grams by Fertilizer (Bonferroni)

<table>
<thead>
<tr>
<th>Row Mean - Col Mean</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>-59.17</td>
<td>0.001</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>-33.25</td>
<td>25.9167</td>
<td>0.042</td>
</tr>
<tr>
<td>4</td>
<td>-34.4</td>
<td>24.7667</td>
<td>-1.15</td>
</tr>
</tbody>
</table>

The results of the Bonferroni test are presented as a matrix. The first entry, $-59.17$, represents the difference between fertilizer concentrations 2 and 1 (labeled “Row Mean - Col Mean” in the upper stub of the table). Remember that in the previous example we requested the tabulate option. Looking back, we find that the means of concentrations 1 and 2 are 111.90 and 52.73, respectively. Thus, $52.73 - 111.90 = -59.17$.

Underneath that number is reported “0.001”. This is the Bonferroni-adjusted significance of the difference. The difference is significant at the 0.1% level. Looking down the column, we see that concentration 3 is also worse than concentration 1 (4.2% level), as is concentration 4 (3.6% level).

On the basis of this evidence, we would use concentration 1 if we grew apple trees.

Example 4: Scheffé multiple-comparison test

We can just as easily obtain the Scheffé-adjusted significance levels. Rather than specifying the bonferroni option, we specify the scheffe option.
We will also add the noanova option to prevent Stata from redisplaying the ANOVA table:

```
.oneway weight treatment, noanova scheffe
```

Comparison of Average weight in grams by Fertilizer

<table>
<thead>
<tr>
<th>Row Mean-Col Mean</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>-59.1667</td>
<td>0.001</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>-33.25</td>
<td>25.9167</td>
<td>0.039</td>
</tr>
<tr>
<td>4</td>
<td>-34.4</td>
<td>24.7667</td>
<td>-1.15</td>
</tr>
</tbody>
</table>

The differences are the same as those we obtained in the Bonferroni output, but the significance levels are not. According to the Bonferroni-adjusted numbers, the significance of the difference between fertilizer concentrations 1 and 3 is 4.2%. The Scheffé-adjusted significance level is 3.9%.

We will leave it to you to decide which results are more accurate.

Example 5: Šidák multiple-comparison test

Let’s conclude this example by obtaining the Šidák-adjusted multiple-comparison tests. We do this to illustrate Stata’s capabilities to calculate these results, because searching across adjustment methods until you find the results you want is not a valid technique for obtaining significance levels.

```
.oneway weight treatment, noanova sidak
```

</tbody>
</table>

We find results that are similar to the Bonferroni-adjusted numbers.

Henry Scheffé (1907–1977) was born in New York. He studied mathematics at the University of Wisconsin, gaining a doctorate with a dissertation on differential equations. He taught mathematics at Wisconsin, Oregon State University, and Reed College, but his interests changed to statistics and he joined Wilks at Princeton. After periods at Syracuse, UCLA, and Columbia, Scheffé settled in Berkeley from 1953. His research increasingly focused on linear models and particularly ANOVA, on which he produced a celebrated monograph. His death was the result of a bicycle accident.
Weighted data

Example 6

Oneway can work with both weighted and unweighted data. Let’s assume that we wish to perform a one-way layout of the deathrate on the four census regions of the United States using state data. Our data contain three variables, d rate (the deathrate), region (the region), and pop (the population of the state).

To fit the model, we type oneway d rate region [weight=pop], although we typically abbreviate weight as w. We will also add the tabulate option to demonstrate how the table of summary statistics differs for weighted data:

```
. use https://www.stata-press.com/data/r18/census8
(1980 Census data by state)
. oneway d rate region [w=pop], tabulate
(analytic weights assumed)
```

<table>

</tbody>
</table>

Bartlett’s equal-variances test: chi2(3) = 5.4971  Prob>chi2 = 0.139

When the data are weighted, the summary table has four columns rather than three. The column labeled “Freq.” reports the sum of the weights. The overall frequency tells us that there are approximately 226 million people in the United States, or at least there were in 1980.

The ANOVA table is appropriately weighted. Also see [U] 11.1.6 weight.

Methods and formulas

Methods and formulas are presented under the following headings:

- **One-way analysis of variance**
- **Bartlett’s test**
- **Multiple-comparison tests**

One-way analysis of variance

The model of one-way ANOVA is

\[ y_{ij} = \mu + \alpha_i + \epsilon_{ij} \]

for levels \( i = 1, \ldots, k \) and observations \( j = 1, \ldots, n_i \). Define \( \bar{y}_j \) as the (weighted) mean of \( y_{ij} \) over \( j \) and \( \bar{y} \) as the overall (weighted) mean of \( y_{ij} \). Define \( w_{ij} \) as the weight associated with \( y_{ij} \), which is 1 if the data are unweighted. \( w_{ij} \) is normalized to sum to \( n = \sum_i n_i \) if `aweights` are used and is otherwise not normalized. \( w_i \) refers to \( \sum_j w_{ij} \), and \( w \) refers to \( \sum_i w_i \).

The between-group sum of squares is then

\[ S_1 = \sum_i w_i (\bar{y}_i - \bar{y})^2 \]

The TSS is

\[ S = \sum_i \sum_j w_{ij} (y_{ij} - \bar{y})^2 \]

The within-group sum of squares is given by \( S_e = S - S_1 \).

The between-group mean square is \( s_1^2 = S_1/(k - 1) \), and the within-group mean square is \( s_e^2 = S_e/(w - k) \). The test statistic is \( F = s_1^2/s_e^2 \). See, for instance, Snedecor and Cochran (1989).

Bartlett’s test

Bartlett’s test assumes that you have \( m \) independent, normal, random samples and tests the hypothesis \( \sigma_1^2 = \sigma_2^2 = \cdots = \sigma_m^2 \). The test statistic, \( M \), is defined as

\[ M = \frac{(T - m) \ln \hat{\sigma}^2 - \sum (T_i - 1) \ln \hat{\sigma}_i^2}{1 + \frac{1}{3(m-1)} \left\{ \left( \sum \frac{1}{T_i-1} \right) - \frac{1}{T-m} \right\}} \]
where there are $T$ overall observations, $T_i$ observations in the $i$th group, and

$$(T_i - 1)\hat{\sigma}_i^2 = \sum_{j=1}^{T_i} (y_{ij} - \bar{y}_i)^2$$

$$(T - m)\hat{\sigma}^2 = \sum_{i=1}^{m} (T_i - 1)\hat{\sigma}_i^2$$

An approximate test of the homogeneity of variance is based on the statistic $M$ with critical values obtained from the $\chi^2$ distribution of $m - 1$ degrees of freedom. See Bartlett (1937) or Draper and Smith (1998, 56–57).

**Multiple-comparison tests**

Let’s begin by reviewing the logic behind these adjustments. The “standard” $t$ statistic for the comparison of two means is

$$t = \frac{\bar{y}_i - \bar{y}_j}{s \sqrt{\frac{1}{n_i} + \frac{1}{n_j}}}$$

where $s$ is the overall standard deviation, $\bar{y}_i$ is the measured average of $y$ in group $i$, and $n_i$ is the number of observations in the group. We perform hypothesis tests by calculating this $t$ statistic. We simultaneously choose a critical level, $\alpha$, and look up the $t$ statistic corresponding to that level in a table. We reject the hypothesis if our calculated $t$ exceeds the value we looked up. Alternatively, because we have a computer at our disposal, we calculate the significance level $e$ corresponding to our calculated $t$ statistic, and if $e < \alpha$, we reject the hypothesis.

This logic works well when we are performing one test. Now consider what happens when we perform several separate tests, say, $n$ of them. Let’s assume, just for discussion, that we set $\alpha$ equal to 0.05 and that we will perform six tests. For each test, we have a 0.05 probability of falsely rejecting the equality-of-means hypothesis. Overall, then, our chances of falsely rejecting at least one of the hypotheses is $1 - (1 - 0.05)^6 \approx 0.26$ if the tests are independent.

The idea behind multiple-comparison tests is to control for the fact that we will perform multiple tests and to reduce our overall chances of falsely rejecting each hypothesis to $\alpha$ rather than letting our chances increase with each additional test. (See Miller [1981] and Hochberg and Tamhane [1987] for rather advanced texts on multiple-comparison procedures.)

The Bonferroni adjustment (see Miller [1981]; also see van Belle et al. [2004, 534–537]) does this by (falsely but approximately) asserting that the critical level we should use, $a$, is the true critical level, $\alpha$, divided by the number of tests, $n$; that is, $a = \alpha/n$. For instance, if we are going to perform six tests, each at the 0.05 significance level, we want to adopt a critical level of 0.05/6 ≈ 0.00833.

We can just as easily apply this logic to $e$, the significance level associated with our $t$ statistic, as to our critical level $\alpha$. If a comparison has a calculated significance of $e$, then its “real” significance, adjusted for the fact of $n$ comparisons, is $n \times e$. If a comparison has a significance level of, say, 0.012, and we perform six tests, then its “real” significance is 0.072. If we adopt a critical level of 0.05, we cannot reject the hypothesis. If we adopt a critical level of 0.10, we can reject it.

Of course, this calculation can go above 1, but that just means that there is no $\alpha < 1$ for which we could reject the hypothesis. (This situation arises because of the crude nature of the Bonferroni adjustment.) Stata handles this case by simply calling the significance level 1. Thus, the formula for the Bonferroni significance level is

$$e_b = \min(1, en)$$

where $n = k(k - 1)/2$ is the number of comparisons.
The Šidák adjustment (Šidák [1967]; also see Winer, Brown, and Michels [1991, 165–166]) is slightly different and provides a tighter bound. It starts with the assertion that

\[ a = 1 - (1 - \alpha)^{1/n} \]

Turning this formula around and substituting calculated significance levels, we obtain

\[ e_s = \min \left\{ 1, 1 - (1 - e)^{1/n} \right\} \]

For example, if the calculated significance is 0.012 and we perform six tests, the “real” significance is approximately 0.07.

The Scheffé test (Scheffé [1953, 1959]; also see Kuehl [2000, 97–98]) differs in derivation, but it attacks the same problem. Let there be \( k \) means for which we want to make all the pairwise tests. Two means are declared significantly different if

\[ t \geq \sqrt{(k - 1)F(\alpha; k - 1, \nu)} \]

where \( F(\alpha; k - 1, \nu) \) is the \( \alpha \)-critical value of the \( F \) distribution with \( k - 1 \) numerator and \( \nu \) denominator degrees of freedom. Scheffé’s test has the nicety that it never declares a contrast significant if the overall \( F \) test is not significant.

Turning the test around, Stata calculates a significance level

\[ \hat{\alpha} = F \left( \frac{t^2}{k - 1}, k - 1, \nu \right) \]

For instance, you have a calculated \( t \) statistic of 4.0 with 50 degrees of freedom. The simple \( t \) test says that the significance level is 0.00021. The \( F \) test equivalent, 16 with 1 and 50 degrees of freedom, says the same. If you are comparing three means, however, you calculate an \( F \) test of 8.0 with 2 and 50 degrees of freedom, which says that the significance level is 0.0010.

Syntax

oprobit  \textit{depvar}  \textit{[indepvars]}  \textit{[if]}  \textit{[in]}  \textit{[weight]}  \textit{[, options]}

\textbf{options} \hspace{1cm} \textbf{Description}

Model
\begin{itemize}
  \item \texttt{offset(varname)} \hspace{1cm} include \textit{varname} in model with coefficient constrained to 1
  \item \texttt{constraints(constraints)} \hspace{1cm} apply specified linear constraints
\end{itemize}

SE/Robust
\begin{itemize}
  \item \texttt{vce(vcetype)} \hspace{1cm} \textit{vcetype} may be \textit{oim}, \textit{opg}, \textit{robust}, \textit{cluster clustvar}, \textit{bootstrap}, or \textit{jackknife}
\end{itemize}

Reporting
\begin{itemize}
  \item \texttt{level(\#)} \hspace{1cm} set confidence level; default is \texttt{level(95)}
  \item \texttt{nocnsreport} \hspace{1cm} do not display constraints
  \item \texttt{display_options} \hspace{1cm} control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
\end{itemize}

Maximization
\begin{itemize}
  \item \texttt{maximize_options} \hspace{1cm} control the maximization process; seldom used
  \item \texttt{collinear} \hspace{1cm} keep collinear variables
  \item \texttt{coeflegend} \hspace{1cm} display legend instead of statistics
\end{itemize}

\textit{indepvars} may contain factor variables; see \textbf{[U] 11.4.3 Factor variables.}
\textit{depvar} and \textit{indepvars} may contain time-series operators; see \textbf{[U] 11.4.4 Time-series varlists.}
\texttt{vce(bootstrap)} and \texttt{vce(jackknife)} are not allowed with the \textit{mi estimate} prefix; see \textbf{[MI] mi estimate.}
Weights are not allowed with the \textit{bootstrap} prefix; see \textbf{[R] bootstrap.}
\texttt{vce()} and weights are not allowed with the \textit{svy} prefix; see \textbf{[SVY] svy.}
\texttt{fweights}, \texttt{iweights}, and \texttt{pweights} are allowed; see \textbf{[U] 11.1.6 weight.}
collinear and coeflegend do not appear in the dialog box.

See \textbf{[U] 20 Estimation and postestimation commands} for more capabilities of estimation commands.

\subsection*{Options}

\begin{itemize}
  \item \texttt{Model}
    \begin{itemize}
      \item \texttt{offset(varname), constraints(constraints)}; see \textbf{[R] Estimation options.}
    \end{itemize}
  \item \texttt{SE/Robust}
    \begin{itemize}
      \item \texttt{vce(vcetype)} specifies the type of standard error reported, which includes types that are derived from asymptotic theory (\textit{oim}, \textit{opg}), that are robust to some kinds of misspecification (\textit{robust}), that allow for intragroup correlation (\textit{cluster clustvar}), and that use bootstrap or jackknife methods (\textit{bootstrap}, \textit{jackknife}); see \textbf{[R] vce_option.}
    \end{itemize}
\end{itemize}
level(#); see [R] Estimation options.
nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#), fvwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] Estimation options.

Maximization:
maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

The following options are available with oprobit but not shown in the dialog box:
collinear, coeflegend; see [R] Estimation options.

Remarks and examples

An ordered probit model is used to estimate relationships between an ordinal dependent variable and a set of independent variables. An ordinal variable is a variable that is categorical and ordered, for instance, “poor”, “good”, and “excellent”, which might indicate a person’s current health status or the repair record of a car. If there are only two outcomes, see [R] logistic, [R] logit, and [R] probit. This entry is concerned only with more than two outcomes. If the outcomes cannot be ordered (for example, residency in the north, east, south, or west), see [R] mlogit. This entry is concerned only with models in which the outcomes can be ordered. See [R] logistic for a list of related estimation commands.

In ordered probit, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome \(i\) corresponds to the probability that the estimated linear function, plus random error, is within the range of the cutpoints estimated for the outcome:

\[
\Pr(\text{outcome}_j = i) = \Pr(\kappa_{i-1} < \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_k x_{kj} + u_j \leq \kappa_i)
\]

\(u_j\) is assumed to be normally distributed. In either case, we estimate the coefficients \(\beta_1, \beta_2, \ldots, \beta_k\) together with the cutpoints \(\kappa_1, \kappa_2, \ldots, \kappa_{I-1}\), where \(I\) is the number of possible outcomes. \(\kappa_0\) is taken as \(-\infty\), and \(\kappa_I\) is taken as \(+\infty\). All of this is a direct generalization of the ordinary two-outcome probit model.

Example 1

In example 2 of [R] ologit, we use a variation of the automobile dataset (see [U] 1.2.2 Example datasets) to analyze the 1977 repair records of 66 foreign and domestic cars. We use ordered logit to explore the relationship of rep77 in terms of foreign (origin of manufacture), length (a proxy for size), and mpg. Here we fit the same model using ordered probit rather than ordered logit:
. use https://www.stata-press.com/data/r18/fullauto
(Automobile models)
. oprobit rep77 foreign length mpg
Iteration 0: Log likelihood = -89.895098
Iteration 1: Log likelihood = -78.106316
Iteration 2: Log likelihood = -78.020086
Iteration 3: Log likelihood = -78.020025
Iteration 4: Log likelihood = -78.020025
Ordered probit regression
Number of obs = 66
LR chi2(3) = 23.75
Prob > chi2 = 0.0000
Log likelihood = -78.020025 Pseudo R2 = 0.1321

rep77  Coefficient  Std. err.  z  P>|z|  [95% conf. interval]
foreign  1.704861  .4246796  4.01  0.000  .8725037  2.537217
length   .0468675  .012648  3.71  0.000  .022078  .0716571
mpg     .1304559  .0378628  3.45  0.001  .0562463  .2046656
/cut1    10.1589  3.076754  4.12  0.000  6.126897  14.2518
/cut2    11.21003  3.107527  5.12  0.000  5.034401  17.38566
/cut3    12.54561  3.155233  6.36  0.000  6.360041  18.7312
/cut4    13.98059  3.218793  7.67  0.000  7.59329  20.36789

We find that foreign cars have better repair records, as do larger cars and cars with better mileage ratings.

Stored results
oprobit stores the following in e():

Scalars
  e(N)          number of observations
  e(N_cd)      number of completely determined observations

<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

*forecast, hausman, and lrtest are not appropriate with svy estimation results. forecast is also not appropriate with mi estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
gooffset ]

predict [type] stub* [if] [in] , scores

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>predicted probabilities; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
</tbody>
</table>

You specify one or \( k \) new variables with pr, where \( k \) is the number of outcomes. If you specify one new variable and you do not specify outcome(), then outcome(#1) is assumed.

You specify one new variable with xb and stdp.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

pr, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify \( k \) new variables, where \( k \) is the number of categories of the dependent variable. Alternatively, you can specify stub*; in which case, pr will store predicted probabilities in variables stub1, stub2, ..., stubk. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option outcome(); if you omit outcome(), the first outcome value, outcome(#1), is assumed.

Say that you fit a model by typing estimation_cmd y x1 x2, and y takes on four values. Then, you could type predict p1 p2 p3 p4 to obtain all four predicted probabilities; alternatively, you could type predict p* to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type predict p1, outcome(#1) (or simply predict p1), predict p2, outcome(#2), and so on. See option outcome() for other ways to refer to outcome values.

xb calculates the linear prediction. You specify one new variable, for example, predict linear, xb. The linear prediction is defined, ignoring the contribution of the estimated cutpoints.
stdp calculates the standard error of the linear prediction. You specify one new variable, for example, `predict se, stdp`.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is available only with the default `pr` option.

`nooffset` is relevant only if you specified `offset(varname)` for oprobit. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as $x_j b$ rather than as $x_j b + offset_j$. `nooffset` is not allowed with `scores`.

`scores` calculates equation-level score variables. The number of score variables created will equal the number of outcomes in the model. If the number of outcomes in the model was $k$, then the first new variable will contain $\partial \ln L / \partial (x_j b)$; the second new variable will contain $\partial \ln L / \partial \kappa_1$; the third new variable will contain $\partial \ln L / \partial \kappa_2$; ...

and the $k$th new variable will contain $\partial \ln L / \partial \kappa_{k-1}$, where $\kappa_i$ refers to the $i$th cutpoint.

### margins

**Description for margins**

`margins` estimates margins of response for probabilities and linear predictions.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

```
margins [ marginlist ] [, options ]
margins [ marginlist ] , predict(statistic ...) [ predict(statistic ...) ... ] [ options ]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>probabilities for each outcome</td>
</tr>
<tr>
<td><code>pr</code></td>
<td>probability for a specified outcome</td>
</tr>
<tr>
<td><code>xb</code></td>
<td>linear prediction</td>
</tr>
<tr>
<td><code>stdp</code></td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

`pr` defaults to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than $e(b)$.

For the full syntax, see `[R] margins`. 
Remarks and examples

See [U] 20 Estimation and postestimation commands for instructions on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests. Also see [R] lrtest for performing likelihood-ratio tests.

Example 1

In example 1 of [R] oprobit, we fit the model \( \text{oprobit rep77 foreign length mpg} \). The predict command can be used to obtain the predicted probabilities. We type predict followed by the names of the new variables to hold the predicted probabilities, ordering the names from low to high. In our data, the lowest outcome is “poor” and the highest is “excellent”. We have five categories, so we must type five names following predict; the choice of names is up to us:

\[
\begin{align*}
\text{use https://www.stata-press.com/data/r18/fullauto} \\
\text{(Automobile models)} \\
\text{ooprobit rep77 foreign length mpg} \\
\text{(output omitted)} \\
\text{predict poor fair avg good exc} \\
\text{(option \texttt{pr} assumed; predicted probabilities)} \\
\text{list make model exc good if rep77>=., sep(4) divider}
\end{align*}
\]

<table>
<thead>
<tr>
<th>make</th>
<th>model</th>

</tr>
</tbody>
</table>

Technical note

For ordered probit, predict, xb produces \( S_j = x_{1j} \beta_1 + x_{2j} \beta_2 + \cdots + x_{kj} \beta_k \). Ordered probit is identical to ordered logit, except that we use different distribution functions for calculating probabilities. The ordered-probit predictions are then the probability that \( S_j + u \) lies between a pair of cutpoints \( \kappa_2 - S_j \) and \( \kappa_1 - S_j \). The formulas for ordered probit are

\[
\begin{align*}
\Pr(S_j + u < \kappa) &= \Phi(\kappa - S_j) \\
\Pr(S_j + u > \kappa) &= 1 - \Phi(\kappa - S_j) = \Phi(S_j - \kappa) \\
\Pr(\kappa_1 - S_j < u < \kappa_2) &= \Phi(\kappa_2 - S_j) - \Phi(\kappa_1 - S_j)
\end{align*}
\]

Rather than using predict directly, we could calculate the predicted probabilities by hand.

\[
\begin{align*}
\text{. predict pscore, xb} \\
\text{. generate probexc = normal(pscore-_b[/cut4])} \\
\text{. generate probgood = normal(_b[/cut4]-pscore) - normal(_b[/cut3]-pscore)}
\end{align*}
\]

[U] 20 Estimation and postestimation commands
**orthog — Orthogonalize variables and compute orthogonal polynomials**

<table>
<thead>
<tr>
<th>Description</th>
<th>Quick start</th>
<th>Menu</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Options for orthog</td>
<td>Options for orthopoly</td>
</tr>
<tr>
<td>Remarks and examples</td>
<td>Methods and formulas</td>
<td>References</td>
</tr>
<tr>
<td>Also see</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

`orthog` orthogonalizes a set of variables, creating a new set of orthogonal variables (all of type `double`), using a modified Gram–Schmidt procedure (Golub and Van Loan 2013). The order of the variables determines the orthogonalization; hence, the “most important” variables should be listed first.

Execution time is proportional to the square of the number of variables. With many (>10) variables, `orthog` will be fairly slow.

`orthopoly` computes orthogonal polynomials for one variable.

**Quick start**

Generate `ox1`, `ox2`, and `ox3` containing orthogonalized versions of `x1`, `x2`, and `x3`

```
orthog x1 x2 x3, generate(ox1 ox2 ox3)
```

Same as above

```
orthog x1 x2 x3, generate(ox*)
```

Generate `op1`, `op2`, and `op3` containing degree 1, 2, and 3 orthogonal polynomials for `x1`

```
orthopoly x1, generate(op1 op2 op3) degree(3)
```

Same as above

```
orthopoly x1, generate(op1-op3) degree(3)
```

Same as above, and generate matrix `op` containing coefficients of the orthogonal polynomials

```
orthopoly x1, generate(op1-op3) degree(3) poly(op)
```

**Menu**

- **orthog**
  - Data > Create or change data > Other variable-creation commands > Orthogonalize variables

- **orthopoly**
  - Data > Create or change data > Other variable-creation commands > Orthogonal polynomials

2073
Syntax

Orthogonalize variables

```
orthog [varlist] [if] [in] [weight], generate(newvarlist) [matrix(matname)]
```

Compute orthogonal polynomial

```
orthopoly varname [if] [in] [weight],
{ generate(newvarlist) | poly(matname) } [degree(#)]
```

orthopoly requires that generate(newvarlist) or poly(matname), or both, be specified.

varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists.
iweights, aweights, fweights, and pweights are allowed, see [U] 11.1.6 weight.

Options for orthog

- **generate(newvarlist)** is required. generate() creates new orthogonal variables of type double.

  For orthog, newvarlist will contain the orthogonalized varlist. If varlist contains \(d\) variables, then so will newvarlist. newvarlist can be specified by giving a list of exactly \(d\) new variable names, or it can be abbreviated using the styles newvar1-newvar\(d\) or newvar*. For these two styles of abbreviation, new variables newvar1, newvar2, ..., newvar\(d\) are generated.

- **matrix(matname)** creates a \((d+1) \times (d+1)\) matrix containing the matrix \(R\) defined by \(X = QR\), where \(X\) is the \(N \times (d+1)\) matrix representation of varlist plus a column of ones and \(Q\) is the \(N \times (d+1)\) matrix representation of newvarlist plus a column of ones (\(d = \) number of variables in varlist, and \(N = \) number of observations).

Options for orthopoly

- **generate(newvarlist)** or poly(), or both, must be specified. generate() creates new orthogonal variables of type double. newvarlist will contain orthogonal polynomials of degree 1, 2, ..., \(d\) evaluated at varname, where \(d\) is as specified by degree(d). newvarlist can be specified by giving a list of exactly \(d\) new variable names, or it can be abbreviated using the styles newvar1-newvar\(d\) or newvar*. For these two styles of abbreviation, new variables newvar1, newvar2, ..., newvar\(d\) are generated.

- **poly(matname)** creates a \((d+1) \times (d+1)\) matrix called matname containing the coefficients of the orthogonal polynomials. The orthogonal polynomial of degree \(i \leq d\) is

  \[
  \text{matname}[i, d+1] + \text{matname}[i, 1] \times \text{varname} + \text{matname}[i, 2] \times \text{varname}^2 \\
  + \cdots + \text{matname}[i, i] \times \text{varname}^i
  \]

  The coefficients corresponding to the constant term are placed in the last column of the matrix. The last row of the matrix is all zeros, except for the last column, which corresponds to the constant term.

- **degree(#)** specifies the highest-degree polynomial to include. Orthogonal polynomials of degree 1, 2, ..., \(d = #\) are computed. The default is \(d = 1\).
Orthogonal variables are useful for two reasons. The first is numerical accuracy for highly collinear variables. Stata’s `regress` and other estimation commands can face much collinearity and still produce accurate results. But, at some point, these commands will drop variables because of collinearity. If you know with certainty that the variables are not perfectly collinear, you may want to retain all their effects in the model. If you use `orthog` or `orthpoly` to produce a set of orthogonal variables, all variables will be present in the estimation results.

Users are more likely to find orthogonal variables useful for the second reason: ease of interpreting results. `orthog` and `orthpoly` create a set of variables such that the “effects” of all the preceding variables have been removed from each variable. For example, if we issue the command

```
. orthog x1 x2 x3, generate(q1 q2 q3)
```

the effect of the constant is removed from `x1` to produce `q1`; the constant and `x1` are removed from `x2` to produce `q2`; and finally the constant, `x1`, and `x2` are removed from `x3` to produce `q3`. Hence,

\[
\begin{align*}
q_1 &= r_{01} + r_{11} x_1 \\
q_2 &= r_{02} + r_{12} x_1 + r_{22} x_2 \\
q_3 &= r_{03} + r_{13} x_1 + r_{23} x_2 + r_{33} x_3
\end{align*}
\]

This effect can be generalized and written in matrix notation as

\[
X = QR
\]

where `X` is the `N \times (d + 1)` matrix representation of `varlist` plus a column of ones, and `Q` is the `N \times (d + 1)` matrix representation of `newvarlist` plus a column of ones (`d =` number of variables in `varlist` and `N =` number of observations). The `(d + 1) \times (d + 1)` matrix `R` is a permuted upper-triangular matrix, that is, `R` would be upper triangular if the constant were first, but the constant is last, so the first row/column has been permuted with the last row/column. Because Stata’s estimation commands list the constant term last, this allows `R`, obtained via the `matrix()` option, to be used to transform estimation results.

Example 1: `orthog`

Consider Stata’s `auto.dta` dataset. Suppose that we postulate a model in which `price` depends on the car’s `length`, `weight`, `headroom`, and trunk size (`trunk`). These predictors are collinear, but not extremely so—the correlations are not that close to 1:

```
. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. correlate length weight headroom trunk
   (obs=74)
```

<table>
<thead>
<tr>
<th></th>
<th>length</th>
<th>weight</th>
<th>headroom</th>
<th>trunk</th>
</tr>
</thead>
<tbody>
<tr>
<td>length</td>
<td>1.0000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>weight</td>
<td>0.9460</td>
<td>1.0000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>headroom</td>
<td>0.5163</td>

<td>8699525.97</td>
<td>Adj R-squared = 0.3352</td>
</tr>
</tbody>
</table>

| price | Coefficient | Std. err. | t       | P>|t| | [95% conf. interval] |
|-------|-------------|-----------|---------|------|---------------------------|
| length | -101.7092 | 42.12534 | -2.41  | 0.018 | -185.747 -17.67147 |
| weight | 4.753066 | 1.120054 | 4.24   | 0.000 | 2.518619 6.987512 |
| headroom | -711.5679 | 445.0204 | -1.60  | 0.114 | -1599.359 176.2236 |
| trunk  | 114.0859 | 109.9488 | 1.04   | 0.303 | -105.2559 333.4277 |
| _cons  | 11488.47 | 4543.902 | 2.53   | 0.014 | 2423.638 20553.31 |

However, we may believe a priori that length is the most important predictor, followed by weight, headroom, and trunk. We would like to remove the “effect” of length from all the other predictors, remove weight from headroom and trunk, and remove headroom from trunk. We can do this by running orthog, and then we fit the model again using the orthogonal variables:

```
. orthog length weight headroom trunk, gen(olength oweight oheadroom otrunk)
> matrix(R)
. regress price olength oweight oheadroom otrunk
```

<table>
<thead>
<tr>
<th></th>
<th>SS</th>
<th>df</th>
<th>MS</th>

<td>Adj R-squared = 0.3352</td>
</tr>
<tr>
<td>Total</td>
<td>635065396</td>
<td>73</td>
<td>8699525.97</td>
<td>Root MSE = 2404.9</td>
</tr>
</tbody>
</table>

| price | Coefficient | Std. err. | t       | P>|t| | [95% conf. interval] |
|-------|-------------|-----------|---------|------|---------------------------|
| olength | 1265.049 | 279.5584 | 4.53   | 0.000 | 707.3454 1822.753 |
| oweight | 1175.765 | 279.5584 | 4.21   | 0.000 | 618.0617 1733.469 |
| oheadroom | -349.9916 | 279.5584 | -1.25  | 0.215 | -907.6955 207.7122 |
| otrunk  | 290.0776 | 279.5584 | 1.04   | 0.303 | -267.6262 847.7815 |
| _cons  | 6165.257 | 279.5584 | 22.05  | 0.000 | 5607.553 6722.961 |

Using the matrix R, we can transform the results obtained using the orthogonal predictors back to the metric of original predictors:

```
. matrix b = e(b)*inv(R)
. matrix list b
b[1,5]
 length    weight    headroom    trunk    _cons
 y1    -101.70924   4.7530659  -711.56789   114.08591  11488.475
```

Technical note

The matrix R obtained using the matrix() option with orthog can also be used to recover X (the original varlist) from Q (the orthogonalized newvarlist), one variable at a time. Continuing with the previous example, we illustrate how to recover the trunk variable:
Here the recovered variable \texttt{rtrunk} is almost exactly the same as the original \texttt{trunk} variable. When you are orthogonalizing many variables, this procedure can be performed to check the numerical soundness of the orthogonalization. Because of the ordering of the orthogonalization procedure, the last variable and the variables near the end of the \textit{varlist} are the most important ones to check.

The \texttt{orthpoly} command effectively does for polynomial terms what the \texttt{orthog} command does for an arbitrary set of variables.

\textbf{Example 2: orthpoly}

Again consider the \texttt{auto.dta} dataset. Suppose that we wish to fit the model

\[
\texttt{mpg} = \beta_0 + \beta_1 \texttt{weight} + \beta_2 \texttt{weight}^2 + \beta_3 \texttt{weight}^3 + \beta_4 \texttt{weight}^4 + \epsilon
\]

We will first compute the regression with natural polynomials:

\begin{verbatim}
. generate double w1 = weight
. generate double w2 = w1*w1
. generate double w3 = w2*w1
. generate double w4 = w3*w1
. correlate w1-w4
  (obs=74)
   |   w1   w2   w3   w4
-------------+------------------
   w1 | 1.0000
   w2 | 0.9915    1.0000
   w3 | 0.9665 0.9916   1.0000
   w4 | 0.9279 0.9679 0.9922   1.0000

. regress mpg w1-w4
  Source | SS      df    MS           Number of obs =  74
--------+----------------------------------- F(4, 69) = 36.06
Model   | 1652.73666  4 413.184164    Prob > F =  0.0000
Residual| 790.722803  69 11.4597508   R-squared =  0.6764
        | Adj R-squared =  0.6576
Total   | 2443.45946  73 33.4720474   Root MSE =  3.3852
        |                      Source : http://www.stata.com
| mpg         Coefficient Std. err.       t     P>|t|    [95% conf. interval]
--------+--------------------------------------------------
     w1  | 0.0289302 .1161939 0.25 0.804 -.2028704 .2607307
     w2  | -.0000229 .0000566 -0.40 0.687 -.0001359 .0000901
     w3  | 5.74e-09 1.19e-08 0.48 0.631 -1.80e-08 2.95e-08
     w4  | -4.86e-13 9.14e-13 -0.53 0.596 -2.31e-12 1.34e-12
_cons | 23.94421 86.60667 0.28 0.783 -148.8314 196.7198
\end{verbatim}
Some of the correlations among the powers of weight are very large, but this does not create any problems for regress. However, we may wish to look at the quadratic trend with the constant removed, the cubic trend with the quadratic and constant removed, etc. orthopoly will generate polynomial terms with this property:

```
. orthopoly weight, generate(pw*) deg(4) poly(P)
. regress mpg pw1-pw4
```

Compare the p-values of the terms in the natural polynomial regression with those in the orthogonal polynomial regression. With orthogonal polynomials, it is easy to see that the pure cubic and quartic trends are not significant and that the constant, linear, and quadratic terms each have \( p < 0.05 \).

The matrix \( P \) obtained with the poly() option can be used to transform coefficients for orthogonal polynomials to coefficients for natural polynomials:

```
. orthopoly weight, poly(P) deg(4)
. matrix b = e(b)*P
. matrix list b
```

<table>
<thead>
<tr>

<td>23.944212</td>
</tr>
</tbody>
</table>

**Methods and formulas**

orthog’s orthogonalization can be written in matrix notation as

\[
X = QR
\]

where \( X \) is the \( N \times (d + 1) \) matrix representation of varlist plus a column of ones and \( Q \) is the \( N \times (d + 1) \) matrix representation of newvarlist plus a column of ones \( (d = \) number of variables in varlist, and \( N = \) number of observations). The \( (d + 1) \times (d + 1) \) matrix \( R \) is a permuted upper-triangular matrix; that is, \( R \) would be upper triangular if the constant were first, but the constant is last, so the first row/column has been permuted with the last row/column.

\( Q \) and \( R \) are obtained using a modified Gram–Schmidt procedure; see Golub and Van Loan (2013, 254–255) for details. The traditional Gram–Schmidt procedure is notoriously unsound, but the modified procedure is good. orthog performs two passes of this procedure.

orthopoly uses the Christoffel–Darboux recurrence formula (Abramowitz and Stegun 1964).
Both `orthog` and `orthpoly` normalize the orthogonal variables such that

\[ Q'WQ = MI \]

where \( W = \text{diag}(w_1, w_2, \ldots, w_N) \) with weights \( w_1, w_2, \ldots, w_N \) (all 1 if weights are not specified), and \( M \) is the sum of the weights (the number of observations if weights are not specified).

pcorr — Partial and semipartial correlation coefficients

**Description**

pcorr displays the partial and semipartial correlation coefficients of a specified variable with each variable in a varlist after removing the effects of all other variables in the varlist. The squared correlations and corresponding significance are also reported.

**Quick start**

Partial and semipartial correlations of v1 with v2, v3, and v4

```
pcorr v1 v2 v3 v4
```

Same as above, but for each level of categorical variable catvar

```
by catvar: pcorr v1 v2 v3 v4
```

Partial and semipartial correlations of v5 with v6, v7, and v8, and a one-period lag of v5 using tsset data

```
pcorr v5 L.v5 v6 v7 v8
```

**Menu**

Syntax

```
pcorr varname varlist [if] [in] [weight]
```

varlist may contain factor variables; see [U] 11.4.3 Factor variables.
varname and varlist may contain time-series operators; see [U] 11.4.4 Time-series varlists.
by and collect are allowed; see [U] 11.1.10 Prefix commands.
aweights and fweights are allowed; see [U] 11.1.6 weight.

Remarks and examples

Assume that $y$ is determined by $x_1, x_2, \ldots, x_k$. The partial correlation between $y$ and $x_1$ is an attempt to estimate the correlation that would be observed between $y$ and $x_1$ if the other $x$’s did not vary. The semipartial correlation, also called part correlation, between $y$ and $x_1$ is an attempt to estimate the correlation that would be observed between $y$ and $x_1$ after the effects of all other $x$’s are removed from $x_1$ but not from $y$.

Both squared correlations estimate the proportion of the variance of $y$ that is explained by each predictor. The squared semipartial correlation between $y$ and $x_1$ represents the proportion of variance in $y$ that is explained by $x_1$ only. This squared correlation can also be interpreted as the decrease in the model’s $R^2$ value that results from removing $x_1$ from the full model. Thus, one could use the squared semipartial correlations as criteria for model selection. The squared partial correlation between $y$ and $x_1$ represents the proportion of variance in $y$ not associated with any other $x$’s that is explained by $x_1$. Thus, the squared partial correlation gives an estimate of how much of the variance of $y$ not explained by the other $x$’s is explained by $x_1$.

Example 1

Using our automobile dataset (described in [U] 1.2.2 Example datasets), we can obtain the simple correlations between price, mpg, weight, and foreign from correlate (see [R] correlate):

```
  . use https://www.stata-press.com/data/r18/auto
  (1978 automobile data)
  . correlate price mpg weight foreign
```

<table>
<thead>
<tr>
<th></th>
<th>price</th>
<th>mpg</th>
<th>weight</th>
<th>foreign</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>1.0000</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>mpg</td>
<td>-0.4686</td>
<td>1.0000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>weight</td>
<td>0.5386</td>
<td>-0.8072</td>
<td>1.0000</td>
<td></td>
</tr>
<tr>
<td>foreign</td>
<td>0.0487</td>
<td>0.3934</td>
<td>-0.5928</td>
<td>1.0000</td>
</tr>
</tbody>
</table>

Although correlate gave us the full correlation matrix, our interest is in just the first column. We find, for instance, that the higher the mpg, the lower the price. We obtain the partial and semipartial correlation coefficients by using pcorr:

```
  . pcorr price mpg weight foreign
  (obs=74)
```

Partial and semipartial correlations of price with

<table>
<thead>
<tr>
<th>Variable</th>
<th>Partial corr.</th>
<th>Semipartial corr.</th>
<th>Partial corr.^2</th>
<th>Semipartial corr.^2</th>
<th>Significance value</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>0.0352</td>
<td>0.0249</td>
<td>0.0012</td>
<td>0.0006</td>
<td>0.7693</td>
</tr>
<tr>
<td>weight</td>
<td>0.5488</td>
<td>0.4644</td>
<td>0.3012</td>
<td>0.2157</td>
<td>0.0000</td>
</tr>
<tr>
<td>foreign</td>
<td>0.5402</td>
<td>0.4541</td>
<td>0.2918</td>
<td>0.2062</td>
<td>0.0000</td>
</tr>
</tbody>
</table>
We now find that the partial and semipartial correlations of `price` with `mpg` are near 0. In the simple correlations, we found that `price` and `foreign` were virtually uncorrelated. In the partial and semipartial correlations, we find that `price` and `foreign` are positively correlated. The nonsignificance of `mpg` tells us that the amount in which $R^2$ decreases by removing `mpg` from the model is not significant. We find that removing either `weight` or `foreign` results in a significant drop in the $R^2$ of the model.

**Technical note**

Use caution when interpreting the above results. As we said at the outset, the partial and semipartial correlation coefficients are an attempt to estimate the correlation that would be observed if the effects of all other variables were taken out of both $y$ and $x$ or only $x$. `pcorr` makes it too easy to ignore the fact that we are fitting a model. In the example above, the model is

$$\text{price} = \beta_0 + \beta_1\text{mpg} + \beta_2\text{weight} + \beta_3\text{foreign} + \epsilon$$

which is, in all honesty, a rather silly model. Even if we accept the implied economic assumptions of the model—that consumers value `mpg`, `weight`, and `foreign`—do we really believe that consumers place equal value on every extra 1,000 pounds of weight? That is, have we correctly parameterized the model? If we have not, then the estimated partial and semipartial correlation coefficients may not represent what they claim to represent. Partial and semipartial correlation coefficients are a reasonable way to summarize data if we are convinced that the underlying model is reasonable. We should not, however, pretend that there is no underlying model and that these correlation coefficients are unaffected by the assumptions and parameterization.

**Stored results**

`pcorr` stores the following in `r()`:

<table>
<thead>
<tr>
<th>Scalars</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>$r(N)$</td>
<td>number of observations</td>
</tr>
<tr>
<td>$r(df)$</td>
<td>degrees of freedom</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Matrices</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>$r(p_corr)$</td>
<td>partial correlation coefficient vector</td>
</tr>
<tr>
<td>$r(sp_corr)$</td>
<td>semipartial correlation coefficient vector</td>
</tr>
</tbody>
</table>

**Methods and formulas**

Results are obtained by fitting a linear regression of `varname` on `varlist`; see `[R] regress`. The partial correlation coefficient between `varname` and each variable in `varlist` is then calculated as

$$\frac{t}{\sqrt{t^2 + n - k}}$$

(Greene 2018, 39), where $t$ is the $t$ statistic, $n$ is the number of observations, and $k$ is the number of independent variables, including the constant but excluding any dropped variables.
The semipartial correlation coefficient between `varname` and each variable in `varlist` is calculated as

\[
\text{sign}(t) \sqrt{\frac{t^2(1 - R^2)}{n - k}}
\]

(Cohen et al. 2003, 89), where \( R^2 \) is the model \( R^2 \) value, and \( t, n, \) and \( k \) are as described above.

The significance is given by \( 2\Pr(t_{n-k} > |t|) \), where \( t_{n-k} \) follows a Student’s \( t \) distribution with \( n - k \) degrees of freedom.

**Acknowledgment**

The addition of semipartial correlation coefficients to `pcorr` is based on the `pcorr2` command by Richard Williams of the Department of Sociology at the University of Notre Dame.

[R] `correlate` — Correlations of variables

[R] `spearman` — Spearman’s and Kendall’s correlations
permute — Permutation tests

Description

permute performs permutation tests using Monte Carlo permutations or by enumeration of all possible distinct permutations. A single variable is chosen to be permuted, and the permutation distribution is estimated (or in the case of enumeration, fully determined) for specified statistics returned by a Stata command or a user-written program.

Quick start

Estimate $p$-values for a permutation test of the coefficient of $x$ in a linear regression, permuting values of the outcome $y$

```
permute y _b[x]: regress y x
```

Test for $r($mystat$)$ returned by program myprog, permuting values of $y$

```
permute y r(mystat): myprog
```

Same as above, but increase the number of permutations from the default of 100 to 10,000

```
permute y r(mystat), reps(10000): myprog
```

Same as above, but display a dot for every 100 permutations instead of every permutation

```
permute y r(mystat), reps(10000) dots(100): myprog
```

Same as above, but set the random-number seed for reproducibility, and save the permuted statistics in myfile.dta

```
permute y r(mystat), reps(10000) dots(100) rseed(1) saving(myfile): ///
myprog
```

Test for $r($mystat1$)$ and $r($mystat2$)$, naming the statistics stat1 and stat2, respectively

```
permute y stat1=r(mystat1) stat2=r(mystat2), reps(10000) rseed(1): ///
myprog
```

Perform permutations within strata defined by svar

```
permute y stat=r(mystat), reps(10000) rseed(1) strata(svar): myprog
```

Enumerate the full permutation distribution and display a dot for every 1,000 permutations

```
permute y stat=r(mystat), enumerate dots(1000): myprog
```

**exp_list** contains:

- `(name: elist)`
  - `elist`
  - `eexp`

**elist** contains:

- `newvar = (exp)`
  - `(exp)`

**eexp** is:

- `specname`
  - `[eqno]specname`

**specname** is:

- `_b`
  - `_b[]`
- `_se`
  - `_se[]`

**eqno** is:

- `##`
  - `name`

*exp* is a standard Stata expression; see [U] 13 Functions and expressions.

Distinguish between [], which are to be typed, and [], which indicate optional arguments.

#### Main Options

**reps(#)** specifies the number of Monte Carlo permutations to perform. The default is `reps(100)`.

The default of 100 permutations is chosen for convenience. In real-world applications, you will most likely need to use more permutations. `permute` reports the Monte Carlo error, which you can use to evaluate whether the specified number of permutations provides sufficient precision for the reported *p*-value estimates.

**enumerate** specifies that all possible distinct permutations be computed. This gives the full permutation distribution and *p*-values with no error. `reps()` and `rseed()` cannot be specified with `enumerate`.

The number of all possible distinct permutations is typically extremely large. Only for some small problems will it be practical to fully enumerate the permutation distribution. If all the values of `permvar` are unique, the number of possible permutations is \(N!\), where \(N\) is the number of observations. When `permvar` has a lot of repeated values (when, for example, it is a 0/1 variable), the number of possible distinct permutations can be considerably less than \(N!\) and may make enumeration feasible.
Before beginning the enumeration, `permute` will calculate and display the number of distinct permutations, allowing you to press `Break` when you see that the number of permutations is so large as to make computation time impossibly long.

### Options

- **rseed(#)** sets the random-number seed. Specifying this option is equivalent to typing the following command prior to calling `permute`:

  ```
  . set seed #
  ```

- **strata(varlist)** specifies that the permutations be performed within each stratum defined by the values of `varlist`.

- **saving(filename[, double every(#) replace])** creates a Stata data file (.dta file) consisting of variables for each statistic in `exp_list` containing the results for each permutation.

  - `double` specifies that the results for each permutation be saved as doubles, meaning 8-byte reals. By default, they are saved as floats, meaning 4-byte reals.

  - `every(#)` specifies that results be written to disk every #th permutation. `every()` should be specified only in conjunction with `saving()` when `command` takes a long time for each permutation. This will allow recovery of partial results should some other software crash your computer. See [R] `postfile`.

  - `replace` specifies that `filename` be overwritten if it exists.

### Reporting

- **standardize** specifies that the observed value of each test statistic be standardized. That is, the observed test statistic $T_{obs}$ is standardized by calculating $[T_{obs} - \text{mean}(T)]/\sqrt{\text{Var}(T)}$, where $\text{mean}(T)$ and $\text{Var}(T)$ are the mean and variance of the permutation distribution of $T$. Standardized test statistics are useful for seeing roughly how extreme (and in what direction) the observed test statistic is.

- **level(#)** specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [R] `level`.

- **title(text)** specifies a title to be displayed above the table of permutation results.

- **dots(#)** and **nodots** specify whether to display permutation dots. By default, one dot character is displayed for each successful permutation. An “x” is displayed if `command` returns an error or if any value in `exp_list` is missing. You can also control whether dots are displayed using `set dots`; see [R] `set`.

  - `dots(#)` displays dots every # permutations. `dots(0)` is a synonym for `nodots`.

  - `nodots` suppresses display of the permutation dots.

- **nowarning** suppresses the printing of a warning message when `command` does not set `e(sample)`.

- **noisily** requests that any output from `command` be displayed. This option implies the `nodots` option.

- **trace** causes a trace of the execution of `command` to be displayed. This option implies the `noisily` option.

- **verbose** requests that the full table legend be displayed when multiple coefficients or standard errors are specified using the `_b` or `_se` notation.

- **noheader** suppresses display of the table header. This option implies the `nolegend` option.
nolegend suppresses display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

nodrop prevents \texttt{permute} from dropping observations outside the \texttt{if} and \texttt{in} qualifiers. \texttt{nodrop} will also cause \texttt{permute} to ignore the contents of \texttt{e(sample)} if it exists as a result of running \texttt{command}. By default, \texttt{permute} temporarily drops out-of-sample observations. \texttt{nodrop} will also cause \texttt{permute} to ignore the contents of \texttt{e(sample)} if it exists as a result of running \texttt{command}.

\texttt{reject(exp)} specifies an expression that indicates when results should be rejected. When \texttt{exp} is true, the resulting values are reset to missing values.

\texttt{eps(#)} specifies the numerical tolerance for testing $T \leq T_{\text{obs}}$ and $T \geq T_{\text{obs}}$, where $T$ is the test statistic and $T_{\text{obs}}$ is its observed value. These are considered true if, respectively, $T \leq T_{\text{obs}} + \#$ or $T \geq T_{\text{obs}} - \#$. The default is \texttt{eps(1e-7)}. You will not have to specify \texttt{eps()} under normal circumstances.

\section*{Remarks and examples}

Remarks are presented under the following headings:

  \item \textit{Monte Carlo permutation tests}
  \item \textit{Two-sided p-values from permutation tests}
  \item \textit{One-sided permutation test}
  \item \textit{Enumeration}
  \item \textit{Efficiency considerations for Monte Carlo permutations}
  \item \textit{Efficiency considerations for enumeration}
\end{itemize}

\section*{Introduction}

Permutation tests are based on the idea of scrambling—that is, permuting—the order of a variable in all possible ways, calculating the value of a test statistic for each permutation, and taking this set of values of the statistic as its distribution.

For instance, consider the correlation of two variables, \texttt{corr(x, y)}, where \texttt{x} = $x_1, \ldots, x_n$ and \texttt{y} = $y_1, \ldots, y_n$. We hold the order of \texttt{x} fixed and permute the order of \texttt{y} in all possible ways. For each permutation \texttt{y*}, we calculate $T^* = \text{corr}(x, y^*)$. The set of $T^*$ gives the permutation distribution for the correlation. This permutation distribution is the distribution of the correlation under the null hypothesis that the ordering of the elements of \texttt{y} are independent of the ordering of the elements of \texttt{x}, conditional on the observed values of \texttt{x} and \texttt{y}.

Aside: Actually, the null hypothesis does not require independence. A weaker assumption of exchangeability is sufficient. If \texttt{x} and \texttt{y} are observed values of the random variates $X = (X_1, \ldots, X_n)$ and $Y = (Y_1, \ldots, Y_n)$, then the joint distribution $f(X, Y)$ is called exchangeable when it is invariant to the orderings of $X_1, \ldots, X_n$ and $Y_1, \ldots, Y_n$.

The \textit{p}-value for the permutation test is the proportion of permutations that produce a test statistic $T^*$ as extreme or more extreme than the test statistic $T_{\text{obs}}$ computed using the observed data. \texttt{permute} estimates \textit{p}-values for permutation tests using Monte Carlo permutations or by enumerating all possible permutations when the \texttt{enumerate} option is specified. To do Monte Carlo permutations, you type

\begin{verbatim}
. permute permvar exp_list, reps(#): command
\end{verbatim}
The values in the variable `permvar` are randomly permuted # times, each time executing `command` and collecting the associated values from the expressions in `exp_list`.

`command` defines the statistical command to be executed. Most Stata commands and user-written programs can be used with `permute`, as long as they follow standard Stata syntax; see [U] 11 Language syntax. `exp_list` specifies the statistics to be collected from the execution of `command`. Despite the fact that `permute` works with most Stata commands, that does not mean the resulting permutation test is a sensible test. See, for example, Good (2006).

To enumerate all possible distinct permutations, you type

```
. permute permvar exp_list, enumerate: command
```

`permute` may be used for replaying results, but this feature is appropriate only when a dataset generated by `permute` is currently in memory or is identified by the `using` specification.

Monte Carlo permutation tests

We first demonstrate how to apply the `permute` prefix by testing for a difference in the distribution of a variable across two groups. Here we perform the test using Monte Carlo permutations. In example 3, we do the same test using complete enumeration.

Example 1: Wilcoxon rank-sum test

Let’s consider calculating the \( p \)-value for the Wilcoxon rank-sum test performed by `ranksum`. Suppose that we collected data from some experiment: `y` is some measure we took on 17 individuals, and `group` identifies the group to which an individual belongs.

```
. use https://www.stata-press.com/data/r18/permute2
. list, sepby(group)
```

Adjusted variance 98.03

H0: y(group==0) = y(group==1)

\[ z = -2.020 \]

Prob > |z| = 0.0434
Exact prob = 0.0436

The test gives an approximate \( p \)-value of 0.0434 and an exact \( p \)-value of 0.0436.

Let’s try to reproduce these results using `permute`. The test statistic \( T \) for the Wilcoxon rank-sum test is the sum of the ranks for the first group, which is 79, and is stored as `r(sum_obs)`. We specify `reps(10000)` to do 10,000 Monte Carlo permutations and `dots(100)` to display a dot every 100th permutation. We set the random-number seed so that we can duplicate our results.

```
.set seed 1234
.permute group r(sum_obs), reps(10000) dots(100): ranksum y, by(group)
```

Warning: `ranksum` does not set `e(sample)`, so no observations will be excluded from the permutations because of missing values or other reasons. To exclude observations, press Break, save the data, drop any observations that are to be excluded, and rerun `permute`.

Permutations (10,000): ........1,000.........2,000.........3,000.........4,000
> ........5,000.........6,000.........7,000.........8,000.........9,000........
> ..10,000 done

Notes: For lower one-sided test, \( c = \#\{T <= T(obs)\} \) and \( p = p\text{lower} = c/n \).
For upper one-sided test, \( c = \#\{T >= T(obs)\} \) and \( p = p\text{upper} = c/n \).
For two-sided test, \( p = 2*\min(p\text{lower}, p\text{upper}); SE \) and CI approximate.

The lengthy message about `e(sample)` is worth noting. If there were missing values in the data, we might want to drop those observations before running `permute`. To suppress the message in future runs, use the `nowarning` option.

The two-sided \( p \)-value obtained by this Monte Carlo procedure is 0.0446, which is close to the exact \( p \)-value of 0.0436 computed by `ranksum`. See the next section for a description of how two-sided
p-values are calculated when performing permutation tests. See example 2 for a test that requires a one-sided p-value.

Note that we typed

```plaintext
.permute group ...
```

rather than

```plaintext
.permute y ...
```

We permuted the 0/1 variable `group`, which defines the groups, rather than the outcome variable `y`. For a statistic dependent on only two variables, it obviously does not matter which one we permute in terms of the theory of the test, but it does matter in terms of the efficiency of how `permute` does the computation. `permute` uses a different random shuffling algorithm for 0/1 (or dichotomous) variables than it does with other variables. See "Efficiency considerations for Monte Carlo permutations" below for details.

`permute` reports standard errors and confidence intervals for p-values because, as with any other Monte Carlo procedure, they are approximations to the true exact p-values. These statistics are useful to assess the precision of the computed p-values. If you need more precision, specify more permutations in the `reps()` option. See "Methods and formulas" for a description of how the standard errors and confidence intervals are calculated.

The confidence interval for the Monte Carlo two-sided p-value in this example is [0.0406, 0.0486]. If we want to increase the precision of the p-value, we could run `permute` again with more random permutations to narrow the confidence interval. The total number of possible distinct permutations of `group`, however, is not extremely large, and we can perform the permutation test using enumeration. See example 3, where we do just that.

## Two-sided p-values from permutation tests

In the above example, we used the two-sided p-value for our hypothesis testing. For permutation distributions, two-sided p-values require some explanation about how they are calculated.

`permute` calculates the two-sided p-value as \( p = 2 \min(p_{\text{lower}}, p_{\text{upper}}) \), where \( p_{\text{lower}} \) is the lower one-sided p-value and \( p_{\text{upper}} \) the upper one-sided p-value. (More precisely, \( p = \min[1, 2 \min(p_{\text{lower}}, p_{\text{upper}})] \) is used because obviously p-values must be bounded by 1.)

In general, the p-value is defined as the probability under the null hypothesis of obtaining a value of the test statistic \( T \) equal to or more extreme than the value \( T_{\text{obs}} \) that was actually observed. For one-sided p-values, what is “more extreme” is clear. For lower one-sided p-values, it is the probability that \( T \leq T_{\text{obs}} \), and for upper one-sided p-values, it is the probability that \( T \geq T_{\text{obs}} \). When \( T \) has a symmetric distribution, the two-sided p-value is typically defined as the probability that \( |T| \geq |T_{\text{obs}}| \).

Permutation distributions, however, are not in general symmetric.

Under a permutation-based null hypothesis, the domain of \( T \) consists of all the possible permutations of the underlying data used to calculate \( T \). The domain is discrete and finite, and hence the permutation distribution of \( T \) is discrete and finite. These finite distributions are symmetric only in certain cases. For instance, with our example of the Wilcoxon rank-sum test, if the data consist of untied ranks, the distribution is symmetric. When there are ties in the ranks, however, the distribution is in most cases not symmetric.

When distributions are asymmetric, what values of \( T \) are “more extreme” than \( T_{\text{obs}} \)? Suppose \( T_{\text{obs}} \) is below the mean of the distribution. Clearly, the lower-tail values \( T \leq T_{\text{obs}} \) are more extreme. But what values of \( T \) from the upper tail are more extreme?
For asymmetric distributions, the rationale for using \( p = 2 \min(p_{\text{lower}}, p_{\text{upper}}) \) for two-sided tests is the following: It takes the smallest one-sided \( p \)-value and doubles it. Comparing this two-sided \( p \)-value against a significance level of, say, 0.05 is equivalent to comparing the smallest one-sided \( p \)-value against a level of 0.025. It essentially turns the two-sided test into a one-sided test with the significance level cut in half. So this definition conveniently sidesteps the need to define what values of \( T \) from the opposite tail from \( T_{\text{obs}} \) are more extreme! Also, it is appropriate for both symmetric and asymmetric distributions.

**One-sided permutation test**

In some cases, we will want to perform a permutation test based on a one-sided \( p \)-value.

> **Example 2:** Permutation tests with ANOVA

Consider some fictional data from an experimental randomized complete-block design in which there are 5 subjects each receiving 10 different treatments. We want to test whether any of the treatments have an effect different from the effects of the other treatments.

Let’s load the data and list the data for the first two subjects:

```
. use https://www.stata-press.com/data/r18/permute1, clear
. sort subject treatment
. list subject treatment y in 1/20, abbrev(10)
```

```

`anova` gives a $p$-value of 0.1174 for the treatment effect. This $p$-value is calculated with the assumption of normality for the distribution of the outcome conditional on the means of each treatment and subject effect.

Suppose we do not want to assume normality. The treatments were assigned in a random order to each of the subjects. A null hypothesis of no treatment effect means that the observed values of $y$ and their order were determined by factors other than the treatments. The treatments were essentially labels that had nothing to do with the outcomes, and any other ordering of the labels would be a possible occurrence. That is, we imagine running the experiment multiple times, each with a different ordering of the treatments, but each time, we get the same observed values of $y$. This is the permutation-based formulation of the null hypothesis.

What about the subjects? Each subject gets each of the 10 treatments, so clearly we must permute the treatments within each subject independently of the permutations for the other subjects. We can do this using the `strata()` option with `permute`.

If we type `ereturn list` after `anova`, we see that the $F$ statistic for treatment is stored in `e(F_1)`. This is our test statistic for our permutation test.

We save the dataset containing all the permutations of the test statistic using the `saving()` option. Specifying the test statistic as `F_treatment=e(F_1)` labels the test statistic as `F_treatment` in the output and is also the name of the variable containing the test statistic in `permanova.dta`, the dataset created by `saving()`. We set the seed for the random-number generator and also specify the `nodots` option to suppress the dots in the output.

Notes: For lower one-sided test, c = #{T <= T(obs)} and p = p_lower = c/n.
For upper one-sided test, c = #{T >= T(obs)} and p = p_upper = c/n.
For two-sided test, p = 2*min(p_lower, p_upper); SE and CI approximate.

Our test statistic is an $F$ statistic, so we are interested in the number of permutations that have a larger (more extreme) statistic than the 1.73 we obtained with our original data. Therefore, we want the upper one-sided $p$-value, which is 0.1212. This value is close to the $p$-value given by `anova` of 0.1174 for the treatment effect.

For an additional example of a permutation test, with an application in epidemiology, see Hayes and Moulton (2017, 237–241).

**Enumeration**

When the number of observations, $N$, in a dataset is small, it may be possible to enumerate all possible permutations and obtain $p$-values without the error involved in computing Monte Carlo $p$-values.

When `permute` does an enumeration, not only does $N$ matter, but the number of distinct values of the permutation variable matters as well. `permute` does the enumeration by computing only permutations that give different arrangements of the permutation variable; that is, it does not compute any duplicate permutations. So the number of distinct values (and their multiplicity) of the permutation variable determines the number of permutations enumerated and so determines whether enumeration is feasible. See `Efficiency considerations for enumeration` below for details.

**Example 3: Wilcoxon rank-sum test using enumeration**

Here we repeat example 1, but this time we do it by enumerating all possible permutations. We load the data:

. `use https://www.stata-press.com/data/r18/permute2`
The data consist of an outcome \( y \) grouped by the variable \( \text{group} \). If we tabulate \( \text{group} \),

\[
\begin{array}{lrr}
\text{Group} & \text{Freq.} & \text{Percent} \\
0 & 11 & 64.71 \\
1 & 6 & 35.29 \\
\hline
\text{Total} & 17 & 100.00
\end{array}
\]

we see that \( \text{group} \) consists of 11 zeros and 6 ones. Hence, there are only \( \binom{17}{6} = 12,376 \) possible distinct permutations of \( \text{group} \).

In example 1, we used \texttt{ranksum} to compute the test statistic, but each time \texttt{ranksum} is called, it computes the ranks of \( y \). It is unnecessary to recompute the ranks for each permutation. It is better to compute the ranks just once at the outset. We can do this using the \texttt{rank()} function of \texttt{egen}:

\[
\texttt{egen r = rank(y)}
\]

The test statistic is the sum of the ranks for either one of the groups. The sum can be computed efficiently using \texttt{summarize} with an \texttt{if} restriction and the \texttt{meanonly} option.

\[
\texttt{permute \text{group} r(sum), enumerate nodrop nowarning dots(100): summarize r if \text{group} == 1, meanonly}
\]

<table>
<thead>
<tr>
<th>T</th>
<th>T(obs)</th>
<th>Test</th>
<th>c</th>
<th>n</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>
<td>_pm_1</td>
<td>74</td>

<td>12376</td>
<td>.9811</td>
</tr>
<tr>
<td></td>
<td></td>
<td>upper</td>
<td>270</td>
<td>12376</td>
<td>.0218</td>
</tr>
<tr>
<td></td>
<td></td>
<td>two-sided</td>
<td></td>
<td></td>
<td>.0436</td>
</tr>
</tbody>
</table>

Notes: For lower one-sided test, \( c = \#\{T \leq T\text{(obs)}\} \) and \( p = p\_\text{lower} = c/n \). For upper one-sided test, \( c = \#\{T \geq T\text{(obs)}\} \) and \( p = p\_\text{upper} = c/n \). For two-sided test, \( p = 2\times\min(p\_\text{lower}, p\_\text{upper}) \).

Note that it is necessary to specify the \texttt{nodrop} option. Otherwise, \texttt{permute} would drop all observations not satisfying \texttt{if group == 1} before doing the permutations, and that would not give us what we want.

\texttt{permute} with the \texttt{enumerate} option gave a two-sided \( p \)-value of 0.0436, which is the same as the exact \( p \)-value reported by \texttt{ranksum}, as it should be.
With group as the variable being permuted, the number of distinct permutations is quite small. If, however, we attempt to do the enumeration for all the distinct permutations of r:

```
. permute r r(sum), enumerate nodrop nowarning dots(100):
> summarize r if group == 1, meanonly
(running summarize on estimation sample)
(enumerating all 3.71e+12 possible permutations)
Permutations (3,705,077,376,000): ..........1,000..........2,000..........3,000
> ........4,000.........—Break—
r(1);
```

Each permutation takes about 0.1 millisecond on our computer. Thus, the enumeration will take $0.1 \times 3.71 \times 10^{12} / (365 \times 24 \times 60 \times 60 \times 1000) \approx 12$ years, so we pressed `Break`.

### Efficiency considerations for Monte Carlo permutations

Suppose you want to perform a randomization two-sample $t$ test, which is like the two-sample $t$ test that assumes normality, only the randomization test is based on permuting the variable that defines the samples. It is the same as the Wilcoxon rank-sum test, except the observed values of the outcome, rather than their ranks, are used for the test statistic.

So say we have a variable $x$ with continuous outcomes for two groups defined by the variable group, with values 0 or 1. The randomization two-sample $t$ test could be done using Monte Carlo permutations by typing

```
. permute x r(mu_1), reps(10000): ttest x, by(group)
```

Or by typing

```
. permute group r(mu_1), reps(10000): ttest x, by(group)
```

In the first case, $x$ was permuted, and in the second, group. Both are valid ways to do Monte Carlo permutations. `permute` is smart, however, and treats a 0/1 variable differently from how it treats a variable with lots of distinct values.

Suppose there are fewer 1s than 0s in group. Rather than randomly permuting all the 0s and 1s, `permute` randomly shuffles the 1s into the 0s. If there are only a few 1s relative to the number of 0s, this method is much faster than permuting all the values. Hence, if you are doing a permutation test that involves two variables, pick the one with the fewest distinct values to be the permvar.

When the `strata()` option is specified, `permute` uses special code for the case in which the permvar is dichotomous (with, say, values $y_0$ and $y_1$) and each stratum contains a single observation equal to $y_1$ and all other observations in the stratum equal to $y_0$ (and $y_0$ and $y_1$ do not flip or change in value across strata). If you are doing a stratified permutation test and you have such a variable whose permutations will give the test you want, be sure to make it the permvar.

For all types of data, Monte Carlo permutations of the permvar are computed quickly. If the command calculating the test statistic for each permutation is not fast, it is unlikely you will notice the greater speed of permuting a dichotomous variable. If, however, you are using a fast command such as `regress`, you likely will notice the greater speed.
Efficiency considerations for enumeration

Doing an enumeration of all possible distinct permutations using the `enumerate` option, however, is a different story. Here the selection of the `permvar` is crucial and typically determines whether it is feasible to do the enumeration.

Consider performing the randomization $t$ test we described earlier using enumeration:

```plaintext
. permute group r(mu_1), enumerate: ttest x, by(group)
```

Suppose there are 20 observations, 10 with `group = 0` and 10 with `group = 1`. Typing `permute group ...` will enumerate all $\binom{20}{10} = 184,756$ possible distinct permutations of `group`. (When we say “distinct permutations”, we mean that duplicate permutations are not computed.)

If, however, we type

```plaintext
. permute x r(mu_1), enumerate: ttest x, by(group)
```

`permute x ...` will attempt to enumerate all possible permutations of `x`. If all the values of `x` are unique, there are $20! \approx 2.4 \times 10^{18}$ possible permutations of `x`, which is much larger than 184,756.

Hence, a dichotomous variable or a variable with few distinct values should always be chosen as the `permvar` rather than another variable with many distinct values whenever possible. (To be precise, both the number of distinct values and their multiplicities determine the number of permutations. See `Methods and formulas`.)

See example 3 for an example using enumeration.

Stored results

`permute` stores the following in `r()`:

Scalars
- `r(N)` number of observations for `command`
- `r(n_reps)` number of permutations performed
- `r(k_exp)` number of standard expressions
- `r(k_eexp)` number of `_b` and `_se` expressions
- `r(n_strata)` number of strata, if `strata()` specified
- `r(level)` confidence level

Macros
- `r(cmd)` `permute`
- `r(command)` `command` following colon
- `r(permvar)` permutation variable
- `r(enumerate)` "enumerate", if `enumerate` specified
- `r(title)` title in output
- `r(rngstate)` random-number state used for Monte Carlo permutations
- `r(exp#)` $#^{th}$ expression
- `r(strata)` strata variable, if `strata()` specified
- `r(missing)` "missing" when one or more expressions equal missing value

Matrices
- `r(b)` observed statistics
- `r(b_std)` standardized observed statistics, if `standardize` specified
- `r(n)` number of nonmissing results
- `r(c_lower)` counts for lower one-sided $p$-values
- `r(c_upper)` counts for upper one-sided $p$-values
- `r(p_lower)` lower one-sided $p$-values
- `r(p_upper)` upper one-sided $p$-values
- `r(p_twosided)` two-sided $p$-values
- `r(se_p_lower)` Monte Carlo standard errors of lower one-sided $p$-values
- `r(se_p_upper)` Monte Carlo standard errors of upper one-sided $p$-values
Methods and formulas

One-sided \( p \)-values are based on counts of the test statistic \( T \) calculated for each permutation that are more extreme than the observed value \( T_{\text{obs}} \). The lower one-sided \( p \)-value uses the count \( c = \# \{ T \leq T_{\text{obs}} \} \), and the upper one-sided \( p \)-value uses \( c = \# \{ T \geq T_{\text{obs}} \} \).

The counts from Monte Carlo permutations are assumed to have a binomial distribution. Standard errors and confidence intervals are computed using cii proportions \( n/c \), where \( n \) is the number of permutations that yielded nonmissing results and \( c \) is the count. The confidence intervals are exact binomial confidence intervals. See Methods and formulas in \([R]\) ci.

permute calculates the two-sided \( p \)-value as \( p = \min[1, 2 \min(p_{\text{lower}}, p_{\text{upper}})] \), where \( p_{\text{lower}} \) is the lower one-sided \( p \)-value and \( p_{\text{upper}} \) the upper one-sided \( p \)-value. Because the definition of the two-sided \( p \)-value does not yield a simple formula for the standard error or confidence interval for Monte Carlo permutations, the following ad hoc procedure is used. If \( p_{\text{lower}} \) is the minimum one-sided \( p \)-value, its count \( c_{\text{lower}} \) is doubled. If \( p_{\text{upper}} \) is the minimum one-sided \( p \)-value, its count \( c_{\text{upper}} \) is doubled. More precisely, the value \( c_2 = \min[n, 2 \min(c_{\text{lower}}, c_{\text{upper}})] \) is used, and its distribution is assumed to be approximately binomial. Standard errors and confidence intervals are computed using cii proportions \( n/c_2 \), wald. The confidence intervals produced are asymptotic binomial confidence intervals.

When enumerate is specified, the \( p \)-values have no error.

Suppose there are \( N \) observations and the variable being permuted contains \( K \) distinct values, each with multiplicity \( n_k, k = 1, \ldots, K \). The total number of distinct permutations is

\[
\frac{N!}{n_1! n_2! \cdots n_K!}
\]

This is the number of permutations computed when enumerate is specified.

When standardize is specified, instead of displaying the observed test statistic \( T_{\text{obs}} \), the standardized statistic

\[
\frac{T_{\text{obs}} - \text{mean}(T)}{\sqrt{\text{Var}(T)}}
\]

is displayed where mean\((T)\) and Var\((T)\) are the mean and variance of the permutation distribution of \( T \):

\[
\text{mean}(T) = \frac{1}{n} \sum_{i=1}^{n} T_i
\]

\[
\text{Var}(T) = \frac{1}{n} \sum_{i=1}^{n} (T_i - \text{mean}(T))^2
\]

\( n \) is the number of permutations, and \( T_i \) is the test statistic calculated for the \( i \)th permutation.

pk — Pharmacokinetic (biopharmaceutical) data

Description
The term pk refers to pharmacokinetic data and the Stata commands, all of which begin with the letters pk, designed to do some of the analyses commonly performed in the pharmaceutical industry. The system is intended for the analysis of pharmacokinetic data, although some of the commands are for general use.

The pk commands are

- **pkexamine [R]**: Calculate pharmacokinetic measures
- **pksumm [R]**: Summarize pharmacokinetic data
- **pkshape [R]**: Reshape (pharmacokinetic) Latin-square data
- **pkcross [R]**: Analyze crossover experiments
- **pkequiv [R]**: Perform bioequivalence tests
- **pkcollapse [R]**: Generate pharmacokinetic measurement dataset

Also see [ME] menl for fitting pharmacokinetic models using nonlinear mixed-effects models; for instance, see example 15 in [ME] menl.

Remarks and examples
Several types of clinical trials are commonly performed in the pharmaceutical industry. Examples include combination trials, multicenter trials, equivalence trials, and active control trials. For each type of trial, there is an optimal study design for estimating the effects of interest. The pk system can be used to analyze equivalence trials, which are usually conducted using a crossover design; however, it is possible to use a parallel design and still draw conclusions about equivalence.

Equivalence trials assess bioequivalence between two drugs. Although proving that two drugs behave the same is impossible, regulatory agencies believe that if the absorption properties of two drugs are similar, the two drugs will produce similar effects and have similar safety profiles. Generally, the goal of an equivalence trial is to assess the equivalence of a generic drug to an existing drug. This goal is commonly accomplished by comparing a confidence interval about the difference between a pharmacokinetic measurement of two drugs with an equivalence limit constructed from regulations. If the confidence interval is entirely within the equivalence limit, the drugs are declared bioequivalent. Another approach to assessing bioequivalence is to use the method of interval hypotheses testing. pkequiv is used to conduct these tests of bioequivalence.

Several pharmacokinetic measures can be used to ascertain how available a drug is for cellular absorption. The most common measure is the area under the concentration–time curve (AUC). Another common measure of drug availability is the maximum concentration ($C_{\text{max}}$) achieved by the drug during the follow-up period. Stata reports these and other less common measures of drug availability, including the time at which the maximum drug concentration was observed and the duration of the period during which the subject was being measured. Stata also reports the elimination rate, that is, the rate at which the drug is metabolized, and the drug’s half-life, that is, the time it takes for the drug concentration to fall to one-half of its maximum concentration.
pkexamine computes and reports all the pharmacokinetic measures that Stata produces, including four calculations of the AUC. The standard AUC from 0 to the maximum observed time ($AUC_{0,t_{\text{max}}}$) is computed using cubic splines or the trapezoidal rule. Additionally, pkexamine also computes the AUC from 0 to infinity by extending the standard concentration–time curve from the maximum observed time using three different methods. The first method simply extends the standard curve by using a least-squares linear fit through the last few data points. The second method extends the standard curve by fitting a decreasing exponential curve through the last few data points. The third method extends the curve by fitting a least-squares linear regression line on the log concentration. The mathematical details of these extensions are described in Methods and formulas of [R] pkexamine.

Data from an equivalence trial may also be analyzed using methods appropriate to the particular study design. When you have a crossover design, pkcross can be used to fit an appropriate ANOVA model. A crossover design is simply a restricted Latin square; therefore, pkcross can also be used to analyze any Latin-square design.

Some practical concerns arise when dealing with data from equivalence trials. Primarily, the data must be organized in a manner that Stata can use. The pk commands include pkcollapse and pkshape, which are designed to help transform data from a common format to one that is suitable for analysis with Stata.

In the following examples, we illustrate several different data formats that are often encountered in pharmaceutical research and describe how these formats can be transformed to formats that can be analyzed with Stata.

### Example 1

Assume that we have one subject and are interested in determining the drug profile for that subject. A reasonable experiment would be to give the subject the drug and then measure the concentration of the drug in the subject’s blood over a given period. For example, here is part of a dataset from Chow and Liu (2009, 13):

```stata
use https://www.stata-press.com/data/r18/auc
(Primidone concentrations)
list, abbrev(14)
```

<table>
<thead>
<tr>
<th>id</th>
<th>time</th>
<th>concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>0.5</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>2.8</td>
</tr>
<tr>
<td>4</td>
<td>1.5</td>
<td>4.4</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
<td>4.4</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
<td>4.7</td>
</tr>
<tr>
<td>7</td>
<td>4</td>
<td>4.1</td>
</tr>
<tr>
<td>8</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>9</td>
<td>8</td>
<td>3.6</td>
</tr>
<tr>
<td>10</td>
<td>12</td>
<td>3</td>
</tr>
<tr>
<td>11</td>
<td>16</td>
<td>2.5</td>
</tr>
<tr>
<td>12</td>
<td>24</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>32</td>
<td>1.6</td>
</tr>
</tbody>
</table>

Examining these data, we notice that the concentration quickly increases, plateaus for a short period, and then slowly decreases over time. `pkexamine` is used to calculate the pharmacokinetic measures of interest. `pkexamine` is explained in detail in [R] *pkexamine*. The output is

```
pkexamine time concentration
```

<table>
<thead>
<tr>
<th>Maximum concentration =</th>
<th>4.7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time of maximum concentration =</td>
<td>3</td>
</tr>
<tr>
<td>Time of last observation (Tmax) =</td>
<td>32</td>
</tr>
<tr>
<td>Elimination rate =</td>
<td>0.0279</td>
</tr>
<tr>
<td>Half life =</td>
<td>24.8503</td>
</tr>
</tbody>
</table>

Area under the curve

<table>
<thead>
<tr>
<th>AUC [0, Tmax]</th>
<th>AUC [0, inf.) Linear of log conc.</th>
<th>AUC [0, inf.) Linear fit</th>
<th>AUC [0, inf.) Exponential fit</th>
</tr>
</thead>
<tbody>
<tr>
<td>85.24</td>
<td>142.603</td>
<td>107.759</td>
<td>142.603</td>
</tr>
</tbody>
</table>

Fit based on last 3 points.

---

### Example 2

Clinical trials require that data be collected on more than one subject. There are several ways to enter raw measured data collected on several subjects. It would be reasonable to enter for each subject the drug concentration value at specific points in time. Such data could be

```
<table>
<thead>
<tr>
<th>id</th>
<th>conc1</th>
<th>conc2</th>
<th>conc3</th>
<th>conc4</th>
<th>conc5</th>
<th>conc6</th>
<th>conc7</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
<td>4</td>
<td>7</td>
<td>5</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>2</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>5</td>
<td>4</td>
<td>1</td>
</tr>
</tbody>
</table>
```

where `conc1` is the concentration at the first measured time, `conc2` is the concentration at the second measured time, etc. This format requires that each drug concentration measurement be made at the same time on each subject. Another more flexible way to enter the data is to have an observation with three variables for each time measurement on a subject. Each observation would have a subject ID, the time at which the measurement was made, and the corresponding drug concentration at that time. The data would be as follows:
Stata expects the data to be organized in the second form, as shown in pkdata.dta. If your data are organized as described in the first format, you will need to reshape the data to the second form; see \[D\] reshape. Because the data in the second (or long) format contain information for one drug on several subjects, \texttt{pksumm} can be used to produce summary statistics of the pharmacokinetic measurements. The output is

\begin{verbatim}
 . pksumm id time conc1

\end{verbatim}

Number of observations = 16
Until now, we have been concerned with the profile of only one drug. We have characterized the profile of that drug by individual subjects by using **pkexamine** and by a group of subjects by using **pksumm**. The goal of an equivalence trial, however, is to compare two drugs, which we will do in the rest of this example.

For equivalence trials, the study design most often used is the crossover design. For a complete discussion of crossover designs, see Ratkowsky, Evans, and Alldredge (1993).

In brief, crossover designs require that each subject be given both treatments at two different times. The order in which the treatments are applied changes between groups. For example, if we had 16 subjects numbered 1–16, the first 8 would receive reference treatment “R” during the first period of the study, and then they would be given test treatment “T”. The second 8 subjects would be given treatment “T” during the first period of the study, and then they would be given treatment “R”. Each subject in the study will have four variables that describe the observation: a subject identifier, a sequence identifier that indicates the order of treatment, and two outcome variables, one for each treatment. The outcome variables for each subject are the pharmacokinetic measures. The data must be transformed from a series of measurements on individual subjects to data containing the pharmacokinetic measures for each subject. In Stata parlance, this is referred to as a collapse, which can be done with **pkcollapse**; see [R] **pkcollapse**.

Here is part of our data:

```

</tbody>
</table>
```
This format is similar to the second format described above, except that now we have measurements for two drugs at each time for each subject. We transform these data with `pkcollapse`:

```
    . pkcollapse time conc1 conc2, id(id) keep(seq) stat(auc)
```

```
    ................................
    . list, sep(8) abbrev(10)
    id seq auc_conc1 auc_conc2
    1. 1 1 150.9643 218.5551
    2. 2 1 146.7606 133.3201
    3. 3 1 160.6548 126.0635
    4. 4 1 157.8622 96.17461
    5. 5 1 133.6957 188.9038
    6. 6 1 160.639 223.6922
    7. 7 1 131.2604 104.0139
    8. 8 1 168.5186 237.8962
    9. 9 2 137.0627 139.7382
    10. 10 2 153.4038 202.3942
    11. 11 2 163.4593 136.7848
    12. 12 2 146.0462 104.5191
    13. 13 2 158.1457 165.8654
    14. 14 2 147.1977 139.235
    15. 15 2 164.9988 166.2391
    16. 16 2 145.3823 158.5146
```

For this example, we chose to use the $AUC_{0,t_{\text{max}}}$ for two drugs as our pharmacokinetic measure. We could have used any of the measures computed by `pkexamine`. In addition to the $AUC$s, the dataset also contains a sequence variable for each subject indicating when each treatment was administered.

The data produced by `pkcollapse` are in what Stata calls wide format; that is, there is one observation per subject containing two or more outcomes. To use `pkcross` and `pkequiv`, we need to transform these data to long format, which we can do using `pkshape`; see [R] `pkshape`.

Consider the first subject in the dataset. This subject is in sequence 1, which means that treatment “R” was applied during the first period of the study and treatment “T” was applied in the second period of the study. We need to split the first observation into two observations so that the outcome measure is only in one variable. We also need two new variables, one indicating the treatment the subject received and another recording the period of the study when the subject received that treatment. We might expect the expansion of the first subject to be

```
    id sequence auc treat period
    1 1 150.9643 R 1
    1 1 218.5551 T 2
```

We see that subject number 1 was in sequence 1, had an $AUC_{0,t_{\text{max}}}$ of 150.9643 when treatment “R” was applied in the first period of the study, and had an $AUC_{0,t_{\text{max}}}$ of 218.5551 when treatment “T” was applied in the second period.

Similarly, the expansion of subject 9 (the first subject in sequence 2) would be

```
    id sequence auc treat period
    9 2 137.0627 T 1
    9 2 139.7382 R 2
```

Here treatment “T” was applied to the subject during the first period of the study, and treatment “R” was applied to the subject during the second period of the study.

An additional complication is common in crossover study designs. The treatment applied in the first period of the study might still have some effect on the outcome in the second period. In this example,
each subject was given one treatment followed by another treatment. To get accurate estimates of
treatment effects, it is necessary to account for the carryover effect, the effect that the first treatment has
in the second period of the study. We must, therefore, have a variable that indicates which treatment
was applied in the first treatment period. pkshape creates a variable that indicates the carryover
effect. For treatments applied during the first treatment period, there will never be a carryover effect.
The sequence, treatment, and carryover variables all receive value labels. Thus, the expanded data
created by pkshape for subject 1 will be

<table>
<thead>
<tr>
<th>id</th>
<th>sequence</th>
<th>outcome</th>
<th>treat</th>
<th>period</th>
<th>carry</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>RT</td>
<td>150.9643</td>
<td>R</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>RT</td>
<td>218.5551</td>
<td>T</td>
<td>2</td>
<td>R</td>
</tr>
</tbody>
</table>

and the expanded data for subject 9 will be

<table>
<thead>
<tr>
<th>id</th>
<th>sequence</th>
<th>outcome</th>
<th>treat</th>
<th>period</th>
<th>carry</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>TR</td>
<td>137.0627</td>
<td>T</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>9</td>
<td>TR</td>
<td>139.7382</td>
<td>R</td>
<td>2</td>
<td>T</td>
</tr>
</tbody>
</table>

We pkshape the data:

```
pkshape id seq auc*, order(RT TR)
sort id sequence period
list, sep(16)
```

<table>

</tbody>
</table>
Crossover designs do not require that each subject receive each treatment, but if they do, the crossover design is referred to as a complete crossover design.

The dataset (pkdata.dta) in this example is organized in a manner that can be analyzed with Stata. To fit an ANOVA model to these data, we can use `anova` or `pkcross`. To conduct equivalence tests, we can use `pkequiv`.

**Description**

pkcollapse generates new variables with the pharmacokinetic summary measures of interest.
pkcollapse is one of the pk commands. Please read \[R\] pk before reading this entry.

**Quick start**

Single concentration, v1, measured over time, tvar, for patients identified by idvar

pkcollapse tvar v1, id(idvar)

Same as above, but add additional drug concentration data stored in v2

pkcollapse tvar v1 v2, id(idvar)

Same as above, but use trapezoidal rule for calculating area under the concentration–time curve \( (AUC_{0,\infty}, t_{\text{max}}) \)

pkcollapse tvar v1 v2, id(idvar) trapezoid

Same as above, and increase the number of data points used to estimate \( AUC_{0,\infty} \) to 10

pkcollapse tvar v1 v2, id(idvar) trapezoid fit(10)

Retain variables v3 and v4 when collapsing dataset

pkcollapse tvar v1 v2, id(idvar) keep(v3 v4)

**Menu**

Statistics > Epidemiology and related > Other > Generate pharmacokinetic measurement dataset
Syntax

`pkcollapse time concentration [concentration [...] [if], id(id_var) [options]]`

Options

`id(id_var)` is required and specifies the variable that contains the subject ID over which `pkcollapse` is to operate.

`stat(measures)` specifies the measures to be generated. The default is to generate all the measures.

`trapezoid` tells Stata to use the trapezoidal rule when calculating the $\text{AUC}_{0,t_{\text{max}}}$. The default is to use cubic splines, which give better results for most functions. When the curve is irregular, `trapezoid` may give better results.

`fit(#)` specifies the number of points to use in estimating the $\text{AUC}_{0,\infty}$. The default is `fit(3)`, the last three points. This number should be viewed as a minimum; the appropriate number of points will depend on your data.

`keep(varlist)` specifies the variables to be kept during the collapse. Variables not specified with the `keep()` option will be dropped. When `keep()` is specified, the kept variables are checked to ensure that all values of the variables are the same within `id_var`.

`force` forces the collapse, even when values of the `keep()` variables differ within `id_var`.

`nodots` suppresses the display of dots during calculation.
Remarks and examples

pkcollapse generates all the summary pharmacokinetic measures.

Example 1

We demonstrate the use of pkcollapse with pkdata.dta described in example 2 of [R] pk. We have drug concentration data on 16 subjects. Each subject is measured at 13 time points over a 32-hour period. Some of the records are as follows:

```
. use https://www.stata-press.com/data/r18/pkdata
(Fictional drug concentration data)
. list, sep(0)

The resulting dataset contains one observation per subject and is in wide format. If we want to use \texttt{pkcross} or \texttt{pkequiv}, we must transform these data to long format with the \texttt{pkshape} command, which we do in example 2 of [R] \texttt{pk}.

**Methods and formulas**

The statistics generated by \texttt{pkcollapse} are described in [R] \texttt{pkexamine}.

**Also see**

[R] \texttt{pk} — Pharmacokinetic (biopharmaceutical) data
pkcross analyzes data from a crossover design experiment. When analyzing pharmaceutical trial data, if the treatment, carryover, and sequence variables are known, the omnibus test for separability of the treatment and carryover effects is calculated.

pkcross is one of the pk commands. Please read [R] pk before reading this entry.

Quick start

For pharmacokinetic outcome y measured for subjects identified by idvar given treatments treat in sequences identified by seq in periods period with potential carryover effects from previous treatment carry:

Sequence, treatment, and period effects for a 2 × 2 design
pkcross y, param(3) id(idvar) sequence(seq) treatment(treat) ///
   period(period)

Same as above, but estimate the carryover effect instead of the sequence effect
pkcross y, param(1) id(idvar) treatment(treat) period(period) ///
   carryover(carry)

Only estimate sequence, treatment, and period effects in higher-order designs
pkcross y, id(idvar) sequence(seq) treatment(treat) carryover(none)

Also estimate carryover effect and omnibus measure of separability of treatment and carryover effects
pkcross y, model(seq / idvar|seq treat carry period) ///
   treatment(treat) carryover(carry) sequence(seq)
Syntax

```
pkcross outcome [if] [in] [, options]
```

Parameterization

| param(3)        | estimate mean and the period, treatment, and sequence effects; assume no carryover effects exist; the default |
| param(1)        | estimate mean and the period, treatment, and carryover effects; assume no sequence effects exist               |
| param(2)        | estimate mean, period and treatment effects, and period-by-treatment interaction; assume no sequence or carryover effects exist |
| param(4)        | estimate mean, sequence and treatment effects, and sequence-by-treatment interaction; assume no period or carryover effects exist |

Options

- `sequence(varname)` specifies the variable that contains the sequence in which the treatment was administered. If this option is not specified, `sequence(sequence)` is assumed.
- `treatment(varname)` specifies the variable that contains the treatment information. If this option is not specified, `treatment(treat)` is assumed.
- `period(varname)` specifies the variable that contains the period information. If this option is not specified, `period(period)` is assumed.
- `id(varname)` specifies the variable that contains the subject identifiers. If this option is not specified, `id(id)` is assumed.
- `carryover(varname|none)` specifies the variable that contains the carryover information. If `carry(none)` is specified, the carryover effects are omitted from the model. If this option is not specified, `carryover(carry)` is assumed.
- `model(string)` specifies the model to be fit. For higher-order crossover designs, this option can be useful if you want to fit a model other than the default. However, `anova` (see [R] `anova`) can also be used to fit a crossover model. The default model for higher-order crossover designs is outcome predicted by sequence, period, treatment, and carryover effects. By default, the model statement is `model(sequence period treat carry)`.
- `sequential` specifies that sequential sums of squares be estimated.
pkcross — Analyze crossover experiments

Parameterization

\text{\texttt{param(\#)}} specifies which of the four parameterizations to use for the analysis of a $2 \times 2$ crossover experiment. This option is ignored with higher-order crossover designs. The default is \texttt{param(3)}. See the technical note in this entry for $2 \times 2$ crossover designs for more details.

\texttt{param(3)} estimates the overall mean, the period effects, the treatment effects, and the sequence effects, assuming that no carryover effects exist. This is the default parameterization.

\texttt{param(1)} estimates the overall mean, the period effects, the treatment effects, and the carryover effects, assuming that no sequence effects exist.

\texttt{param(2)} estimates the overall mean, the period effects, the treatment effects, and the period-by-treatment interaction, assuming that no sequence or carryover effects exist.

\texttt{param(4)} estimates the overall mean, the sequence effects, the treatment effects, and the sequence-by-treatment interaction, assuming that no period or carryover effects exist. When the sequence-by-treatment interaction is equivalent to the period effect, this reduces to the third parameterization.

Remarks and examples

\texttt{pkcross} is designed to analyze crossover experiments. Use \texttt{pkshape} first to reshape your data; see \texttt{[R] pkshape}. \texttt{pkcross} assumes that the data were reshaped by \texttt{pkshape} or are organized in the same manner as produced with \texttt{pkshape}. Washout periods are indicated by the number 0. See the technical note below for more information on analyzing $2 \times 2$ crossover experiments.

Technical note

The $2 \times 2$ crossover design cannot be used to estimate more than four parameters because there are only four pieces of information (the four cell means) collected. \texttt{pkcross} uses ANOVA models to analyze the data, so one of the four parameters must be the overall mean of the model, leaving just 3 degrees of freedom to estimate the remaining effects (period, sequence, treatment, and carryover). Thus, the model is overparameterized. Estimation of treatment and carryover effects requires the assumption of either no period effects or no sequence effects. Some researchers maintain that estimating carryover effects at the expense of other effects is a bad idea. This is a limitation of this design. \texttt{pkcross} implements four parameterizations for this model. They are numbered sequentially from one to four and are described in \textit{Options}.

Example 1

Consider the example data published in \textit{Chow and Liu (2009, 71)}. There are 24 patients, 12 in each sequence. Sequence 1 is the reference formulation followed by the test formulation; sequence 2 is the test formulation followed by the reference formulation. After reshaping the data with \texttt{pkshape}, we have variables that identify the subjects, periods, treatments, sequence, and carryover treatment. The \texttt{outcome} variable contains the reported $\text{AUC}_{0,t_{\text{max}}}$. To compute the ANOVA table, use \texttt{pkcross}:
. use https://www.stata-press.com/data/r18/chowliu
. pkshape id seq period1 period2, order(RT TR)
. pkcross outcome

Sequence variable = sequence  
Period variable = period  
Treatment variable = treat  
Carryover variable = carry  
ID variable = id

</tbody>
</table>

Omnibus measure of separability of treatment and carryover = 29.2893%

There is evidence of intersubject variability, but there are no other significant effects. The omnibus test for separability is a measure reflecting the degree to which the study design allows the treatment effects to be estimated independently of the carryover effects. The measure of separability of the treatment and carryover effects indicates approximately 29% separability, which can be interpreted as the degree to which the treatment and carryover effects are orthogonal. This is a characteristic of the design of the study. For a complete discussion, see Ratkowsky, Evans, and Alldredge (1993). Compared with the output in Chow and Liu (2009), the sequence effect is mislabeled as a carryover effect. See Ratkowsky, Evans, and Alldredge (1993, sec. 3.2) for a complete discussion of the mislabeling.

By specifying `param(1)`, we obtain parameterization 1 for this model.

Omnibus measure of separability of treatment and carryover = 29.2893%

Example 2

Consider the case of a two-treatment, four-sequence, two-period crossover design. This design is commonly referred to as Balaam’s design (Balaam 1968). Ratkowsky, Evans, and Alldredge (1993, 140) published the following data from an amantadine trial, originally published by Taka and Armitage (1983):
The sequence identifier must be a string with 0s to indicate washout or baseline periods, or a number. If the sequence identifier is numeric, the `order()` option must be specified with `pkshape`. If the sequence identifier is a string, `pkshape` will use the string values to create sequence, period, and treatment variables. In this example, the dash is used to indicate a baseline period, which is an invalid code for this purpose. Therefore, we use the `subinstr()` function to replace each dash with a 0. After doing so, we can use `pkshape` to format the data in a way that can be used with `pkcross`. We leave most `pkcross` options at their defaults, but we specify the `sequential` option to calculate sequential sums of squares instead of the default partial sums of squares.

```
. replace seq = subinstr(seq, ",", "0", .)
   (17 real changes made)
. pkshape id seq period1 period2 period3
. pkcross outcome, sequential
```

Omnibus measure of separability of treatment and carryover = 64.6447%
Example 3

For this example, we return to \texttt{pkdata.dta} from example 2 of \texttt{[R] pk} and use \texttt{pkcollapse} and \texttt{pkshape} on the data as discussed in that example.

\begin{verbatim}
use https://www.stata-press.com/data/r18/pkdata, clear
(Fictional drug concentration data)
.pkcollapse time conc1 conc2, id(id) keep(seq) stat(auc)
................................
.pkshape id seq auc*, order(RT TR)
\end{verbatim}

After sorting the data with \texttt{sort}, our data appear as follows:

\begin{verbatim}
.sort period id
.list, sep(8)
\end{verbatim}

When the model statement is used and the omnibus measure of separability is desired, specify the variables in the `treatment()`, `carryover()`, and `sequence()` options to `pkcross`.

### Methods and formulas

`pkcross` uses ANOVA to fit models for crossover experiments; see [R] `anova`.

The omnibus measure of separability is

\[
S = 100(1 - V)\%
\]

where \( V \) is Cramér’s \( V \) and is defined as

\[
V = \left\{ \frac{\chi^2}{N \min(r-1, c-1)} \right\}^{\frac{1}{2}}
\]

\( N \) is the sample size and \( \chi^2 \) is calculated as

\[
\chi^2 = \sum_i \sum_j \left\{ \frac{(O_{ij} - E_{ij})^2}{E_{ij}} \right\}
\]

where \( O \) and \( E \) are the observed and expected counts in an \( r \times c \) table of the number of times each treatment is followed by the other treatments.

[R] pk — Pharmacokinetic (biopharmaceutical) data
pkequiv — Perform bioequivalence tests

**Description**

pkequiv performs bioequivalence testing for two treatments. By default, pkequiv calculates a standard confidence interval (CI) symmetric about the difference between the two treatment means. pkequiv also calculates CIs symmetric about 0 and intervals based on Fieller’s theorem. Also, pkequiv can perform interval hypothesis tests for bioequivalence.

pkequiv is one of the pk commands. Please read [R] pk before reading this entry.

**Quick start**

Classic CI for difference in pharmacokinetic outcome y1 between treatments v1 given over period v2 in sequence v3 with subjects identified by idvar

```
pkequiv y1 v1 v2 v3 idvar
```

Same as above, but calculate an exact CI by Fieller’s theorem

```
pkequiv y1 v1 v2 v3 idvar, fieller
```

Schuirmann’s two one-sided tests for bioequivalence

```
pkequiv y1 v1 v2 v3 idvar, tost
```

Specify the two treatments, 2 and 3, that are to be tested for equivalence

```
pkequiv y1 v1 v2 v3 idvar, compare(2 3)
```
Syntax

collect is allowed; see [U] 11.1.10 Prefix commands.

Options

- \texttt{compare(string)} specifies the two treatments to be tested for equivalence. Sometimes there may be more than two treatments, but the equivalence can be determined only between any two treatments.
- \texttt{limit(#)} specifies the equivalence limit. The default is \texttt{limit(0.2)}. The equivalence limit can be changed only symmetrically; for example, it is not possible to have a 0.15 lower limit and a 0.2 upper limit in the same test.
- \texttt{level(#)} specifies the confidence level, as a percentage, for CIs. The default is \texttt{level(90)}. This setting is not controlled by the \texttt{set level} command.
- \texttt{fieller} specifies that a CI based on Fieller’s theorem be calculated.
- \texttt{symmetric} specifies that a symmetric CI be calculated.
- \texttt{anderson} specifies that the Anderson and Hauck (1983) hypothesis test for bioequivalence be computed. This option is ignored when calculating a CI based on Fieller’s theorem or when calculating a CI that is symmetric about 0.
- \texttt{tost} specifies that the two one-sided hypothesis tests for bioequivalence be computed. This option is ignored when calculating a CI based on Fieller’s theorem or when calculating a CI that is symmetric about 0.
- \texttt{noboot} prevents the estimation of the probability that the CI lies within the equivalence limits. If this option is not specified, this probability is estimated by resampling the data.

Remarks and examples

\texttt{pkequiv} is designed to conduct tests for bioequivalence based on data from a crossover experiment. \texttt{pkequiv} requires that the user specify the \texttt{outcome}, \texttt{treatment}, \texttt{period}, \texttt{sequence}, and \texttt{id} variables. The data must be in the same format as that produced by \texttt{pkshape}; see [R] \texttt{pkshape}.
Example 1

</table>
We use `pkequiv` to conduct a bioequivalence test between reference treatment “R” and test treatment “T”.

```
. set seed 123
. pkequiv outcome treat period seq id
```

Classic confidence interval for bioequivalence

<table>
<thead>
<tr>
<th></th>
<th>[equivalence limits]</th>
<th>[ test limits ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>difference:</td>
<td>-30.296 30.296</td>
<td>-11.332 26.416</td>
</tr>
<tr>
<td>ratio:</td>
<td>80% 120%</td>
<td>92.519% 117.439%</td>
</tr>
</tbody>
</table>

Probability test limits are within equivalence limits = 0.6590
Note: Reference treatment = 1.

The default output for `pkequiv` shows a CI for the difference between the means (test limits), the ratio of the means, and the user-specified equivalence limits. The classic CI can be constructed around the difference between the average measure of effect for the two drugs or around the ratio of the average measure of effect for the two drugs. `pkequiv` reports both the difference measure and the ratio measure. Following Chow and Liu (2009), we can apply the ±20 rule to the difference and ratio measures to determine equivalence limits. For these data, the CI for the difference must be entirely contained within the range \([-30.296, 30.296]\) and for the ratio between 80% and 120%. Here the test limits are within the equivalence limits. Although the test limits are inside the equivalence limits, there is only a 66% assurance that the observed CI will be within the equivalence limits in the long run. This is an interesting case because, although this sample shows bioequivalence, the evaluation of the long-run performance indicates possible problems. These fictitious data were generated with high intrasubject variability, which causes poor long-run performance.

We now use the data published in Chow and Liu (2009, 71), which we describe in example 1 of [R] pkshape. As shown in example 1, we also use pkshape to reshape the data. We use the same pkequiv command used above to conduct a bioequivalence test on the data.

```
. use https://www.stata-press.com/data/r18/chowliu, clear
. pkshape id seq period1 period2, order(RT TR)
. set seed 123
. pkequiv outcome treat period seq id
```

Classic confidence interval for bioequivalence

<table>
<thead>
<tr>
<th></th>
<th>[equivalence limits]</th>
<th>[ test limits ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>ratio:</td>
<td>80% 120%</td>
<td>89.464% 104.994%</td>
</tr>
</tbody>
</table>

Probability test limits are within equivalence limits = 0.9940
Note: Reference treatment = 1.

For these data, the test limits are well within the equivalence limits, and the probability that the test limits are within the equivalence limits is 99.4%. 
Example 2

pkequiv displays interval hypothesis tests of bioequivalence if you specify the tost or the anderson option, or both. For example,

```
. set seed 123
. pkequiv outcome treat period seq id, tost anderson
```

Classic confidence interval for bioequivalence

<table>
<thead>
<tr>
<th>[equivalence limits]</th>
<th>[ test limits ]</th>
</tr>
</thead>
<tbody>
<tr>
<td>difference:</td>
<td></td>
</tr>
<tr>
<td>-16.512</td>
<td>16.512</td>
</tr>
<tr>
<td>ratio:</td>
<td></td>
</tr>
<tr>
<td>80%</td>
<td>120%</td>
</tr>
</tbody>
</table>

Probability test limits are within equivalence limits = 0.9940

Schuirmann’s two one-sided tests

- upper test statistic = -5.036 p-value = 0.000
- lower test statistic = 3.810 p-value = 0.000

Anderson and Hauck’s test

- noncentrality parameter = 4.423
- test statistic = -0.613 empirical p-value = 0.0005

Note: Reference treatment = 1.

Both of Schuirmann’s one-sided tests are highly significant, suggesting that the two drugs are bioequivalent. A similar conclusion is drawn from the Anderson and Hauck test of bioequivalence.

Stored results

pkequiv stores the following in r():

Scalars

- r(stddev)          pooled-sample standard deviation of period differences from both sequences
- r(uci)             upper limit of a classic CI
- r(lci)             lower limit of a classic CI
- r(delta)           delta value used in calculating a symmetric CI
- r(u3)              upper limit of Fieller’s CI
- r(l3)              lower limit of Fieller’s CI

Methods and formulas

The lower limit for the difference in the two treatments for the classic shortest CI is

\[
L_1 = (\overline{Y}_T - \overline{Y}_R) - t_{(\alpha, n_1 + n_2 - 2)} \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}
\]

The upper limit is

\[
U_1 = (\overline{Y}_T - \overline{Y}_R) + t_{(\alpha, n_1 + n_2 - 2)} \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}
\]
The limits for the ratio measure are

\[ L_2 = \left( \frac{L_1}{Y_R} + 1 \right) \times 100\% \]

and

\[ U_2 = \left( \frac{U_1}{Y_R} + 1 \right) \times 100\% \]

where \( Y_T \) is the marginal mean of the test formulation of the drug, \( Y_R \) is the marginal mean of the reference formulation of the drug, and \( t_{(\alpha,n_1+n_2-2)} \) is the \( t \) distribution with \( n_1 + n_2 - 2 \) degrees of freedom. \( \hat{\sigma}_d \) is the pooled sample variance of the period differences from both sequences, defined as

\[ \hat{\sigma}_d = \frac{1}{n_1 + n_2 - 2} \sum_{k=1}^{2} \sum_{i=1}^{n_k} (d_{ik} - \bar{d}_k)^2 \]

The finite sample performance of the classical CI is assessed via bootstrap simulation of the CI. One thousand bootstrap samples are drawn using the patient IDs as clusters. For each sample, the classical CI is constructed and compared with the equivalence limits.

The upper and lower limits for the symmetric CI are \( Y_R + \Delta \) and \( Y_R - \Delta \), where

\[ \Delta = k_1 \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} - (Y_R - Y_T) \]

and (simultaneously)

\[ \Delta = -k_2 \hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} + (Y_R - Y_T) \]

and \( k_1 \) and \( k_2 \) are computed iteratively to satisfy the above equalities and the condition

\[ \int_{k_1}^{k_2} f(t) dt = 1 - 2\alpha \]

where \( f(t) \) is the probability density function of the \( t \) distribution with \( n_1 + n_2 - 2 \) degrees of freedom.

See Chow and Liu (2009, 88–92) for details about calculating the CI based on Fieller’s theorem.

The two test statistics for the two one-sided tests of equivalence are

\[ T_L = \frac{(Y_T - Y_R) - \theta_L}{\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \]

and

\[ T_U = \frac{(Y_T - Y_R) - \theta_U}{\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \]

where \(-\theta_L = \theta_U\), both of these being the regulated confidence limits.
The logic of the Anderson and Hauck test is tricky; see Chow and Liu (2009) for a complete explanation. However, the test statistic is

\[ T_{AH} = \frac{(\bar{Y}_T - \bar{Y}_R) - (\theta_L + \theta_U/2)}{\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \]

and the noncentrality parameter is estimated by

\[ \hat{\delta} = \frac{\theta_U - \theta_L}{2\hat{\sigma}_d \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \]

The empirical p-value is calculated as

\[ p = F_t(|T_{AH}| - \hat{\delta}) - F_t(-|T_{AH}| - \hat{\delta}) \]

where \( F_t \) is the cumulative distribution function of the t distribution with \( n_1 + n_2 - 2 \) degrees of freedom.

[R] pk — Pharmacokinetic (biopharmaceutical) data
**pkexamine — Calculate pharmacokinetic measures**

**Description**

pkexamine calculates pharmacokinetic measures from concentration-and-time subject-level data. pkexamine computes and displays the maximum measured concentration, the time at the maximum measured concentration, the time of the last measurement, the elimination time, the half-life, and the area under the concentration–time curve ($AUC_{0,t_{max}}$). Three estimates of the AUC from 0 to infinity ($AUC_{0,\infty}$) are also calculated.

pkexamine is one of the pk commands. Please read [R] pk before reading this entry.

**Quick start**

Pharmacokinetic measures for concentrations $y$ at times $tvar$ where $idvar = 4$

```
      pkexamine tvar y if idvar==4
```

Same as above, but use trapezoidal rule to calculate $AUC_{0,t_{max}}$

```
      pkexamine tvar y if idvar==4, trapezoid
```

Plot concentration–time curve where $idvar = 2$

```
      pkexamine tvar y if idvar==2, graph
```

Same as above, and save graph as mygraph

```
      pkexamine tvar y if idvar==2, graph saving(mygraph)
```

  fit(#)         use # points to estimate AUC$_{0,\infty}$; default is fit(3)

  trapezoid     use trapezoidal rule; default is cubic splines

  graph         graph the AUC

  line          graph the linear extension

  log           graph the log extension

  exp(#)        plot the exponential fit for the AUC$_{0,\infty}$

AUC plot

  cline_options affect rendition of plotted points connected by lines

  marker_options change look of markers (color, size, etc.)

  marker_label_options add marker labels; change look or position

Add plots

  addplot(plot) add other plots to the generated graph

Y axis, X axis, Titles, Legend, Overall

  twoway_options any options other than by() documented in [G-3] twoway_options

by and collect are allowed; see [U] 11.1.10 Prefix commands.

Options

fit(#) specifies the number of points, counting back from the last measurement, to use in fitting the extension to estimate the AUC$_{0,\infty}$. The default is fit(3), or the last three points. This value should be viewed as a minimum; the appropriate number of points will depend on your data.

trapezoid specifies that the trapezoidal rule be used to calculate the AUC$_{0,t_{\text{max}}}$. The default is cubic splines, which give better results for most functions. When the curve is irregular, trapezoid may give better results.

graph tells pkexamine to graph the concentration–time curve.

line and log specify the estimates of the AUC$_{0,\infty}$ to display when graphing the AUC$_{0,\infty}$. If the graph option is not also specified, then these options are ignored.

exp(#) specifies that the exponential fit for the AUC$_{0,\infty}$ be plotted. You must specify the maximum time value to which you want to plot the curve, and this time value must be greater than the maximum time measurement in the data. If you specify 0, the curve will be plotted to the point at which the linear extension would cross the $x$ axis. If the graph option is not also specified, then this option is ignored. This option is not valid with the line or log option.

cline_options affect the rendition of the plotted points connected by lines; see [G-3] cline_options.

marker_options specify the look of markers. This look includes the marker symbol, size, color, and outline; see [G-3] marker_options.
marker_label_options specify if and how the markers are to be labeled; see [G-3] marker_label_options.

addplot(plot) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

twoway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

Remarks and examples

pkexamine computes summary statistics for a given patient in a pharmacokinetic trial. If by idvar: is specified, statistics will be displayed for each subject in the data.

Example 1

Chow and Liu (2009, 13) present data on a study examining primidone concentrations versus time over a 32-hour period after dosing a subject.

. use https://www.stata-press.com/data/r18/auc
(Primidone concentrations)
. list, abbrev(14)

|12. | 1  | 24       | 2
|13. | 1  | 32       | 1.6
We use `pkexamine` to produce the summary statistics:

```
.pkexamine time concentration, graph
```

<table>
<thead>
<tr>
<th></th>
<th>Max. conc. = 4.7</th>
<th>Time of max. conc. = 3</th>
<th>Time of last obs. (Tmax) = 32</th>
<th>Elim. rate = 0.0279</th>
<th>Half life = 24.8503</th>
</tr>
</thead>
</table>

Area under the curve

<table>
<thead>
<tr>
<th>AUC [0, Tmax]</th>
<th>AUC [0, inf.] Linear of log conc.</th>
<th>AUC [0, inf.] Linear fit</th>
<th>AUC [0, inf.] Exponential fit</th>
</tr>
</thead>
<tbody>
<tr>
<td>85.24</td>
<td>142.603</td>
<td>107.759</td>
<td>142.603</td>
</tr>
</tbody>
</table>

Fit based on last 3 points.

The maximum concentration of 4.7 occurs at time 3, and the time of the last observation (Tmax) is 32. In addition to \( AUC_{0,T_{\text{max}}} \), which is calculated from 0 to the maximum value of time, `pkexamine` also reports \( AUC_{0,\infty} \), the AUC computed by extending the curve with each of three methods: a linear fit to the log of the concentration, a linear regression line, and a decreasing exponential regression line. See *Methods and formulas* for details on these three methods.

By default, all extensions to the AUC are based on the last three points. In looking at the graph for these data, it seems more appropriate to use the last seven points to estimate the \( AUC_{0,\infty} \):

```
.pkexamine time concentration, fit(7)
```

<table>
<thead>
<tr>
<th></th>
<th>Max. conc. = 4.7</th>
<th>Time of max. conc. = 3</th>
<th>Time of last obs. (Tmax) = 32</th>
<th>Elim. rate = 0.0349</th>
<th>Half life = 19.8354</th>
</tr>
</thead>
</table>

Area under the curve

<table>
<thead>
<tr>
<th>AUC [0, Tmax]</th>
<th>AUC [0, inf.] Linear of log conc.</th>
<th>AUC [0, inf.] Linear fit</th>
<th>AUC [0, inf.] Exponential fit</th>
</tr>
</thead>
<tbody>
<tr>
<td>85.24</td>
<td>131.027</td>
<td>96.805</td>
<td>129.181</td>
</tr>
</tbody>
</table>

Fit based on last 7 points.
This approach decreased the estimate of the $AUC_{0,\infty}$ for all extensions. To see a graph of the $AUC_{0,\infty}$ using a linear extension, specify the `graph` and `line` options.

```
. pkexamine time concentration, fit(7) graph line
```

Maximum concentration = 4.7
Time of maximum concentration = 3
Time of last observation (Tmax) = 32
Elimination rate = 0.0349
Half life = 19.8354

Area under the curve

<table>
<thead>
<tr>
<th>AUC [0, Tmax]</th>
<th>AUC [0, inf.) Linear of log conc.</th>
<th>AUC [0, inf.) Linear fit</th>
<th>AUC [0, inf.) Exponential fit</th>
</tr>
</thead>
<tbody>
<tr>
<td>85.24</td>
<td>131.027</td>
<td>96.805</td>
<td>129.181</td>
</tr>
</tbody>
</table>

Fit based on last 7 points.

Stored results

`pkexamine` stores the following in `r()`:

Scalars

- `r(auc)`: AUC
- `r(half)`: half-life of the drug
- `r(ke)`: elimination rate
- `r(tmax)`: time at last concentration measurement
- `r(cmax)`: maximum concentration
- `r(tomc)`: time of maximum concentration
- `r(auc_line)`: $AUC_{0,\infty}$ estimated with a linear fit
- `r(auc_exp)`: $AUC_{0,\infty}$ estimated with an exponential fit
- `r(auc_ln)`: $AUC_{0,\infty}$ estimated with a linear fit of the natural log
Methods and formulas

Let \( i \) index the observations sorted by time, let \( k \) be the number of observations, and let \( f \) be the number of points specified in the \texttt{fit(#)} option.

The \( \text{AUC}_{0,t_{\text{max}}} \) is defined as

\[
\text{AUC}_{0,t_{\text{max}}} = \int_0^{t_{\text{max}}} C_t \, dt
\]

where \( C_t \) is the concentration at time \( t \). By default, the integral is calculated numerically using cubic splines. However, if the trapezoidal rule is used, the \( \text{AUC}_{0,t_{\text{max}}} \) is given as

\[
\text{AUC}_{0,t_{\text{max}}} = \sum_{i=2}^{k} \frac{C_{i-1} + C_i}{2} (t_i - t_{i-1})
\]

The \( \text{AUC}_{0,\infty} \) is the \( \text{AUC}_{0,t_{\text{max}}} + \text{AUC}_{t_{\text{max}},\infty} \), or

\[
\text{AUC}_{0,\infty} = \int_0^{t_{\text{max}}} C_t \, dt + \int_{t_{\text{max}}}^{\infty} C_t \, dt
\]

When using the linear extension to the \( \text{AUC}_{0,t_{\text{max}}} \), the integration is cut off when the line crosses the \( x \) axis. The log extension is a linear extension on the log concentration scale. The area for the exponential extension is

\[
\text{AUC}_{t_{\text{max}},\infty} = \int_{t_{\text{max}}}^{\infty} e^{\beta_0 + t\beta_1} \, dt = \frac{e^{\beta_0 + t_{\text{max}}\beta_1}}{-\beta_1}
\]

where \( \beta_0 > 0 \) and \( \beta_1 < 0 \) are the intercept and slope, respectively, of an exponential accelerated failure-time regression of concentration on time.

The elimination rate \( K_{\text{eq}} \) is the negative of the slope from a linear regression of log concentration on time fit to the number of points specified in the \texttt{fit(#)} option:

\[
K_{\text{eq}} = -\frac{\sum_{i=k-f+1}^{k} (t_i - \bar{t}) (\ln C_i - \ln \bar{C})}{\sum_{i=k-f+1}^{k} (t_i - \bar{t})^2}
\]

The half-life is

\[
t_{\text{half}} = \frac{\ln 2}{K_{\text{eq}}}
\]

[R] pk — Pharmacokinetic (biopharmaceutical) data
pkshape — Reshape (pharmacokinetic) Latin-square data

Description

pkshape reshapes data for use with \texttt{anova}, \texttt{pkcross}, and \texttt{pkequiv}; see \texttt{R anova}, \texttt{R pkcross}, and \texttt{R pkequiv}. Latin-square and crossover data are often organized in a manner that cannot be analyzed easily with Stata. \texttt{pkshape} reorganizes the data in memory for use in Stata.

\texttt{pkshape} is one of the \texttt{pk} commands. Please read \texttt{R pk} before reading this entry.

Quick start

Reshape data when string sequence variable \texttt{seq = TR or RT} for patients identified by \texttt{idvar} observed at \texttt{tvar1} and \texttt{tvar2}

\begin{verbatim}
 pkshape idvar seq tvar1 tvar2
\end{verbatim}

Same as above, but with numeric \texttt{seq = 1} indicating \texttt{TR} and \texttt{seq = 2} indicating \texttt{RT}

\begin{verbatim}
 pkshape idvar seq tvar1 tvar2, order(TR RT)
\end{verbatim}

Indicate that period 2 is a washout and the second treatment is administered in period 3

\begin{verbatim}
 pkshape idvar seq tvar1 tvar2 tvar3, order(T0R ROT)
\end{verbatim}

Menu

Statistics > Epidemiology and related > Other > Reshape pharmacokinetic Latin-square data
Syntax

pkshape `id` `sequence` `period1` `period2` [ `periodlist` ] [ , `options` ]

Variable `id` specifies unique subject identifiers. Variable `sequence` specifies the sequence (numeric or string) in which treatments were received. Variables `period1`, `period2`, and so on specify the pharmacokinetic measurements such as AUC in the corresponding periods.

<table>
<thead>
<tr>
<th><code>options</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>order(string)</code></td>
<td>apply treatments in specified order; required with numeric <code>sequence</code></td>
</tr>
<tr>
<td><code>outcome(newvar)</code></td>
<td>name for outcome variable; default is <code>outcome(outcome)</code></td>
</tr>
<tr>
<td><code>treatment(newvar)</code></td>
<td>name for treatment variable; default is <code>treatment(treat)</code></td>
</tr>
<tr>
<td><code>carryover(newvar)</code></td>
<td>name for carryover variable; default is <code>carryover(carry)</code></td>
</tr>
<tr>
<td><code>sequence(newvar)</code></td>
<td>name for sequence variable; default is <code>sequence(sequence)</code></td>
</tr>
<tr>
<td><code>period(newvar)</code></td>
<td>name for period variable; default is <code>period(period)</code></td>
</tr>
</tbody>
</table>

Options

`order(string)` specifies the order in which treatments were applied when generating the sequence, treatment, and carryover variables in the reorganized data. This option is required if the input sequence variable, `sequence`, is numeric. It is not allowed if `sequence` is a string variable. For crossover designs, any washout periods can be indicated with the number 0.

`outcome(newvar)` specifies the name for the outcome variable in the reorganized data. By default, `outcome(outcome)` is used.

`treatment(newvar)` specifies the name for the treatment variable in the reorganized data. By default, `treatment(treat)` is used.

`carryover(newvar)` specifies the name for the carryover variable in the reorganized data. By default, `carryover(carry)` is used.

`sequence(newvar)` specifies the name for the sequence variable in the reorganized data. By default, `sequence(sequence)` is used.

`period(newvar)` specifies the name for the period variable in the reorganized data. By default, `period(period)` is used.

Remarks and examples

Often, data from a Latin-square experiment are naturally organized in a manner that Stata cannot manage easily. `pkshape` reorganizes Latin-square data so that they can be used with `anova` (see [R] `anova`) or any `pk` command. This includes the classic $2 \times 2$ crossover design commonly used in pharmaceutical research, as well as many other Latin-square designs. When using `pkshape`, newly created variables will automatically be labeled and system value labels will be created. The value label `_treatlbl` will be attached to the treatment and carryover variables, to indicate which treatment is applied in a given period and which treatment is being carried over from the previous period. The value label `_seqlbl` will be attached to the sequence variable, indicating the sequence of treatments.

`pkshape` expects the data to be organized in the same format as that produced by [R] `pckollapse`—with variables representing time periods of the study.
Example 1

Consider the example data published in Chow and Liu (2009, 71). There are 24 patients, 12 in each sequence. Sequence 1 is the reference formulation followed by the test formulation; sequence 2 is the test formulation followed by the reference formulation. The measurements reported are the $\text{AUC}_{0,t_{\text{max}}}$ for each patient and for each period.

</tbody>
</table>

Because the outcome for one person is in two different variables, the treatment that was applied to an individual is a function of the period and the sequence. To analyze this treatment using `anova`, all the outcomes must be in one variable, and each covariate must be in its own variable. To reorganize these data, use `pkshape`: 
. pkshape id seq period1 period2, order(RT TR)
. sort seq id period
. list, sep(8)

<table>

</tbody>
</table>
Now, the data are organized into separate variables that indicate each factor level for each of the covariates, so the data may be used with `anova` or `pkcross`; see [R] `anova` and [R] `pkcross`.

Initially, the output from `list` displayed sequence values 1 and 2, but now we see sequences RT and TR listed for the individuals. `pkshape` used the information we provided in the `order()` option to assign value labels to the numeric variables `sequence`, `treat`, and `carry`. Because we did not specify any new variable names, the default names were used.

### Example 2

Consider the study of background music on bank teller productivity published in Kutner et al. (2005). The data are

<td>12(C)</td>
<td>15(A)</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>4(B)</td>
<td>12(C)</td>
<td>9(A)</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>12(A)</td>
<td>14(B)</td>
<td>3(C)</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>13(A)</td>
<td>14(B)</td>
<td>3(C)</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>7(C)</td>
<td>18(A)</td>
<td>6(B)</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>5(C)</td>
<td>20(A)</td>
<td>4(B)</td>
</tr>
</tbody>
</table>

We entered the data into Stata:

```
. use https://www.stata-press.com/data/r18/applesales, clear
(Dispaly impact on apple sales)
. list, sep(2)
```

```
  id seq p1 p2 p3 square
1.  1   1   9  12  15  1
2.  2   1   4  12  9  2
3.  3   2  12  14  3  1
4.  4   2  13  14  3  2
5.  5   3   7  18  6  1
6.  6   3   5  20  4  2
```

Now, the data can be reorganized using descriptive names for the outcome variables.

```
. pkshape id seq p1 p2 p3, order(bca abc cab) seq(pattern) treat(displays)
. anova outcome pattern period displays id|pattern
```

```

[R] pk — Pharmacokinetic (biopharmaceutical) data
pksumm — Summarize pharmacokinetic data

Description

pksumm obtains summary measures based on the first four moments from the empirical distribution of each pharmacokinetic measurement and tests the null hypothesis that the distribution of that measurement is normally distributed.

pksumm is one of the pk commands. Please read \texttt{R pk} before reading this entry.

Quick start

Table of pharmacokinetic measures for concentrations \( y \) at times \( t\text{var} \) for patients identified by \( \text{idvar} \)

\begin{verbatim}
pksumm idvar tvar y
\end{verbatim}

Add a histogram of \( \text{AUC}_{0,t_{\text{max}}} \) values

\begin{verbatim}
pksumm idvar tvar y, graph
\end{verbatim}

Same as above

\begin{verbatim}
pksumm idvar tvar y, graph stat(auc)
\end{verbatim}

Same as above, but plot \( \text{AUC} \) calculated from 0 to \( \infty \) using a linear extension

\begin{verbatim}
pksumm idvar tvar y, graph stat(aucline)
\end{verbatim}

Same as above, but use 10 bins for the histogram

\begin{verbatim}
pksumm idvar tvar y, graph stat(aucline) bins(10)
\end{verbatim}

Options

```
[Main]
```

trapezoid specifies that the trapezoidal rule be used to calculate the $AUC_{0,t_{\text{max}}}$. The default is cubic splines, which give better results for most situations. When the curve is irregular, the trapezoidal rule may give better results.

fit(#) specifies the number of points, counting back from the last time measurement, to use in fitting the extension to estimate the $AUC_{0,\infty}$. The default is fit(3), the last three points. This default should be viewed as a minimum; the appropriate number of points will depend on the data.

notimechk suppresses the check that the follow-up time for all subjects is the same. By default, pksumm expects the maximum follow-up time to be equal for all subjects.

nodots suppresses the progress dots during calculation. By default, a dot (a period) is displayed for every call to calculate the pharmacokinetic measures.

graph requests a graph of the distribution of the statistic specified with stat().

stat(statistic) specifies the statistic that pksumm should graph. The default is stat(auc). If the graph option is not also specified, then this option is ignored.
histogram_options are any of the options documented in [R] histogram, excluding by(). For pksumm, fraction is the default, not density.

Remarks and examples

pksumm produces summary statistics for the distribution of nine common pharmacokinetic measurements. If there are more than eight subjects, pksumm also computes a test for normality on each measurement. The nine measurements summarized by pksumm are listed above and are described in Methods and formulas of [R] pkexamine.

Example 1

We demonstrate the use of pksumm on a variation of the data described in [R] pk. We have drug concentration data on 15 subjects, each measured at 13 time points over a 32-hour period. A few of the records are as follows:

```
. use https://www.stata-press.com/data/r18/pksumm
. list, sep(0)
```

<table>

</table>
```

For the 15 subjects, the mean $AUC_{0,t_{\text{max}}}$ is 150.74, and $\sigma^2 = 123.07$. The skewness of $-0.26$ indicates that the distribution is slightly skewed left. The $p$-value of 0.69 for the $\chi^2$ test of normality indicates that we cannot reject the null hypothesis that the distribution is normal.

If we were to consider any of the three variants of the $AUC_{0,\infty}$, we would see that there is huge variability and that the distribution is heavily skewed. A skewness different from 0 and a kurtosis different from 3 are expected because the distribution of the $AUC_{0,\infty}$ is not normal.

We now graph the distribution of $AUC_{0,t_{\text{max}}}$ by specifying the `graph` option.

```
graph, by default, plots $\text{AUC}_{0,t_{\text{max}}}$. To plot a graph of one of the other pharmacokinetic measurements, we need to specify the `stat()` option. For example, we can ask Stata to produce a plot of the $\text{AUC}_{0,\infty}$ using the log extension:

```
.pksumm id time conc, stat(auclog) graph bins(20)
```

Methods and formulas

The $\chi^2$ test for normality is conducted with `sktest`; see [R] `sktest` for more information on the test of normality.

The statistics reported by `pksumm` are identical to those reported by `summarize` and `sktest`; see [R] `summarize` and [R] `sktest`.

Also see

[R] `pk` — Pharmacokinetic (biopharmaceutical) data
poisson fits a Poisson regression of `depvar` on `indepvars`, where `depvar` is a nonnegative count variable.

If you have panel data, see [XT] `xtpoisson`.

**Quick start**

Poisson regression of `y` on `x`

```
poisson y x
```

Add categorical variable `a`

```
poisson y x i.a
```

Add exposure variable `v`

```
poisson y x i.a, exposure(v)
```

With robust standard errors

```
poisson y x i.a, vce(robust)
```

Report results as incidence-rate ratios

```
poisson y x i.a, irr
```

Replace data in memory with the results of running a Poisson regression model on each level of `catvar`

```
statsby, by(catvar) clear: poisson y x
```

### Reporting

- `level(#)`
  - set confidence level; default is `level(95)`
- `irr`
  - report incidence-rate ratios
- `nocsreport`
  - do not display constraints
- `display_options`
  - control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

### Maximization

`maximize_options`

- control the maximization process; seldom used
- `collinear`
  - keep collinear variables
- `coeflegend`
  - display legend instead of statistics

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.

`depvar`, `indepvars`, `varname_e`, and `varname_o` may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes`, `bootstrap`, `by`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: poisson and [FMM] fmm: poisson.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] mi estimate.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] svy.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

- `noconstant`, `exposure(varname_e)`, `offset(varname_o)`, `constraints(constraints)`; see [R] Estimation options.
vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

Reporting

level(#) ; see [R] Estimation options.

irr reports estimated coefficients transformed to incidence-rate ratios, that is, $e^{\beta_i}$ rather than $\beta_i$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. irr may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#) , fvwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] Estimation options.

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), itolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following options are available with poisson but are not shown in the dialog box: collinear, coeflegend; see [R] Estimation options.

Remarks and examples

The basic idea of Poisson regression was outlined by Coleman (1964, 378–379). See Cameron and Trivedi (2013; 2022, chap. 20) and Johnson, Kemp, and Kotz (2005, chap. 4) for information about the Poisson distribution. See Cameron and Trivedi (2013), Long (1997, chap. 8), Long and Freese (2014, chap. 9), McNeil (1996, chap. 6), and Selvin (2011, chap. 6) for an introduction to Poisson regression. Also see Selvin (2004, chap. 5) for a discussion of the analysis of spatial distributions, which includes a discussion of the Poisson distribution. An early example of Poisson regression was Cochran (1940).

Poisson regression fits models of the number of occurrences (counts) of an event. The Poisson distribution has been applied to diverse events, such as the number of soldiers kicked to death by horses in the Prussian army (von Bortkiewicz 1898); the pattern of hits by buzz bombs launched against London during World War II (Clarke 1946); telephone connections to a wrong number (Thorndike 1926); and disease incidence, typically with respect to time, but occasionally with respect to space. The basic assumptions are as follows:

1. There is a quantity called the incidence rate that is the rate at which events occur. Examples are 5 per second, 20 per 1,000 person-years, 17 per square meter, and 38 per cubic centimeter.
2. The incidence rate can be multiplied by exposure to obtain the expected number of observed events. For example, a rate of 5 per second multiplied by 30 seconds means that 150 events are expected; a rate of 20 per 1,000 person-years multiplied by 2,000 person-years means that 40 events are expected; and so on.

3. Over very small exposures $\epsilon$, the probability of finding more than one event is small compared with $\epsilon$.

4. Nonoverlapping exposures are mutually independent.

With these assumptions, to find the probability of $k$ events in an exposure of size $E$, you divide $E$ into $n$ subintervals $E_1, E_2, \ldots, E_n$, and approximate the answer as the binomial probability of observing $k$ successes in $n$ trials. If you let $n \to \infty$, you obtain the Poisson distribution.

In the Poisson regression model, the incidence rate for the $j$th observation is assumed to be given by

$$r_j = e^{\beta_0 + \beta_1 x_{1,j} + \cdots + \beta_k x_{k,j}}$$

If $E_j$ is the exposure, the expected number of events, $C_j$, will be

$$C_j = E_j e^{\beta_0 + \beta_1 x_{1,j} + \cdots + \beta_k x_{k,j}} = e^{\ln(E_j) + \beta_0 + \beta_1 x_{1,j} + \cdots + \beta_k x_{k,j}}$$

This model is fit by the `poisson` command. Without the `exposure()` or `offset()` options, $E_j$ is assumed to be 1 (equivalent to assuming that exposure is unknown), and controlling for exposure, if necessary, is your responsibility.

Comparing rates is most easily done by calculating incidence-rate ratios (IRRs). For instance, what is the relative incidence rate of chromosome interchanges in cells as the intensity of radiation increases; the relative incidence rate of telephone connections to a wrong number as load increases; or the relative incidence rate of deaths due to cancer for females relative to males? That is, you want to hold all the $x$’s in the model constant except one, say, the $i$th. The IRR for a one-unit change in $x_i$ is

$$e^{\frac{\ln(E) + \beta_1 x_1 + \cdots + \beta_i (x_i + 1) + \cdots + \beta_k x_k}{\ln(E) + \beta_1 x_1 + \cdots + \beta_i x_i + \cdots + \beta_k x_k}} = e^{\beta_i}$$

More generally, the IRR for a $\Delta x_i$ change in $x_i$ is $e^{\beta_i \Delta x_i}$. The `lincom` command can be used after `poisson` to display incidence-rate ratios for any group relative to another; see [R] `lincom`.

### Example 1

Chatterjee and Hadi (2012, 174) give the number of injury incidents and the proportion of flights for each airline out of the total number of flights from New York for nine major U.S. airlines in one year:
To their data, we have added a fictional variable, *XYZowned*. We will imagine that an accusation is made that the airlines owned by *XYZ* Company have a higher injury rate.

```
. poisson injuries XYZowned, exposure(n) irr
Iteration 0: Log likelihood = -23.027197
Iteration 1: Log likelihood = -23.027177
Iteration 2: Log likelihood = -23.027177
Poisson regression
Number of obs = 9
LR chi2(1) = 1.77
Prob > chi2 = 0.1836
Log likelihood = -23.027177
Pseudo R2 = 0.0370
```

```
injuries | IRR       Std. err. z  P>|z|   [95% conf. interval]
---------|-----------|-------------|--------|----------------------
 XYZowned | 1.463467  .406872  1.37  0.171   .8486578  2.523675
       _cons | 58.04416  8.558145  27.54  0.000  43.47662  77.49281
       ln(n)  | 1 (exposure)
```

Note: _cons estimates baseline incidence rate.

We specified *irr* to see the IRRs rather than the underlying coefficients. We estimate that *XYZ* Airlines’ injury rate is 1.46 times larger than that for other airlines, but the 95% confidence interval is 0.85 to 2.52; we cannot even reject the hypothesis that *XYZ* Airlines has a lower injury rate.

---

### Technical note

In example 1, we assumed that each airline’s exposure was proportional to its fraction of flights out of New York. What if “large” airlines, however, also used larger planes, and so had even more passengers than would be expected, given this measure of exposure? A better measure would be each airline’s fraction of passengers on flights out of New York, a number that we do not have. Even so, we suppose that *n* represents this number to some extent, so a better estimate of the effect might be
Here rather than specifying the `exposure()` option, we explicitly included the variable that would normalize for exposure in the model. We did not specify the `irr` option, so we see coefficients rather than IRRs. We started with the model

\[ \text{rate} = e^{\beta_0 + \beta_1 \text{XYZowned}} \]

The observed counts are therefore

\[ \text{count} = ne^{\beta_0 + \beta_1 \text{XYZowned}} = e^{\ln(n) + \beta_0 + \beta_1 \text{XYZowned}} \]

which amounts to constraining the coefficient on \( \ln(n) \) to 1. This is what was estimated when we specified the `exposure(n)` option. In the above model, we included the normalizing exposure ourselves and, rather than constraining the coefficient to be 1, estimated the coefficient.

The estimated coefficient is 1.42, a respectable distance away from 1, and is consistent with our speculation that larger airlines also use larger airplanes. With this small amount of data, however, we also have a wide confidence interval that includes 1.

Our estimated coefficient on \( \text{XYZowned} \) is now 0.684, and the implied IRR is \( e^{0.684} \approx 1.98 \) (which we could also see by typing `poisson, irr`). The 95% confidence interval for the coefficient still includes 0 (the interval for the IRR includes 1), so although the point estimate is now larger, we still cannot be certain of our results.

Our expert opinion would be that, although there is not enough evidence to support the charge, there is enough evidence to justify collecting more data.

---

Example 2

In a famous age-specific study of coronary disease deaths among male British doctors, Doll and Hill (1966) reported the following data (reprinted in Lash et al. [2021, 417]):

<table>
<thead>
<tr>
<th>Age</th>
<th>Smokers Deaths</th>
<th>Smokers Person-years</th>
<th>Nonsmokers Deaths</th>
<th>Nonsmokers Person-years</th>
</tr>
</thead>
<tbody>
<tr>
<td>35–44</td>
<td>32</td>
<td>52,407</td>
<td>2</td>
<td>18,790</td>
</tr>
<tr>
<td>45–54</td>
<td>104</td>
<td>43,248</td>
<td>12</td>
<td>10,673</td>
</tr>
<tr>
<td>55–64</td>
<td>206</td>
<td>28,612</td>
<td>28</td>
<td>5,710</td>
</tr>
<tr>
<td>65–74</td>
<td>186</td>
<td>12,663</td>
<td>28</td>
<td>2,585</td>
</tr>
<tr>
<td>75–84</td>
<td>102</td>
<td>5,317</td>
<td>31</td>
<td>1,462</td>
</tr>
</tbody>
</table>
The first step is to enter these data into Stata, which we have done:

```
. use https://www.stata-press.com/data/r18/dollhill3, clear
(Doll and Hill (1966))
. list
```

<table>
<thead>
<tr>
<th>agecat</th>
<th>smokes</th>
<th>deaths</th>
<th>pyyears</th>
</tr>
</thead>
<tbody>
<tr>
<td>35-44</td>
<td>1</td>
<td>32</td>
<td>52,407</td>
</tr>
<tr>
<td>45-54</td>
<td>1</td>
<td>104</td>
<td>43,248</td>
</tr>
<tr>
<td>55-64</td>
<td>1</td>
<td>206</td>
<td>28,612</td>
</tr>
<tr>
<td>65-74</td>
<td>1</td>
<td>186</td>
<td>12,663</td>
</tr>
<tr>
<td>75-84</td>
<td>1</td>
<td>102</td>
<td>5,317</td>
</tr>
<tr>
<td>35-44</td>
<td>0</td>
<td>2</td>
<td>18,790</td>
</tr>
<tr>
<td>45-54</td>
<td>0</td>
<td>12</td>
<td>10,673</td>
</tr>
<tr>
<td>55-64</td>
<td>0</td>
<td>28</td>
<td>5,710</td>
</tr>
<tr>
<td>65-74</td>
<td>0</td>
<td>28</td>
<td>2,585</td>
</tr>
<tr>
<td>75-84</td>
<td>0</td>
<td>31</td>
<td>1,462</td>
</tr>
</tbody>
</table>

The most “natural” analysis of these data would begin by introducing indicator variables for each age category and one indicator for smoking:

```
. poisson deaths smokes i.agecat, exposure(pyears) irr
```

```
Iteration 0:  Log likelihood = -33.823284
Iteration 1:  Log likelihood = -33.600471
Iteration 2:  Log likelihood = -33.600153
Iteration 3:  Log likelihood = -33.600153

Poisson regression  Number of obs = 10
LR chi2(5) = 922.93
Prob > chi2 = 0.0000
Log likelihood = -33.600153  Pseudo R2 = 0.9321

| deaths | IRR  | Std. err. | z    | P>|z| | [95% conf. interval] |
|--------|------|-----------|------|-----|---------------------|
| smokes | 1.425519 | .1530638 | 3.30 | 0.001 | 1.154984 1.759421 |
| agecat |        |           |      |      |                     |
| 45-54  | 4.410584 | .8605197 | 7.61 | 0.000 | 3.009011 6.464997 |
| 55-64  | 13.8392  | 2.542638 | 14.30| 0.000 | 9.654328 19.83809 |
| 65-74  | 28.51678 | 5.269878 | 18.13| 0.000 | 19.85177 40.96395 |
| 75-84  | 40.45121 | 7.775511 | 19.25| 0.000 | 27.75326 58.95885 |
| _cons | .0003636 | .0000697 | -41.30| 0.000 | .0002497 .0005296 |
| ln(pyears) | 1 (exposure) | | | | |
```

Note: _cons estimates baseline incidence rate.

In the above, we specified irr to obtain IRRs. We estimate that smokers have 1.43 times the mortality rate of nonsmokers. See, however, example 1 in [R] poisson postestimation.
poisson stores the following in `e()`:

Scalars

- `e(N)` number of observations
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(r2_p)` pseudo-$R^2$
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(N_clust)` number of clusters
- `e(chi2)` \( \chi^2 \)
- `e(p)` \( p \)-value for model test
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

Macros

- `e(cmd)` poisson
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset)` linear offset variable
- `e(chi2type)` Wald or LR; type of model \( \chi^2 \) test
- `e(vce)` vcetype specified in vce()
- `e(vcetype)` title used to label Std. err.
- `e(opt)` type of optimization
- `e(which)` max or min; whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of ml method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` b V
- `e(estat_cmd)` program used to implement estat
- `e(predict)` program used to implement predict
- `e(asbalanced)` factor variables fvset as asbalanced
- `e(asobserved)` factor variables fvset as asobserved

Matrices

- `e(b)` coefficient vector
- `e(Cns)` constraints matrix
- `e(ilog)` iteration log (up to 20 iterations)
- `e(gradient)` gradient vector
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance

Functions

- `e(sample)` marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices

- `r(table)` matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.
Methods and formulas

The log likelihood (with weights $w_j$ and offsets) is given by

$$\Pr(Y = y) = \frac{e^{-\lambda \lambda y}}{y!}$$

$$\xi_j = x_j \beta + \text{offset}_j$$

$$f(y_j) = \frac{e^{\exp(\xi_j) e^{\xi_j y_j}}}{y_j!}$$

$$\ln L = \sum_{j=1}^{n} w_j \left\{ -e^{\xi_j} + \xi_j y_j - \ln(y_j!) \right\}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] \_robust}, particularly \texttt{Maximum likelihood estimators} and \texttt{Methods and formulas}.

\texttt{poisson} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] Variance estimation}.

Siméon-Denis Poisson (1781–1840) was a French mathematician and physicist who contributed to several fields: his name is perpetuated in Poisson brackets, Poisson’s constant, Poisson’s differential equation, Poisson’s integral, and Poisson’s ratio. Among many other results, he produced a version of the law of large numbers. His rather misleadingly titled \textit{Recherches sur la probabilité des jugements} embraces a complete treatise on probability, as the subtitle indicates, including what is now known as the Poisson distribution. That, however, was discovered earlier by the Huguenot–British mathematician Abraham de Moivre (1667–1754).

Postestimation commands

The following postestimation commands are of special interest after `poisson`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat gof</code></td>
<td>goodness-of-fit test</td>
</tr>
<tr>
<td><code>lassogof</code></td>
<td>calculate goodness-of-fit predictions</td>
</tr>
</tbody>
</table>

`estat gof` is not appropriate with `svy` estimation results.

The following standard postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat ic</code></td>
<td>Akaike’s, consistent Akaike’s, corrected Akaike’s, and Schwarz’s Bayesian information criteria (AIC, CAIC, AICc, and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estat (svy)</code></td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td><code>estimates</code></td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td><code>etable</code></td>
<td>table of estimation results</td>
</tr>
<tr>
<td><code>*forecast</code></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><code>*hausman</code></td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td><code>lincom</code></td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td><code>linktest</code></td>
<td>link test for model specification</td>
</tr>
<tr>
<td><code>*lrtest</code></td>
<td>likelihood-ratio test</td>
</tr>
<tr>
<td><code>margins</code></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td><code>marginsplot</code></td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td><code>nlcom</code></td>
<td>point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients</td>
</tr>
<tr>
<td><code>predict</code></td>
<td>number of events, incidence rates, probabilities, etc.</td>
</tr>
<tr>
<td><code>predictnl</code></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td><code>pwcompare</code></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><code>suest</code></td>
<td>seemingly unrelated estimation</td>
</tr>
<tr>
<td><code>test</code></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><code>testnl</code></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.*

2160
predict

Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, standard errors, and the equation-level score.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset ]
```

<table>

</tr>
<tr>
<td>pr(a,b)</td>
<td>probability Pr(a ≤ yj ≤ b)</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
<tr>
<td>score</td>
<td>first derivative of the log likelihood with respect to xjβ</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

n, the default, calculates the predicted number of events, which is \( \exp(x_j\beta) \) if neither offset() nor exposure() was specified when the model was fit; \( \exp(x_j\beta + \text{offset}_j) \) if offset() was specified; or \( \exp(x_j\beta) \times \text{exposure}_j \) if exposure() was specified.

ir calculates the incidence rate \( \exp(x_j\beta) \), which is the predicted number of events when exposure is 1. Specifying ir is equivalent to specifying n when neither offset() nor exposure() was specified when the model was fit.

pr(n) calculates the probability \( \Pr(y_j = n) \), where n is a nonnegative integer that may be specified as a number or a variable.

pr(a,b) calculates the probability \( \Pr(a \leq y_j \leq b) \), where a and b are nonnegative integers that may be specified as numbers or variables; 

b missing (b ≥ .) means +∞;

pr(20,.) calculates \( \Pr(y_j \geq 20) \);

pr(20,b) calculates \( \Pr(y_j \geq 20) \) in observations for which b ≥ . and calculates \( \Pr(20 \leq y_j \leq b) \) elsewhere.
\( \text{pr}(a, b) \) produces a syntax error. A missing value in an observation of the variable \( a \) causes a missing value in that observation for \( \text{pr}(a, b) \).

\( \text{xb} \) calculates the linear prediction, which is \( x_j \beta \) if neither \text{offset()}\) nor \text{exposure()}\) was specified; \( x_j \beta + \text{offset}_j \) if \text{offset()}\) was specified; or \( x_j \beta + \ln(\text{exposure}_j) \) if \text{exposure()}\) was specified; see \text{nooffset} below.

\( \text{stdp} \) calculates the standard error of the linear prediction.

\( \text{score} \) calculates the equation-level score, \( \partial \ln L / \partial (x_j \beta) \).

\text{nooffset} is relevant only if you specified \text{offset()}\) or \text{exposure()}\) when you fit the model. It modifies the calculations made by \text{predict} so that they ignore the offset or exposure variable; the linear prediction is treated as \( x_j \beta \) rather than as \( x_j \beta + \text{offset}_j \) or \( x_j \beta + \ln(\text{exposure}_j) \). Specifying \text{predict ...}, \text{nooffset} is equivalent to specifying \text{predict ...}, \text{ir}.

\text{margins}

\text{Description for margins}

\text{margins} estimates margins of response for numbers of events, incidence rates, probabilities, and linear predictions.

\text{Menu for margins}

Statistics > Postestimation

\text{Syntax for margins}

\text{margins} [\text{marginlist}] [, \text{options}]  
\text{margins} [\text{marginlist}], \text{predict(statistic ...)} [\text{predict(statistic ...)} ...] [\text{options}]

<tr>
<td>( \text{score} )</td>
<td>not allowed with \text{margins}</td>
</tr>
</tbody>
</table>

Statistics not allowed with \text{margins} are functions of stochastic quantities other than \( e(\beta) \).

For the full syntax, see [R] \text{margins}.  

Description for estat

estat gof performs a goodness-of-fit test of the model. Both the deviance statistic and the Pearson statistic are reported. If the tests are significant, the Poisson regression model is inappropriate.

Menu for estat

Statistics > Postestimation

Syntax for estat

estat gof

collect is allowed; see [U] 11.1.10 Prefix commands.

Remarks and examples

Example 1

Continuing with example 2 of [R] poisson, we use estat gof to determine whether the model fits the data well.

. use https://www.stata-press.com/data/r18/dollhill3
   (Doll and Hill (1966))
. poisson deaths smokes i.agecat, exp(pyears) irr
   (output omitted)
. estat gof

Deviance goodness-of-fit = 12.13237
Prob > chi2(4) = 0.0164
Pearson goodness-of-fit = 11.15533
Prob > chi2(4) = 0.0249

The deviance goodness-of-fit test tells us that, given the model, we can reject the hypothesis that these data are Poisson distributed at the 1.64% significance level. The Pearson goodness-of-fit test tells us that we can reject the hypothesis at the 2.49% significance level.

So let us now back up and be more careful. We can most easily obtain the incidence-rate ratios within age categories by using ir; see [R] Epitab:

. ir deaths smokes pyears, by(agecat) nohet

Stratified incidence-rate analysis

We find that the mortality incidence ratios are greatly different within age category, being highest for the youngest categories and actually dropping below 1 for the oldest. (In the last case, we might argue that those who smoke and who have not died by age 75 are self-selected to be particularly robust.)

Seeing this, we will now parameterize the smoking effects separately for each category, although we will begin by constraining the smoking effects on third and fourth age categories to be equivalent:

```
constraint 1 smokes#3.agecat = smokes#4.agecat
poisson deaths c.smokes#agecat i.agecat, exposure(pyears) irr constraints(1)
```

|                  | IRR           | Std. err. | z    | P>|z|  | [95% conf. interval] |
|------------------|---------------|-----------|------|------|----------------------|
| agecat#          |               |           |      |      |                      |
| c.smokes         |               |           |      |      |                      |
| 35-44            | 5.736637      | 4.181256  | 2.40 | 0.017| 1.374811             | 23.93711              |
| 45-54            | 2.138812      | 0.6520701 | 2.49 | 0.013| 1.176691             | 3.887609              |
| 55-64            | 1.412229      | 0.2017485 | 2.42 | 0.016| 1.067343             | 1.868557              |
| 65-74            | 1.412229      | 0.2017485 | 2.42 | 0.016| 1.067343             | 1.868557              |
| 75-84            | 0.9047304     | 0.1855513 | -0.49| 0.625| 0.6052658            | 1.35236               |

Note: `_cons` estimates baseline incidence rate.

```
estat gof
Deviance goodness-of-fit = .0773491
Prob > chi2(1) = .7809
Pearson goodness-of-fit = .0773885
Prob > chi2(1) = .7809
```

The goodness-of-fit is now small; we are no longer running roughshod over the data. Let us now consider simplifying the model. The point estimate of the incidence-rate ratio for smoking in age category 1 is much larger than that for smoking in age category 2, but the confidence interval for `smokes#1.agecat` is similarly wide. Is the difference real?

```
test smokes#1.agecat = smokes#2.agecat
( 1) [deaths]3.agecat#c.smokes - [deaths]4.agecat#c.smokes = 0
    chi2(  1) =    1.56
    Prob > chi2 =   0.2117
```

The point estimates of the incidence-rate ratio for smoking in the 35–44 age category is much larger than that for smoking in the 45–54 age category, but there is insufficient data, and we may be
observing random differences. With that success, might we also combine the smokers in the third and fourth categories with those in the first and second categories?

```
. test smokes#2.agecat = smokes#3.agecat, accum
  ( 1) [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0
  ( 2) [deaths]2.agecat#c.smokes - [deaths]3.agecat#c.smokes = 0
    chi2(  2) =  4.73
    Prob > chi2 =  0.0938
```

Combining the first four categories may be overdoing it—the 9.38% significance level is enough to stop us, although others may disagree.

Thus, we now fit our final model:

```
. constraint 2 smokes#1.agecat = smokes#2.agecat
. poisson deaths c.smokes#agecat i.agecat, exposure(pyears) irr constraints(1/2)
```

```
Iteration 0:  Log likelihood = -31.550722
Iteration 1:  Log likelihood = -28.525057
Iteration 2:  Log likelihood = -28.514535
Iteration 3:  Log likelihood = -28.514535

Poisson regression Number of obs = 10
Wald chi2(7) = 642.25
Log likelihood = -28.514535 Prob > chi2 = 0.0000

( 1) [deaths]3.agecat#c.smokes - [deaths]4.agecat#c.smokes = 0
( 2) [deaths]1b.agecat#c.smokes - [deaths]2.agecat#c.smokes = 0
```

```
  | IRR     Std. err.     z    P>|z|     [95% conf. interval]
---|---------|-----------------|-----|--------|----------------------
  | agecat#
  | c.smokes

  | ln(pyears)
    1 (exposure)
```

Note: _cons estimates baseline incidence rate.
The above strikes us as a fair representation of the data. The probabilities of observing the deaths seen in these data are estimated using the following `predict` command:

```
.predict p, pr(0, deaths)
.list deaths p
```

<table>
<thead>
<tr>
<th>deaths</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>

<tr>
<td>10.</td>
<td>31</td>
</tr>
</tbody>
</table>

The probability $Pr(y \leq \text{deaths})$ ranges from 0.23 to 0.80.

### Stored results

`estat gof` after `poisson` stores the following in `r()`:

Scalars

- `r(df)`: degrees of freedom (Pearson and deviance)
- `r(chi2_p)`: $\chi^2$ (Pearson)
- `r(chi2_d)`: $\chi^2$ (deviance)
- `r(p_p)`: $p$-value for $\chi^2$ test (Pearson)
- `r(p_d)`: $p$-value for $\chi^2$ test (deviance)

### Methods and formulas

In the following, we use the same notation as in [R] `poisson`.

The equation-level score is given by

$$\text{score}(x/\beta)_j = y_j - e^{\xi_j}$$

The deviance (D) and Pearson (P) goodness-of-fit statistics are given by

$$\ln L_{\text{max}} = \sum_{j=1}^{n} w_j [y_j \{ \ln(y_j) - 1 \} - \ln(y_j!)]$$

$$\chi^2_D = -2 \{ \ln L - \ln L_{\text{max}} \}$$

$$\chi^2_P = \sum_{j=1}^{n} \frac{w_j(y_j - e^{\xi_j})^2}{e^{\xi_j}}$$

Statistics > Postestimation

Syntax

postest

Remarks and examples

Remarks are presented under the following headings:

Overview
Video example

Overview

Stata uses an estimation followed by postestimation analysis paradigm. You type regress ... to fit a regression model, then you type test ... to test linear relationships among the estimated parameters, or you type contrast ... to compare marginal means, or you type rvpplot to see a residual-versus-fitted plot, or you type one of a myriad of other postestimation commands. This is an extension of Stata’s “type a little, get a little” concept. The Postestimation Selector exposes this type of postestimation analysis to those who prefer to use the dialog boxes to fit and analyze models, or at least they sometimes prefer the dialogs when exploring their data. We might call this “click a little, get a little”.

The Postestimation Selector knows what is available after any estimation command. It shows the full list of postestimation features that are available after any estimation, and it shows only those that are available. For example, if you fit a linear regression, you can choose from 59 postestimation analyses, including “Likelihood-ratio test comparing models”. If, however, you fit that linear regression using survey estimation, the likelihood-ratio test is not available because that test has no meaning for survey estimation. You will, however, see 8 new postestimation features for survey-data analysis, including “Design and misspecification effects”.

If you are using the menus and dialogs, we recommend you launch the Postestimation Selector and just leave it up—select Statistics > Postestimation, or type postest at the command line. All available postestimation features for whatever model you are analyzing will then be just a click away.

2168
Here is what the Selector looks like after a linear regression,
And, here is what it looks like with all the groupings expanded.

[U] 20 Estimation and postestimation commands
predict — Obtain predictions, residuals, etc., after estimation

Description

predict calculates predictions, residuals, influence statistics, and the like after estimation. Exactly what predict can do is determined by the previous estimation command; command-specific options are documented with each estimation command. Regardless of command-specific options, the actions of predict share certain similarities across estimation commands:

1. predict newvar creates newvar containing “predicted values” — numbers related to the \( E(y_j|x_j) \). For instance, after linear regression, predict newvar creates \( x_j \beta \) and, after probit, creates the probability \( \Phi(x_j \beta) \).
2. predict newvar, xb creates newvar containing \( x_j \beta \). This may be the same result as option 1 (for example, linear regression) or different (for example, probit), but regardless, option xb is allowed.
3. predict newvar, stdp creates newvar containing the standard error of the linear prediction \( x_j \beta \).
4. predict newvar, other_options may create newvar containing other useful quantities; see help or the reference manual entry for the particular estimation command to find out about other available options.
5. nooffset added to any of the above commands requests that the calculation ignore any offset or exposure variable specified by including the offset(\textit{varname}_o) or exposure(\textit{varname}_e) option when you fit the model.

predict can be used to make in-sample or out-of-sample predictions:

6. predict calculates the requested statistic for all possible observations, whether they were used in fitting the model or not. predict does this for standard options 1 through 3 and generally does this for estimator-specific options 4.
7. predict newvar if \textit{e(sample)}, ... restricts the prediction to the estimation subsample.
8. Some statistics make sense only with respect to the estimation subsample. In such cases, the calculation is automatically restricted to the estimation subsample, and the documentation for the specific option states this. Even so, you can still specify if \textit{e(sample)} if you are uncertain.
9. predict can make out-of-sample predictions even using other datasets. In particular, you can

```
. use ds1
. (fit a model)
. use two /* another dataset */
. predict yhat, /* fill in the predictions */
```
Quick start

Create `newvar1` containing the default prediction for the previous estimation command

```plaintext
predict newvar1
```

Create `newvar2` containing the linear prediction

```plaintext
predict newvar2, xb
```

Same as above, but only for observations used in the previous estimation

```plaintext
predict newvar2 if e(sample), xb
```

Create `newvar3`, the default prediction for the first equation in a multiple-equation model

```plaintext
predict newvar3, equation(#1)
```

Same as above when `y1` is the name of the first equation

```plaintext
predict newvar3, equation(y1)
```

Note: For a complete list of options available with `predict` after an estimation command, see the corresponding postestimation entry.

Menu for predict

Options

Main

\[ \hat{y}_j = b_1 x_{1j} + b_2 x_{2j} + \cdots + b_k x_{kj}, \]

\[ \hat{y}_j = x_j \beta. \]

For linear regression, the values \( \hat{y}_j \) are called the predicted values or, for out-of-sample predictions, the forecast. For logit and probit, \( \hat{y}_j \) is called the logit or probit index.

\( x_{1j}, x_{2j}, \ldots, x_{kj} \) are obtained from the data currently in memory and do not necessarily correspond to the data on the independent variables used to fit the model (obtaining \( b_1, b_2, \ldots, b_k \)).

stdp calculates the standard error of the linear prediction. Here the prediction means the same thing as the “index”, namely, \( x_j \beta \). The statistic produced by stdp can be thought of as the standard error of the predicted expected value, or mean index, for the observation’s covariate pattern. The standard error of the prediction is also commonly referred to as the standard error of the fitted value. The calculation can be made in or out of sample.
stddp is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions \((x_{1j} - x_{2j}) \hat{b}\) between equations 1 and 2 is calculated. This option requires that `equation(eqno1, eqno2)` be specified.

`score` calculates the equation-level score, \(\partial \ln L / \partial (x_j \beta)\). Here \(\ln L\) refers to the log-likelihood function.

`scores` is the ME model equivalent of the `score` option, resulting in multiple equation-level score variables. An equation-level score variable is created for each equation in the model; ancillary parameters—such as \(\ln \sigma\) and \(\operatorname{atanh} \rho\)—make up separate equations.

`equation(eqno[, eqno])`—synonym `outcome()`—is relevant only when you have previously fit a multiple-equation model. It specifies the equation to which you are referring.

`equation()` is typically filled in with one `eqno`—it would be filled in that way with options `xb` and `stdp`, for instance. `equation(#1)` would mean the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named `income` and `equation(hours)` to the equation named `hours`.

If you do not specify `equation()`, results are the same as if you specified `equation(#1)`.

Other statistics, such as `stddp`, refer to between-equation concepts. In those cases, you might specify `equation(#1,#2)` or `equation(income,hours)`. When two equations must be specified, `equation()` is required.

---

Options

`nooffset` may be combined with most statistics and specifies that the calculation should be made, ignoring any offset or exposure variable specified when the model was fit.

This option is available, even if it is not documented for `predict` after a specific command. If neither the `offset(varname_o)` option nor the `exposure(varname_e)` option was specified when the model was fit, specifying `nooffset` does nothing.

`other_options` refers to command-specific options that are documented with each command.

---

Remarks and examples

Remarks are presented under the following headings:

- Estimation-sample predictions
- Out-of-sample predictions
- Residuals
- Single-equation (SE) models
- SE model scores
- Multiple-equation (ME) models
- ME model scores

Most of the examples are presented using linear regression, but the general syntax is applicable to all estimators.

You can think of any estimation command as estimating a set of coefficients \(b_1, b_2, \ldots, b_k\) corresponding to the variables \(x_1, x_2, \ldots, x_k\), along with a (possibly empty) set of ancillary statistics \(\gamma_1, \gamma_2, \ldots, \gamma_m\). All estimation commands store the \(b_is\) and \(\gamma_is\). `predict` accesses that stored information and combines it with the data currently in memory to make various calculations. For instance, `predict` can calculate the linear prediction, \(\hat{y}_j = b_1x_{1j} + b_2x_{2j} + \cdots + b_kx_{kj}\). The data on which `predict` makes the calculation can be the same data used to fit the model or a different
predict — Obtain predictions, residuals, etc., after estimation

predict uses the stored parameter estimates from the model, obtains the corresponding values of \( x \) for each observation in the data, and then combines them to produce the desired result.

Estimation-sample predictions

Example 1

We have a 74-observation dataset on automobiles, including the mileage rating (mpg), the car’s weight (weight), and whether the car is foreign (foreign). We fit the model

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight if foreign
```

```
          Source |        SS     df    MS
----------+----------------------
       Model | 427.990298     1 427.990298
     Residual | 489.873338    20 24.4936669
        Total | 917.863636    21 43.7077922

Number of obs = 22
F(1, 20) = 17.47
Prob > F = 0.0005
R-squared = 0.4663
Adj R-squared = 0.4396

mpg       Coefficient   Std. err.     t    P>|t|    [95% conf. interval]
----------+-----------------------+----------+--------+---------------------+---------------------
weight    -.010426   .0024942   -4.18   0.000   -.0156287   -.0052232
_cons       48.9183   5.871851    8.33   0.000   36.66983    61.16676
```

If we were to type `predict pmpg` now, we would obtain the linear predictions for all 74 observations. To obtain the predictions just for the sample on which we fit the model, we could type

```
. predict pmpg if e(sample)
(option xb assumed; fitted values)
(52 missing values generated)
```

Here `e(sample)` is true only for foreign cars because we typed `if foreign` when we fit the model and because there are no missing values among the relevant variables. If there had been missing values, `e(sample)` would also account for those.

By the way, the `if e(sample)` restriction can be used with any Stata command, so we could obtain summary statistics on the estimation sample by typing

```
. summarize if e(sample)
(output omitted)
```

Out-of-sample predictions

By out-of-sample predictions, we mean predictions extending beyond the estimation sample. In the example above, typing `predict pmpg` would generate linear predictions using all 74 observations.

`predict` will work on other datasets, too. You can use a new dataset and type `predict` to obtain results for that sample.
Example 2

Using the same auto dataset, assume that we wish to fit the model

\[ mpg = \beta_1 \text{weight} + \beta_2 \ln(\text{weight}) + \beta_3 \text{foreign} + \beta_4 \]

We first create the \( \ln(\text{weight}) \) variable, and then type the `regress` command:

```
use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
generate lnweight = ln(weight)
regress mpg weight lnweight foreign
```

```

```

If we typed `predict pmpg` now, we would obtain predictions for all 74 cars in the current data. Instead, we are going to use a new dataset.

`newautos.dta` contains the make, weight, and place of manufacture of two cars, the Pontiac Sunbird and the Volvo 260. Let’s use the dataset and create the predictions:

```
use https://www.stata-press.com/data/r18/newautos, clear
(New automobile models)
list

<table>
<thead>
<tr>
<th>make</th>
<th>weight</th>
<th>foreign</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pont. Sunbird</td>
<td>2690</td>
<td>Domestic</td>
</tr>
<tr>
<td>Volvo 260</td>
<td>3170</td>
<td>Foreign</td>
</tr>
</tbody>
</table>
```

```
predict mpg
(option xb assumed; fitted values)

variable lnweight not found
r(111);
```

Things did not work. We typed `predict mpg`, and Stata responded with the message “variable lnweight not found”. `predict` can calculate predicted values on a different dataset only if that dataset contains the variables that went into the model. Here our dataset does not contain a variable called `lnweight`. `lnweight` is just the log of weight, so we can create it and try again:
. generate lnweight = ln(weight)
. predict mpg
  (option xb assumed; fitted values)
. list

<table>
<thead>
<tr>
<th>make</th>
<th>weight</th>
<th>foreign</th>
<th>lnweight</th>
<th>mpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Pont. Sunbird</td>
<td>2690</td>
<td>Domestic</td>
<td>7.897296</td>
<td>23.25097</td>
</tr>
<tr>
<td>2. Volvo 260</td>
<td>3170</td>
<td>Foreign</td>
<td>8.061487</td>
<td>17.85295</td>
</tr>
</tbody>
</table>

We obtained our predicted values. The Pontiac Sunbird has a predicted mileage rating of 23.3 mpg, whereas the Volvo 260 has a predicted rating of 17.9 mpg.

Residuals

Example 3

With many estimators, predict can calculate more than predicted values. With most regression-type estimators, we can, for instance, obtain residuals. Using our regression example, we return to our original data and obtain residuals by typing

. use https://www.stata-press.com/data/r18/auto, clear
  (1978 automobile data)
. generate lnweight = ln(weight)
. regress mpg weight lnweight foreign
  (output omitted)
. predict double resid, residuals
. summarize resid

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>resid</td>
<td>74</td>
<td>-1.31e-14</td>
<td>3.212091</td>
<td>-5.453078</td>
<td>13.83719</td>
</tr>
</tbody>
</table>

We could do this without refitting the model. Stata always remembers the last set of estimates, even as we use new datasets.

It was not necessary to type the double in predict double resid, residuals, but we wanted to remind you that you can specify the type of a variable in front of the variable’s name; see [U] 11.4.2 Lists of new variables. We made the new variable resid a double rather than the default float.

If we had not specified %double, the mean of resid would have been roughly $9 \times 10^{-9}$ rather than $1 \times 10^{-14}$. Although $1 \times 10^{-14}$ sounds more precise than $9 \times 10^{-9}$, the difference really does not matter.

For linear regression, predict can also calculate standardized residuals and Studentized residuals with the options rstandard and rstudent; for examples, see [R] regress postestimation.
Single-equation (SE) models

If you have not read the discussion above on using predict after linear regression, please do so. And predict’s default calculation almost always produces a statistic in the same metric as the dependent variable of the fitted model—for example, predicted counts for Poisson regression. In any case, xb can always be specified to obtain the linear prediction.

predict can calculate the standard error of the prediction, which is obtained by using the covariance matrix of the estimators.

Example 4

After most binary outcome models (for example, logistic, logit, probit, cloglog, scobit), predict calculates the probability of a positive outcome if we do not tell it otherwise. We can specify the xb option if we want the linear prediction (also known as the logit or probit index). The odd abbreviation xb is meant to suggest $x\beta$. In logit and probit models, for example, the predicted probability is $p = F(x\beta)$, where $F()$ is the logistic or normal cumulative distribution function, respectively.

```
. logistic foreign mpg weight
(output omitted)
. predict phat
(option pr assumed; Pr(foreign))
. predict idxhat, xb
. summarize foreign phat idxhat

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign</td>
<td>74</td>
<td>.2972973</td>
<td>.4601885</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>phat</td>
<td>74</td>
<td>.2972973</td>
<td>.3052979</td>
<td>.000729</td>
<td>.8980594</td>
</tr>
<tr>
<td>idxhat</td>
<td>74</td>
<td>-1.678202</td>
<td>2.321509</td>
<td>-7.223107</td>
<td>2.175845</td>
</tr>
</tbody>
</table>
```

Because this is a logit model, we could obtain the predicted probabilities ourselves from the predicted index

```
. generate phat2 = exp(idxhat)/(1+exp(idxhat))
```

but using predict without options is easier.

Example 5

For all models, predict attempts to produce a predicted value in the same metric as the dependent variable of the model. We have seen that for dichotomous outcome models, the default statistic produced by predict is the probability of a success. Similarly, for Poisson regression, the default statistic produced by predict is the predicted count for the dependent variable. You can always specify the xb option to obtain the linear combination of the coefficients with an observation’s $x$ values (the inner product of the coefficients and $x$ values). For poisson (without an explicit exposure), this is the natural log of the count.

```
. use https://www.stata-press.com/data/r18/airline, clear
. poisson injuries XYZowned
(output omitted)
```
predict — Obtain predictions, residuals, etc., after estimation 2179

. predict injhat
  (option n assumed; predicted number of events)
. predict idx, xb
. generate exp_idx = exp(idx)
. summarize injuries injhat exp_idx idx

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>injuries</td>
<td>9</td>
<td>7.11111</td>
<td>5.487359</td>
<td>1</td>
<td>19</td>
</tr>
<tr>
<td>injhat</td>
<td>9</td>
<td>7.11111</td>
<td>.833333</td>
<td>6</td>
<td>7.66667</td>
</tr>
<tr>
<td>exp_idx</td>
<td>9</td>
<td>7.11111</td>
<td>.833333</td>
<td>6</td>
<td>7.66667</td>
</tr>
<tr>
<td>idx</td>
<td>9</td>
<td>1.955174</td>
<td>.1225612</td>
<td>1.791759</td>
<td>2.036882</td>
</tr>
</tbody>
</table>

We note that our “hand-computed” prediction of the count (exp_idx) matches what was produced by the default operation of predict.

If our model has an exposure-time variable, we can use predict to obtain the linear prediction with or without the exposure. Let’s verify what we are getting by obtaining the linear prediction with and without exposure, transforming these predictions to count predictions and comparing them with the default count prediction from predict. We must remember to multiply by the exposure time when using predict ..., nooffset.

. use https://www.stata-press.com/data/r18/airline, clear
. poisson injuries XYZowned, exposure(n)
  (output omitted)
. predict double injhat
  (option n assumed; predicted number of events)
. predict double idx, xb
. generate double exp_idx = exp(idx)
. predict double idxn, xb nooffset
. generate double exp_idxn = exp(idxn)*n
. summarize injuries injhat exp_idx exp_idxn idx idxn

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>injuries</td>
<td>9</td>
<td>7.11111</td>
<td>5.487359</td>
<td>1</td>
<td>19</td>
</tr>
<tr>
<td>injhat</td>
<td>9</td>
<td>7.11111</td>
<td>3.10936</td>
<td>2.919621</td>
<td>12.06158</td>
</tr>
<tr>
<td>exp_idx</td>
<td>9</td>
<td>7.11111</td>
<td>3.10936</td>
<td>2.919621</td>
<td>12.06158</td>
</tr>
<tr>
<td>exp_idxn</td>
<td>9</td>
<td>7.11111</td>
<td>3.10936</td>
<td>2.919621</td>
<td>12.06158</td>
</tr>
<tr>
<td>idx</td>
<td>9</td>
<td>1.869722</td>
<td>.4671044</td>
<td>1.071454</td>
<td>2.490025</td>
</tr>
<tr>
<td>idxn</td>
<td>9</td>
<td>4.18814</td>
<td>.1904042</td>
<td>4.061204</td>
<td>4.442013</td>
</tr>
</tbody>
</table>

Looking at the identical means and standard deviations for injhat, exp_idx, and exp_idxn, we see that we can reproduce the default computations of predict for poisson estimations. We have also demonstrated the relationship between the count predictions and the linear predictions with and without exposure.

SE model scores

Example 6

With most maximum likelihood estimators, predict can calculate equation-level scores. The first derivative of the log likelihood with respect to $x_j \beta$ is the equation-level score.
predict — Obtain predictions, residuals, etc., after estimation

. use https://www.stata-press.com/data/r18/auto, clear
   (1978 automobile data)
. logistic foreign mpg weight
   (output omitted)
. predict double sc, score
. summarize sc

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>sc</td>
<td>74</td>
<td>-1.37e-12</td>
<td>.3533133</td>
<td>-0.8760856</td>
<td>.8821309</td>
</tr>
</tbody>
</table>

See [P] _robust and [SVY] Variance estimation for details regarding the role equation-level scores play in linearization-based variance estimators.

Technical note

predict after some estimation commands, such as regress and cnsreg, allows the score option as a synonym for the residuals option.

Multiple-equation (ME) models

If you have not read the above discussion on using predict after SE models, please do so. With the exception of the ability to select specific equations to predict from, the use of predict after ME models follows almost the same form that it does for SE models.

Example 7

The details of prediction statistics that are specific to particular ME models are documented with the estimation command. If you are using ME commands that do not have separate discussions on obtaining predictions, read Obtaining predicted values in [R] mlogit postestimation, even if your interest is not in multinomial logistic regression. As a general introduction to the ME models, we will demonstrate predict after sureg:

. use https://www.stata-press.com/data/r18/auto, clear
   (1978 automobile data)
. sureg (price foreign displ) (weight foreign length)
   (Seemingly unrelated regression

predict — Obtain predictions, residuals, etc., after estimation 2181

sureg estimated two equations, one called price and the other weight; see [R] sureg.

. predict pred_p, equation(price)
   (option xb assumed; fitted values)
. predict pred_w, equation(weight)
   (option xb assumed; fitted values)
. summarize price pred_p weight pred_w

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>74</td>
<td>6165.257</td>
<td>2949.496</td>
<td>3291</td>
<td>15906</td>
</tr>
<tr>
<td>pred_p</td>
<td>74</td>
<td>6165.257</td>
<td>1678.805</td>
<td>2664.81</td>
<td>10485.33</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
<tr>
<td>pred_w</td>
<td>74</td>
<td>3019.459</td>
<td>726.0468</td>
<td>1501.602</td>
<td>4447.996</td>
</tr>
</tbody>
</table>

You may specify the equation by name, as we did above, or by number: equation(#1) means the same thing as equation(price) in this case.

ME model scores

Example 8

For ME models, predict allows you to specify a stub when generating equation-level score variables. predict generates new variables using this stub by appending an equation index. Depending upon the command, the index will start with 0 or 1. Here is an example where predict starts indexing the score variables with 0.

. ologit rep78 mpg weight
   (output omitted)
. predict double sc*, scores
. summarize sc*

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>sc0</td>
<td>69</td>
<td>-1.33e-11</td>
<td>.5337363</td>
<td>-.9854088</td>
<td>.921433</td>
</tr>
<tr>
<td>sc1</td>

<td>.360525</td>
<td>-.921433</td>
<td>.6140182</td>
</tr>
</tbody>
</table>
Methods and formulas

Denote the previously estimated coefficient vector as $\mathbf{b}$ and its estimated variance matrix as $\mathbf{V}$. predict works by recalling various aspects of the model, such as $\mathbf{b}$, and combining that information with the data currently in memory. Let’s write $\mathbf{x}_j$ for the $j$th observation currently in memory.

The predicted value (xb option) is defined as $\hat{y}_j = \mathbf{x}_j \mathbf{b} + \text{offset}_j$

The standard error of the prediction (the stdp option) is defined as $s_{p_j} = \sqrt{\mathbf{x}_j \mathbf{V} \mathbf{x}_j'}$

The standard error of the difference in linear predictions between equations 1 and 2 is defined as

$$s_{dp_j} = \{(\mathbf{x}_{1j}, -\mathbf{x}_{2j}, 0, \ldots, 0) \mathbf{V} (\mathbf{x}_{1j}, -\mathbf{x}_{2j}, 0, \ldots, 0)'\}^{\frac{1}{2}}$$

See the individual estimation commands for information about calculating command-specific predict statistics.

[U] 20 Estimation and postestimation commands
**Title**

**predictnl** — Obtain nonlinear predictions, standard errors, etc., after estimation

---

### Description

`predictnl` calculates (possibly) nonlinear predictions after any Stata estimation command and optionally calculates the variances, standard errors, Wald test statistics, *p*-values, and confidence limits for these predictions. Unlike its companion nonlinear postestimation commands `testnl` and `nlcom`, `predictnl` generates functions of the data (that is, predictions), not scalars. The quantities generated by `predictnl` are thus vectorized over the observations in the data.

Consider some general prediction, \( g(\theta, x_i) \), for \( i = 1, \ldots, n \), where \( \theta \) are the model parameters and \( x_i \) are some data for the \( i \)th observation; \( x_i \) is assumed fixed. Typically, \( g(\theta, x_i) \) is estimated by \( \hat{g}(\hat{\theta}, x_i) \), where \( \hat{\theta} \) are the estimated model parameters, which are stored in `e(b)` following any Stata estimation command.

In its most common use, `predictnl` generates two variables: one containing the estimated prediction, \( \hat{g}(\hat{\theta}, x_i) \), the other containing the estimated standard error of \( \hat{g}(\hat{\theta}, x_i) \). The calculation of standard errors (and other obtainable quantities that are based on the standard errors, such as test statistics) is based on the delta method, an approximation appropriate in large samples; see **Methods and formulas**.

`predictnl` can be used with svy estimation results (assuming that `predict` is also allowed), see [SVY] `svy postestimation`.

The specification of \( g(\hat{\theta}, x_i) \) is handled by specifying `pnl_exp`, and the values of \( g(\hat{\theta}, x_i) \) are stored in the new variable `newvar` of storage type `type`. `pnl_exp` is any valid Stata expression and may also contain calls to two special functions unique to `predictnl`:

1. `predict([predict_options])`: When you are evaluating `pnl_exp`, `predict()` is a convenience function that replicates the calculation performed by the command

   \[ \text{predict ...}, \text{predict_options} \]

   As such, the `predict()` function may be used either as a shorthand for the formula used to make this prediction or when the formula is not readily available. When used without arguments, `predict()` replicates the default prediction for that particular estimation command.

2. `xb([eqno])`: The `xb()` function replicates the calculation of the linear predictor \( x_i b \) for equation `eqno`. If `xb()` is specified without `eqno`, the linear predictor for the first equation (or the only equation in single-equation estimation) is obtained.

   For example, `xb(#1)` (or equivalently, `xb()` with no arguments) translates to the linear predictor for the first equation, `xb(#2)` for the second, and so on. You could also refer to the equations by their names, such as `xb(income)`.

When specifying `pnl_exp`, both of these functions may be used repeatedly, in combination, and in combination with other Stata functions and expressions. See **Remarks and examples** for examples that use both of these functions.

---

2183
Quick start

After `regress`, create `yhat` containing the default linear prediction

```plaintext
predictnl yhat = predict()
```

After `probit y x1 x2`, create `pr1` containing predicted probability that `y = 1`

```plaintext
predictnl pr1 = predict(pr)
```

Same as above, and create `lb1` and `ub1` containing the upper and lower bounds of the 95% confidence interval for the prediction

```plaintext
predictnl pr1 = predict(pr), ci(lb1 ub1)
```

Same as above, specified as a function of the linear prediction

```plaintext
predictnl pr1 = normal(xb()), ci(lb1 ub1)
```

Same as above, specified as a function of the coefficients

```plaintext
predictnl pr1 = normal(_b[_cons]+_b[x1]*x1+_b[x2]*x2), ci(lb1 ub1)
```

Same as above, but create the prediction using `x1` equal to 0

```plaintext
predictnl pr1 = normal(_b[_cons]+_b[x1]*0+_b[x2]*x2), ci(lb1 ub1)
```

Same as above, but create variable `se1` containing the standard error of the prediction

```plaintext
predictnl pr1 = normal(_b[_cons]+_b[x1]*0+_b[x2]*x2), se(se1)
```

After a multiple-equation model, create `ratio` as the ratio of the linear predictions from the second and third equations

```plaintext
predictnl ratio = xb(#2)/xb(#3)
```
predictnl — Obtain nonlinear predictions, standard errors, etc., after estimation

**Syntax**

```
predictnl [type] newvar = pnl_exp [if] [in] [ , options]
```

**Options**

**Main**

- `se(newvar)` adds `newvar` of storage type `type`, where for each `i` in the prediction sample, `newvar[i]` contains the estimated standard error of $g(\hat{\theta}, x_i)$.
- `variance(newvar)` adds `newvar` of storage type `type`, where for each `i` in the prediction sample, `newvar[i]` contains the estimated variance of $g(\hat{\theta}, x_i)$.
- `wald(newvar)` adds `newvar` of storage type `type`, where for each `i` in the prediction sample, `newvar[i]` contains the Wald test statistic for the test of the hypothesis $H_0: g(\theta, x_i) = 0$.
- `p(newvar)` adds `newvar` of storage type `type`, where `newvar[i]` contains the p-value for the Wald test of $H_0: g(\theta, x_i) = 0$ versus the two-sided alternative.
- `ci(newvars)` requires the specification of two `newvars`, such that the `i`th observation of each will contain the left and right endpoints (respectively) of a confidence interval for $g(\theta, x_i)$. The level of the confidence intervals is determined by `level(#)`.
- `level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals.
- `g(stub)` specifies that new variables, `stub1`, `stub2`, ..., `stubk` be created, where `k` is the dimension of `\theta`. `stub1` will contain the observation-specific derivatives of $g(\theta, x_i)$ with respect to the first element, $\theta_1$, of `\theta`; `stub2` will contain the derivatives of $g(\theta, x_i)$ with respect to $\theta_2$, etc.; If the derivative of $g(\theta, x_i)$ with respect to a particular coefficient in `\theta` equals zero for all observations in the prediction sample, the `stub` variable for that coefficient is not created. The ordering of the parameters in `\theta` is precisely that of the stored vector of parameter estimates `e(b)`. 

iterate(#) specifies the maximum number of iterations used to find the optimal step size in the
calculation of numerical derivatives of \( g(\theta, x_i) \) with respect to \( \theta \). By default, the maximum
number of iterations is 100, but convergence is usually achieved after only a few iterations. You should
rarely have to use this option.

force forces the calculation of standard errors and other inference-related quantities in situations
where predictnl would otherwise refuse to do so. The calculation of standard errors takes place
by evaluating (at \( \hat{\theta} \)) the numerical derivative of \( g(\theta, x_i) \) with respect to \( \theta \). If predictnl detects
that \( g(\cdot) \) is possibly a function of random quantities other than \( \hat{\theta} \), it will refuse to calculate standard
errors or any other quantity derived from them. The force option forces the calculation to take
place anyway. If you use the force option, there is no guarantee that any inference quantities (for
example, standard errors) will be correct or that the values obtained can be interpreted.

The following option is available with predictnl but is not shown in the dialog box:

\( \text{df}(#) \) specifies that the \( F \) distribution with \( # \) denominator degrees of freedom be used for the
reference distribution of the test statistic.

Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Nonlinear transformations and standard errors
- Using xb() and predict()
- Multiple-equation (ME) estimators
- Test statistics and \( p \)-values
- Manipulability
- Confidence intervals

Introduction

predictnl and nlcom both use the delta method. They take a nonlinear transformation of the
estimated parameter vector from some fitted model and apply the delta method to calculate the
variance, standard error, Wald test statistic, etc., of this transformation. nlcom is designed for scalar
functions of the parameters, and predictnl is designed for functions of the parameters and of the
data, that is, for predictions.

Nonlinear transformations and standard errors

We begin by fitting a probit model to the low-birthweight data of Hosmer, Lemeshow, and
Sturdivant (2013, 24). The data are described in detail in example 1 of [R] logistic.
predictnl — Obtain nonlinear predictions, standard errors, etc., after estimation 2187

After we fit such a model, we first would want to generate the predicted probabilities of a low birthweight, given the covariate values in the estimation sample. This is easily done using predict after probit, but it doesn’t answer the question, “What are the standard errors of those predictions?”

For the time being, we will consider ourselves ignorant of any automated way to obtain the predicted probabilities after probit. The formula for the prediction is

$$Pr(y \neq 0|x_i) = \Phi(x_i \beta)$$

where $\Phi$ is the standard cumulative normal. Thus for this example, $g(\theta,x_i) = \Phi(x_i \beta)$. Armed with the formula, we can use predictnl to generate the predictions and their standard errors:

.preditcnel phat = normal(_b[_cons] + _b[ht]*ht + _b[ptl]*ptl + _b[smoke]*smoke + _b[lwt]*lwt), se(phat_se)

.list phat phat_se lwt smoke ptl ht in -10/l

Thus, subject 180 in our data has an estimated probability of low birthweight of 23.6% with standard error 4.3%.

Used without options, predictnl is not much different from generate. By specifying the se(phat_se) option, we were able to obtain a variable containing the standard errors of the predictions; therein lies the utility of predictnl.
Using \texttt{xb()} and \texttt{predict()} \\

As was the case above, a prediction is often not a function of a few isolated parameters and their corresponding variables but instead is some (possibly elaborate) function of the entire linear predictor. For models with many predictors, the brute-force expression for the linear predictor can be cumbersome to type. An alternative is to use the inline function \texttt{xb()}. \texttt{xb()} is a shortcut for having to type \( \_b[\_cons] + \_b[ht]*ht + \_b[ptl]*ptl + \ldots \),

\begin{verbatim}
. drop pat pat_se
. predictnl pat = norm(xb()), se(pat_se)
. list pat pat_se lwt smoke ptl ht in -10/l
phat phat_se lwt smoke ptl ht 180.
   .2363556 .042707 120 Non smoker 0 0
181.
   .6577712 .1580714 154 Non smoker 1 1
182.
   .2793261 .0519958 106 Non smoker 0 0
183.
   .1502118 .0676339 190 Smoker 0 0
184.
   .5702871 .0819911 101 Smoker 1 0
185.
   .4477045 .079889 95 Smoker 0 0
186.
   .2988379 .0576306 100 Non smoker 0 0
187.
   .4514706 .080815 94 Smoker 0 0
188.
   .5615571 .1551051 142 Non smoker 0 1
189.
   .7316517 .1361469 130 Smoker 0 1
\end{verbatim}

which yields the same results. This approach is easier, produces more readable code, and is less prone to error, such as forgetting to include a term in the sum.

Here we used \texttt{xb()} without arguments because we have only one equation in our model. In multiple-equation (ME) settings, \texttt{xb()} (or equivalently \texttt{xb(#1)}) yields the linear predictor from the first equation, \texttt{xb(#2)} from the second, etc. You can also refer to equations by their names, for example, \texttt{xb(income)}.

\section*{Technical note}

Most estimation commands in Stata allow the postestimation calculation of linear predictors and their standard errors via \texttt{predict}. For example, to obtain these for the first (or only) equation in the model, you could type

\begin{verbatim}
predict \texttt{xbvar}, \texttt{xb}
predict \texttt{stdpvar}, \texttt{stdp}
\end{verbatim}

Equivalently, you could type

\begin{verbatim}
predictnl \texttt{xbvar} = \texttt{xb()}, \texttt{se(\texttt{stdpvar})}
\end{verbatim}

but we recommend the first method, because it is faster. As we demonstrated above, however, \texttt{predictnl} is more general.

Returning to our \texttt{probit} example, we can further simplify the calculation by using the inline function \texttt{predict()}. \texttt{predict(pred_options)} works by substituting, within our \texttt{predictnl} expression, the calculation performed by

\begin{verbatim}
predict ..., pred_options
\end{verbatim}
In our example, we are interested in the predicted probabilities after a probit regression, normally obtained via

```
predict ..., p
```

We can obtain these predictions (and standard errors) by using

```
. drop phat phat_se
. predictnl phat = predict(p), se(phat_se)
. list phat phat_se lwt smoke ptl ht in -10/l
```

</tbody>
</table>

which again replicates what we have already done by other means. However, this version did not require knowledge of the formula for the predicted probabilities after a probit regression—`predict(p)` took care of that for us.

Because the predicted probability is the default prediction after `probit`, we could have just used `predict()` without arguments, namely,

```
. predictnl phat = predict(), se(phat_se)
```

Also, the expression `pnl_exp` can be inordinately complicated, with multiple calls to `predict()` and `xb()`. For example,

```
. predictnl phat = normal(invnormal(predict()) + predict(xb)/xb() - 1), > se(phat_se)
```

is perfectly valid and will give the same result as before, albeit a bit inefficiently.

⚠️ Technical note

When using `predict()` and `xb()`, the `formula` for the calculation is substituted within `pnl_exp`, not the values that result from the application of that formula. To see this, note the subtle difference between

```
. predict xbeta, xb
. predictnl phat = normal(xbeta), se(phat_se)
```

and

```
. predictnl phat = normal(xb()), se(phat_se)
```
Both sequences will yield the same phat, yet for the first sequence, phat_se will equal zero for all observations. The reason is that, once evaluated, xbeta will contain the values of the linear predictor, yet these values are treated as fixed and nonstochastic as far as predictnl is concerned. By contrast, because xb() is shorthand for the formula used to calculate the linear predictor, it contains not values, but references to the estimated regression coefficients and corresponding variables. Thus, the second method produces the desired result.

Multiple-equation (ME) estimators

In [R] mlogit, data on insurance choice (Tarlov et al. 1989; Wells et al. 1989) were examined, and a multinomial logit was used to assess the effects of age, gender, race, and site of study (one of three sites) on the type of insurance:

```
use https://www.stata-press.com/data/r18/sysdsn1, clear
(Health insurance data)
.mlogit insure age male nonwhite i.site, nolog
```

Of particular interest is the estimation of the relative risk, which, for a given selection, is the ratio of the probability of making that selection to the probability of selecting the base category (Indemnity here), given a set of covariate values. In a multinomial logit model, the relative risk (when comparing to the base category) simplifies to the exponentiated linear predictor for that selection.

Using this example, we can estimate the observation-specific relative risks of selecting a prepaid plan over the base category (with standard errors) by either referring to the Prepaid equation by name or number,

```
.predictnl RRppaid = exp(xb(Prepaid)), se(SERRppaid)
```
or

```
predictnl RRppaid = exp(xb(#1)), se(SERRppaid)
```

because Prepaid is the first equation in the model.

Those of us for whom the simplified formula for the relative risk does not immediately come to mind may prefer to calculate the relative risk directly from its definition, that is, as a ratio of two predicted probabilities. After mlogit, the predicted probability for a category may be obtained using predict, but we must specify the category as the outcome:

```
predictnl RRppaid = predict(outcome(Prepaid))/predict(outcome(Indemnity)),
> se(SERRppaid)
```

(1 missing value generated)

```
.list RRppaid SERRppaid age male nonwhite site in 1/10

The “(1 missing value generated)” message is not an error; further examination of the data would reveal that age is missing in one observation and that the offending observation (among others) is not in the estimation sample. Just as with predict, predictnl can generate predictions in or out of the estimation sample.

Thus, we estimate (among other things) that a white, female, 73-year-old from site 2 is less likely to choose a prepaid plan over an indemnity plan—her relative risk is about 62% with standard error 15%.

### Test statistics and p-values

Often, a standard error calculation is just a means to an end, and what is really desired is a test of the hypothesis,

\[ H_0 : g(\theta, x_i) = 0 \]

versus the two-sided alternative.

We can use predictnl to obtain the Wald test statistics or p-values (or both) for the above tests, whether or not we want standard errors. To obtain the Wald test statistics, we use the `wald()` option; for p-values, we use `p()`.

Returning to our mlogit example, suppose that we wanted for each observation a test of whether the relative risk of choosing a prepaid plan over an indemnity plan is different from one. One way to do this would be to define \( g(\cdot) \) to be the relative risk minus one and then test whether \( g(\cdot) \) is different from zero.
. predictnl RRm1 = exp(xb(Prepaid)) - 1, wald(W_RRm1) p(sig_RRm1)
(1 missing value generated)

</table>

The newly created variable W_RRm1 contains the Wald test statistic for each observation, and sig_RRm1 contains the p-value. Thus, our 73-year-old white female represented by the first observation would have a relative risk of choosing prepaid over indemnity that is significantly different from 1, at least at the 5% level. For this test, it was not necessary to generate a variable containing the standard error of the relative risk minus 1, but we could have done so had we wanted. We could have also omitted specifying wald(W_RRm1) if all we cared about were, say, the p-values for the tests.

In this regard, predictnl acts as an observation-specific version of testnl, with the test results vectorized over the observations in the data. The p-values are pointwise—they are not adjusted to reflect any simultaneous testing over the observations in the data.

**Manipulability**

There are many ways to specify \( g(\theta, x_i) \) to yield tests such that, for multiple specifications of \( g(\cdot) \), the theoretical conditions for which

\[
H_0: g(\theta, x_i) = 0
\]

is true will be equivalent. However, this does not mean that the tests themselves will be equivalent. This is known as the manipulability of the Wald test for nonlinear hypotheses; also see [R] boxcox.

As an example, consider the previous section where we defined \( g(\cdot) \) to be the relative risk between choosing a prepaid plan over an indemnity plan, minus 1. We could also have defined \( g(\cdot) \) to be the risk difference—the probability of choosing a prepaid plan minus the probability of choosing an indemnity plan. Either specification of \( g(\cdot) \) yields a mathematically equivalent specification of \( H_0: g(\cdot) = 0 \); that is, the risk difference will equal zero when the relative risk equals one. However, the tests themselves do not give the same results:
predictnl — Obtain nonlinear predictions, standard errors, etc., after estimation

predictnl RD = predict(outcome(Prepaid)) - predict(outcome(Indemnity)), > wald(W_RD) p(sig_RD)

(1 missing value generated)

note: p-values are with respect to the chi-squared(1) distribution.

</tbody>
</table>

In certain cases (such as subject 8), the difference can be severe enough to potentially change the conclusion. The reason for this inconsistency is that the nonlinear Wald test is actually a standard Wald test of a first-order Taylor approximation of \( g(\cdot) \), and this approximation can differ according to how \( g(\cdot) \) is specified.

As such, keep in mind the manipulability of nonlinear Wald tests when drawing scientific conclusions.

Confidence intervals

We can also use `predictnl` to obtain confidence intervals for the observation-specific \( g(\theta, x_i) \) by using the `ci()` option to specify two new variables to contain the left and right endpoints of the confidence interval, respectively. For example, we could generate confidence intervals for the risk differences calculated previously:

```
.drop RD
.predictnl RD = predict(outcome(Prepaid)) - predict(outcome(Indemnity)), > ci(RD_lcl RD_rcl)

(1 missing value generated)

note: confidence intervals calculated using Z critical values.

```

The confidence level, here, 95%, is either set using the `level()` option or obtained from the current default level, `c(level)`; see [U] 20.8 Specifying the width of confidence intervals.
From the above output, we can see that, for subjects 1, 8, and 10, a 95% confidence interval for the risk difference does not contain zero, meaning that, for these subjects, there is some evidence of a significant difference in risks.

The confidence intervals calculated by predictnl are pointwise; there is no adjustment (such as a Bonferroni correction) made so that these confidence intervals may be considered jointly at the specified level.

Methods and formulas

For the \( i \)th observation, consider the transformation \( g(\theta, x_i) \), estimated by \( g(\hat{\theta}, x_i) \), for the \( 1 \times k \) parameter vector \( \theta \) and data \( x_i \) (\( x_i \) is assumed fixed). The variance of \( g(\hat{\theta}, x_i) \) is estimated by

\[
\hat{\text{Var}}\left\{ g(\hat{\theta}, x_i) \right\} = G V G'
\]

where \( G \) is the vector of derivatives

\[
G = \left\{ \frac{\partial g(\theta, x_i)}{\partial \theta} \bigg|_{\theta = \hat{\theta}} \right\}_{(1 \times k)}
\]

and \( V \) is the estimated variance–covariance matrix of \( \hat{\theta} \). Standard errors, \( \hat{\text{se}} \{ g(\hat{\theta}, x_i) \} \), are obtained as the square roots of the variances.

The Wald test statistic for testing

\[ H_0: g(\theta, x_i) = 0 \]

versus the two-sided alternative is given by

\[
W_i = \frac{\left\{ g(\hat{\theta}, x_i) \right\}^2}{\hat{\text{Var}}\left\{ g(\hat{\theta}, x_i) \right\}}
\]

When the variance–covariance matrix of \( \hat{\theta} \) is an asymptotic covariance matrix, \( W_i \) is approximately distributed as \( \chi^2 \) with 1 degree of freedom. For linear regression, \( W_i \) is taken to be approximately distributed as \( F_{1, r} \), where \( r \) is the residual degrees of freedom from the original model fit. The \( p \)-values for the observation-by-observation tests of \( H_0 \) versus the two-sided alternative are given by

\[
p_i = \Pr(T > W_i)
\]

where \( T \) is either a \( \chi^2 \)- or \( F \)-distributed random variable, as described above.

A \( (1 - \alpha) \times 100\% \) confidence interval for \( g(\theta, x_i) \) is given by

\[
g(\hat{\theta}, x_i) \pm z_{\alpha/2} \left[ \hat{\text{se}} \left\{ g(\hat{\theta}, x_i) \right\} \right]
\]

when \( W_i \) is \( \chi^2 \)-distributed, and

\[
g(\hat{\theta}, x_i) \pm t_{\alpha/2, r} \left[ \hat{\text{se}} \left\{ g(\hat{\theta}, x_i) \right\} \right]
\]
when \( W_i \) is \( F \)-distributed. \( z_p \) is the \( 1 - p \) quantile of the standard normal distribution, and \( t_{p,r} \) is the \( 1 - p \) quantile of the \( t \) distribution with \( r \) degrees of freedom.

**Description**

`probit` fits a probit model for a binary dependent variable, assuming that the probability of a positive outcome is determined by the standard normal cumulative distribution function. `probit` can compute robust and cluster–robust standard errors and adjust results for complex survey designs.

**Quick start**

Probit model of \( y \) on continuous variable \( x_1 \)

```
probit y x1
```

Add square of \( x_1 \)

```
probit y c.x1##c.x1
```

Same as above, but report bootstrap standard errors

```
probit y c.x1##c.x1, vce(bootstrap)
```

Bootstrap estimates of coefficients

```
bootstrap _b: probit y c.x1##c.x1
```

Adjust for complex survey design using `svyset` data and add \( x_2 \)

```
svy: probit y c.x1##c.x1 x2
```

**Menu**

Statistics > Binary outcomes > Probit regression
Syntax

**depvar** may contain factor variables; see [U] 11.4.3 Factor variables.
*depvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

*bayes*, *bootstrap*, *by*, *collect*, *fmm*, *fp*, *jackknife*, *mfp*, *mi estimate*, *nestreg*, *rolling*, *statsby*,
*stepwise*, and *svy* are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: probit
and [FMM] fmm: probit.

vce(bootstrap) and vce(jackknife) are not allowed with the *mi estimate* prefix; see [MI] mi estimate.
*Weights are not allowed with the bootstrap prefix; see [R] bootstrap.*

vce(), nocoef, and weights are not allowed with the *svy* prefix; see [SVY] svy.

*fweight*, *iweight*, and *pweight* are allowed; see [U] 11.1.6 weight.

nocoef, collinear, and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

```
Model
```

noconstant, offset(varname), constraints(cons); see [R] Estimation options.

**asis** specifies that all specified variables and observations be retained in the maximization process.
This option is typically not specified and may introduce numerical instability. Normally probit
omits variables that perfectly predict success or failure in the dependent variable along with their
associated observations. In those cases, the effective coefficient on the omitted variables is infinity
(negative infinity) for variables that completely determine a success (failure). Dropping the variable
and perfectly predicted observations has no effect on the likelihood or estimates of the remaining coefficients and increases the numerical stability of the optimization process. Specifying this option forces retention of perfect predictor variables and their associated observations.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see `vce_option`.  

Reporting

level(#); see `Estimation options`.  
nocnsreport; see `Estimation options`.  
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see `Estimation options`.  

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see `Maximize`. These options are seldom used.

The following options are available with `probit` but are not shown in the dialog box:

nocoeff specifies that the coefficient table not be displayed. This option is sometimes used by programmers but is of no use interactively.

collinear, coeflegend; see `Estimation options`.

Remarks and examples

Remarks are presented under the following headings:

Robust standard errors  
Model identification  
Video examples

`probit` fits maximum likelihood models with dichotomous dependent (left-hand-side) variables coded as 0/1 (more precisely, coded as 0 and not 0).

For grouped data or data in binomial form, a `probit` model can be fit using `glm` with the family(binomial) and link(probit) options.

Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a `probit` model explaining whether a car is foreign based on its weight and mileage. Here is an overview of our data:
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. keep make mpg weight foreign
. describe
Contains data from https://www.stata-press.com/data/r18/auto.dta

(2 unique values)
foreign is labeled and all values are documented in the label.
The foreign variable takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.
The model that we wish to fit is
\[
\Pr(\text{foreign} = 1) = \Phi(\beta_0 + \beta_1 \text{weight} + \beta_2 \text{mpg})
\]
where \(\Phi\) is the cumulative normal distribution.
To fit this model, we type
. probit foreign weight mpg
Iteration 0:  Log likelihood =  -45.03321
Iteration 1:  Log likelihood =  -27.914626
(output omitted)
Iteration 5:  Log likelihood =  -26.844189
Probit regression
Number of obs = 74
LR chi2(2) = 36.38
Prob > chi2 = 0.0000
Pseudo R2 = 0.4039
Log likelihood =  -26.844189

| foreign | Coefficient | Std. err. | z    | P>|z| | [95% conf. interval] |
|---------|-------------|-----------|------|-------|----------------------|
| weight  | -.0023355   | .0005661  | -4.13| 0.000 | -.003445 .0012261   |
| mpg     | -.1039503   | .0515689  | -2.02| 0.044 | -.2050235 -.0028772 |
| _cons   | 8.275464    | 2.554142  | 3.24 | 0.001 | 3.269437 13.28149 |
We find that heavier cars are less likely to be foreign and that cars yielding better gas mileage are also less likely to be foreign, at least holding the weight of the car constant.

See [R] Maximize for an explanation of the output.

Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

If you prefer a more formal mathematical statement, when you type `probit y x`, Stata fits the model

$$Pr(y_j \neq 0 | x_j) = \Phi(x_j \beta)$$

where $\Phi$ is the standard cumulative normal.

Robust standard errors

If you specify the `vce(robust)` option, `probit` reports robust standard errors; see [U] 20.22 Obtaining robust variance estimates.

Example 2

For the model from example 1, the robust calculation increases the standard error of the coefficient on `mpg` by almost 15%:

```
. probit foreign weight mpg, vce(robust) nolog
Probit regression
Number of obs = 74
Wald chi2(2) = 30.26
Prob > chi2 = 0.0000
Log pseudolikelihood = -26.844189 Pseudo R2 = 0.4039

Robust
foreign Coefficient std. err. z P>|z| [95% conf. interval]
weight -.0023355 .0004934 -4.73 0.000 -.0033025 -.0013686
mpg -.1039503 .0593548 -1.75 0.080 -.2202836 .0123829
_cons 8.275464 2.539177 3.26 0.001 3.298769 13.25216

Without `vce(robust)`, the standard error for the coefficient on `mpg` was reported to be 0.052 with a resulting confidence interval of $[-0.21, -0.00]$.

Example 3

The `vce(cluster clustvar)` option can relax the independence assumption required by the probit estimator to independence between clusters. To demonstrate, we will switch to a different dataset.

We are studying unionization of women in the United States and have a dataset with 26,200 observations on 4,434 women between 1970 and 1988. We will use the variables `age` (the women were 14–26 in 1968, and our data span the age range of 16–46), `grade` (years of schooling completed, ranging from 0 to 18), `not_smsa` (28% of the person-time was spent living outside an SMSA—standard metropolitan statistical area), `south` (41% of the person-time was in the South), and `year`. Each of
these variables is included in the regression as a covariate along with the interaction between south and year. This interaction, along with the south and year variables, is specified in the probit command using factor-variables notation, south##c.year. We also have variable union, indicating union membership. Overall, 22% of the person-time is marked as time under union membership, and 44% of these women have belonged to a union.

We fit the following model, ignoring that the women are observed an average of 5.9 times each in these data:

```
. use https://www.stata-press.com/data/r18/union, clear
(NLS Women 14-24 in 1968)
. probit union age grade not_smsa south##c.year
Iteration 0:  Log likelihood =  -13864.23
Iteration 1:  Log likelihood =  -13545.541
Iteration 2:  Log likelihood =  -13544.385
Iteration 3:  Log likelihood =  -13544.385

Probit regression               Number of obs =  26,200
LR chi2(6)  =   639.69
Prob > chi2 =  0.0000
Log likelihood =  -13544.385  Pseudo R2 =  0.0231

union | Coefficient  Std. err.      z    P>|z|     [95% conf. interval]
-------------|-------------------------------|-----------|-------|-----------------------------|
      age |   0.0118481   0.0029072    4.08   0.000     0.0061502     0.017546

```

The reported standard errors in this model are probably meaningless. Women are observed repeatedly, and so the observations are not independent. Looking at the coefficients, we find a large southern effect against unionization and a time trend for the south that is almost significantly different from the overall downward trend. The vce(cluster clustvar) option provides a way to fit this model and obtains correct standard errors:
. probit union age grade not_smsa south##c.year, vce(cluster id)

Iteration 0:  Log pseudolikelihood =  -13864.23
Iteration 1:  Log pseudolikelihood =  -13545.541
Iteration 2:  Log pseudolikelihood =  -13544.385
Iteration 3:  Log pseudolikelihood =  -13544.385

Probit regression
Number of obs = 26,200
Wald chi2(6) = 166.53
Prob > chi2 =  0.0000
Pseudo R2 =  0.0231

(Std. err. adjusted for 4,434 clusters in idcode)

|          | Coefficient | Std. err. | z     | P>|z|  | [95% conf. interval] |
|----------|-------------|-----------|-------|-----|----------------------|
| union    |             |           |       |     |                      |
| age      | .0118481    | .0056625  | 2.09  | 0.036| .0007499 .0229463    |
| grade    | .0267365    | .0078124  | 3.42  | 0.001| .0114244 .0402486    |
| not_smsa | -.1293525   | .0403885  | -3.20 | 0.001| -.2085125 -.0501925  |
| 1south   | -.8281077   | .3201584  | -2.59 | 0.010| -1.455607 -.206089    |
| year     | -.0080931   | .0060829  | -1.33 | 0.183| -.0200153 .0038292   |
| south#c.year | 1 | .0057369  | .0040133 | 1.43 | 0.153| -0.002129 .0136029   |
| _cons    | -.6542487   | .3485976  | -1.88 | 0.061| -1.337487 .02899     |

These standard errors are larger than those reported by the inappropriate conventional calculation. By comparison, another model we could fit is an equal-correlation population-averaged probit model:

. xtprobit union age grade not_smsa south##c.year, pa

Iteration 1:  Tolerance = .12544249
Iteration 2:  Tolerance = .0034686
Iteration 3:  Tolerance = .00017448
Iteration 4:  Tolerance = 8.382e-06
Iteration 5:  Tolerance = 3.997e-07

GEE population-averaged model
Number of obs = 26,200
Group variable:  idcode
Number of groups =  4,434
Family:  Binomial
Obs per group:
  min = 1
  avg =  5.9
  max = 12

Wald chi2(6) = 242.57
Prob > chi2 =  0.0000

|          | Coefficient | Std. err. | z     | P>|z|  | [95% conf. interval] |
|----------|-------------|-----------|-------|-----|----------------------|
| union    |             |           |       |     |                      |
| age      | .0089699    | .0053208  | 1.69  | 0.092| -.0014586 .0193985   |
| grade    | .0333174    | .0062352  | 5.34  | 0.000| .0210966 .0455382    |
| not_smsa | -.0715717   | .027543   | -2.60 | 0.009| -.1255551 -.0175884  |
| 1south   | -1.017368   | .207931   | -4.89 | 0.000| -1.424905 -.6098308  |
| year     | -.0062708   | .0055314  | -1.13 | 0.257| -.0171122 .0045706   |
| south#c.year | 1 | .0086294  | .00258  | 3.34 | 0.001| .0035727 .013686     |
| _cons    | -.8670997   | .294771   | -2.94 | 0.003| -1.44484 -.2893592   |
The coefficient estimates are similar, but these standard errors are smaller than those produced by `probit, vce(cluster clustvar)`, as we would expect. If the equal-correlation assumption is valid, the population-averaged probit estimator above should be more efficient.

Is the assumption valid? That is a difficult question to answer. The default population-averaged estimates correspond to an assumption of exchangeable correlation within person. It would not be unreasonable to assume an AR(1) correlation within person or to assume that the observations are correlated but that we do not wish to impose any structure. See [XT] `xtprobit` and [XT] `xtgee` for full details.

`probit, vce(cluster clustvar)` is robust to assumptions about within-cluster correlation. That is, it inefficiently sums within cluster for the standard error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation.

### Model identification

The `probit` command has one more feature that is probably the most useful. It will automatically check the model for identification and, if the model is underidentified, omit whatever variables and observations are necessary for estimation to proceed.

#### Example 4

Have you ever fit a probit model where one or more of your independent variables perfectly predicted one or the other outcome?

For instance, consider the following data:

<table>
<thead>
<tr>
<th>Outcome y</th>
<th>Independent variable x</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Say that we wish to predict the outcome on the basis of the independent variable. The outcome is always zero when the independent variable is one. In our data, \( \Pr(y = 0 \mid x = 1) = 1 \), which means that the probit coefficient on \( x \) must be minus infinity with a corresponding infinite standard error. At this point, you may suspect that we have a problem.

Unfortunately, not all such problems are so easily detected, especially if you have many independent variables in your model. If you have ever had such difficulties, then you have experienced one of the more unpleasant aspects of computer optimization. The computer has no idea that it is trying to solve for an infinite coefficient as it begins its iterative process. All it knows is that, at each step, making the coefficient a little bigger, or a little smaller, works wonders. It continues on its merry way until either 1) the whole thing comes crashing to the ground when a numerical overflow error occurs or 2) it reaches some predetermined cutoff that stops the process. Meanwhile, you have been waiting. And the estimates that you finally receive, if any, may be nothing more than numerical roundoff.

Stata watches for these sorts of problems, alerts you, fixes them, and then properly fits the model.

Let’s return to our automobile data. Among the variables we have in the data is one called `repair` that takes on three values. A value of 1 indicates that the car has a poor repair record, 2 indicates an average record, and 3 indicates a better-than-average record. Here is a tabulation of our data:
. use https://www.stata-press.com/data/r18/repair
(1978 automobile data)
. tabulate foreign repair

<table>
<thead>
<tr>
<th>Car origin</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>10</td>
<td>27</td>
<td>9</td>
<td>46</td>
</tr>
<tr>
<td>Foreign</td>
<td>0</td>
<td>3</td>
<td>9</td>
<td>12</td>
</tr>
<tr>
<td>Total</td>
<td>10</td>
<td>30</td>
<td>18</td>
<td>58</td>
</tr>
</tbody>
</table>

All the cars with poor repair records (repair = 1) are domestic. If we were to attempt to predict foreign on the basis of the repair records, the predicted probability for the repair = 1 category would have to be zero. This in turn means that the probit coefficient must be minus infinity, and that would set most computer programs buzzing.

Let's try using Stata on this problem.

. probit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly;
1.repair omitted and 10 obs not used.
Iteration 0: Log likelihood = -26.992087
Iteration 1: Log likelihood = -22.276479
Iteration 2: Log likelihood = -22.229184
Iteration 3: Log likelihood = -22.229138
Iteration 4: Log likelihood = -22.229138
Probit regression Number of obs = 48
LR chi2(1) = 9.53
Prob > chi2 = 0.0020
Log likelihood = -22.229138 Pseudo R2 = 0.1765

| foreign | Coefficient | Std. err. | z     | P>|z| | [95% conf. interval] |
|---------|-------------|-----------|-------|------|---------------------|
| repair  |             |           |       |      |                     |
| 1       | 0 (empty)   |           |       |      |                     |
| 2       | -1.281552   | .4297326  | -2.98 | 0.003| -2.123812 -.4392911 |
| _cons   | 1.16e-16    | .295409   | 0.00  | 1.000| -.578991 .578991   |

Remember that all the cars with poor repair records (repair = 1) are domestic, so the model cannot be fit, or at least it cannot be fit if we restrict ourselves to finite coefficients. Stata noted that fact “note: 1.repair != 0 predicts failure perfectly”. This is Stata's mathematically precise way of saying what we said in English. When repair is 1, the car is domestic.

Stata then went on to say, “1.repair omitted and 10 obs not used”. This is Stata eliminating the problem. First, 1.repair had to be removed from the model because it would have an infinite coefficient. Then, the 10 observations that led to the problem had to be eliminated, as well, so as not to bias the remaining coefficients in the model. The 10 observations that are not used are the 10 domestic cars that have poor repair records.

Stata then fit what was left of the model, using the remaining observations. Because no observations remained for cars with poor repair records, Stata reports “(empty)” in the row for repair = 1.
Technical note

Stata is pretty smart about catching these problems. It will catch “one-way causation by a dummy variable”, as we demonstrated above.

Stata also watches for “two-way causation”, that is, a variable that perfectly determines the outcome, both successes and failures. Here Stata says that the variable “predicts outcome perfectly” and stops. Statistics dictate that no model can be fit.

Stata also checks your data for collinear variables; it will say “so-and-so omitted because of collinearity”. No observations need to be eliminated here and model fitting will proceed without the offending variable.

It will also catch a subtle problem that can arise with continuous data. For instance, if we were estimating the chances of surviving the first year after an operation, and if we included in our model age, and if all the persons over 65 died within the year, Stata will say, “age > 65 predicts failure perfectly”. It will then inform us about how it resolves the issue and fit what can be fit of our model.

probit (and logit, logistic, and ivprobit) will also occasionally fail to converge and then display messages such as

Note: 4 failures and 0 successes completely determined.

The cause of this message and what to do if you see it are described in [R] logit.

Video examples

Probit regression with categorical covariates
Probit regression with continuous covariates
Probit regression with categorical and continuous covariates

Stored results

probit stores the following in e():

Scalars
- e(N) number of observations
- e(N_cds) number of completely determined successes
- e(N_cdf) number of completely determined failures
- e(k) number of parameters
- e(k_eq) number of equations in e(b)
- e(k_eq_model) number of equations in overall model test
- e(k_dv) number of dependent variables
- e(df_m) model degrees of freedom
- e(r2_p) pseudo-$R^2$
- e(ll) log likelihood
- e(ll_0) log likelihood, constant-only model
- e(N_clust) number of clusters
- e(chi2) $\chi^2$
- e(p) p-value for model test
- e(rank) rank of e(V)
- e(ic) number of iterations
- e(rc) return code
- e(converged) 1 if converged, 0 otherwise
Macros

- \texttt{e(cmd)}: \texttt{probit}
- \texttt{e(cmdline)}: command as typed
- \texttt{e(depvar)}: name of dependent variable
- \texttt{e(wtype)}: weight type
- \texttt{e(wexp)}: weight expression
- \texttt{e(title)}: title in estimation output
- \texttt{e(clustvar)}: name of cluster variable
- \texttt{e(offset)}: linear offset variable
- \texttt{e(chi2type)}: Wald or LR; type of model $\chi^2$ test
- \texttt{e(vcetype)}: \texttt{vcetype} specified in \texttt{vce()}
- \texttt{e(title)}: title used to label Std. err.
- \texttt{e(opt)}: type of optimization
- \texttt{e(which)}: \texttt{max} or \texttt{min}; whether optimizer is to perform maximization or minimization
- \texttt{e(ml\_method)}: name of likelihood-evaluator program
- \texttt{e(technique)}: maximization technique
- \texttt{e(properties)}: \texttt{b V}
- \texttt{e(estat\_cmd)}: program used to implement \texttt{estat}
- \texttt{e(predict)}: program used to implement \texttt{predict}
- \texttt{e(marginsok)}: predictions allowed by \texttt{margins}
- \texttt{e(marginsnotok)}: predictions disallowed by \texttt{margins}
- \texttt{e(asbalanced)}: factor variables \texttt{fvset} as \texttt{asbalanced}
- \texttt{e(asobserved)}: factor variables \texttt{fvset} as \texttt{asobserved}

Matrices

- \texttt{e(b)}: coefficient vector
- \texttt{e(Cns)}: constraints matrix
- \texttt{e(ilog)}: iteration log (up to 20 iterations)
- \texttt{e(gradient)}: gradient vector
- \texttt{e(mns)}: vector of means of the independent variables
- \texttt{e(rules)}: information about perfect predictors
- \texttt{e(V)}: variance–covariance matrix of the estimators
- \texttt{e(V\_modelbased)}: model-based variance

Functions

- \texttt{e(sample)}: marks estimation sample

In addition to the above, the following is stored in \texttt{r()}: 

Matrices

- \texttt{r(table)}: matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in \texttt{r()} are updated when the command is replayed and will be replaced when any \texttt{r}-class command is run after the estimation command.

Methods and formulas

Probit analysis originated in connection with bioassay, and the word probit, a contraction of “probability unit”, was suggested by Bliss (1934a, 1934b). For an introduction to probit and logit, see, for example, Aldrich and Nelson (1984), Cameron and Trivedi (2022), Long (1997), Pampel (2021), or Powers and Xie (2008). Long and Freese (2014, chap. 5 and 6) and Jones (2007, chap. 3) provide introductions to probit and logit, along with Stata examples.

The log-likelihood function for probit is

$$
\ln L = \sum_{j \in S} w_j \ln \Phi(x_j \beta) + \sum_{j \not\in S} w_j \ln \left\{ 1 - \Phi(x_j \beta) \right\}
$$
where $\Phi$ is the cumulative normal and $w_j$ denotes the optional weights. $\ln L$ is maximized, as described in [R] \texttt{Maximize}.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See [P] \texttt{_robust}, particularly \texttt{Maximum likelihood} estimators and \texttt{Methods and formulas}. The scores are calculated as $u_j = \{\phi(x_j b)/\Phi(x_j b)\}x_j$ for the positive outcomes and $-\{\phi(x_j b)/(1 - \Phi(x_j b))\}x_j$ for the negative outcomes, where $\phi$ is the normal density.

\texttt{probit} also supports estimation with survey data. For details on VCEs with survey data, see [SVY] \texttt{Variance estimation}.

Chester Ittner Bliss (1899–1979) was born in Ohio. He was educated as an entomologist, earning degrees from Ohio State and Columbia, and was employed by the United States Department of Agriculture until 1933. When he lost his job because of the Depression, Bliss then worked with R. A. Fisher in London and at the Institute of Plant Protection in Leningrad before returning to a post at the Connecticut Agricultural Experiment Station in 1938. He was also a lecturer at Yale for 25 years. Among many contributions to biostatistics, his development and application of probit methods to biological problems are outstanding.

Postestimation commands

The following postestimation commands are of special interest after `probit`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat classification</code></td>
<td>report various summary statistics, including the classification table</td>
</tr>
<tr>
<td><code>estat gof</code></td>
<td>Pearson or Hosmer–Lemeshow goodness-of-fit test</td>
</tr>
<tr>
<td><code>lroc</code></td>
<td>compute area under ROC curve and graph the curve</td>
</tr>
<tr>
<td><code>lsens</code></td>
<td>graph sensitivity and specificity versus probability cutoff</td>
</tr>
<tr>
<td><code>lassogof</code></td>
<td>calculate goodness-of-fit predictions</td>
</tr>
</tbody>
</table>

These commands are not appropriate with `svy` estimation results.

The following standard postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><code>estat ic</code></td>
<td>Akaike’s, consistent Akaike’s, corrected Akaike’s, and Schwarz’s Bayesian information criteria (AIC, CAIC, AICc, and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estat (svy)</code></td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td><code>estimates</code></td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td><code>etable</code></td>
<td>table of estimation results</td>
</tr>
<tr>
<td><code>*forecast</code></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><code>*hausman</code></td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td><code>lincom</code></td>
<td>point estimates, standard errors, testing, and inference for linear combina-</td>
</tr>
<tr>
<td><code>linktest</code></td>
<td>link test for model specification</td>
</tr>
<tr>
<td><code>*lrtest</code></td>
<td>likelihood-ratio test</td>
</tr>
<tr>
<td><code>margins</code></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td><code>marginsplot</code></td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td><code>nlcom</code></td>
<td>point estimates, standard errors, testing, and inference for nonlinear combin-</td>
</tr>
<tr>
<td><code>predict</code></td>
<td>probabilities, linear predictions and their SEs, etc.</td>
</tr>
<tr>
<td><code>predictnl</code></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
</tbody>
</table>

2209
predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, standard errors, deviance residuals, and the equation-level score.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset rules asif]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>probability of a positive outcome; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
<tr>
<td>*deviance</td>
<td>deviance residual</td>
</tr>
<tr>
<td>score</td>
<td>first derivative of the log likelihood with respect to $x_j\beta$</td>
</tr>
</tbody>
</table>

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

Options for predict

- pr, the default, calculates the probability of a positive outcome.
- xb calculates the linear prediction.
- stdp calculates the standard error of the linear prediction.
- deviance calculates the deviance residual.
- score calculates the equation-level score, $\partial \ln L / \partial (x_j\beta)$. 

*forecast, hausman, and lrtest are not appropriate with svy estimation results. forecast is also not appropriate with mi estimation results.
nooffset is relevant only if you specified offset(varname) for probit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as \( x_j b \) rather than as \( x_j b + \text{offset}_j \).

rules requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations.

asif requests that Stata ignore the rules and exclusion criteria and calculate predictions for all observations possible using the estimated parameter from the model.

# margins

## Description for margins

margins estimates margins of response for probabilities and linear predictions.

## Menu for margins

Statistics > Postestimation

## Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>probability of a positive outcome; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
<tr>
<td>deviance</td>
<td>not allowed with margins</td>
</tr>
<tr>
<td>score</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than \( \mathbf{e}(b) \).

For the full syntax, see [R] margins.

## Remarks and examples

Remarks are presented under the following headings:

- Obtaining predicted values
- Performing hypothesis tests
Once you have fit a probit model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [U] 20 Estimation and postestimation commands and [R] predict. Here we will make only a few additional comments.

`predict` without arguments calculates the predicted probability of a positive outcome. With the `xb` option, `predict` calculates the linear combination $x_j \cdot b$, where $x_j$ are the independent variables in the $j$th observation and $b$ is the estimated parameter vector. This is known as the index function because the cumulative density indexed at this value is the probability of a positive outcome.

In both cases, Stata remembers any rules used to identify the model and calculates missing for excluded observations unless `rules` or `asif` is specified. This is covered in the following example.

With the `stdp` option, `predict` calculates the standard error of the prediction, which is not adjusted for replicated covariate patterns in the data.

You can calculate the unadjusted-for-replicated-covariate-patterns diagonal elements of the hat matrix, or leverage, by typing

```
. predict pred
. predict stdp, stdp
. generate hat = stdp^2 * pred * (1-pred)
```

### Example 1

In example 4 of [R] probit, we fit the probit model `probit foreign b3.repair`. To obtain predicted probabilities, we type

```
. predict p
  (option `pr` assumed; Pr(foreign))
  (10 missing values generated)
. summarize foreign p

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign</td>
<td>58</td>
<td>.2068966</td>
<td>.4086186</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>p</td>
<td>48</td>
<td>.25</td>
<td>.1956984</td>
<td>.1</td>
<td>.5</td>
</tr>
</tbody>
</table>
```

Stata remembers any rules used to identify the model and sets predictions to missing for any excluded observations. In example 4 of [R] probit, `probit` omitted the variable `1.repair` from our model and excluded 10 observations. When we typed `predict p`, those same 10 observations were again excluded and their predictions set to missing.

`predict`’s `rules` option uses the rules in the prediction. During estimation, we were told, “1.repair != 0 predicts failure perfectly”, so the rule is that when `1.repair` is not zero, we should predict 0 probability of success or a positive outcome:

```
. predict p2, rules
  (option `pr` assumed; Pr(foreign))
. summarize foreign p p2

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign</td>
<td>58</td>
<td>.2068966</td>
<td>.4086186</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>p</td>
<td>48</td>
<td>.25</td>
<td>.1956984</td>
<td>.1</td>
<td>.5</td>
</tr>
<tr>
<td>p2</td>
<td>58</td>
<td>.2068966</td>
<td>.2016268</td>
<td>0</td>
<td>.5</td>
</tr>
</tbody>
</table>
```

`predict`’s `asif` option ignores the rules and the exclusion criteria and calculates predictions for all observations possible using the estimated parameters from the model:
. predict p3, asif
   (option pr assumed; Pr(foreign))
. summarize for p p2 p3

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreign</td>
<td>58</td>
<td>.2069</td>
<td>.4086</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>p</td>
<td>48</td>
<td>.25</td>
<td>.1957</td>
<td>.1</td>
<td>.5</td>
</tr>
<tr>
<td>p2</td>
<td>58</td>
<td>.2069</td>
<td>.2016</td>
<td>0</td>
<td>.5</td>
</tr>
<tr>
<td>p3</td>
<td>58</td>
<td>.2931</td>
<td>.2016</td>
<td>.1</td>
<td>.5</td>
</tr>
</tbody>
</table>

Which is right? By default, predict uses the most conservative approach. If many observations had been excluded due to a simple rule, we could be reasonably certain that the rules prediction is correct. The asif prediction is correct only if the exclusion is a fluke and we would be willing to exclude the variable from the analysis, anyway. Then, however, we should refit the model to include the excluded observations.

Performing hypothesis tests

After estimation with probit, you can perform hypothesis tests by using the test or testnl command; see [U] 20 Estimation and postestimation commands.

Methods and formulas

Let index \( j \) be used to index observations. Define \( M_j \) for each observation as the total number of observations sharing \( j \)'s covariate pattern. Define \( Y_j \) as the total number of positive responses among observations sharing \( j \)'s covariate pattern. Define \( p_j \) as the predicted probability of a positive outcome for observation \( j \).

For \( M_j > 1 \), the deviance residual \( d_j \) is defined as

\[
d_j = \pm \left( 2 \left[ Y_j \ln \left( \frac{Y_j}{M_j p_j} \right) + (M_j - Y_j) \ln \left( \frac{M_j - Y_j}{M_j (1 - p_j)} \right) \right] \right)^{1/2}
\]

where the sign is the same as the sign of \((Y_j - M_j p_j)\). In the limiting cases, the deviance residual is given by

\[
d_j = \begin{cases} 
-\sqrt{2M_j \ln(1 - p_j)} & \text{if } Y_j = 0 \\
\sqrt{2M_j \ln p_j} & \text{if } Y_j = M_j 
\end{cases}
\]

## Description

`proportion` produces estimates of proportions, along with standard errors, for the categories identified by the values in each variable of `varlist`.

### Quick start

- Proportions, standard errors, and 95% CIs for each level of `v1`
  ```
  proportion v1
  ```
- Also compute statistics for `v2`
  ```
  proportion v1 v2
  ```
- Same as above, for each subpopulation defined by the levels of `catvar`
  ```
  proportion v1 v2, over(catvar)
  ```
- Standardizing across strata defined by `svar` with stratum weight `wvar1`
  ```
  proportion v1, stdize(svar) stdweight(wvar1)
  ```
- Weighting by sampling weight `wvar2`
  ```
  proportion v1 [pweight=wvar2]
  ```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Proportions
proportion — Estimate proportions

**Syntax**

```plaintext
proportion varlist [if] [in] [weight] [, options]
```

**options**

</tbody>
</table>

`varlist` may contain factor variables; see [U] 11.4.3 Factor variables.

Only numeric, nonnegative, integer-valued variables are allowed in `varlist`.

`bootstrap`, `collect`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] mi estimate.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] svy.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

stdize(varname) specifies that the point estimates be adjusted by direct standardization across the strata identified by varname. This option requires the stdweight() option.

stdweight(varname) specifies the weight variable associated with the standard strata identified in the stdize() option. The standardization weights must be constant within the standard strata.

nostdrescale prevents the standardization weights from being rescaled within the over() groups. This option requires stdize() but is ignored if the over() option is not specified.

over(varlist, o) specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in varlist. Only numeric, nonnegative, integer-valued variables are allowed in over(varlist).

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (analytic), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

vce(analytic), the default, uses the analytically derived variance estimator associated with the sample proportion.

level(#) specifies how to compute the limits of confidence intervals. ctype may be one of logit (default), agresti, exact, jeffreys, normal, wald, or wilson.

percent specifies that the proportions be reported as percentages.

noheader prevents the table header from being displayed.

display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), and nolstretch; see [R] Estimation options.

The following option is available with proportion but is not shown in the dialog box: coeflegend; see [R] Estimation options.
Remarks and examples

Example 1

We can estimate the proportion of each repair rating in auto2.dta:

```
. proportion rep78
```

<table>
<thead>
<tr>
<th>rep78</th>
<th>Proportion</th>
<th>Std. err.</th>
<th>Logit [95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Poor</td>
<td>0.0289855</td>
<td>0.0201966</td>
<td>0.0070794 0.1110924</td>
</tr>
<tr>
<td>Fair</td>
<td>0.115942</td>
<td>0.0385422</td>
<td>0.058317 0.2173648</td>
</tr>
<tr>
<td>Average</td>
<td>0.4347826</td>
<td>0.0596787</td>
<td>0.3214848 0.5553295</td>
</tr>
<tr>
<td>Good</td>
<td>0.2608696</td>
<td>0.0528625</td>
<td>0.1695907 0.3788629</td>
</tr>
<tr>
<td>Excellent</td>
<td>0.1594203</td>
<td>0.0440694</td>
<td>0.0895793 0.267702</td>
</tr>
</tbody>
</table>

`marginsplot` will produce a graph of the results from `proportion`:

```
. marginsplot
```

Variables that uniquely identify proportions: `rep78`
Example 2

We can also estimate proportions over groups:

```
. proportion rep78, over(foreign)
```

<table>
<thead>
<tr>
<th>Proportion estimation</th>
<th>Number of obs = 69</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Logit</td>
</tr>
<tr>
<td></td>
<td>Proportion</td>
</tr>
<tr>
<td>rep78@foreign</td>
<td></td>
</tr>
<tr>
<td>Poor Domestic</td>
<td>.0416667</td>
</tr>
<tr>
<td>Poor Foreign</td>
<td>0</td>
</tr>
<tr>
<td>Fair Domestic</td>
<td>.1666667</td>
</tr>
<tr>
<td>Fair Foreign</td>
<td>0</td>
</tr>
<tr>
<td>Average Domestic</td>
<td>.5625</td>
</tr>
<tr>
<td>Average Foreign</td>
<td>.1428571</td>
</tr>
<tr>
<td>Good Domestic</td>
<td>.1875</td>
</tr>
<tr>
<td>Good Foreign</td>
<td>.4285714</td>
</tr>
<tr>
<td>Excellent Domestic</td>
<td>.0416667</td>
</tr>
<tr>
<td>Excellent Foreign</td>
<td>.4285714</td>
</tr>
</tbody>
</table>

To see the results as percentages instead of proportions, we add the `percent` option:

```
. proportion rep78, over(foreign) percent
```

<table>
<thead>
<tr>
<th>Percent estimation</th>
<th>Number of obs = 69</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Logit</td>
</tr>
<tr>
<td></td>
<td>Percent</td>
</tr>
<tr>
<td>rep78@foreign</td>
<td></td>
</tr>
<tr>
<td>Poor Domestic</td>
<td>4.17</td>
</tr>
<tr>
<td>Poor Foreign</td>
<td>0.00</td>
</tr>
<tr>
<td>Fair Domestic</td>
<td>16.67</td>
</tr>
<tr>
<td>Fair Foreign</td>
<td>0.00</td>
</tr>
<tr>
<td>Average Domestic</td>
<td>56.25</td>
</tr>
<tr>
<td>Average Foreign</td>
<td>14.29</td>
</tr>
<tr>
<td>Good Domestic</td>
<td>18.75</td>
</tr>
<tr>
<td>Good Foreign</td>
<td>42.86</td>
</tr>
<tr>
<td>Excellent Domestic</td>
<td>4.17</td>
</tr>
<tr>
<td>Excellent Foreign</td>
<td>42.86</td>
</tr>
</tbody>
</table>

We can now use `marginsplot` to graph the percentages for each group. We add the `bydimension(foreign)` option to plot the groups in separate graph panels. The `xlabel(, angle(30))` option prevents the x-axis labels from running into each other.
We estimate that only 19% of domestic cars have good repair records and only 4% have excellent repair records. For foreign cars, however, we find that 43% have good repair records and 43% have excellent repair records.

Example 3

Instead of estimating percentages within the foreign and domestic groupings, we might want to know overall percentages. For instance, what percentage of all cars are foreign and have excellent repair records? What percentage are domestic and have average records? We can obtain all such percentages by specifying an interaction between `rep78` and `foreign`.

```
. proportion rep78#foreign, percent
Percent estimation Number of obs = 69

<table>
<thead>
<tr>
<th></th>
<th>Percent</th>
<th>Std. err.</th>
<th>Logit [95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rep78#foreign</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Poor#Domestic</td>
<td>2.90</td>
<td>2.02</td>
<td>0.71</td>
</tr>
<tr>
<td>Poor#Foreign</td>
<td>0.00</td>
<td>(no observations)</td>
<td></td>
</tr>
<tr>
<td>Fair#Domestic</td>
<td>11.59</td>
<td>3.85</td>
<td>5.83</td>
</tr>
<tr>
<td>Fair#Foreign</td>
<td>0.00</td>
<td>(no observations)</td>
<td></td>
</tr>
<tr>
<td>Average#Domestic</td>
<td>39.13</td>
<td>5.88</td>
<td>28.21</td>
</tr>
<tr>
<td>Average#Foreign</td>
<td>4.35</td>
<td>2.46</td>
<td>1.38</td>
</tr>
<tr>
<td>Good#Domestic</td>
<td>13.04</td>
<td>4.05</td>
<td>6.85</td>
</tr>
<tr>
<td>Good#Foreign</td>
<td>13.04</td>
<td>4.05</td>
<td>6.85</td>
</tr>
<tr>
<td>Excellent#Domestic</td>
<td>2.90</td>
<td>2.02</td>
<td>0.71</td>
</tr>
<tr>
<td>Excellent#Foreign</td>
<td>13.04</td>
<td>4.05</td>
<td>6.85</td>
</tr>
</tbody>
</table>
```

Looking at the last line of this output, we estimate that 13% of all cars are foreign with excellent repair records.
Stored results

proportion stores the following in e():

Scalars
- e(N): number of observations
- e(N_over): number of subpopulations
- e(N_stdize): number of standard strata
- e(N_clust): number of clusters
- e(k_eq): number of equations in e(b)
- e(df_r): sample degrees of freedom
- e(rank): rank of e(V)

Macros
- e(cmd): proportion
- e(cmdline): command as typed
- e(varlist): varlist
- e(stdize): varname from stdize()
- e(stdweight): varname from stdweight()
- e(utype): weight type
- e(wexp): weight expression
- e(title): title in estimation output
- e(clustvar): name of cluster variable
- e(over): varlist from over()
- e(vce): vcetype specified in vce()
- e(vcetype): title used to label Std. err.
- e(properties): b V
- e(estat_cmd): program used to implement estat
- e(marginsnotok): predictions disallowed by margins

Matrices
- e(b): vector of proportion estimates
- e(V): (co)variance estimates
- e(_N): vector of numbers of nonmissing observations
- e(_N_stdsum): number of nonmissing observations within the standard strata
- e(_p_stdize): standardizing proportions
- e(freq): vector of frequency estimates
- e(error): error code corresponding to e(b)

Functions
- e(sample): marks estimation sample

In addition to the above, the following is stored in r():

Matrices
- r(table): matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

Methods and formulas

Proportions are means of indicator variables; see [R] mean.

Confidence intervals

For an overview of confidence interval methods for binomial proportions, see Dean and Pagano (2015).

Given $k$ successes of $n$ trials, the estimated proportion (probability of a success) is $\hat{p} = k/n$ with estimated standard error $\hat{s} = \sqrt{\hat{p}(1-\hat{p})}/n$. 
The logit-transformed confidence interval is given by
\[
\log \left( \frac{\hat{p}}{1 - \hat{p}} \right) \pm t_{1-\alpha/2,\nu} \frac{\hat{s}}{\hat{p}(1 - \hat{p})}
\]
where \( t_{p,\nu} \) is the \( p \)th quantile of Student’s \( t \) distribution with \( \nu \) degrees of freedom.

The endpoints of this confidence interval are transformed back to the proportion metric by using the inverse of the logit transform
\[
f^{-1}(y) = \frac{e^y}{1 + e^y}
\]
Hence, the displayed confidence intervals for proportions are
\[
f^{-1} \left\{ \ln \left( \frac{\hat{p}}{1 - \hat{p}} \right) \pm t_{1-\alpha/2,\nu} \frac{\hat{s}}{\hat{p}(1 - \hat{p})} \right\}
\]

The Wald-type 100(1 - \( \alpha \))\% confidence interval is given by
\[
\hat{p} \pm t_{1-\alpha/2,\nu} \hat{s}
\]

The Wilson interval is given by
\[
\frac{\hat{p} + z^2_{1-\alpha/2}/2n \pm z_{1-\alpha/2}\sqrt{\hat{p}(1 - \hat{p})/n + z^2_{1-\alpha/2}/4n^2}}{1 + z^2_{1-\alpha/2}/n}
\]
where \( z_p \) is the \( p \)th quantile of the standard normal distribution.

The exact (Clopper–Pearson) interval is given by
\[
\left\{ \frac{\nu_1 F_{\alpha/2,\nu_1,\nu_2}}{\nu_2 + \nu_1 F_{\alpha/2,\nu_1,\nu_2}}, \frac{\nu_3 F_{1-\alpha/2,\nu_3,\nu_4}}{\nu_4 + \nu_3 F_{1-\alpha/2,\nu_3,\nu_4}} \right\}
\]
where \( \nu_1 = 2k \), \( \nu_2 = 2(n - k + 1) \), \( \nu_3 = 2(k + 1) \), \( \nu_4 = 2(n - k) \), and \( F_{p,\nu_1,\nu_2} \) is the \( p \)th quantile of an \( F \) distribution with \( \nu_1 \) and \( \nu_2 \) degrees of freedom.

The Jeffreys interval is given by
\[
\{ \text{Beta}_{\alpha/2,\alpha_1,\beta_1}; \text{Beta}_{1-\alpha/2,\alpha_1,\beta_1} \}
\]
where \( \alpha_1 = k + 0.5 \), \( \beta_1 = n - k + 0.5 \), and \( \text{Beta}_{p,\alpha_1,\beta_1} \) is the \( p \)th quantile of a Beta distribution with \( \alpha_1 \) and \( \beta_1 \) degrees of freedom.

The Agresti–Coull interval is given by
\[
\tilde{p} \pm z_{1-\alpha/2}\sqrt{\tilde{p}(1 - \tilde{p})/\tilde{n}}
\]
where \( \tilde{k} = k + z^2_{1-\alpha/2}/2 \), \( \tilde{n} = n + z^2_{1-\alpha/2} \), and \( \tilde{p} = \tilde{k}/\tilde{n} \).
With the svy prefix, pweights, or the vce(cluster clustvar) option, the Wilson, exact, Jeffreys, and Agresti–Coull intervals use $n^*$ in place of $n$, where

$$n^* = \frac{\hat{p}(1 - \hat{p})}{\hat{s}^2} \left\{ \frac{z_{1-\alpha/2}}{t_{1-\alpha/2,\nu}} \right\}^2$$

$\hat{s}^2$ is the linearized VCE, and $k = n^*\hat{p}$.

</tbody>
</table>

Remarks and examples

Example 1

In example 2 of [R] proportion, we computed the proportions of cars with different repair records for each group, foreign or domestic. We use test to test whether the proportion of cars with repair record equal to 4 is the same for domestic and foreign cars.

```
use https://www.stata-press.com/data/r18/auto
(proportion rep78, over(foreign)
(test 4.rep78@0.foreign=4.rep78@1.foreign
( 1) 4.rep78@0bn.foreign - 4.rep78@1.foreign = 0
F( 1, 68) = 3.92
Prob > F = 0.0518
```

There is not a significant difference between those proportions at the 5% level.
Example 2

Continuing with `auto.dta` from example 1, we generate a new variable, `highprice`, that indicates if the price is larger than $5,000 and then use `proportion` to see the proportion of cars with high price among domestic and foreign cars separately.

```
. generate highprice = price>5000
. proportion highprice, over(foreign)
```

<table>
<thead>
<tr>
<th>Proportion estimation</th>
<th>Number of obs = 74</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proportion</td>
<td>Std. err.</td>
</tr>
<tr>
<td>highprice@foreign</td>
<td></td>
</tr>
<tr>
<td>0 Domestic</td>
<td>.5576923</td>
</tr>
<tr>
<td>0 Foreign</td>
<td>.3636364</td>
</tr>
<tr>
<td>1 Domestic</td>
<td>.4423077</td>
</tr>
<tr>
<td>1 Foreign</td>
<td>.6363636</td>
</tr>
</tbody>
</table>

We will compute the odds ratio of having a high price in group `Foreign` to having a high price in group `Domestic`. Usually, odds ratios are computed by using the `logistic` command, but here we will perform the computation by using `nlcom` after `proportion`.

```
. nlcom OR: (_b[1.highprice@1.foreign]/_b[0.highprice@1.foreign])/(_b[1.highprice@0.foreign]/_b[0.highprice@0.foreign])
```

| Proportion | Coefficient | Std. err. | z     | P>|z| | [95% conf. interval] |
|------------|-------------|-----------|-------|-----|---------------------|
| OR         | 2.206522    | 1.155825  | 1.91  | 0.056 | -.0588533 to 4.471897 |

This is the same odds ratio that we would obtain from

```
. logistic highprice foreign
```

The odds ratio is slightly larger than 2, which means that the odds of having a high price among foreign cars are more than twice that of having a high price among domestic cars.

Also see

[R] proportion — Estimate proportions
[U] 20 Estimation and postestimation commands
prtest performs tests on the equality of proportions using large-sample statistics. The test can be performed for one sample against a hypothesized population value or for no difference in population proportions estimated from two samples. Clustered data are supported.

prtesti is the immediate form of prtest; see [U] 19 Immediate commands.

Quick start

One-sample test that the proportion of 1s in v is equal to 0.1

```
prtest v == 0.1
```

Same as above, but using the 90% confidence level and adjusting for clustering with clusters defined by cvar and an intraclass correlation of 0.5

```
prtest v == 0.1, level(90) cluster(cvar) rho(0.5)
```

Test that the proportion of 1s in v is equal between two groups defined by catvar

```
prtest v, by(catvar)
```

Same as above, and adjust for clustering with clusters defined by cvar and an intraclass correlation of 0.5 in the two groups

```
prtest v, by(catvar) cluster(cvar) rho(0.5)
```

Test equality of proportions between v1 and v2

```
prtest v1 == v2
```

Test \( p_1 = p_2 \) if \( \hat{p}_1 = 0.10, \hat{p}_2 = 0.17, n_1 = 29, \) and \( n_2 = 36 \)

```
prtesti 29 0.10 36 0.17
```

\texttt{rho1(#)} \hspace{1cm} intraclass correlation for group 1  
\texttt{rho2(#)} \hspace{1cm} intraclass correlation for group 2

\texttt{*by(groupvar)} is required.

by is allowed with prtest, and collect is allowed with prtest and prtesti; see [U] 11.1.10 Prefix commands.

Options for prtest

\texttt{by(groupvar)} specifies a numeric variable that contains the group information for a given observation. This variable must have only two values. Do not confuse the \texttt{by()} option with the \texttt{by} prefix; both may be specified.
level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.

cluster(varname) specifies the variable that identifies clusters. The cluster() option is required to adjust the computation for clustering.

rho(#) specifies the intraclass correlation for a one-sample test or the common intraclass correlation for a two-sample test. The rho() option is required to adjust the computation for clustering for a one-sample test.

rho1(#) specifies the intraclass correlation of the first group for a two-sample test using groups. The rho() option or both rho1() and rho2() options are required to adjust the computation for clustering.

rho2(#) specifies the intraclass correlation of the second group for a two-sample test using groups. The rho() option or both rho1() and rho2() options are required to adjust the computation for clustering.

**Options for prtesti**

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.

count specifies that integer counts instead of proportions be used in the immediate forms of prtest. In the first syntax, prtesti expects that #obs1 and #p1 are counts—#p1 ≤ #obs1—and #p2 is a proportion. In the second syntax, prtesti expects that all four numbers are integer counts, that #obs1 ≥ #p1, and that #obs2 ≥ #p2.

**Remarks and examples**

Remarks are presented under the following headings:

- Tests of proportions
- Adjust for clustering
- Immediate form

**Tests of proportions**

The prtest output follows the output of ttest in providing a lot of information. Each proportion is presented along with a confidence interval. The appropriate one- or two-sample test is performed, and the two-sided and both one-sided results are included at the bottom of the output. For a two-sample test, the calculated difference is also presented with its confidence interval. This command may be used for both large-sample testing and large-sample interval estimation. For one-sample tests of proportions with small-sample sizes and to obtain exact \( p \)-values, researchers should use bitest; see [R] bitest.

**Example 1: One-sample test of proportion**

In the first form, prtest tests whether the mean of the sample is equal to a known constant. Assume that we have a sample of 74 automobiles. We wish to test whether the proportion of automobiles that are foreign is different from 40%.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
```
The test indicates that we cannot reject the hypothesis that the proportion of foreign automobiles is 0.40 at the 5% significance level.

Example 2: Two-sample test of proportions

We have two headache remedies that we give to patients. Each remedy’s effect is recorded as 0 for failing to relieve the headache and 1 for relieving the headache. We wish to test the equality of the proportion of people relieved by the two treatments.

We find that the proportions are statistically different from each other at any level greater than 3.9%.

Adjust for clustering

When observations are not independent and can be grouped into clusters, we need to adjust for clustering in a proportion test. For example, in a cluster randomized design, groups of individuals are randomized instead of individuals. To adjust for clustering, we need to specify the cluster identifier variable in the `cluster()` option. In the case of a one-sample proportion test, we need to also specify the intraclass correlation in the `rho()` option. In the case of a two sample proportions test, we need to also specify the common population intraclass correlation in the `rho()` option or group-specific population intraclass correlations in the `rho1()` and `rho2()` options.
Example 3: One-sample test of proportion, adjusting for clusters

Consider data from Hujoel, Moulton, and Loesche (1990) on the accuracy of an enzymatic diagnostic test (EDT) of bacterial infections for 29 patients with multiple sites. The EDT was conducted on each site, a specific area in a patient’s mouth, to determine infection by two strings of bacteria. A separate reference test was also conducted on each site with an antibody assay against the two strings of bacteria. The data record whether there was a positive EDT result at each infected site, a true positive result.

We want to test whether the proportion of infected sites that were correctly diagnosed by the EDT is different from 0.6. Because we have multiple infections per patient, we cluster by the patient-identifier subject and use a value of 0.2 from Ahn, Heo, and Zhang (2015, 33) for the intrapatient correlation.

To perform the test, we specify the `cluster(subject)` and `rho(0.2)` options:

```
. use https://www.stata-press.com/data/r18/infection
(Target infections detected by EDT (Hujoel, Moulton, and Loesche 1990))
. prtest infect == 0.6, cluster(subject) rho(0.2)
```

This results in:

```
One-sample test of proportion
Number of obs = 142
Cluster variable: subject
Number of clusters = 29
Avg. cluster size = 4.90
CV cluster size = 0.2419
Intraclass corr. = 0.2000

Variable | Mean | Std. err. | [95% conf. interval]
----------|------|-----------|---------------------
infection | .6619718 | .0537974 | .5565308 -.7674129
```

The test statistic is $z = 1.1123$, and the p-values are:

- For $H_0: p = 0.6$, $Pr(Z < z) = 0.8670$,
- For $H_a: p < 0.6$, $Pr(|Z| > |z|) = 0.2660$,
- For $H_a: p > 0.6$, $Pr(Z > z) = 0.1330$.

We do not find statistical evidence to reject the null hypothesis of $H_0: P_{infection} = 0.6$ versus the two-sided alternative $H_a: P_{infection} \neq 0.6$ at the 5% significance level; the $p$-value $= 0.2660 > 0.05$.

Example 4: Two-sample test of proportions using groups, adjusting for clusters

Consider a dataset provided by Hayes and Moulton (2009), which contains a random subsample of the original participants in a cluster randomized trial of a pneumococcal conjugate vaccine in American Indian populations in the southwestern United States. There are two groups of infants with 18 clusters in each group. The control group received a meningococcal C conjugate vaccine (MnCC), and the experimental group received the seven-valent pneumococcal conjugate vaccine (PnCRM7). The two groups are identified by the `vaccine` variable, and the `pneumonia` variable records 1 if an infant had at least one bacterial pneumonia episode and 0 otherwise. These data are originally from O’Brien et al. (2003).

We want to test the equality of the proportion of cases of pneumonia in the two vaccine groups. We assume a common known intraclass correlation of 0.02. To perform the test, we type

```
```
. use https://www.stata-press.com/data/r18/pneumoniacrt
(Bacterial pneumonia episodes data from CRT (Hayes and Moulton 2009))
. prtest pneumonia, by(vaccine) cluster(cluster) rho(0.02)

Two-sample test of proportions
Cluster variable: cluster

| Group    | Mean   | Std. err. | z     | P>|z|  | [95% conf. interval] |
|----------|--------|-----------|-------|------|---------------------|
| MnCC     | .222691| .0329017  | .1582029 | .2871753 |                     |
| PnCRM7   | .1658768| .0299027 | .1072686 | .224485 |                     |

diff = prop(MnCC) - prop(PnCRM7)

z = 1.2691
H0: diff = 0
Ha: diff < 0
Ha: diff != 0
Ha: diff > 0
Pr(Z < z) = 0.8978
Pr(|Z| > |z|) = 0.2044
Pr(Z > z) = 0.1022

We do not find statistical evidence to reject the null hypothesis of $H_0: P_{diff} = 0$ versus the two-sided alternative $H_a: P_{diff} \neq 0$ at the 5% significance level; the $p$-value = 0.2044 > 0.05.

Immediate form

Example 5: Immediate form of one-sample test of proportion

prtesti is like prtest, except that you specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the proportion of registered voters among 50 randomly selected eligible voters as 0.52. We wish to test whether the proportion is 0.7:

. prtesti 50 0.52 0.70

One-sample test of proportion
x: Number of obs = 50

<table>
<thead>
<tr>
<th>Mean</th>
<th>Std. err.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>.52</td>
<td>.3815205 .6584795</td>
</tr>
</tbody>
</table>

p = proportion(x) z = -2.7775
H0: p = 0.7
Ha: p < 0.7
Ha: p != 0.7
Ha: p > 0.7
Pr(Z < z) = 0.0027 Pr(|Z| > |z|) = 0.0055 Pr(Z > z) = 0.9973
Example 6: Immediate form of two-sample test of proportions

To judge teacher effectiveness, we wish to test whether the same proportion of people from two classes will answer an advanced question correctly. In the first classroom of 30 students, 40% answered the question correctly, whereas in the second classroom of 45 students, 67% answered the question correctly.

```
.prtesti 30 0.4 45 0.67
Two-sample test of proportions

|       | Mean | Std. err. | z     | P>|z|     | [95% conf. interval] |
|-------|------|-----------|-------|---------|---------------------|
| x     | .4   | .0894427  | .2246955 | .5753045 |                     |
| y     | .67  | .0700952  | .532616 | .807384  |                     |
| diff  | -.27 | .1136368  | -.4927241 | -.0472759 |                     |
|       | under H0: | .1169416 | -2.31 | 0.021 |                     |
```

\[
\text{diff} = \text{prop}(x) - \text{prop}(y) \\
\text{z} = -2.3088
\]

H0: \( \text{diff} = 0 \)  
Ha: \( \text{diff} < 0 \)  
Ha: \( \text{diff} \neq 0 \)  
Ha: \( \text{diff} > 0 \)  
Pr(\( Z < z \)) = 0.0105  
Pr(\( |Z| > |z| \)) = 0.0210  
Pr(\( Z > z \)) = 0.9895

Stored results

One-sample \texttt{prtest} and \texttt{prtesti} store the following in \texttt{r()}:  
Scalars  
- \texttt{r(N)}: sample size  
- \texttt{r(P)}: sample proportion  
- \texttt{r(se)}: standard error of sample proportion  
- \texttt{r(lb)}: lower confidence bound of sample proportion  
- \texttt{r(ub)}: upper confidence bound of sample proportion  
- \texttt{r(z)}: z statistic  
- \texttt{r(p_l)}: lower one-sided p-value  
- \texttt{r(p)}: two-sided p-value  
- \texttt{r(p_u)}: upper one-sided p-value  
- \texttt{r(level)}: confidence level

Cluster-adjusted one-sample \texttt{prtest} also stores the following in \texttt{r()}:  
Scalars  
- \texttt{r(K)}: number of clusters \( K \)  
- \texttt{r(M)}: cluster size \( M \)  
- \texttt{r(rho)}: intraclass correlation  
- \texttt{r(CV_cluster)}: coefficient of variation for cluster sizes

Two-sample \texttt{prtest} and two-sample \texttt{prtesti} store the following in \texttt{r()}:  
Scalars  
- \texttt{r(N1)}: sample size of population one  
- \texttt{r(N2)}: sample size of population two  
- \texttt{r(P1)}: sample proportion for population one  
- \texttt{r(P2)}: sample proportion for population two  
- \texttt{r(P_diff)}: difference of proportions  
- \texttt{r(se1)}: standard error of population-one sample proportion  
- \texttt{r(se2)}: standard error of population-two sample proportion
Cluster-adjusted two-sample prtest using the by() option also stores the following in r():

Scalars
- \( r(K1) \) population-one number of clusters \( K_1 \)
- \( r(K2) \) population-two number of clusters \( K_2 \)
- \( r(M1) \) population-one cluster size \( M_1 \)
- \( r(M2) \) population-two cluster size \( M_2 \)
- \( r(rho) \) common intraclass correlation
- \( r(rho1) \) population-one intraclass correlation
- \( r(rho2) \) population-two intraclass correlation
- \( r(CV\_cluster1) \) population-one coefficient of variation for cluster sizes
- \( r(CV\_cluster2) \) population-two coefficient of variation for cluster sizes

Methods and formulas

Remarks are presented under the following headings:

One-sample test
Two-sample test

For all the tests below, the test statistic \( z \) has an asymptotic standard normal distribution, and the \( p \)-value is computed as

\[
p = \begin{cases} 
1 - \Phi(z) & \text{for an upper one-sided test} \\
\Phi(z) & \text{for a lower one-sided test} \\
2 \{1 - \Phi(|z|)\} & \text{for a two-sided test}
\end{cases}
\]

where \( \Phi(\cdot) \) is the cdf of a standard normal distribution and \( |z| \) is an absolute value of \( z \).

See Acock (2023, 158–164) for additional examples of tests of proportions using Stata.

One-sample test

Let \( n \) be the number of observations, \( \hat{p} \) be the observed proportion, and \( \hat{q} = 1 - \hat{p} \).

The one-tailed and two-tailed tests of a population proportion use an asymptotically normally distributed test statistic calculated as

\[
z = \frac{\hat{p} - p_0}{s_0}
\]

where \( p_0 \) is the hypothesized proportion, \( q_0 = 1 - p_0 \), and \( s_0 = \sqrt{p_0q_0/n} \) is the standard error of \( \hat{p} \) under the null hypothesis of \( p = p_0 \).
A large-sample 100(1 - \(\alpha\))% confidence interval for a proportion \(p\) is

\[
\hat{p} \pm z_{1-\alpha/2} s
\]

where \(s = \sqrt{\hat{p} \hat{q}/n}\) and \(z_{1-\alpha/2}\) is the \((1 - \alpha/2)\)th quantile of the standard normal distribution.

With clustered data, suppose that there are \(K\) clusters, each of size \(M_i\) such that \(n = \sum_{i=1}^{K} M_i\). Let \(\rho\) be the intraclass correlation. Following Ahn, Heo, and Zhang (2015), we assume that the cluster sizes \(M_i\) are independent and identically distributed. Let \(C_{adj}\) be the adjustment to the standard error for clustered data,

\[
C_{adj} = \sqrt{\frac{1}{K} \sum_{i=1}^{K} M_i \{1 + \rho(M_i - 1)\} / n}
\]

such that \(s_{0,cl} = C_{adj}s_0\) and \(s_{cl} = C_{adj}s\).

\(C_{adj}\) can be equivalently written as

\[
C_{adj} = \sqrt{1 + \rho(\bar{M} - 1) + \rho \bar{M} CV_{cl}^2}
\]

where \(\bar{M} = \frac{\sum_{i=1}^{K} M_i}{K}\) is the average cluster size and \(CV_{cl}\) is the coefficient of variation for cluster sizes:

\[
CV_{cl} = \sqrt{\frac{\sum_{i=1}^{K} (M_i - \bar{M})^2 / K}{\bar{M}}}
\]

To adjust the test statistic \(z\) and the confidence interval for clustering, replace \(s_0\) with \(s_{0,cl}\) and \(s\) with \(s_{cl}\) in the corresponding formulas. In the presence of clustering, the test statistic \(z\) is asymptotically normally distributed conditional on the empirical distribution of \(M_i\)’s.

**Two-sample test**

Let \(n_1\) be the number of observations in population one and \(n_2\) be the number of observations in population two, \(\hat{p}_1\) be the observed proportion in population one and \(\hat{p}_2\) be the observed proportion in population two, and \(\hat{q}_1 = 1 - \hat{p}_1\) and \(\hat{q}_2 = 1 - \hat{p}_2\). Let \(x_1\) and \(x_2\) be the total number of successes in the two populations.

A test of the difference of two proportions uses an asymptotically normally distributed test statistic calculated as

\[
z = \frac{\hat{p}_1 - \hat{p}_2}{s_{d0}}
\]

where \(s_{d0} = \sqrt{\hat{p}_p \hat{q}_p (1/n_1 + 1/n_2)}\) is the standard error of \(\hat{p}_1 - \hat{p}_2\) under the null hypothesis of \(p_1 = p_2\), with \(\hat{p}_p = (x_1 + x_2)/(n_1 + n_2)\) and \(\hat{q}_p = 1 - \hat{p}_p\).

The 100(1 - \(\alpha\))% confidence interval for the difference of two proportions is given by

\[
(\hat{p}_1 - \hat{p}_2) \pm z_{1-\alpha/2} \sqrt{s_1^2 + s_2^2}
\]
where \( s_1 = \sqrt{\hat{p}_1 \hat{q}_1 / n_1} \) and \( s_2 = \sqrt{\hat{p}_2 \hat{q}_2 / n_2} \) are the standard errors of the two sample proportions and \( z_{1-\alpha/2} \) is the \((1 - \alpha/2)\)th quantile of the standard normal distribution.

With clustered data, suppose that there are \( K_1 \) and \( K_2 \) clusters in population one and population two with the corresponding average cluster sizes of \( \bar{M}_1 \) and \( \bar{M}_2 \). Let \( \rho_1 \) and \( \rho_2 \) be the intraclass correlations and \( CV_{cl,1} \) and \( CV_{cl,2} \) be the coefficients of variation for cluster sizes for population one and population two. Let \( C_{adj,1} \) and \( C_{adj,2} \) be the adjustments to standard errors of the two sample proportions for clustered data, defined analogously to \( C_{adj} \) in One-sample test for each population.

Let \( s_{d0,cl} = \sqrt{\hat{p}_p \hat{q}_p \left( C_{adj,1}^2 / n_1 + C_{adj,2}^2 / n_2 \right)} \) be the standard error of \( \hat{p}_1 - \hat{p}_2 \) under the null hypothesis of \( p_1 = p_2 \) adjusted for clustered data. Also, let \( s_{1,cl} = C_{adj,1} s_1 \) and \( s_{2,cl} = C_{adj,2} s_2 \) be the standard errors of \( \hat{p}_1 \) and \( \hat{p}_2 \) adjusted for clustered data. To adjust the two-sample test statistic and the confidence interval for clustering, replace \( s_{d0} \) with \( s_{d0,cl} \), \( s_1 \) with \( s_{1,cl} \), and \( s_2 \) with \( s_{2,cl} \) in the corresponding formulas.

**pwcompare** performs pairwise comparisons across the levels of factor variables from the most recently fit model. *pwcompare* can compare estimated cell means, marginal means, intercepts, marginal intercepts, slopes, or marginal slopes—collectively called margins. *pwcompare* reports the comparisons as contrasts (differences) of margins along with significance tests or confidence intervals for the contrasts. The tests and confidence intervals can be adjusted for multiple comparisons.

*pwcompare* can be used with *svy* estimation results; see [SVY] svy postestimation.

See [R] margins, *pwcompare* for performing pairwise comparisons of margins of linear and nonlinear predictions.

**Quick start**

All pairwise comparisons of the means of \(y\) across levels of \(a\) after *regress* \(y\ i.a\)

\[
pwcompare a
\]

Same as above, and report test statistics and \(p\)-values for tests of differences in means

\[
pwcompare a, effects
\]

Adjust \(p\)-values and confidence intervals for multiple comparisons using Tukey’s method

\[
pwcompare a, effects mcompare(tukey)
\]

Same as above, but adjust for multiple comparisons using Bonferroni’s method

\[
pwcompare a, effects mcompare(bonferroni)
\]

Report means for the levels of \(a\), and group those that are not significantly different

\[
pwcompare a, groups
\]

Pairwise comparisons of cell means after *regress* \(y1\ a##b\)

\[
pwcompare a#b
\]

Pairwise comparisons of the marginal means of \(a\)

\[
pwcompare a
\]

Pairwise comparisons of slopes for continuous \(x\) after *regress* \(y1\ a##c.x\)

\[
pwcompare a#c.x
\]

Pairwise comparisons of log odds after *logit* \(y2\ i.a\)

\[
pwcompare a
\]

Pairwise comparisons of the means of \(y2\) across levels of \(a\) after *mvreg* \(y1\ y2\ y3 = i.a\)

\[
pwcompare a, equation(y2)
\]

2235
Same as above, but report pairwise comparisons of $a$ for each equation

`pwcompare a, atequations`

Pairwise comparisons of overall margins of $y_1$, $y_2$, and $y_3$

`pwcompare _eqns`

Menu

Statistics > Postestimation
Syntax

pwcompare marginlist [ , options ]

where marginlist is a list of factor variables or interactions that appear in the current estimation results or _eqns to reference equations. The variables may be typed with or without the i. prefix, and you may use any factor-variable syntax:

. pwcompare i.sex i.group i.sex#i.group
  . pwcompare sex group sex#group

options Description

Main
  mcompare(method) adjust for multiple comparisons; default is mcompare(noadjust)
  asobserved treat all factor variables as observed

Equations
  equation(eqspec) perform comparisons within equation eqspec
  atequations perform comparisons within each equation

Advanced
  emptycells(empspec) treatment of empty cells for balanced factors
  noestimcheck suppress estimability checks

Reporting
  level(#) confidence level; default is level(95)
  cieffects show effects table with confidence intervals; the default
  pveffects show effects table with p-values
  effects show effects table with confidence intervals and p-values
  cimargins show table of margins and confidence intervals
  groups show table of margins and group codes
  sort sort the margins or contrasts within each term
  post post margins and their VCEs as estimation results
  display_options control column formats, row spacing, line width, and factor-variable labeling
  eform_option report exponentiated contrasts
  df(#) use t distribution with # degrees of freedom for computing p-values and confidence intervals

df(#) does not appear in the dialog box.
**method** | Description
--- | ---
noadjust | do not adjust for multiple comparisons; the default
**bonferroni [ adjustall]** | Bonferroni’s method; adjust across all terms
**sidak [ adjustall]** | Šidák’s method; adjust across all terms
**scheffe** | Scheffé’s method
*tukey** | Tukey’s method
*snk** | Student–Newman–Keuls’s method
*duncan** | Duncan’s method
*dunnnett** | Dunnett’s method

*tukey, snk, duncan, and dunnnett are only allowed with results from anova, manova, regress, and mvreg.
tukey, snk, duncan, and dunnnett are not allowed with results from svy.

Time-series operators are allowed if they were used in the estimation.
collect is allowed; see [U] 11.1.10 Prefix commands.

**Options**

**Main**

mcompare(method) specifies the method for computing $p$-values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate, $\alpha_c$, to achieve a prespecified experimentwise error rate, $\alpha_e$.

mcompare(noadjust) is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

mcompare(bonferroni) adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality:

$$\alpha_e \leq m \alpha_c$$

where $m$ is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \frac{\alpha_e}{m}$$

mcompare(sidak) adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where $m$ is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the $m$ comparisons are independent.

mcompare(scheffe) controls the experimentwise error rate using the $F$ (or $\chi^2$) distribution with degrees of freedom equal to the rank of the term.

For results from anova, regress, manova, and mvreg (see [R] anova, [R] regress, [MV] manova, and [MV] mvreg), pwcompare allows the following additional methods. These methods are not allowed with results that used vce(robust) or vce(cluster clustvar).
**mcompare(tukey)** uses what is commonly referred to as Tukey's honestly significant difference. This method uses the Studentized range distribution instead of the \( t \) distribution.

**mcompare(snk)** is a variation on **mcompare(tukey)** that counts only the number of margins in the range for a given comparison instead of the full number of margins.

**mcompare(duncan)** is a variation on **mcompare(snk)** with additional adjustment to the significance probabilities.

**mcompare(dunnett)** uses Dunnett’s method for making comparisons with a reference category.

**mcompare(method adjustall)** specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in `marginlist`. This option is compatible only with the **bonferroni** and **sidak** methods.

**asobserved** specifies that factor covariates be evaluated using the cell frequencies observed when the model was fit. The default is to treat all factor covariates as though there were an equal number of observations at each level.

**equations**

* equation(**eqspec**) specifies the equation from which margins are to be computed. The default is to compute margins from the first equation.

* **atequations** specifies that the margins be computed within each equation.

**Advanced**

**emptycells(**empspec**) specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced.

* **emptycells(strict)** is the default; it specifies that margins involving empty cells be treated as not estimable.

* **emptycells(reweight)** specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the margins estimable but changes their interpretation.

**noestimcheck** specifies that **pwcompare** not check for estimability. By default, the requested margins are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If **noestimcheck** is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations.

**Reporting**

**level(\#)** specifies the confidence level, as a percentage, for confidence intervals. The default is **level(95)** or as set by **set level**; see [U] 20.8 Specifying the width of confidence intervals. The significance level used by the **groups** option is \( 100 - \# \), expressed as a percentage.

**cieffects** specifies that a table of the pairwise comparisons with their standard errors and confidence intervals be reported. This is the default.

**pveffects** specifies that a table of the pairwise comparisons with their standard errors, test statistics, and \( p \)-values be reported.

**effects** specifies that a table of the pairwise comparisons with their standard errors, test statistics, \( p \)-values, and confidence intervals be reported.

**cimargins** specifies that a table of the margins with their standard errors and confidence intervals be reported.
`pwcompare` specifies that a table of the margins with their standard errors and group codes be reported. Margins with the same letter in the group code are not significantly different at the specified significance level.

`sort` specifies that the reported tables be sorted on the margins or differences in each term.

`post` causes `pwcompare` to behave like a Stata estimation (e-class) command. `pwcompare` posts the vector of estimated margins along with the estimated variance–covariance matrix to `e()`, so you can treat the estimated margins just as you would results from any other estimation command. For example, you could use `test` to perform simultaneous tests of hypotheses on the margins, or you could use `lincom` to create linear combinations.

`display_options`: `vsquish`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%,fmt)`, `pformat(%,fmt)`, `sformat(%,fmt)`, and `nolstretch`.

`vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

`nofvlabel` displays factor-variable level values rather than attached value labels. This option overrides the `fvlabel` setting; see `[R] set showbaselevels`.

`fvwrap(#)` specifies how many lines to allow when long value labels must be wrapped. Labels requiring more than # lines are truncated. This option overrides the `fvwrap` setting; see `[R] set showbaselevels`.

`fvwrapon(style)` specifies whether value labels that wrap will break at word boundaries or break based on available space.

`fvwrapon(word)`, the default, specifies that value labels break at word boundaries.

`fvwrapon(width)` specifies that value labels break based on available space.

This option overrides the `fvwrapon` setting; see `[R] set showbaselevels`.

`cformat(%,fmt)` specifies how to format contrasts or margins, standard errors, and confidence limits in the table of pairwise comparisons.

`pformat(%,fmt)` specifies how to format \( p \)-values in the table of pairwise comparisons.

`sformat(%,fmt)` specifies how to format test statistics in the table of pairwise comparisons.

`nolstretch` specifies that the width of the table of pairwise comparisons not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the table of pairwise comparisons up to the width of the Results window. Specifying `lstretch` or `nolstretch` overrides the setting given by `set lstretch`. If `set lstretch` has not been set, the default is `lstretch`. `nolstretch` is not shown in the dialog box.

`eform_option` specifies that the contrasts table be displayed in exponentiated form. \( e^{\text{contrast}} \) is displayed rather than contrast. Standard errors and confidence intervals are also transformed. See `[R] eform_option` for the list of available options.

The following option is available with `pwcompare` but is not shown in the dialog box:

`df(#)` specifies that the \( t \) distribution with # degrees of freedom be used for computing \( p \)-values and confidence intervals. The default is to use \( e(df_r) \) degrees of freedom or the standard normal distribution if \( e(df_r) \) is missing.

Remarks and examples

`pwcompare` performs pairwise comparisons of margins across the levels of factor variables from the most recently fit model. The margins can be estimated cell means, marginal means, intercepts,
marginal intercepts, slopes, or marginal slopes. With the exception of slopes, we can also consider these margins to be marginal linear predictions.

The margins are calculated as linear combinations of the coefficients. Let $k$ be the number of levels for a factor term in our model; then there are $k$ margins for that term, and

$$m = \binom{k}{2} = \frac{k(k-1)}{2}$$

unique pairwise comparisons of those margins.

The confidence intervals and $p$-values for these pairwise comparisons can be adjusted to account for multiple comparisons. Bonferroni’s, Šidák’s, and Scheffé’s adjustments can be made for multiple comparisons after fitting any type of model. In addition, Tukey’s, Student–Newman–Keuls’s, Duncan’s, and Dunnett’s adjustments are available when fitting ANOVA, linear regression, MANOVA, or multivariate regression models.

Remarks are presented under the following headings:

In this simple case, the coefficients for fertilizers 10-08-22, 16-04-08, 18-24-06, and 29-03-04 indicate the difference in the mean yield for that fertilizer versus the mean yield for fertilizer 10-10-10. That the standard errors of all four coefficients are identical results from having perfectly balanced data.

**Marginal means**

We can use `pwcompare` with the `cimargins` option to compute the mean yield for each of the fertilizers.

. pwcompare fertilizer, cimargins

Looking at the confidence intervals for fertilizers 10-10-10 and 10-08-22 in the table above, we might be tempted to conclude that these means are not significantly different because the intervals overlap. However, as discussed in *Interaction plots* of [R] marginsplot, we cannot draw conclusions about the differences in means by looking at confidence intervals for the means themselves. Instead, we would need to look at confidence intervals for the difference in means.
**All pairwise comparisons**

By default, `pwcompare` calculates all pairwise differences of the margins, in this case pairwise differences of the mean yields.

```

If a confidence interval does not include zero, the means for the compared fertilizers are significantly different. Therefore, at the 5% significance level, we would reject the hypothesis that the means for fertilizers 10-10-10 and 10-08-22 are equivalent—as we would do for 18-24-06 vs 10-10-10, 29-03-04 vs 10-08-22, 18-24-06 vs 16-04-08, and 29-03-04 vs 18-24-06.

We may prefer to see the $p$-values instead of looking at confidence intervals to determine whether the pairwise differences are significantly different from zero. We could use the `pveffects` option to see the differences with standard errors and $p$-values, or we could use the `effects` option to see both $p$-values and confidence intervals in the same table. Here we specify `effects` as well as the `sort` option so that the differences are sorted from smallest to largest.

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

The letter A that is assigned to fertilizers 29-03-04, 10-10-10, and 16-04-08 designates that the mean yields for these fertilizers are not different at the 5% level.

### Overview of multiple-comparison methods

For a single test, if we choose a 5% significance level, we would have a 5% chance of concluding that two margins are different when the population values are actually equal. This is known as making a type I error. When we perform \( m = \frac{k(k - 1)}{2} \) pairwise comparisons of the \( k \) margins, we have \( m \) opportunities to make a type I error.

\texttt{pwcompare} with the \texttt{mcompare()} option allows us to adjust the confidence intervals and \( p \)-values for each comparison to account for the increased probability of making a type I error when making multiple comparisons. Bonferroni's adjustment, Šidák's adjustment, and Scheffé's adjustment can be used when making pairwise comparisons of the margins after any estimation command. Tukey's honestly significant difference, Student–Newman–Keuls's method, Duncan's method, and Dunnett's method are only available when fitting linear models after \texttt{anova}, \texttt{manova}, \texttt{regress}, or \texttt{mvreg}.

### Fisher's protected least-significant difference (LSD)

\texttt{pwcompare} does not offer an \texttt{mcompare()} option specifically for Fisher’s protected least-significant difference (LSD). In this methodology, no adjustment is made to the confidence intervals or \( p \)-values. However, it is protected in the sense that no pairwise comparisons are tested unless the joint test for the corresponding term in the model is significant. Therefore, the default \texttt{mcompare(noadjust)} corresponds to Fisher’s protected LSD assuming that the corresponding joint test was performed before using \texttt{pwcompare}.

\textit{Milliken and Johnson (2009)} recommend using this methodology for planned comparisons, assuming the corresponding joint test is significant.

### Bonferroni's adjustment

\texttt{mcompare(bonferroni)} adjusts significance levels based on the Bonferroni inequality, which, in the case of multiple testing, tells us that the maximum error rate for all comparisons is the sum of the error rates for the individual comparisons. Assuming that we are using the same significance level for all tests, the experimentwise error rate is the error rate for a single test multiplied by the
number of comparisons. Therefore, a $p$-value for each comparison can be computed by multiplying the unadjusted $p$-value by the total number of comparisons. If the adjusted $p$-value is greater than 1, then {	t pwcompare} will report a $p$-value of 1.

Bonferroni’s adjustment is popular because it is easy to compute manually and because it can be applied to any set of tests, not only the pairwise comparisons available in {	t pwcompare}. In addition, this method does not require equal sample sizes.

Because Bonferroni’s adjustment is so general, it is more conservative than many of the other adjustments. It is especially conservative when a large number of tests is being performed.

Šidák’s adjustment

{	t mcompare(sidak)} performs an adjustment using Šidák’s method. This adjustment, like Bonferroni’s adjustment, is derived from an inequality. However, in this case, the inequality is based on the probability of not making a type I error. For a single test, the probability that we do not make a type I error is $1 - \alpha$. For two independent tests, both using $\alpha$ as a significance level, the probability is $(1 - \alpha)(1 - \alpha)$. Likewise, for $m$ independent tests, the probability of not making a type I error is $(1 - \alpha)^m$. Therefore, the probability of making one or more type I errors is $1 - (1 - \alpha)^m$. When tests are not independent, the probability of making at least one error is less than $1 - (1 - \alpha)^m$. Therefore, we can compute an adjusted $p$-value as $1 - (1 - u p)^m$, where $u p$ is the unadjusted $p$-value for a single comparison.

Šidák’s method is also conservative although slightly less so than Bonferroni’s method. Like Bonferroni’s method, this method does not require equal sample sizes.

Scheffé’s adjustment

Scheffé’s adjustment is used when {	t mcompare(scheffe)} is specified. This adjustment is derived from the joint $F$ test and its correspondence to the maximum normalized comparison. To adjust for multiple comparisons, the absolute value of the $t$ statistic for a particular comparison can be compared with a critical value of $\sqrt{(k - 1)F_{k-1,\nu}}$, where $\nu$ is the residual degrees of freedom. $F_{k-1,\nu}$ is the distribution of the joint $F$ test for the corresponding term in a one-way ANOVA model. Winer, Brown, and Michels (1991, 191–195) discuss this in detail. For estimation commands that report $z$ statistics instead of $t$ statistics for the tests on coefficients, a $\chi^2$ distribution is used instead of an $F$ distribution.

Scheffé’s method allows for making all possible comparisons of the $k$ margins, not just the pairwise comparisons. Unlike the methods described above, it does not take into account the number of comparisons that are currently being made. Therefore, this method is even more conservative than the others. Because this method adjusts for all possible comparisons of the levels of the term, Milliken and Johnson (2009) recommend using this procedure when making unplanned contrasts that are suggested by the data. As Winer, Brown, and Michels (1991, 191) put it, this method is often used to adjust for “unfettered data snooping”. When using this adjustment, a contrast will never be significant if the joint $F$ or $\chi^2$ test for the term is not also significant.

This is another method that does not require equal sample sizes.
Tukey’s HSD adjustment

Tukey’s adjustment is also referred to as Tukey’s honestly significant difference (HSD) and is used when \texttt{mcompare(tukey)} is specified. It is often applied to all pairwise comparisons of means. Tukey’s HSD is commonly used as a post hoc test although this is not a requirement.

To adjust for multiple comparisons, Tukey’s method compares the absolute value of the $t$ statistic from the individual comparison with a critical value based on a Studentized range distribution with parameter equal to the number of levels in the term. When applied to pairwise comparisons of means,

$$ q = \frac{\text{mean}_{\text{max}} - \text{mean}_{\text{min}}}{s} $$

follows a Studentized range distribution with parameter $k$ and $\nu$ degrees of freedom. Here $\text{mean}_{\text{max}}$ and $\text{mean}_{\text{min}}$ are the largest and smallest marginal means, and $s$ is an estimate of the standard error of the means.

Now for the comparison of the smallest and largest means, we can say that the probability of not making a type I error is

$$ \Pr \left( \frac{\text{mean}_{\text{max}} - \text{mean}_{\text{min}}}{s} \leq q_{k,\nu} \right) = 1 - \alpha $$

Then, the following inequality holds for all pairs of means simultaneously:

$$ \Pr \left( \frac{|\text{mean}_i - \text{mean}_j|}{s} \leq q_{k,\nu} \right) \geq 1 - \alpha $$

Based on this procedure, Tukey’s HSD computes the $p$-value for each of the individual comparisons using the Studentized range distribution. However, because the equality holds only for the difference in the largest and smallest means, this procedure produces conservative tests for the remaining comparisons. Winer, Brown, and Michels (1991, 172–182) discuss this in further detail.

With unequal sample sizes, \texttt{mcompare(tukey)} produces the Tukey–Kramer adjustment (Tukey 1953; Kramer 1956).

Student–Newman–Keuls’s adjustment

The Student–Newman–Keuls (SNK) method is used when \texttt{mcompare(snk)} is specified. It is a modification to Tukey’s method and is less conservative. In this procedure, we first order the means. We then test the difference in the smallest and largest means using a critical value from the Studentized range distribution with parameter $k$, where $k$ is the number of levels in the term. This step uses the same methodology as in Tukey’s procedure. However, in the next step, we will then test for differences in the two sets of means that are the endpoints of the two ranges including $k - 1$ means. Specifically, we test the difference in the smallest mean and the second-largest mean using a critical value from the Studentized range distribution with parameter $k - 1$. We would also test the difference in the second-smallest mean and the largest mean using this critical value. Likewise, the means that are the endpoints of ranges including $k - 2$ means when ordered are tested using the Studentized range distribution with parameter $k - 2$, and so on.

Equal sample sizes are required for this method.
Duncan’s adjustment

When `mcompare(duncan)` is specified, tests are adjusted for multiple comparisons using Duncan’s method, which is sometimes referred to as Duncan’s new multiple range method. This adjustment produces tests that are less conservative than both Tukey’s HSD and SNK. This procedure is performed in the same manner as SNK except that the p-values for the individual comparisons are adjusted as \(1 - (1 - \text{snk}P)^{1/(r+1)}\), where \(\text{snk}P\) is the p-value computed using the SNK method and \(r\) represents the number of means that, when ordered, fall between the two that are being compared.

Again, equal sample sizes are required for this adjustment.

Dunnett’s adjustment

Dunnett’s adjustment is obtained by specifying `mcompare(dunnett)`. It is used when one of the levels of a factor can be considered a control or reference level with which each of the other levels is being compared. When Dunnett’s adjustment is requested, \(k - 1\) instead of \(k(k - 1)/2\) pairwise comparisons are made. Dunnett (1955, 1964) developed tables of critical values for what Miller (1981, 76) refers to as the “many-one t statistic”. The t statistics for individual comparisons are compared with these critical values when making many comparisons to a single reference level.

This method also requires equal sample sizes.

Example adjustments using one-way models

Fisher’s protected LSD

Fisher’s protected LSD requires that we first verify that the joint test for a term in our model is significant before proceeding with pairwise comparisons. Using our previous example, we could have first used the `contrast` command to obtain a joint test for the effects of fertilizer.

```

This test for the effects of fertilizer is highly significant. Now we can say we are using Fisher’s protected LSD when looking at the unadjusted p-values that were obtained from our previous command,

```
. pwcompare fertilizer, effects sort
```
Tukey's HSD

Because we fit a linear regression model and are interested in all pairwise comparisons of the marginal means, we may instead choose to use Tukey’s HSD.

```plaintext
. pwcompare fertilizer, effects sort mcompare(tukey)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced

```

This time, our $p$-values have been modified, and we find that only four of the pairwise differences are considered significantly different from zero at the 5% level.

If we are interested only in performing pairwise comparisons of a subset of our means, we can use factor-variable operators to select the levels of the factor that we want to compare. Here we exclude all comparisons involving fertilizer 10-10-10.

The adjusted $p$-values and confidence intervals differ from those in the previous output because Tukey’s adjustment takes into account the total number of comparisons being made when determining the appropriate degrees of freedom to use for the Studentized range distribution.

**Dunnett’s method for comparisons to a control**

If one of our five fertilizer groups represents fields where no fertilizer was applied, we may want to use Dunnett’s method to compare each of the four fertilizers with the control group. In this case, we make only $k - 1$ comparisons for $k$ groups.

In our previous `regress` command, fertilizer 10-10-10 was treated as the base. Therefore, by default, it was treated as the control when using Dunnett’s adjustment, and the pairwise comparisons are equivalent to the coefficients reported by `regress`. Based on our `regress` output, we would conclude that fertilizers 10-08-22 and 18-24-06 are different from fertilizer 10-10-10 at the 5% level. However, using Dunnett’s adjustment, we find only fertilizer 18-24-06 to be different from fertilizer 10-10-10 at this same significance level.

If the model is fit without a base level for a factor variable, then `pwcompare` will choose the first level as the reference level. If we want to make comparisons with a different level than the one `mcompare(dunnett)` chooses by default, we can use the `b.` operator to override the default. Here we use fertilizer 5 (29-03-04) as the reference level.

```

Note: Margins sharing a letter in the group label are not significantly different at the 5% level.

Based on Tukey’s HSD and a 5% significance level, we would conclude that the mean yield for fertilizer 29-03-04 without irrigation is not significantly different from the mean yields for fertilizers 10-10-10, 10-08-22, and 16-04-08 when used without irrigation but is significantly different from the remaining means.

Up to this point, most of the pairwise comparisons that we have performed could have also been obtained with `pwmean` (see [R] `pwmean`) if we had not been interested in examining the results from the estimation command before making pairwise comparisons of the means. For instance, we could reproduce the results from the above `pwcompare` command by typing

```
. pwmean yield, over(fertilizer irrigation) sort group mcompare(tukey)
```

However, `pwcompare` extends the capabilities of `pwmean` in many ways. For instance, `pwmean` only allows for pairwise comparisons of the cell means determined by the highest-level interaction of the variables specified in the `over()` option. However, `pwcompare` allows us to fit a single model, such as the two-way model that we fit above,

```
. regress yield fertilizer##irrigation
```
and compute pairwise comparisons of the marginal means for only one of the variables in the model:

```
. pwcompare fertilizer, sort effects mcompare(tukey)
```

Here the standard errors for the differences in marginal means and the residual degrees of freedom are based on the full model. Therefore, the results will differ from those obtained from `pwcompare` after fitting the one-way model with only `fertilizer` (or equivalently using `pwmean`).

**Pairwise comparisons of slopes**

If we fit a model with a factor variable that is interacted with a continuous variable, `pwcompare` will even allow us to make pairwise comparisons of the slopes of the continuous variable for the levels of the factor variable.

In this case, we have a continuous variable, `NO3_N`, indicating the amount of nitrate nitrogen already existing in the soil, based on a sample taken from each field.

| 10-08-22 vs 10-10-10 | -1.282039 | .8953419 | -1.43 | 0.727 |
| 16-04-08 vs 10-10-10 | -1.00571  | .9025862 | -1.11 | 0.871 |
| 29-03-04 vs 18-24-06 | -2.996772 | .4900939 | -0.61 | 0.984 |
| 16-04-08 vs 10-08-22 | .276328   | .5844405 | 0.47  | 0.994 |

Using Scheffé’s adjustment, we find that five of the pairs have significantly different slopes at the 5% level.
Nonlinear models

pwcompare can also perform pairwise comparisons of the marginal linear predictions after fitting a nonlinear model. For instance, we can use the dataset from *Beyond linear models* in [R] contrast and fit the following logistic regression model of patient satisfaction on hospital:

```stata
use https://www.stata-press.com/data/r18/hospital
(Artificial hospital satisfaction data)
logit satisfied i.hospital
```

```
Iteration 0:  Log likelihood =  -393.72216
Iteration 1:  Log likelihood =  -387.55736
Iteration 2:  Log likelihood =  -387.4768
Iteration 3:  Log likelihood =  -387.47679
```

```
Logistic regression
Number of obs   =  802
LR chi2(2)      =  12.49
Prob > chi2     =  0.0019
Log likelihood  =  -387.47679  Pseudo R2   =  0.0159
```

```
satisfied      Coefficient Std. err.     z     P>|z|   [95% conf. interval]       
hospital
   2            0.5348129   0.2136021  2.50   0.012   .1161604    .9534654       
   3            0.7354519   0.2221929  3.31   0.001   .2999618   1.170942        
_cons          1.034708    0.1391469  7.44   0.000   .7619855   1.307431        
```

For this model, the marginal linear predictions are the predicted log odds for each hospital and can be obtained with the cimargins option:

```
pwcompare hospital, cimargins
```

```
Pairwise comparisons of marginal linear predictions
Margins: asbalanced

|        | Coefficient | Std. err. | z     | P>|z|   | [95% conf. interval] |
|--------|-------------|-----------|-------|-------|---------------------|
| hospital|             |           |       |       |                     |
| 1      | 1.034708    | 0.1391469 | .7619855 | 1.307431 |
| 2      | 1.569521    | 0.1620618 | 1.251886 | 1.887157 |
| 3      | 1.77016     | 0.1732277 | 1.43064  | 2.10968  |
```

The pairwise comparisons are, therefore, differences in the log odds. We can specify mcompare(bonferroni) and effects to request Bonferroni-adjusted $p$-values and confidence intervals.

```
pwcompare hospital, effects mcompare(bonferroni)
```

```
Pairwise comparisons of marginal linear predictions
Margins: asbalanced

|        | Coefficient | Std. err. | z     | P>|z|   | [95% conf. interval] |
|--------|-------------|-----------|-------|-------|---------------------|
| hospital|             |           |       |       |                     |
| 1      |             |           |       |       |                     |
| 2      |             |           |       |       |                     |
| 3      |             |           |       |       |                     |
```

```
 Number of comparisons
satisfied     hospital      3
```

For this model, the marginal linear predictions are the predicted log odds for each hospital and can be obtained with the cimargins option:
For nonlinear models, only Bonferroni’s adjustment, Šidák’s adjustment, and Scheffé’s adjustment are available.

If we want pairwise comparisons reported as odds ratios, we can specify the `or` option.

```
. pwcompare hospital, effects mcompare(bonferroni) or
```

Pairwise comparisons of marginal linear predictions
Margins: asbalanced

<table>

Notice that these tests are still performed on the marginal linear predictions. The odds ratios reported here are the exponentiated versions of the pairwise differences of log odds in the previous output. For further discussion, see \([R]\) contrast.

### Multiple-equation models

`pwcompare` works with models containing multiple equations. Commands such as `intreg` and `gnbreg` allow their ancillary parameters to be modeled as a function of independent variables, and `pwcompare` can compare the margins within these equations. The `equation()` option can be used to specify the equation for which pairwise comparisons of the margins should be made. The `atequations` option specifies that pairwise comparisons be computed for each equation. In addition, `pwcompare` allows a special pseudofactor for equation—called `_eqns`—when working with results from `manova`, `mvreg`, `mlogit`, and `mprobit`.

Here we use the jaw fracture dataset described in example 4 of \([MV]\) `manova`. We fit a multivariate regression model including one independent factor variable, `fracture`.
```
use https://www.stata-press.com/data/r18/jaw
(Table 4.6. Two-way unbalanced data for fractures of the jaw, Rencher (1998))

. mvreg y1 y2 y3 = i.fracture

```

`pwcompare` performs pairwise comparisons of the margins using the coefficients from the first equation by default:

```
. pwcompare fracture, mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced

<table>
<thead>
<tr>
<th></th>
<th>Number of comparisons</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>y1 fracture</td>
<td>3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Contrast</th>
<th>Std. err.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>y1 fracture</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Two compound fractures vs One compound fracture</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>One simple fracture vs One compound fracture</td>
<td>-8.83333 4.957441</td>
<td>-21.59201 3.925341</td>
<td></td>
</tr>
<tr>
<td>One compound fracture vs One simple fracture</td>
<td>6 5.394759</td>
<td>-7.884173 19.88417</td>
<td></td>
</tr>
<tr>
<td>Two compound fractures vs One simple fracture</td>
<td>14.83333 4.75773</td>
<td>2.588644 27.07802</td>
<td></td>
</tr>
</tbody>
</table>
```

We can use the `equation()` option to get `pwcompare` to perform comparisons in the `y2` equation:

```
. pwcompare fracture, equation(y2) mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced

<table>
<thead>
<tr>
<th></th>
<th>Number of comparisons</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>y2 fracture</td>
<td>3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Contrast</th>
<th>Std. err.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>y2 fracture</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Two compound fractures vs One compound fracture</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>One simple fracture vs One compound fracture</td>
<td>-5.761905 3.008327</td>
<td>-13.50426 1.980449</td>
<td></td>
</tr>
<tr>
<td>One compound fracture vs One simple fracture</td>
<td>-3.053571 3.273705</td>
<td>-11.47891 5.371769</td>
<td></td>
</tr>
<tr>
<td>Two compound fractures vs One simple fracture</td>
<td>2.708333 2.887136</td>
<td>-4.722119 10.13879</td>
<td></td>
</tr>
</tbody>
</table>
```
Because we are working with `mvreg` results, we can use the `_eqns` pseudofactor to compare the margins between the three dependent variables. The levels of `_eqns` index the equations: 1 for the first equation, 2 for the second, and 3 for the third.

```plaintext
. pwcompare _eqns, mcompare(bonferroni)
Pairwise comparisons of marginal linear predictions
Margins: asbalanced

Number of comparisons

<table>
<thead>
<tr>
<th>_eqns</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>_eqns</th>
<th>Contrast</th>
<th>Std. err.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>2 vs 1</td>
<td>-.5654762</td>
<td>2.545923</td>
<td>-7.117768 5.986815</td>
</tr>
<tr>
<td>3 vs 1</td>
<td>24.24603</td>
<td>2.320677</td>
<td>18.27344 30.21862</td>
</tr>
<tr>
<td>3 vs 2</td>
<td>24.81151</td>
<td>2.368188</td>
<td>18.71664 30.90637</td>
</tr>
</tbody>
</table>
```

For the previous command, the only methods available are `mcompare(bonferroni)`, `mcompare(sidak)`, or `mcompare(scheffe)`. Methods that use the Studentized range are not appropriate for making comparisons across equations.

**Unbalanced data**

`pwcompare` treats all factors as balanced when it computes the marginal means. By “balanced”, we mean that the number of observations in each combination of factor levels (in each cell mean) is equal. We can alternatively specify the `asobserved` option when we have unbalanced data to obtain marginal means that are based on the observed cell frequencies from the model fit. For more details on the difference in these two types of marginal means and a discussion of when each may be appropriate, see [R] `margins` and [R] `contrast`.

In addition, when our data are not balanced, some of the multiple-comparison adjustments are no longer appropriate. Student–Newman–Keuls’s method, Duncan’s method, and Dunnett’s method assume equal numbers of observations per group.

Here we use an unbalanced dataset and fit a two-way ANOVA model for cholesterol levels on race and age group. Then we perform pairwise comparisons of the mean cholesterol levels for each race, requesting Šidák’s adjustment as well as marginal means that are computed using the observed cell frequencies.

Empty cells

An empty cell is a combination of the levels of factor variables that is not observed in the estimation sample. When we have empty cells in our data, the marginal means involving those empty cells are not estimable as described in [R] margins. In addition, all pairwise comparisons involving a marginal mean that is not estimable are themselves not estimable. Here we use a dataset where we do not have any observations for white individuals in the 20–29 age group. We can use the emptycells(reweight) option to reweight the nonempty cells so that we can estimate the marginal mean for whites and compute pairwise comparisons involving that marginal mean.

For further details on the emptycells(reweight) option, see [R] margins and [R] contrast.
Stored results

`pwcompare` stores the following in `r()`:

Scalars
- `r(df_r)`: variance degrees of freedom
- `r(k_terms)`: number of terms in `marginlist`
- `r(level)`: confidence level of confidence intervals
- `r(balanced)`: 1 if fully balanced data, 0 otherwise

Macros
- `r(cmd)`: `pwcompare`
- `r(cmdline)`: command as typed
- `r(est_cmd)`: `e(cmd)` from original estimation results
- `r(est_cmdline)`: `e(cmdline)` from original estimation results
- `r(title)`: title in output
- `r(emptycells)`: `empspec` from `emptycells()`
- `r(groups#)`: group codes for the #th margin in `r(b)`
- `r(mcmethod_vs)`: `method` from `mcompare()`
- `r(mctitle_vs)`: title for `method` from `mcompare()`
- `r(mcadjustall_vs)`: adjustall or empty
- `r(margin_method)`: `asbalanced` or `asobserved`
- `r(vce)`: `vcetype` specified in `vce()` in original estimation command

Matrices
- `r(b)`: margin estimates
- `r(V)`: variance–covariance matrix of the margin estimates
- `r(error)`: margin estimability codes;
  - 0 means estimable,
  - 8 means not estimable
- `r(table)`: matrix containing the margins with their standard errors, test statistics, `p`-values, and confidence intervals
- `r(M)`: matrix that produces the margins from the model coefficients
- `r(b_vs)`: margin difference estimates
- `r(V_vs)`: variance–covariance matrix of the margin difference estimates
- `r(error_vs)`: margin difference estimability codes;
  - 0 means estimable,
  - 8 means not estimable
- `r(table_vs)`: matrix containing the margin differences with their standard errors, test statistics, `p`-values, and confidence intervals
- `r(L)`: matrix that produces the margin differences from the model coefficients
- `r(k_groups)`: number of significance groups for each term
pwcompare with the post option also stores the following in e():

Scalars
- e(df_r) variance degrees of freedom
- e(k_terms) number of terms in marginlist
- e(balanced) 1 if fully balanced data, 0 otherwise

Macros
- e(cmd) pwcompare
- e(cmdline) command as typed
- e(properties) b V
- e(est_cmd) e(cmd) from original estimation results
- e(est_cmdline) e(cmdline) from original estimation results
- e(title) title in output
- e(emptycells) empspec from emptycells()
- e(margin_method) asbalanced or asobserved
- e(asbalanced) factor variables fvset as asbalanced
- e(asobserved) factor variables fvset as asobserved
- e(vce) vcetype specified in vce() in original estimation command

Matrices
- e(b) margin estimates
- e(V) variance–covariance matrix of the margin estimates
- e(error) margin estimability codes;
  - 0 means estimable,
  - 8 means not estimable
- e(M) matrix that produces the margins from the model coefficients
- e(b_vs) margin difference estimates
- e(V_vs) variance–covariance matrix of the margin difference estimates
- e(error_vs) margin difference estimability codes;
  - 0 means estimable,
  - 8 means not estimable
- e(L) matrix that produces the margin differences from the model coefficients

Methods and formulas

Methods and formulas are presented under the following headings:

Notation
- Unadjusted comparisons
- Bonferroni’s method
- Šidák’s method
- Scheffé’s method
- Tukey’s method
- Student-Newman-Keuls’s method
- Duncan’s method
- Dunnett’s method

Notation

pwcompare performs comparisons of margins; see Methods and formulas in [R] contrast.

If there are $k$ margins for a given factor term, then there are

$$m = \binom{k}{2} = \frac{k(k - 1)}{2}$$
unique pairwise comparisons. Let the $i$th pairwise comparison be denoted by

$$\hat{\delta}_i = l_i'b$$

where $b$ is a column vector of coefficients from the fitted model and $l_i$ is a column vector that forms the corresponding linear combination. If $\hat{V}$ denotes the estimated variance matrix for $b$, then the standard error for $\hat{\delta}_i$ is given by

$$\hat{se}(\hat{\delta}_i) = \sqrt{l_i'\hat{V}l_i}$$

The corresponding test statistic is then

$$t_i = \frac{\hat{\delta}_i}{\hat{se}(\hat{\delta}_i)}$$

and the limits for a $100(1 - \alpha)\%$ confidence interval for the expected value of $\hat{\delta}_i$ are

$$\hat{\delta}_i \pm c_i(\alpha) \hat{se}(\hat{\delta}_i)$$

where $c_i(\alpha)$ is the critical value corresponding to the chosen multiple-comparison method.

### Unadjusted comparisons

`pwcompare` computes unadjusted $p$-values and confidence intervals by default. `pwcompare` uses the $t$ distribution with $\nu = e(df_r)$ degrees of freedom when $e(df_r)$ is posted by the estimation command. The unadjusted two-sided $p$-value is

$$u p_i = 2 \Pr(t_\nu > |t_i|)$$

and the unadjusted critical value $u c_i(\alpha)$ satisfies the following probability statement:

$$\alpha = 2 \Pr\{t_\nu > u c_i(\alpha)\}$$

`pwcompare` uses the standard normal distribution when $e(df_r)$ is not posted.

### Bonferroni’s method

For `mcompare(bonferroni)`, the adjusted $p$-value is

$$b p_i = \min(1, m u p_i)$$

and the adjusted critical value is

$$b c_i(\alpha) = u c_i(\alpha/m)$$
Šidák’s method

For $mcompare(sidak)$, the adjusted $p$-value is

$$s_i p_i = 1 - (1 - u p_i)^m$$

and the adjusted critical value is

$$s_i c_i(\alpha) = u c_i \left\{ 1 - (1 - \alpha)^{1/m} \right\}$$

Scheffé’s method

For $mcompare(scheffe)$, the adjusted $p$-value is

$$s_c p_i = \Pr \left( F_{d, \nu} > t_i^2 / d \right)$$

where $F_{d, \nu}$ is distributed as an $F$ with $d$ numerator and $\nu$ denominator degrees of freedom and $d$ is the rank of the VCE for the term. The adjusted critical value satisfies the following probability statement:

$$\alpha = \Pr \left[ F_{d, \nu} > \left\{ s_c c_i(\alpha) \right\}^2 / d \right]$$

pwcompare uses the $\chi^2$ distribution when \(e(df_r)\) is not posted.

Tukey’s method

For $mcompare(tukey)$, the adjusted $p$-value is

$$t p_i = \Pr \left( q_{k, \nu} > |t_i| \sqrt{2} \right)$$

where $q_{k, \nu}$ is distributed as the Studentized range statistic for $k$ means and $\nu$ residual degrees of freedom (Miller 1981). The adjusted critical value satisfies the following probability statement:

$$\alpha = \Pr \left\{ q_{k, \nu} > t c_i(\alpha) \sqrt{2} \right\}$$

Student–Newman–Keuls’s method

For $mcompare(snk)$, suppose $t_i$ is comparing two margins that have $r$ other margins between them. Then the adjusted $p$-value is

$$snk p_i = \Pr \left( q_{r+2, \nu} > |t_i| \sqrt{2} \right)$$

where $r$ ranges from 0 to $k - 2$. The adjusted critical value $snk c_i(\alpha)$ satisfies the following probability statement:

$$\alpha = \Pr \left\{ q_{r+2, \nu} > snk c_i(\alpha) \sqrt{2} \right\}$$
**Duncan’s method**

For `mcompare(duncan)`, the adjusted $p$-value is

$$duncP_i = 1 - (1 - snkP_i)^{1/(r+1)}$$

and the adjusted critical value is

$$dunc_{c_i}(\alpha) = snk_{c_i}\{1 - (1 - \alpha)^{r+1}\}$$

**Dunnett’s method**

For `mcompare(dunnett)`, the margins are compared with a reference category, resulting in only $k - 1$ pairwise comparisons. The adjusted $p$-value is

$$dunnP_i = \Pr(d_{k-1,\nu} > |t_i|)$$

where $d_{k-1,\nu}$ is distributed as the many-one $t$ statistic (Miller 1981, 76). The adjusted critical value $dunn_{c_i}(\alpha)$ satisfies the following probability statement:

$$\alpha = \Pr\{d_{k-1,\nu} > dunn_{c_i}(\alpha)\}$$

The multiple-comparison methods for `mcompare(tukey)`, `mcompare(snk)`, `mcompare(duncan)`, and `mcompare(dunnett)` assume the normal distribution with equal variance; thus, these methods are allowed only with results from `anova`, `regress`, `manova`, and `mvreg`. `mcompare(snk)`, `mcompare(duncan)`, and `mcompare(dunnett)` assume equal sample size for each marginal mean. These options will cause `pwcompare` to report a footnote if unbalanced factors are detected.

</tr>
<tr>
<td>test</td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td>testnl</td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

Remarks and examples

When we use the `post` option with `pwcompare`, the marginal linear predictions are posted as estimation results, and we can use postestimation commands to perform further analysis on them.

In *Pairwise comparisons of means* of [R] `pwcompare`, we fit a regression of wheat yield on types of fertilizers.

```
. use https://www.stata-press.com/data/r18/yield
(Artificial wheat yield dataset)
. regress yield i.fertilizer
(output omitted)
```

We also used `pwcompare` with the `cimargins` option to obtain the marginal mean yield for each fertilizer. We can add the `post` option to this command to post these marginal means and their VCEs as estimation results.
. pwcompare fertilizer, cimargins post
Pairwise comparisons of marginal linear predictions
Margins: asbalanced

<table>
<thead>

</tbody>
</table>

Now, we can use \texttt{nlcom} to compute a percentage improvement in the mean yield for fertilizer 2 when compared with fertilizer 1.

. \texttt{nlcom (pct_chg: 100*(_b[2.fertilizer] - _b[1.fertilizer])/_b[1.fertilizer])}

\begin{tabular}{lrrrr}
\textit{pct_chg:} & \multicolumn{4}{c}{Coefficient Std. err. z P>|z| [95\% conf. interval]} \\
\hline
\textit{pct_chg} & 8.758479 & 4.015932 & 2.18 & 0.029 & 0.8873982 16.62956 \\
\end{tabular}

The mean yield for fertilizer 2 is about 9\% higher than that of fertilizer 1, with a standard error of 4\%.

[R] \texttt{pwcompare} — Pairwise comparisons

[U] 20 Estimation and postestimation commands
pwmean — Pairwise comparisons of means

Description

pwmean performs pairwise comparisons of means. It computes all pairwise differences of the means of `varname` over the combination of the levels of the variables in `varlist`. The tests and confidence intervals for the pairwise comparisons assume equal variances across groups. `pwmean` also allows for adjusting the confidence intervals and p-values to account for multiple comparisons using Bonferroni’s method, Scheffé’s method, Tukey’s method, Dunnett’s method, and others.

See `[R] pwcompare` for performing pairwise comparisons of means, estimated marginal means, and other types of marginal linear predictions after `anova`, `regress`, and most other estimation commands.

Quick start

All pairwise differences in the means of `y` over levels of categorical variable `catvar`

```
pwmean y, over(catvar)
```

Same as above, and report test statistics and p-values for tests that differences equal zero

```
pwmean y, over(catvar) effects
```

Adjust p-values and confidence intervals for multiple comparisons using Tukey’s method

```
pwmean y, over(catvar) effects mcompare(tukey)
```

Same as above, but adjust for multiple comparisons using Bonferroni’s method

```
pwmean y, over(catvar) effects mcompare(bonferroni)
```

Report mean of `y` for each level of `catvar`, grouping means that are not significantly different

```
pwmean y, over(catvar) groups
```

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Pairwise comparisons of means

Options

over(varlist) is required and specifies that means are computed for each combination of the levels of the variables in varlist.

mcompare(method) specifies the method for computing p-values and confidence intervals that account for multiple comparisons.

Most methods adjust the comparisonwise error rate, \( \alpha_c \), to achieve a prespecified experimentwise error rate, \( \alpha_e \).

mcompare(noadjust) is the default; it specifies no adjustment.

\[ \alpha_c = \alpha_e \]
mcompare(bonferroni) adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality:

$$\alpha_e \leq m\alpha_c$$

where $m$ is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \frac{\alpha_e}{m}$$

mcompare(sidak) adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where $m$ is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the $m$ comparisons are independent.

mcompare(scheffe) controls the experimentwise error rate using the $F$ (or $\chi^2$) distribution with degrees of freedom equal to $k - 1$ where $k$ is the number of means being compared.

mcompare(tukey) uses what is commonly referred to as Tukey’s honestly significant difference. This method uses the Studentized range distribution instead of the $t$ distribution.

mcompare(snk) is a variation on mcompare(tukey) that counts only the number of means participating in the range for a given comparison instead of the full number of means.

mcompare(dunnett) is a variation on mcompare(snk) with additional adjustment to the significance probabilities.

mcompare(duncan) uses Dunnett’s method for making comparisons with a reference category.

---

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.

The significance level used by the groups option is $100 - #$, expressed as a percentage.

cieffects specifies that a table of the pairwise comparisons of means with their standard errors and confidence intervals be reported. This is the default.

pveffects specifies that a table of the pairwise comparisons of means with their standard errors, test statistics, and $p$-values be reported.

effects specifies that a table of the pairwise comparisons of means with their standard errors, test statistics, $p$-values, and confidence intervals be reported.

cimeans specifies that a table of the means with their standard errors and confidence intervals be reported.

groups specifies that a table of the means with their standard errors and group codes be reported. Means with the same letter in the group code are not significantly different at the specified significance level.

sort specifies that the reported tables be sorted by the mean or difference that is displayed in the table.

display_options: nofvl, fwrap(#), fwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch.
nofvlabel displays factor-variable level values rather than attached value labels. This option overrides the fvlabel setting; see [R] set showbaselevels.

fvwrap(#) specifies how many lines to allow when long value labels must be wrapped. Labels requiring more than # lines are truncated. This option overrides the fvwrap setting; see [R] set showbaselevels.

fvwrapon(style) specifies whether value labels that wrap will break at word boundaries or break based on available space.

fvwrapon(word), the default, specifies that value labels break at word boundaries.

fvwrapon(width) specifies that value labels break based on available space.

This option overrides the fvwrapon setting; see [R] set showbaselevels.

cformat(%,fmt) specifies how to format means, standard errors, and confidence limits in the table of pairwise comparison of means.

pformat(%,fmt) specifies how to format \( p \)-values in the table of pairwise comparison of means.

sformat(%,fmt) specifies how to format test statistics in the table of pairwise comparison of means.

nolstretch specifies that the width of the table of pairwise comparisons not be automatically widened to accommodate longer variable names. The default, lstretch, is to automatically widen the table of pairwise comparisons up to the width of the Results window. Specifying lstretch or nolstretch overrides the setting given by set lstretch. If set lstretch has not been set, the default is lstretch. nolstretch is not shown in the dialog box.

Remarks and examples

pwmean performs pairwise comparisons (differences) of means, assuming a common variance among groups. It can easily adjust the \( p \)-values and confidence intervals for the differences to account for the elevated type I error rate due to multiple comparisons. Adjustments for multiple comparisons can be made using Bonferroni’s method, Scheffé’s method, Tukey’s method, Dunnett’s method, and others.

See [R] margins, pwcompare for performing pairwise comparisons of marginal probabilities and other linear and nonlinear predictions after estimation commands.

Remarks are presented under the following headings:

- Group means
- Pairwise differences of means
- Group output
- Adjusting for multiple comparisons
  - Tukey’s method
  - Dunnett’s method
- Multiple over() variables
- Equal variance assumption

Group means

Suppose we have data on the wheat yield of fields that were each randomly assigned an application of one of five types of fertilizers. Let’s first look at the mean yield for each type of fertilizer.

</table>
The contrast in the row labeled (10-08-22 vs 10-10-10) is the difference in the mean wheat yield for fertilizer 10-08-22 and fertilizer 10-10-10. At a 5% significance level, we conclude that there is a difference in the means for these two fertilizers. Likewise, the rows labeled (18-24-06 vs 10-10-10), (29-03-04 vs 10-08-22), (18-24-06 vs 16-04-08) and (29-03-04 vs 18-24-06) show differences in these pairs of means. In all, we find that 5 of the 10 mean differences are significantly different from zero at a 5% significance level.

We can specify the `sort` option to order the differences from smallest to largest in the table.

```

</tbody>
</table>

Note: Means sharing a letter in the group label are not significantly different at the 5% level.

Fertilizers 29-03-04, 10-10-10, and 16-04-08 are all in group A. This means that at our 5% level of significance, we have insufficient information to distinguish their means. Likewise, fertilizers 16-04-08 and 10-08-22 are in group B and cannot be distinguished at the 5% level. The same is true for fertilizers 10-08-22 and 18-24-06 in group C.

Fertilizer 29-03-04 and fertilizer 10-08-22 have no letters in common, indicating that the mean yields of these two groups are significantly different at the 5% level. We can conclude that any other fertilizers without a letter in common have significantly different means as well.

Adjusting for multiple comparisons

The statistics in the examples above take no account that we are performing 10 comparisons. With our 5% significance level and assuming the comparisons are independent, we expect 1 in 20 tests of comparisons to be significant, even if all the population means are truly the same. If we are performing many comparisons, then we should account for the fact that some tests will be found significant by chance alone. More formally, the test for each pairwise comparison is made without adjusting for the elevated type I experimentwise error rate that is introduced when performing multiple tests. We can use the `mcompare()` option to adjust the confidence intervals and $p$-values for multiple comparisons.

Tukey’s method

Of the available adjustments for multiple comparisons, Tukey’s honestly significant difference, Student–Newman–Keuls’s method, and Duncan’s method are most often used when performing all pairwise comparisons of means. Of these, Tukey’s method is the most conservative and Duncan’s method is the least conservative. For further discussion of each of the multiple-comparison adjustments, see \[R\] `pwcompare`.

Here we use Tukey’s adjustment to compute $p$-values and confidence intervals for the pairwise differences.

When using a 5% significance level, Tukey’s adjustment indicates that four pairs of means are different. With the adjustment, we no longer conclude that the difference in the mean yields for fertilizers 10-08-22 and 10-10-10 is significantly different from zero.
Dunnett’s method

Now, let’s suppose that fertilizer 10-10-10 actually represents fields on which no fertilizer was applied. In this case, we can use Dunnett’s method for comparing each of the fertilizers with the control.

```
.pwmean yield, over(fertilizer) effects mcompare(dunnett)
Pairwise comparisons of means with equal variances
Over: fertilizer

<table>
<thead>
<tr>
<th></th>
<th>Number of comparisons</th>
</tr>
</thead>
<tbody>
<tr>
<td>fertilizer</td>
<td>4</td>
</tr>
</tbody>
</table>
```

|       | Contrast  | Std. err. | t    | P>|t| | Dunnett | Dunnett |
|-------|-----------|-----------|------|------|---------|---------|
| yield |           |           |      |      | [95% conf. interval] |
| fertilizer 10-08-22 | 3.62272 | 1.589997 | 2.28 | 0.079 | -0.2918331 | 7.537273 |
| vs 10-10-10 | .4906299 | 1.589997 | 0.31 | 0.994 | -3.423923 | 4.405183 |
| vs 16-04-08 | 4.922803 | 1.589997 | 3.10 | 0.008 | 1.00825 | 8.837356 |
| vs 18-24-06 | -1.238328 | 1.589997 | -0.78 | 0.852 | -5.152881 | 2.676225 |

Using Dunnett’s adjustment, we conclude that only fertilizer 4 (18-24-06) produces a mean yield that is significantly different from the mean yield of the field with no fertilizer applied.

By default, `pwmean` treats the lowest level of the group variable as the control. If, for instance, fertilizer 3 (16-04-08) was our control group, we could type

```
.pwmean yield, over(b3.fertilizer) effects mcompare(dunnett)
```

using the `b3.` factor-variable operator to specify this level as the reference level.
Multiple over() variables

When we specify more than one variable in the over() option, pairwise comparisons are performed for the means defined by each combination of levels of these variables.

```
. pwmean yield, over(fertilizer irrigation) group
Pairwise comparisons of means with equal variances
Over: fertilizer irrigation
```

<table>
<thead>
<tr>
<th>yield</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Unadjusted groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>10-10-10#0</td>
<td>36.91257</td>
<td>1.116571</td>
<td>A</td>
</tr>
<tr>
<td>10-10-10#1</td>
<td>45.81229</td>
<td>1.116571</td>
<td>B</td>
</tr>
<tr>
<td>10-08-22#0</td>
<td>38.79482</td>
<td>1.116571</td>
<td>A C</td>
</tr>
<tr>
<td>10-08-22#1</td>

<tr>
<td>29-03-04#1</td>
<td>44.55313</td>
<td>1.116571</td>
<td>B D</td>
</tr>
</tbody>
</table>

Note: Means sharing a letter in the group label are not significantly different at the 5% level.

Here the row labeled 10-10-10#0 is the mean for the fields treated with fertilizer 10-10-10 and without irrigation. This mean is significantly different from the mean of all fertilizer/irrigation pairings that do not have an A in the “Unadjusted groups” column. These include all pairings where the fields were irrigated as well as the fields treated with fertilizer 18-24-06 but without irrigation.

Equal variance assumption

The `pwmean` command performs multiple comparisons assuming that there is a common variance for all groups. In the case of two groups, this is equivalent to performing the familiar two-sample t test when equal variances are assumed.
```
test yield, by(irrigation)
Two-sample t test with equal variances

<table>
<thead>
<tr>
<th>Group</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>100</td>
<td>37.91277</td>
<td>.5300607</td>
<td>5.300607</td>
<td>36.86102 38.96453</td>
</tr>
<tr>

</tr>
</tbody>
</table>

diff = mean(0) - mean(1)  \( t = -12.9557 \)
H0: diff = 0  \( \text{Degrees of freedom} = 198 \)
Ha: diff < 0  \( \text{Pr}(T < t) = 0.0000 \)
Ha: diff != 0  \( \text{Pr}(|T| > |t|) = 0.0000 \)
Ha: diff > 0  \( \text{Pr}(T > t) = 1.0000 \)

pwmean yield, over(irrigation) effects
Pairwise comparisons of means with equal variances
Over: irrigation

| yield | Contrast | Std. err. | Unadjusted t | P>|t| | Unadjusted [95% conf. interval] |
|-------|----------|-----------|--------------|--------|-----------------------------|
| irrigation |       |           |              |        |                            |
| 0 vs 1 | 10.01844 | .7732872 | 12.96        | 0.0000 | 8.493509 11.54338          |
```

The signs for the difference, the test statistic, and the confidence intervals are reversed because the difference is taken in the opposite direction. The \( p \)-value from \textit{pwmean} is equivalent to the one for the two-sided test in the \textit{ttest} output.

\textit{pwmean} extends the capabilities of \textit{ttest} to allow for simultaneously comparing all pairs of means and to allow for using one common variance estimate for all the tests instead of computing a separate pooled variance for each pair of means when using multiple \textit{ttest} commands. In addition, \textit{pwmean} allows adjustments for multiple comparisons, many of which rely on an assumption of equal variances among groups.
Stored results

`pwmean` stores the following in `e()`:

Scalars
- `e(df_r)`: variance degrees of freedom
- `e(balanced)`: 1 if fully balanced data, 0 otherwise

Macros
- `e(cmd)`: `pwmean`
- `e(cmdline)`: command as typed
- `e(title)`: title in output
- `e(depvar)`: name of variable from which the means are computed
- `e(over)`: `varlist` from `over()`
- `e(properties)`: `b V`

Matrices
- `e(b)`: mean estimates
- `e(V)`: variance–covariance matrix of the mean estimates
- `e(error)`: mean estimability codes;
  - 0 means estimable,
  - 8 means not estimable
- `e(b_vs)`: mean difference estimates
- `e(V_vs)`: variance–covariance matrix of the mean difference estimates
- `e(error_vs)`: mean difference estimability codes;
  - 0 means estimable,
  - 8 means not estimable

In addition to the above, the following is stored in `r()`:

Scalars
- `r(level)`: confidence level of confidence intervals

Macros
- `r(groups#)`: group codes for the #th margin in `r(b)`
- `r(mcmethod_vs)`: `method` from `mcompare()`
- `r(mctitle_vs)`: title for `method` from `mcompare()`

Matrices
- `r(table)`: matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals
- `r(table_vs)`: matrix containing the margin differences with their standard errors, test statistics, \( p \)-values, and confidence intervals
- `r(k_groups)`: number of significance groups for each term

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

Methods and formulas

`pwmean` is a convenience command that uses `pwcompare` after fitting a fully factorial linear model. See *Methods and formulas* described in [R] `pwcompare`.

<td>1.589997</td>
<td>-9.29693</td>
</tr>
</tbody>
</table>
```

After `pwmean`, we can use `testnl` to test whether the improvement in mean wheat yield when using fertilizer 18-24-06 instead of fertilizer 29-03-04 is significantly different from 10%.
. testnl (_b[4.fertilizer] - _b[5.fertilizer])/_b[5.fertilizer] = 0.1
(1) (_b[4.fertilizer] - _b[5.fertilizer])/_b[5.fertilizer] = 0.1

    chi2(1) =  1.57
    Prob > chi2 =  0.2106

The improvement is not significantly different from 10%.

Also see

[R] pwmean — Pairwise comparisons of means
[U] 20 Estimation and postestimation commands
Description

These commands provide standard quality-control charts. `cchart` draws a c chart; `pchart`, a p (fraction-defective) chart; `rchart`, an R (range or dispersion) chart; `xchart`, an \( \bar{X} \) (control line) chart; and `shewhart`, vertically aligned \( \bar{X} \) and R charts.

Quick start

c chart for dvar defects per unit identified by uvar
   `cchart dvar uvar`

p chart for dvar defective items out of nvar items inspected from each unit identified by uvar
   `pchart dvar uvar nvar`
   Same as above, but stabilize the p chart for unequal numbers of items inspected per unit
   `pchart dvar uvar nvar, stabilized`

R chart for the range of measurements m1, m2, m3, and m4
   `rchart m1 m2 m3 m4, connect(1)`
   Same as above, but use known process standard deviation of 0.5 for control limits
   `rchart m1 m2 m3 m4, connect(1) std(.5)`

\( \bar{X} \) chart for measurements m1, m2, m3, and m4
   `xchart m1 m2 m3 m4, connect(1)`
   Same as above, but use known process standard deviation of 0.5 and grand mean of 10 for control limits
   `xchart m1 m2 m3 m4, connect(1) std(.5) mean(10)`

Shewhart chart with vertically aligned R and \( \bar{X} \) charts
   `shewhart m1 m2 m3 m4, connect(1) std(.5) mean(10)`

### pchart_options

**Main**

- **stabilized**
  - stabilize the p chart when sample sizes are unequal
- **nograph**
  - suppress graph
- **generate(newvar_f, newvar_lcl, newvar_ucl)**
  - store the fractions of defective elements and the lower and upper control limits

**Plot**

- **connect_options**
  - affect rendition of the plotted points
- **marker_options**
  - change look of markers (color, size, etc.)
- **marker_label_options**
  - add marker labels; change look or position

**Control limits**

- **clopts(cline_options)**
  - affect rendition of the control limits

**Add plots**

- **addplot(plot)**
  - add other plots to the generated graph

**Y axis, X axis, Titles, Legend, Overall**

- **twoway_options**
  - any options other than by() documented in [G-3] *twoway_options*

### rchart_options

**Main**

- **std(#)***
  - user-specified standard deviation
- **nograph**
  - suppress graph

**Plot**

- **connect_options**
  - affect rendition of the plotted points
- **marker_options**
  - change look of markers (color, size, etc.)
- **marker_label_options**
  - add marker labels; change look or position

**Control limits**

- **clopts(cline_options)**
  - affect rendition of the control limits

**Add plots**

- **addplot(plot)**
  - add other plots to the generated graph

**Y axis, X axis, Titles, Legend, Overall**

- **twoway_options**
  - any options other than by() documented in [G-3] *twoway_options*
### xchart_options

collect is allowed with all QC commands; see [U] 11.1.10 Prefix commands.

### Options

- stabilized stabilizes the p chart when sample sizes are unequal.
- `std(#)` specifies the standard deviation of the process. The R chart is calculated (based on the range) if this option is not specified.
\texttt{mean(\#)} specifies the grand mean, which is calculated if not specified. \texttt{lower(\#)} and \texttt{upper(\#)} must be specified together or not at all. They specify the lower and upper limits of the $\bar{X}$ chart. Calculations based on the mean and standard deviation (whether specified by option or calculated) are used otherwise.

\texttt{nograph} suppresses the graph.

\texttt{generate(newvar \_f newvar \_lcl newvar \_ucl)} stores the plotted values in the $p$ chart. \texttt{newvar \_f} will contain the fractions of defective elements; \texttt{newvar \_lcl} and \texttt{newvar \_ucl} will contain the lower and upper control limits, respectively.

\texttt{Plot} \[\texttt{connect\_options}\] affect whether lines connect the plotted points and the rendition of those lines; see \[\texttt{G-3 connect\_options}\].

\texttt{marker\_options} affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see \[\texttt{G-3 marker\_options}\].

\texttt{marker\_label\_options} specify if and how the markers are to be labeled; see \[\texttt{G-3 marker\_label\_options}\].

\texttt{Control limits} \[\texttt{clopts(cline\_options)}\] affects the rendition of the control limits; see \[\texttt{G-3 cline\_options}\].

\texttt{Add plots} \[\texttt{addplot(plot)}\] provides a way to add other plots to the generated graph. See \[\texttt{G-3 addplot\_option}\].

\texttt{Y axis, X axis, Titles, Legend, Overall} \[\texttt{twoway\_options}\] are any of the options documented in \[\texttt{G-3 twoway\_options}\], excluding \texttt{by()}. These include options for titling the graph (see \[\texttt{G-3 title\_options}\]) and for saving the graph to disk (see \[\texttt{G-3 saving\_option}\]).

\texttt{combine\_options (shewhart only)} are any of the options documented in \[\texttt{G-2 graph combine}\]. These include options for titling the graph (see \[\texttt{G-3 title\_options}\]) and for saving the graph to disk (see \[\texttt{G-3 saving\_option}\]).

**Remarks and examples**

Control charts may be used to define the goal of a repetitive process, to control that process, and to determine if the goal has been achieved. Walter A. Shewhart of Bell Telephone Laboratories devised the first control chart in 1924. In 1931, Shewhart published \textit{Economic Control of Quality of Manufactured Product}. According to Burr, “Few fields of knowledge have ever been so completely explored and charted in the first exposition” (1976, 29). Shewhart states that “a phenomenon will be said to be controlled when, through the use of past experience, we can predict, at least within limits, how the phenomenon may be expected to vary in the future. Here it is understood that prediction within limits means that we can state, at least approximately, the probability that the observed phenomenon will fall within given limits” (1931, 6).

For more information on quality-control charts, see \textbf{Burr} (1976), \textbf{Duncan} (1986), \textbf{Harris} (1999), or \textbf{Ryan} (2011).
Example 1: cchart

ccchart graphs a c chart showing the number of nonconformities in a unit, where `defect_var` records the number of defects in each inspection unit and `unit_var` records the unit number. The unit numbers need not be in order. For instance, consider the following example dataset from Ryan (2011, 186):

```
.use https://www.stata-press.com/data/r18/ncu
.describe

```
.cchart defects day, title(c chart for nonconforming transistors)
```

The expected number of defects is 10.6, with lower and upper control limits of 0.8327 and 20.37, respectively. No units are out of control.
Example 2: pchart

pchart graphs a p chart, which shows the fraction of nonconforming items in a subgroup, where \( \text{reject}\_var \) records the number rejected in each inspection unit, \( \text{unit}\_var \) records the inspection unit number, and \( \text{ssize}\_var \) records the number inspected in each unit.

Consider the example dataset from Ryan (2011, 186) of the number of nonconforming transistors out of 1,000 inspected each day during the month of April:

```
. use https://www.stata-press.com/data/r18/ncu2
. describe
Contains data from https://www.stata-press.com/data/r18/ncu2.dta
Observations: 30
Variables: 3
2 Dec 2022 15:16

  name      type    format      label          Variable label
---------  ------    -------      -------------      ---------------
  day      byte    %9.0g      Day in April
rejects   byte    %9.0g      Number of nonconforming units
 ssize    int     %9.0g      Sample size
```

Sorted by:
```
. list in 1/5

<table>
<thead>
<tr>
<th>day</th>
<th>rejects</th>
<th>ssize</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>1000</td>
</tr>
<tr>
<td>5</td>
<td>9</td>
<td>1000</td>
</tr>
</tbody>
</table>
```

```
. pchart rejects day ssize
```

All the points are within the control limits, which are 0.0009 for the lower limit and 0.0203 for the upper limit.
Here the sample sizes are fixed at 1,000, so the `ssize` variable contains 1,000 for each observation. Sample sizes need not be fixed, however. Say that our data were slightly different:

```

</tr>
</tbody>
</table>
+-----+-----+-----+
```

\[ \text{. pchart rejects day ssize} \]

![Stabilized p Chart](chart.png)

Here the control limits are, like the sample size, no longer constant. The `stabilize` option will stabilize the control chart:

```
. pchart rejects day ssize, stabilize
```

![Stabilized p Chart](chart.png)

0 units are out of control.
Stabilized p Chart, average number of defects = .0119.
Example 3: rchart

rchart displays an R chart showing the range for repeated measurements at various times. Variables within observations record measurements. Observations represent different samples.

For instance, say that we take five samples of 5 observations each. In our first sample, our measurements are 10, 11, 10, 11, and 12. The data are

<td>12</td>
</tr>
</tbody>
</table>

. rchart m1-m5, connect(1)

The expected range in each sample is 2 with lower and upper control limits of 0 and 4.23, respectively. If we know that the process standard deviation is 0.3, we could specify
Example 4: xchart

xchart graphs an $\bar{X}$ chart for repeated measurements at various times. Variables within observations record measurements, and observations represent different samples. Using the same data as in the previous example, we type

```
xchart m1-m5, connect(l)
```

The average measurement in the sample is 10.64, and the lower and upper control limits are 9.486 and 11.794, respectively. Suppose that we knew from prior information that the mean of the process is 11. Then, we would type
If we also know that the standard deviation of the process is 0.3, we could type

`. xchart m1-m5, connect(1) mean(11) std(.3)`

Finally, `xchart` allows us to specify our own control limits:
Example 5: `shewhart`

`shewhart` displays a vertically aligned $\bar{X}$ and $R$ chart in the same image. To produce the best-looking combined image possible, you will want to use the `xchart` and `rchart` commands separately and then combine the graphs. `shewhart`, however, is more convenient.

Using the same data as previously, but realizing that the standard deviation should have been 0.4, we type

```
    . shewhart m1-m5, connect(l) mean(11) std(.4)
```

The resulting graphs show that 3 units are out of control.
Walter Andrew Shewhart (1891–1967) was born in Illinois and educated as a physicist, with degrees from the Universities of Illinois and California. After a brief period teaching physics, he worked for the Western Electric Company and (from 1925) the Bell Telephone Laboratories. His name is most associated with control charts used in quality controls, but his many other interests ranged generally from quality assurance to the philosophy of science.

Stored results

**cchart** stores the following in r():

Scalars
- r(cbar) expected number of nonconformities
- r(lcl_c) lower control limit
- r(ucl_c) upper control limit
- r(N) number of observations
- r(out_c) number of units out of control
- r(below_c) number of units below the lower limit
- r(above_c) number of units above the upper limit

**pchart** stores the following in r():

Scalars
- r(pbar) average fraction of nonconformities
- r(lcl_p) lower control limit
- r(ucl_p) upper control limit
- r(N) number of observations
- r(out_p) number of units out of control
- r(below_p) number of units below the lower limit
- r(above_p) number of units above the upper limit

**rchart** stores the following in r():

Scalars
- r(central_line) ordinate of the central line
- r(lcl_r) lower control limit
- r(ucl_r) upper control limit
- r(N) number of observations
- r(out_r) number of units out of control
- r(below_r) number of units below the lower limit
- r(above_r) number of units above the upper limit

**xchart** stores the following in r():

 Scalars
- r(xbar) grand mean
- r(lcl_x) lower control limit
- r(ucl_x) upper control limit
- r(N) number of observations
- r(out_x) number of units out of control
- r(below_x) number of units below the lower limit
- r(above_x) number of units above the upper limit

**shewhart** stores in r() the combination of stored results from **xchart** and **rchart**.
Methods and formulas

For the c chart, the number of defects per unit, $C$, is taken to be a value of a random variable having a Poisson distribution. If $k$ is the number of units available for estimating $\lambda$, the parameter of the Poisson distribution, and if $C_i$ is the number of defects in the $i$th unit, then $\lambda$ is estimated by $
olimits C = \sum_i C_i/k$. Then

\[
\text{central line} = C \\
\text{UCL} = C + 3\sqrt{C} \\
\text{LCL} = C - 3\sqrt{C}
\]

Control limits for the p chart are based on the sampling theory for proportions, using the normal approximation to the binomial. If $k$ samples are taken, the estimator of $p$ is given by $\hat{p} = \sum_i \hat{p}_i/k$, where $\hat{p}_i = x_i/n_i$, and $x_i$ is the number of defects in the $i$th sample of size $n_i$. The central line and the control limits are given by

\[
\text{central line} = \hat{p} \\
\text{UCL} = \hat{p} + 3\sqrt{\hat{p}(1-\hat{p})/n_i} \\
\text{LCL} = \hat{p} - 3\sqrt{\hat{p}(1-\hat{p})/n_i}
\]

Control limits for the R chart are based on the distribution of the range of samples of size $n$ from a normal population. If the standard deviation of the process, $\sigma$, is known,

\[
\text{central line} = d_2 \sigma \\
\text{UCL} = D_2 \sigma \\
\text{LCL} = D_1 \sigma
\]

where $d_2$, $D_1$, and $D_2$ are functions of the number of observations in the sample and are obtained from the table published in Beyer (1976).

When $\sigma$ is unknown,

\[
\text{central line} = \bar{R} \\
\text{UCL} = (D_2/d_2)\bar{R} \\
\text{LCL} = (D_1/d_2)\bar{R}
\]

where $\bar{R} = \sum_i R_i/k$ is the range of the $k$ sample ranges $R_i$.

Control limits for the $\bar{X}$ chart are given by

\[
\text{central line} = \bar{x} \\
\text{UCL} = \bar{x} + (3/\sqrt{n})\sigma \\
\text{LCL} = \bar{x} - (3/\sqrt{n})\sigma
\]
if \( \sigma \) is known. If \( \sigma \) is unknown,  

\[
\text{central line} = \bar{x} = \frac{\sum x}{n} \\
\text{UCL} = \bar{x} + A_2 \bar{R} \\
\text{LCL} = \bar{x} - A_2 \bar{R}
\]

where \( \bar{R} \) is the average range as defined above and \( A_2 \) is a function (op. cit.) of the number of observations in the sample.

Isobel Loutit (1909–2009) is known for her work during World War II to improve the accuracy of targeting for anti-aircraft guns and as a contributor to the field of quality control. Loutit was born in Selkirk Manitoba, Canada. She graduated from the University of Manitoba in 1929 with a degree in mathematics and was one of the first women to work as a professional statistician in Canada. After graduation, she obtained a job teaching French. However, because of her training, she served as a substitute math teacher when needed.

When World War II started, Loutit took a job as a quality control statistician at Northern Electric. Shortly after that, the Canadian government advertised for women with technical training to fill jobs that had been vacated by men who had gone to war. She took a position testing equipment for the military. This job eventually returned her to Northern Electric, this time as a government employee verifying the accuracy of Northern Electric’s Vickers anti-aircraft gun predictor, which was used to aim artillery at incoming planes. Recognizing the quality of her work, the CEO of Northern Electric rehired Loutit as an engineer, the only position for which her pay would not be capped as a woman. She later became the first female manager at Northern Electric and the first woman to chair the Montreal Section of the American Society for Quality Control.

**Description**

`qreg` fits quantile (including median) regression models, also known as least absolute value, minimum absolute deviation, or minimum L1-norm value. The quantile regression models fit by `qreg` express the quantiles of the conditional distribution as linear functions of the independent variables.

`iqreg` estimates interquantile range regressions, regressions of the difference in quantiles. The estimated variance–covariance matrix of the estimators (VCE) is obtained via bootstrapping.

`sqreg` estimates simultaneous-quantile regression. It produces the same coefficients as `qreg` for each quantile. Reported standard errors will be similar, but `sqreg` obtains an estimate of the VCE via bootstrapping, and the VCE includes between-quantile blocks. Thus, you can test and construct confidence intervals comparing coefficients describing different quantiles.

 bsqreg is equivalent to `sqreg` with one quantile.

**Quick start**

**Quantile regression**

Median regression of \( y \) on \( x_1 \) and \( x_2 \)

`qreg y x1 x2`

Add categorical covariate `a` using factor-variable syntax

`qreg y x1 x2 i.a`

Same as above, but with standard errors using a biweight kernel for the nonparametric density estimator

`qreg y x1 x2 i.a, vce(, kernel(biweight))`

Quantile regression of the 75th percentile of \( y \) on \( x_1, x_2, \) and \( a \)

`qreg y x1 x2 i.a, quantile(.75)`

**Interquantile range regression**

Difference between the 90th and 10th quantiles of \( y \) on \( x_1, x_2, \) and \( a \) with bootstrap standard errors

`iqreg y x1 x2 i.a, quantiles(.1 .9)`
Simultaneous-quantile regression

Simultaneous estimation of quantile regressions for the 10th and 90th quantiles of $y$ with bootstrap standard errors

sqreg y x1 x2 i.a, quantiles(.1 .9)

Same as above, but for the 25th, 50th, and 75th quantiles of $y$

sqreg y x1 x2 i.a, quantiles(.25 .5 .75)

Same as above, but increase the number of bootstrap replications to 500

sqreg y x1 x2 i.a, quantiles(.25 .5 .75) reps(500)

Bootstrapped quantile regression

Single quantile regression for the 25th quantile with bootstrap standard errors

bsqreg y x1 x2 i.a, quantile(.25)

**indepvars** may contain factor variables; see [U] 11.4.3 Factor variables.

by, collect, mi estimate, rolling, and statsby, are allowed by qreg, iqreg, sqreg, and bsqreg; mfp, nestreg, and stepwise are allowed only with qreg; see [U] 11.1.10 Prefix commands.

qreg allows fweights, iweights, and pweights; see [U] 11.1.6 weight.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

---

### Options for qreg

**Model**

- **quantile(#)**: specifies the quantile to be estimated and should be a number between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default value of 0.5 corresponds to the median.

**SE/Robust**

- **vce([ vctype ], [ vceopts ])**: specifies the type of VCE to compute and the density estimation method to use in computing the VCE.

  - **vctype**: specifies the type of VCE to compute. Available types are iid and robust.
    - **vce(iid)**, the default, computes the VCE under the assumption that the residuals are independent and identically distributed (i.i.d.).
    - **vce(robust)** computes the robust VCE under the assumption that the residual density is continuous and bounded away from 0 and infinity at the specified quantile(); see Koenker (2005, sec. 4.2).
vceopts consists of available `denmethod` and `bwidth` options.

`denmethod` specifies the method to use for the nonparametric density estimator. Available methods are `fitted`, `residual`, or `kernel[ (kernel) ]`, where the optional `kernel` must be one of the kernel choices listed below.

`fitted` and `residual` specify that the nonparametric density estimator use some of the structure imposed by quantile regression. The default `fitted` uses a function of the fitted values and `residual` uses a function of the residuals. `vce(robust, residual)` is not allowed.

`kernel()` specifies that the nonparametric density estimator use a kernel method. The available kernel functions are `epanechnikov`, `epan2`, `biweight`, `cosine`, `gaussian`, `parzen`, `rectangle`, and `triangle`. The default is `epanechnikov`. See `kdensity` for the kernel function forms.

`bwidth` specifies the bandwidth method to use by the nonparametric density estimator. Available methods are `hsheather` for the Hall–Sheather bandwidth, `bofinger` for the Bofinger bandwidth, and `chamberlain` for the Chamberlain bandwidth.

See Koenker (2005, sec. 3.4 and 4.10) for a description of the sparsity estimation techniques and the Hall–Sheather and Bofinger bandwidth formulas. See Chamberlain (1994, eq. 2.2) for the Chamberlain bandwidth.

----------

### Reporting

`level(#)`; see [R] Estimation options.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] Estimation options.

----------

### Optimization

`optimization_options`: `iterate(#)`, `[no]log, `trace`. `iterate()` specifies the maximum number of iterations; `log`/`nolog` specifies whether to show the iteration log (see `set iterlog` in [R] `set`); and `trace` specifies that the iteration log should include the current parameter vector. These options are seldom used.

`wlsiter(#)` specifies the number of weighted least-squares iterations that will be attempted before the linear programming iterations are started. The default is `wlsiter(1)`. If there are convergence problems, increasing this number should help.

----------

### Options for iqreg

`quantiles(# #)` specifies the quantiles to be compared. The first number must be less than the second, and both should be between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. Not specifying this option is equivalent to specifying `quantiles(.25 .75)`, meaning the interquantile range.

`reps(#)` specifies the number of bootstrap replications to be used to obtain an estimate of the variance–covariance matrix of the estimators (standard errors). `reps(20)` is the default and is arguably too small. `reps(100)` would perform 100 bootstrap replications. `reps(1000)` would perform 1,000 replications.
Options for sqreg

Model

quantiles(# [# [# ...]] ) specifies the quantiles to be estimated and should contain numbers between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default value of 0.5 corresponds to the median.

reps(#) specifies the number of bootstrap replications to be used to obtain an estimate of the variance–covariance matrix of the estimators (standard errors). reps(20) is the default and is arguably too small. reps(100) would perform 100 bootstrap replications. reps(1000) would perform 1,000 replications.

Options for bsqreg

Model

quantile(#) specifies the quantile to be estimated and should be a number between 0 and 1, exclusive. Numbers larger than 1 are interpreted as percentages. The default value of 0.5 corresponds to the median.

reps(#) specifies the number of bootstrap replications to be used to obtain an estimate of the variance–covariance matrix of the estimators (standard errors). reps(20) is the default and is arguably too small. reps(100) would perform 100 bootstrap replications. reps(1000) would perform 1,000 replications.
Remarks and examples

Remarks are presented under the following headings:

- Median regression
- Quantile regression
- Estimated standard errors
- Interquantile and simultaneous-quantile regression
- What are the parameters?

Median regression

qreg fits quantile regression models. The default form is median regression, where the objective is to estimate the median of the dependent variable, conditional on the values of the independent variables. This method is similar to ordinary regression, where the objective is to estimate the conditional mean of the dependent variable. Simply put, median regression finds a line through the data that minimizes the sum of the \textit{absolute} residuals rather than the sum of the \textit{squares} of the residuals, as in ordinary regression. Equivalently, median regression expresses the median of the conditional distribution of the dependent variable as a linear function of the conditioning (independent) variables. Cameron and Trivedi (2022, chap. 15) provide a nice introduction to quantile regression using Stata.

\section*{Example 1: Estimating the conditional median}

Consider a two-group experimental design with 5 observations per group:

. qreg y x
Iteration 1: WLS sum of weighted deviations = 60.941342
Iteration 1: Sum of abs. weighted deviations = 55.5
Iteration 2: Sum of abs. weighted deviations = 55
Median regression Number of obs = 10
Raw sum of deviations 78.5 (about 14)
Min sum of deviations 55 Pseudo R2 = 0.2994

|   | Coefficient | Std. err. | t   | P>|t|   | [95% conf. interval] |
|---|-------------|-----------|-----|-------|---------------------|
| x | 17          | 18.23213  | 0.93| 0.378 | -25.04338 - 59.04338 |
| _cons | 3          | 12.89207  | 0.23| 0.822 | -26.72916 - 32.72916 |
We have estimated the equation
\[ \hat{y}_{\text{median}} = 3 + 17x \]
We look back at our data. \( x \) takes on the values 0 and 1, so the median for the \( x = 0 \) group is 3, whereas for \( x = 1 \) it is \( 3 + 17 = 20 \). The output reports that the raw sum of absolute deviations about 14 is 78.5; that is, the sum of \( |y - 14| \) is 78.5. Fourteen is the unconditional median of \( y \), although in these data, any value between 14 and 19 could also be considered an unconditional median (we have an even number of observations, so the median is bracketed by those two values). In any case, the raw sum of deviations of \( y \) about the median would be the same no matter what number we choose between 14 and 19. (With a “median” of 14, the raw sum of deviations is 78.5. Now think of choosing a slightly larger number for the median and recalculating the sum. Half the observations will have larger negative residuals, but the other half will have smaller positive residuals, resulting in no net change.)

We turn now to the actual estimated equation. The sum of the absolute deviations about the solution \( \hat{y}_{\text{median}} = 3 + 17x \) is 55. The pseudo-\( R^2 \) is calculated as \( 1 - 55/78.5 \approx 0.2994 \). This result is based on the idea that the median regression is the maximum likelihood estimate for the double-exponential distribution.

Technical note

\texttt{qreg} is an alternative to regular regression or robust regression—see \texttt{[R] regress} and \texttt{[R] rreg}. Let’s compare the results:

\end{verbatim}

Unlike \texttt{qreg}, \texttt{regress} fits ordinary linear regression and is concerned with predicting the mean rather than the median, so both results are, in a technical sense, correct. Putting aside those technicalities, however, we tend to use either regression to describe the central tendency of the data, of which the mean is one measure and the median another. Thus, we can ask, “which method better describes the central tendency of these data?”

Means—and therefore ordinary linear regression—are sensitive to outliers, and our data were purposely designed to contain two such outliers: 95 for \( x = 0 \) and 14 for \( x = 1 \). These two outliers dominated the ordinary regression and produced results that do not reflect the central tendency well—you are invited to enter the data and graph \( y \) against \( x \).
Robust regression attempts to correct the outlier-sensitivity deficiency in ordinary regression:

```
rreg y x, genwt(wt)
```

Huber iteration 1: Maximum difference in weights = .7311828
Huber iteration 2: Maximum difference in weights = .1769779
Huber iteration 3: Maximum difference in weights = .03149585

Biweight iteration 4: Maximum difference in weights = .1993335
Biweight iteration 5: Maximum difference in weights = .2332905
Biweight iteration 6: Maximum difference in weights = .09960067
Biweight iteration 7: Maximum difference in weights = .02691458
Biweight iteration 8: Maximum difference in weights = .0009113

Robust regression

|       | Coefficient | Std. err. | t     | P>|t| | [95% conf. interval] |
|-------|-------------|-----------|-------|-----|----------------------|
| x     | 18.16597    | 2.023114  | 8.98  | 0.000 | 13.50066 – 22.83128  |
| _cons | 2.000003    | 1.430558  | 1.40  | 0.200 | -1.298869 – 5.298875 |

Robust regression Number of obs = 10
F( 1, 8) = 80.63
Prob > F = 0.0000

Here `rreg` discarded the first outlier completely. (We know this because we included the `genwt()` option on `rreg` and, after fitting the robust regression, examined the weights.) For the other “outlier”, `rreg` produced a weight of 0.47.

In any case, the answers produced by `qreg` and `rreg` to describe the central tendency are similar, but the standard errors are different. In general, robust regression will have smaller standard errors because it is not as sensitive to the exact placement of observations near the median. You are welcome to try removing the first outlier in the `qreg` estimation to observe an improvement in the standard errors by typing

```
rreg y x if _n!=5
```

Also, some authors (Rousseeuw and Leroy 1987, 11) have noted that quantile regression, unlike the unconditional median, may be sensitive to even one outlier if its leverage is high enough. Rousseeuw and Leroy (1987) discuss estimators that are more robust to perturbations to the data than either mean regression or quantile regression.

In the end, quantile regression may be more useful for the interpretation of the parameters that it estimates than for its robustness to perturbations to the data.

Example 2: Median regression

Let’s now consider a less artificial example using the automobile data described in [U] 1.2.2 Example datasets. Using median regression, we will regress each car’s price on its weight and length and whether it is of foreign manufacture:
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. qreg price weight length foreign

Iteration 1: WLS sum of weighted deviations =  56397.829
Iteration 1: Sum of abs. weighted deviations =  55950.5
Iteration 2: Sum of abs. weighted deviations =  55264.718
Iteration 3: Sum of abs. weighted deviations =  54762.283
Iteration 4: Sum of abs. weighted deviations =  54734.152
Iteration 5: Sum of abs. weighted deviations =  54552.638
note: alternate solutions exist.
Iteration 6: Sum of abs. weighted deviations =  54465.511
Iteration 7: Sum of abs. weighted deviations =  54443.699
Iteration 8: Sum of abs. weighted deviations =  54411.294

Median regression  Number of obs =     74
Raw sum of deviations 71102.5 (about 4934)  Pseudo R2 =  0.2347
Min sum of deviations 54411.29

|        | Coefficient | Std. err. | t     | P>|t|   | [95% conf. interval] |
|--------|-------------|-----------|-------|-------|---------------------|
| price  | 3.933588    | 1.328718  | 2.96  | 0.004 | 1.283543 6.583632   |
| weight | -41.25191   | 45.46469  | -0.91 | 0.367 | -131.9284 49.42456  |
| length | 3377.771    | 885.4198  | 3.81  | 0.000 | 1611.857 5143.685   |
| foreign| 344.6489    | 5182.394  | 0.07  | 0.947 | -9991.31 10680.61   |

The estimated equation is

\[ \text{price}_{\text{median}} = 3.93 \text{weight} - 41.25 \text{length} + 3377.8 \text{foreign} + 344.65 \]

The output may be interpreted in the same way as linear regression output; see [R] regress. The variables weight and foreign are significant, but length is not significant. The median price of the cars in these data is $4,934. This value is a median (one of the two center observations), not the median, which would typically be defined as the midpoint of the two center observations.

---

**Quantile regression**

Quantile regression is similar to median regression in that it estimates an equation expressing a quantile of the conditional distribution, albeit one that generally differs from the 0.5 quantile that is the median. For example, specifying `quantile(.25)` estimates the parameters that describe the 25th percentile (first quartile) of the conditional distribution.

Quantile regression allows for effects of the independent variables to differ over the quantiles. For example, Chamberlain (1994) finds that union membership has a larger effect on the lower quantiles than on the higher quantiles of the conditional distribution of U.S. wages. That the effects of the independent variables may vary over quantiles of the conditional distribution is an important advantage of quantile regression over mean regression.
Example 3: Estimating quantiles other than the median

Returning to real data, the equation for the 25th percentile of price conditional on weight, length, and foreign in our automobile data is

```
use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
qreg price weight length foreign, quantile(.25)
```

```
Iteration 1: WLS sum of weighted deviations = 49469.235
Iteration 2: Sum of abs. weighted deviations = 49728.883
Iteration 3: Sum of abs. weighted deviations = 43416.646
Iteration 4: Sum of abs. weighted deviations = 41947.221
Iteration 5: Sum of abs. weighted deviations = 41093.025
Iteration 6: Sum of abs. weighted deviations = 37623.424
Iteration 7: Sum of abs. weighted deviations = 35721.453
Iteration 8: Sum of abs. weighted deviations = 35226.308
Iteration 9: Sum of abs. weighted deviations = 34823.319
Iteration 10: Sum of abs. weighted deviations = 34801.777
```

```
.25 Quantile regression
Number of obs = 74
Raw sum of deviations 41912.75 (about 4187)
Min sum of deviations 34801.78 Pseudo R2 = 0.1697

|     | Coefficient | Std. err. |     t |     P>|t| |     [95% conf. interval] |
|-----|-------------|-----------|------|--------|--------------------------|
|     | price       |           |      |        |                          |
|     | weight      | 1.831789  | .6328903 | 2.89  | 0.005 | .5695289 | 3.094049 |
|     | length      | 2.84556   | 21.65558 | 0.13  | 0.896 | -40.34514 | 46.03626 |
|     | foreign     | 2209.925  | 421.7401 | 5.24  | 0.000 | 1368.791 | 3051.059 |
|     | _cons       | -1879.775 | 2468.46 | -0.76 | 0.449 | -6802.963 | 3043.413 |
```

Compared with our previous median regression, the coefficient on length now has a positive sign, and the coefficients on foreign and weight are reduced. The actual lower quantile is $4,187, substantially less than the median $4,934.
We can also estimate the upper quartile as a function of the same three variables:

```
. qreg price weight length foreign, quantile(.75)
Iteration 1:  WLS sum of weighted deviations =  55465.741
Iteration 1: Sum of abs. weighted deviations =  55652.957
Iteration 2: Sum of abs. weighted deviations =  52994.785
Iteration 3: Sum of abs. weighted deviations =  50189.446
Iteration 4: Sum of abs. weighted deviations =  49898.245
Iteration 5: Sum of abs. weighted deviations =  49398.106
Iteration 6: Sum of abs. weighted deviations =  49241.835
Iteration 7: Sum of abs. weighted deviations =  49197.967
```

<table>
<thead>
<tr>
<th>.75 Quantile regression</th>
<th>Number of obs = 74</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw sum of deviations 79860.75 (about 6342)</td>
<td></td>
</tr>
<tr>
<td>Min sum of deviations 49197.97</td>
<td>Pseudo R2 = 0.3840</td>
</tr>
</tbody>
</table>

| price | Coefficient | Std. err. | t | P>|t| | [95% conf. interval] |
|-------|-------------|-----------|---|------|----------------------|
| weight | 9.22291 | 1.785767 | 5.16 | 0.000 | 5.66131 12.78451 |
| length | -220.7833 | 61.10352 | -3.61 | 0.001 | -342.6504 -98.91616 |
| foreign | 3595.133 | 1189.984 | 3.02 | 0.004 | 1221.785 5968.482 |
| _cons | 20242.9 | 6965.02 | 2.91 | 0.005 | 6351.61 34134.2 |

This result tells a different story: `weight` is much more important, and `length` is now significant—with a negative coefficient! The prices of high-priced cars seem to be determined by factors different from those affecting the prices of low-priced cars.

**Technical note**

One explanation for having substantially different regression functions for different quantiles is that the data are heteroskedastic, as we will demonstrate below. The following statements create a sharply heteroskedastic set of data:

```
. drop _all
. set obs 10000
Number of observations (_N) was 0, now 10,000.
. set seed 50550
. generate x = .1 + .9 * runiform()
. generate y = x * runiform()^2
```
Let’s now fit the regressions for the 5th and 95th quantiles:

```
. qreg y x, quantile(.05)
Iteration 1:  WLS sum of weighted deviations =  555.44181
Iteration 1:  Sum of abs. weighted deviations =  555.25622
Iteration 2:  Sum of abs. weighted deviations =  115.02628
Iteration 3:  Sum of abs. weighted deviations =  89.617883
Iteration 4:  Sum of abs. weighted deviations =  89.61679
  .05 Quantile regression
  Number of obs =  10,000
  Raw sum of deviations 89.68001 (about .00105493)
  Min sum of deviations 89.61679
  Pseudo R2 =  0.0007
        y | Coefficient Std. err.       t     P>|t|   [95% conf. interval]
----------|--------------------|-------|--------|------------------|
     x |  .0028667   .0004395   6.52 0.000   .0020052   .0037283
_cons | -.0001135   .0002661  -0.43 0.670  -.0006352   .0004081
```

```
. qreg y x, quantile(.95)
Iteration 1:  WLS sum of weighted deviations =  624.91903
Iteration 1:  Sum of abs. weighted deviations =  621.88928
Iteration 2:  Sum of abs. weighted deviations =  182.03243
Iteration 3:  Sum of abs. weighted deviations =  170.42588
Iteration 4:  Sum of abs. weighted deviations =  169.05915
Iteration 5:  Sum of abs. weighted deviations =  169.05911
  .95 Quantile regression
  Number of obs =  10,000
  Raw sum of deviations 275.9779 (about .60579139)
  Min sum of deviations 169.05911
  Pseudo R2 =  0.3874
        y | Coefficient Std. err.       t     P>|t|   [95% conf. interval]
----------|--------------------|-------|--------|------------------|
     x |  .9010814   .0087580   102.89 0.000   .8839140   .9182488
_cons | -.0004053   .0053028  -0.08 0.939  -.0107999   .0099893
```

The coefficient on \( x \), in particular, differs markedly between the two estimates. For the mathematically inclined, it is not too difficult to show that the theoretical lines are \( y = 0.0025x \) for the 5th percentile and \( y = 0.9025x \) for the 95th, numbers in close agreement with our numerical results.

The estimator for the standard errors computed by `qreg` assumes that the sample is independent and identically distributed (i.i.d.); see *Estimated standard errors* and *Methods and formulas* for details. Because the data are conditionally heteroskedastic, we should have used `bsqreg` to consistently estimate the standard errors using a bootstrap method.

---

**Estimated standard errors**

The variance–covariance matrix of the estimator (VCE) depends on the reciprocal of the density of the dependent variable evaluated at the quantile of interest. This function, known as the “sparsity function”, is hard to estimate.

The default method, which uses the fitted values for the predicted quantiles, generally performs well, but other methods may be preferred in larger samples. The `vce()` suboptions *denmethod* and *bwidth* provide other estimators of the sparsity function, the details of which are described in *Methods and formulas*. 

Example 4: Obtaining robust standard errors

Example 2 of qreg on real data above was a median regression of price on weight, length, and foreign using auto.dta. Suppose, after investigation, we are convinced that car price observations are not independent. We decide that standard errors robust to non-i.i.d. errors would be appropriate and use the option vce(robust).

```
. use https://www.stata-press.com/data/r18/auto, clear
    (1978 automobile data)
. qreg price weight length foreign, vce(robust)
Iteration 1: WLS sum of weighted deviations =  56397.829
Iteration 1: Sum of abs. weighted deviations =  55950.5
Iteration 2: Sum of abs. weighted deviations =  55264.718
Iteration 3: Sum of abs. weighted deviations =  54762.283
Iteration 4: Sum of abs. weighted deviations =  54734.152
Iteration 5: Sum of abs. weighted deviations =  54552.638
note: alternate solutions exist.
Iteration 6: Sum of abs. weighted deviations =  54465.511
Iteration 7: Sum of abs. weighted deviations =  54443.699
Iteration 8: Sum of abs. weighted deviations =  54411.294
Median regression                       Number of obs =       74
Raw sum of deviations 71102.5 (about 4934)
Min sum of deviations 54411.29           Pseudo R2 =    0.2347

                      Coefficient    std. err.     t    P>|t|      [95% conf. interval]
     price
       weight  3.933588    1.694477     2.32   0.023    0.554060   7.313116
      length -41.25191    51.73571   -0.80   0.428   -144.4355   61.93171
     foreign  3377.771    728.5115     4.64   0.000    1924.801   4830.741
       _cons  344.6489    5096.528    0.07   0.946   -9820.055  10509.35
```

We see that the robust standard error for weight increases, making it less significant in modifying the median automobile price. The standard error for length also increases, but the standard error for the foreign indicator decreases.
For comparison, we repeat the estimation using bootstrap standard errors:

```
. use https://www.stata-press.com/data/r18/auto, clear
   (1978 automobile data)
. set seed 1001
. bsqreg price weight length foreign
   (fitting base model)
Bootstrap replications (20): ........10.........20 done
Median regression, bootstrap(20) SEs Number of obs = 74
   Raw sum of deviations  71102.5  (about 4934)
   Min sum of deviations  54411.29   Pseudo R2 = 0.2347

                      | Coefficient  Std. err.      t    P>|t|      [95% conf. interval]
---------------------|--------------------------|---------|----------|-----------------------------|
      price |weight               | 3.933588  2.941839     1.34     0.186    -1.933726   9.800901
        |length               | -41.25191  73.47105    -0.56     0.576   -187.7853   105.2815
        |foreign              | 3377.771   1352.518     2.50     0.015    680.2582   6075.284
        |_cons               | 344.6489   5927.045     0.06     0.954   -11476.47  12165.77
```

The coefficient estimates are the same—indeed, they are obtained using the same technique. Only the standard errors differ. Therefore, the $t$ statistics, significance levels, and confidence intervals also differ.

Because `bsqreg` (as well as `sqreg` and `iqreg`) obtains standard errors by randomly resampling the data, the standard errors it produces will not be the same from run to run unless we first set the random-number seed to the same number; see `[R] set seed`. 
By default, `bsqreg`, `sqreg`, and `iqreg` use 20 replications. We can control the number of replications by specifying the `reps()` option:

```plaintext
.bsqreg price weight length i.foreign, reps(1000)
```

(fitting base model)

Median regression, bootstrap(1000) SEs
Number of obs = 74
Raw sum of deviations 71102.5 (about 4934)
Min sum of deviations 54411.29 Pseudo R2 = 0.2347

| Variable | Coefficient | Std. err. | t | P>|t| | [95% conf. interval] |
|----------|-------------|-----------|---|-----|---------------------|
| weight   | 3.933588    | 2.58771   | 1.52 | 0.133 | -1.227437 to 9.094613 |
| length   | -41.25191   | 68.02626  | -0.61 | 0.546 | -176.926 to 94.42219  |
| foreign  | 3377.771    | 1070.777  | 3.15 | 0.002 | 1242.174 to 5513.368  |
| Foreign  | 344.6489    | 5862.991  | 0.06 | 0.953 | -11348.72 to 12038.02 |

A comparison of the standard errors is informative.

The results shown above are typical for models with heteroskedastic errors. (Our dependent variable is `price`; if our model had been in terms of \( \ln(price) \), the standard errors estimated by `qreg` and `bsqreg` would have been nearly identical.) Also, even for heteroskedastic errors, 20 replications is generally sufficient for hypothesis tests against 0.

---

**Interquantile and simultaneous-quantile regression**

Consider a quantile regression model where the \( q \)th quantile is given by

\[
Q_q(y) = a_q + b_{q,1}x_1 + b_{q,2}x_2
\]
For instance, the 75th and 25th quantiles are given by

\[
\begin{align*}
Q_{0.75}(y) &= a_{0.75} + b_{0.75,1}x_1 + b_{0.75,2}x_2 \\
Q_{0.25}(y) &= a_{0.25} + b_{0.25,1}x_1 + b_{0.25,2}x_2
\end{align*}
\]

The difference in the quantiles is then

\[
Q_{0.75}(y) - Q_{0.25}(y) = (a_{0.75} - a_{0.25}) + (b_{0.75,1} - b_{0.25,1})x_1 + (b_{0.75,2} - b_{0.25,2})x_2
\]

qreg fits models such as \(Q_{0.75}(y)\) and \(Q_{0.25}(y)\). iqreg fits interquantile models, such as \(Q_{0.75}(y) - Q_{0.25}(y)\). The relationships of the coefficients estimated by qreg and iqreg are exactly as shown: iqreg reports coefficients that are the difference in coefficients of two qreg models, and, of course, iqreg reports the appropriate standard errors, which it obtains by bootstrapping.

sqreg is like qreg in that it estimates the equations for the quantiles

\[
\begin{align*}
Q_{0.75}(y) &= a_{0.75} + b_{0.75,1}x_1 + b_{0.75,2}x_2 \\
Q_{0.25}(y) &= a_{0.25} + b_{0.25,1}x_1 + b_{0.25,2}x_2
\end{align*}
\]

The coefficients it obtains are the same that would be obtained by estimating each equation separately using qreg. sqreg differs from qreg in that it estimates the equations simultaneously and obtains an estimate of the entire variance–covariance matrix of the estimators by bootstrapping. Thus, you can perform hypothesis tests concerning coefficients both within and across equations.

For example, to fit the above model, you could type

```
. qreg y x1 x2, quantile(.25)
. qreg y x1 x2, quantile(.75)
```

By doing this, you would obtain estimates of the parameters, but you could not test whether \(b_{0.25,1} = b_{0.75,1}\) or, equivalently, \(b_{0.75,1} - b_{0.25,1} = 0\). If your interest really is in the difference of coefficients, you could type

```
. iqreg y x1 x2, quantiles(.25 .75)
```

The “coefficients” reported would be the difference in quantile coefficients. You could also estimate both quantiles simultaneously and then test the equality of the coefficients:

```
. sqreg y x1 x2, quantiles(.25 .75)
. test [q25]x1 = [q75]x1
```

Whether you use iqreg or sqreg makes no difference for this test. sqreg, however, because it estimates the quantiles simultaneously, allows you to test other hypotheses. iqreg, by focusing on quantile differences, presents results in a way that is easier to read.

Finally, sqreg can estimate quantiles singly,

```
. sqreg y x1 x2, quantiles(.5)
```

and can thereby be used as a substitute for the slower bsqreg. (Gould [1997b] presents timings demonstrating that sqreg is faster than bsqreg.) sqreg can also estimate more than two quantiles simultaneously:

```
. sqreg y x1 x2, quantiles(.25 .5 .75)
```
Example 5: Simultaneous quantile estimation

In demonstrating qreg, we performed quantile regressions using auto.dta. We discovered that the regression of price on weight, length, and foreign produced vastly different coefficients for the 0.25, 0.5, and 0.75 quantile regressions. Here are the coefficients that we obtained:

<table>
<thead>
<tr>
<th>Variable</th>
<th>25th percentile</th>
<th>50th percentile</th>
<th>75th percentile</th>
</tr>
</thead>
<tbody>
<tr>
<td>weight</td>
<td>1.83</td>
<td>3.93</td>
<td>9.22</td>
</tr>
<tr>
<td>length</td>
<td>2.85</td>
<td>-41.25</td>
<td>-220.8</td>
</tr>
<tr>
<td>foreign</td>
<td>2209.9</td>
<td>3377.8</td>
<td>3595.1</td>
</tr>
<tr>
<td>_cons</td>
<td>-1879.8</td>
<td>344.6</td>
<td>20242.9</td>
</tr>
</tbody>
</table>

All we can say, having estimated these equations separately, is that price seems to depend differently on the weight, length, and foreign variables depending on the portion of the price distribution we examine. We cannot be more precise because the estimates have been made separately. With sqreg, however, we can estimate all the effects simultaneously:

```
. use https://www.stata-press.com/data/r18/auto, clear
   (1978 automobile data)
. set seed 1001
. sqreg price weight length foreign, q(.25 .5 .75) reps(100)
   (fitting base model)
Bootstrap replications (100): ........10.........20.........30.........40........50.........60.........70.........80.........90.........100 done
Simultaneous quantile regression
   Number of obs = 74
   bootstrap(100) SEs
                        .25 Pseudo R2 = 0.1697
                        .50 Pseudo R2 = 0.2347
                        .75 Pseudo R2 = 0.3840

                              Bootstrap                  [95% conf. interval]
                              Coefficient std. err.   t    P>|t|          
q25                          
 weight                      1.831789   1.206151  1.52  0.133  -.573803   4.237381

 _cons                     344.6489  5062.804  0.07  0.946 -9752.795 10442.09
q75                          
 weight                      9.22291   2.631084  3.51  0.001  3.975378  14.47044
 length                     -220.7833  89.54754 -2.47  0.016 -399.3802  -42.18635
 foreign                    3595.133  1208.769  2.97  0.004  1184.319  6005.947
 _cons                     20242.9   9682.24   2.09  0.040  932.2846 39553.52
```

The coefficient estimates above are the same as those previously estimated, although the standard error estimates are a little different. sqreg obtains estimates of variance by bootstrapping. The important thing here, however, is that the full covariance matrix of the estimators has been estimated and stored, and thus it is now possible to perform hypothesis tests. Are the effects of weight the same at the 25th and 75th percentiles?
It appears that they are not. We can obtain a confidence interval for the difference by using `lincom`:

```
.lincom [q75]weight-[q25]weight
( 1) - [q25]weight + [q75]weight = 0
```

| price | Coefficient | Std. err. | t   | P>|t|   | [95% conf. interval] |
|-------|-------------|-----------|-----|------|---------------------|
| (1)   | 7.391121    | 2.524626  | 2.93| 0.005| 2.355914 12.42633   |

Indeed, we could test whether the `weight` and `length` sets of coefficients are equal at the three quantiles estimated:

```
.quietly test [q25]weight = [q50]weight
.quietly test [q25]weight = [q75]weight, accumulate
.quietly test [q25]length = [q50]length, accumulate
.test [q25]length = [q75]length, accumulate
( 1) [q25]weight - [q50]weight = 0
( 2) [q25]weight - [q75]weight = 0
( 3) [q25]length - [q50]length = 0
( 4) [q25]length - [q75]length = 0
.F( 4, 70) = 2.25
Prob > F = 0.0727
```

`iqreg` focuses on one quantile comparison but presents results that are more easily interpreted:

```
.set seed 1001
.iqreg price weight length foreign, q(.25 .75) reps(100) nolog
```

| price | Coefficient | std. err. | t   | P>|t|   | [95% conf. interval] |
|-------|-------------|-----------|-----|------|---------------------|
| weight| 7.391121    | 2.524626  | 2.93| 0.005| 2.355914 12.42633   |
| length| -223.6288   | 84.21504  | -2.66| 0.010| -391.5904 -55.66724 |
| foreign| 1385.208    | 1321.832  | 1.05| 0.298| -1251.103 4021.519  |
| _cons | 22122.68    | 9329.178  | 2.37| 0.020| 3516.219 40729.14   |

Looking only at the 0.25 and 0.75 quantiles (the interquartile range), the `iqreg` command output is easily interpreted. Increases in `weight` correspond significantly to increases in `price` dispersion. Increases in `length` correspond to decreases in `price` dispersion. The `foreign` variable does not significantly change `price` dispersion.

Do not make too much of these results; the purpose of this example is simply to illustrate the `sqreg` and `iqreg` commands and to do so in a context that suggests why analyzing dispersion might be of interest.
lincom after sqreg produced the same $t$ statistic for the interquartile range of weight, as did the iqreg command above. In general, they will not agree exactly because of the randomness of bootstrapping, unless the random-number seed is set to the same value before estimation (as was done here).

Gould (1997a) presents simulation results showing that the coverage—the actual percentage of confidence intervals containing the true value—for iqreg is appropriate.

What are the parameters?

In this section, we use a specific data-generating process (DGP) to illustrate the interpretation of the parameters estimated by qreg. If simulation experiments are not intuitive to you, skip this section.

In general, quantile regression parameterizes the quantiles of the distribution of $y$ conditional on the independent variables $x$ as $x\beta$, where $\beta$ is a vector of estimated parameters. In our example, we include a constant term and a single independent variable, and we express quantiles of the distribution of $y$ conditional on $x$ as $\beta_0 + \beta_1 x$.

We use simulated data to illustrate what we mean by a conditional distribution and how to interpret the parameters $\beta$ estimated by qreg. We also note how we could change our example to illustrate a DGP for which the estimator in qreg would be misspecified.

We suppose that the distribution of $y$ conditional on $x$ has a Weibull form. If $y$ has a Weibull distribution, the distribution function is $F(y) = 1 - \exp\left(-\frac{y}{\lambda}\right)^k$, where the scale parameter $\lambda > 0$ and the shape parameter $k > 0$. We can make $y$ have a Weibull distribution function conditional on $x$ by making the scale parameter or the shape parameter functions of $x$. In our example, we specify a particular DGP by supposing that $\lambda = (1 + \alpha x)$, $\alpha = 1.5$, $x = 1 + \sqrt{\nu}$, and that $\nu$ has a $\chi^2(1)$ distribution. For the moment, we leave the parameter $k$ as is so that we can discuss how this decision relates to model specification.

Plugging in for $\lambda$ yields the functional form for the distribution of $y$ conditional on $x$, which is known as the conditional distribution function and is denoted $F(y|x)$. $F(y|x)$ is the distribution for $y$ for each given value of $x$.

Some algebra yields that $F(y|x) = 1 - \exp[-\{y/(1 + \alpha x)\}^k]$. Letting $\tau = F(y|x)$ implies that $0 \leq \tau \leq 1$, because probabilities must be between 0 and 1.

To obtain the $\tau$ quantile of the distribution of $y$ conditional on $x$, we solve

$$\tau = 1 - \exp[-\{y/(1 + \alpha x)\}^k]$$

for $y$ as a function of $\tau$, $x$, $\alpha$, and $k$. The solution is

$$y = (1 + \alpha x)\left(-\ln(1 - \tau)\right)^{(1/k)}$$

(1)

For any value of $\tau \in (0, 1)$, expression (1) gives the $\tau$ quantile of the distribution of $y$ conditional on $x$. To use qreg, we must rewrite (1) as a function of $x$, $\beta_0$, and $\beta_1$. Some algebra yields that (1) can be rewritten as

$$y = \beta_0 + \beta_1 x$$

where $\beta_0 = \left(-\ln(1 - \tau)\right)^{(1/k)}$ and $\beta_1 = \alpha\left(-\ln(1 - \tau)\right)^{(1/k)}$. We can express the conditional quantiles as linear combinations of $x$, which is a property of the estimator implemented in qreg.
If we parameterize \( k \) as a nontrivial function of \( x \), the conditional quantiles will not be linear in \( x \). If the conditional quantiles cannot be represented as linear functions of \( x \), we cannot estimate the true parameters of the DGP. This restriction illustrates the limits of the estimator implemented in \texttt{qreg}.

We set \( k = 2 \) for our example.

Conditional quantile regression allows the coefficients to change with the specified quantile. For our DGP, the coefficients \( \beta_0 \) and \( \beta_1 \) increase as \( \tau \) gets larger. Substituting in for \( \alpha \) and \( k \) yields that 
\[
\beta_0 = \sqrt{-\ln(1 - \tau)} \quad \text{and} \quad \beta_1 = 1.5 \sqrt{-\ln(1 - \tau)}.
\]
Table 1 presents the true values for \( \beta_0 \) and \( \beta_1 \) implied by our DGP when \( \tau \in \{0.25, 0.5, 0.8\} \).

<table>
<thead>
<tr>
<th>( \tau )</th>
<th>( \beta_0 )</th>
<th>( \beta_1 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.25</td>
<td>0.53636</td>
<td>0.80454</td>
</tr>
<tr>
<td>0.5</td>
<td>0.8325546</td>
<td>1.248832</td>
</tr>
<tr>
<td>0.8</td>
<td>1.268636</td>
<td>1.902954</td>
</tr>
</tbody>
</table>

We can also use (1) to generate data from the specified distribution of \( y \) conditional on \( x \) by plugging in random uniform numbers for \( \tau \). Each random uniform number substituted in for \( \tau \) in (1) yields a draw from the conditional distribution of \( y \) given \( x \).

\textbf{Example 6}

In this example, we generate 100,000 observations from our specified DGP by substituting random uniform numbers for \( \tau \) in (1), with \( \alpha = 1.5 \), \( k = 2 \), \( x = 1 + \sqrt{\nu} \), and \( \nu \) coming from a \( \chi^2(1) \) distribution.

We begin by executing the code that implements this method; below, we discuss each line of the output produced.

```stata
. clear // drop existing variables
. set seed 1234571 // set random-number seed
. set obs 100000 // set number of observations
Number of observations (_N) was 0, now 100,000.
. generate double tau = runiform() // generate uniform variate
. generate double x = 1 + sqrt(rchi2(1)) // generate values for x
. generate double lambda = 1 + 1.5*x // lambda is 1 + alpha*x
. generate double k = 2 // fix value of k
. generate double y = lambda*((-ln(1-tau))^(1/k)) // generate random values for y given x
```

Although the comments at the end of each line briefly describe what each line is doing, we provide a more careful description. The first line drops any variables in memory. The second sets the seed of the random-number generator so that we will always get the same sequence of random uniform numbers. The third line sets the sample size to 100,000 observations, and the fourth line reports the change in sample size.

The fifth line substitutes random uniform numbers for \( \tau \). This line is the key to the algorithm. This standard method, known as inverse-probability transforms, for computing random numbers is discussed by Cameron and Trivedi (2022, 220–221), among others.
Lines 6–8 generate $x$, $\lambda$, and $k$ per our specified DGP. Lines 9–11 implement (1) using the previously generated $\lambda$, $x$, and $k$.

At the end, we have 100,000 observations on $y$ and $x$, with $y$ coming from the conditional distribution that we specified above.

Example 7

In the example below, we use qreg to estimate $\beta_1$ and $\beta_0$, the parameters from the conditional quantile function, for the 0.5 quantile from our simulated data.

```
. qreg y x, quantile(.5)
```

```
Iteration 1:  WLS sum of weighted deviations = 68573.243
Iteration 1:  Sum of abs. weighted deviations = 68571.918
Iteration 2:  Sum of abs. weighted deviations = 68308.342
Iteration 3:  Sum of abs. weighted deviations = 68241.17
Iteration 4:  Sum of abs. weighted deviations = 68232.043
Iteration 5:  Sum of abs. weighted deviations = 68230.45
Iteration 6:  Sum of abs. weighted deviations = 68230.532
Iteration 7:  Sum of abs. weighted deviations = 68229.532
Iteration 8:  Sum of abs. weighted deviations = 68229.514
Iteration 9:  Sum of abs. weighted deviations = 68229.508
Iteration 10: Sum of abs. weighted deviations = 68229.506
Iteration 11: Sum of abs. weighted deviations = 68229.505
```

```
Median regression
Number of obs = 100,000
Raw sum of deviations 73861.64 (about 2.9443724)
Min sum of deviations 68229.51 Pseudo R2 = 0.0763
```

|     | Coefficient | Std. err. | t     | P>|t| | 95% conf. interval |
|-----|-------------|-----------|-------|-----|-------------------|
| x   | 1.266062    | .0117759  | 107.51| 0.000 | 1.242981 to 1.289143|
| _cons | .8083315   | .0222972  | 36.25 | 0.000 | .7646291 to .8520338|

In the qreg output, the results for $x$ correspond to the estimate of $\beta_1$, and the results for _cons correspond to the estimate of $\beta_0$. The reported estimates are close to their true values of 1.248832 and 0.8325546, which are given in table 1.

The intuition in this example comes from the ability of qreg to recover the true parameters of our specified DGP. As we increase the number of observations in our sample size, the qreg estimates will get closer to the true values.
Example 8

In the example below, we estimate the parameters of the conditional quantile function for the 0.25 quantile and compare them with the true values.

```
. qreg y x, quantile(.25)
```

Iteration 1:  WLS sum of weighted deviations =  65395.359
Iteration 1:  Sum of abs. weighted deviations =  65397.892
Iteration 2:  Sum of abs. weighted deviations =  52640.481
Iteration 3:  Sum of abs. weighted deviations =  50706.508
Iteration 4:  Sum of abs. weighted deviations =  49767.356
Iteration 5:  Sum of abs. weighted deviations =  49766.98
Iteration 6:  Sum of abs. weighted deviations =  49765.818
Iteration 7:  Sum of abs. weighted deviations =  49765.589
Iteration 8:  Sum of abs. weighted deviations =  49765.549
Iteration 9:  Sum of abs. weighted deviations =  49765.533
Iteration 10:  Sum of abs. weighted deviations =  49765.528
Iteration 11:  Sum of abs. weighted deviations =  49765.527
Iteration 12:  Sum of abs. weighted deviations =  49765.527
Iteration 13:  Sum of abs. weighted deviations =  49765.527

.25 Quantile regression  
Number of obs =  100,000
Raw sum of deviations 51945.91 (about 1.8560913)
Min sum of deviations 49765.53  
Pseudo R2 =  0.0420

|     | Coefficient | Std. err. | t     | P>|t| | [95% conf. interval] |
|-----|-------------|-----------|-------|-----|---------------------|
| x   | .8207143    | .0106425  | 77.12 | 0.000 | .799855  .8415735 |
| _cons | .5075988    | .0201512  | 25.19 | 0.000 | .4681026 .547095  |

As above, `qreg` reports the estimates of $\beta_1$ and $\beta_0$ in the output table for `x` and `_cons`, respectively. The reported estimates are close to their true values of 0.80454 and 0.53636, which are given in table 1. As expected, the estimates are close to their true values. Also as expected, the estimates for the 0.25 quantile are smaller than the estimates for the 0.5 quantile.
Example 9

We finish this section by estimating the parameters of the conditional quantile function for the 0.8 quantile and comparing them with the true values.

```
. qreg y x, quantile(.8)
Iteration 1: WLS sum of weighted deviations = 66126.751
Iteration 1: Sum of abs. weighted deviations = 66130.001
Iteration 2: Sum of abs. weighted deviations = 55084.287
Iteration 3: Sum of abs. weighted deviations = 52914.276
Iteration 4: Sum of abs. weighted deviations = 52101.59
Iteration 5: Sum of abs. weighted deviations = 51899.426
Iteration 6: Sum of abs. weighted deviations = 51898.269
Iteration 7: Sum of abs. weighted deviations = 51898.268
Iteration 8: Sum of abs. weighted deviations = 51898.267
```

5.8 Quantile regression
Number of obs = 100,000
Raw sum of deviations 60129.76 (about 4.7060381)
Min sum of deviations 51898.27
Pseudo R2 = 0.1369

|     | Coefficient | Std. err. | t     | P>|t| | [95% conf. interval] |
|-----|-------------|-----------|-------|-----|---------------------|
| x   | 1.911771    | 0.014834  | 128.88| 0.000| 1.882697  1.940846 |
| _cons | 1.254583  | 0.0280877 | 44.67 | 0.000 | 1.199531  1.309634 |

As above, \texttt{qreg} reports the estimates of $\beta_1$ and $\beta_0$ in the output table for $x$ and \_cons, respectively. The reported estimates are close to their true values of 1.902954 and 1.268636, which are given in table 1. As expected, the estimates are close to their true values. Also as expected, the estimates for the 0.8 quantile are larger than the estimates for the 0.5 quantile.
Stored results

qreg stores the following in \texttt{e}():

**Scalars**

\begin{itemize}
\item \texttt{e(N)} \quad \text{number of observations}
\item \texttt{e(df_m)} \quad \text{model degrees of freedom}
\item \texttt{e(df_r)} \quad \text{residual degrees of freedom}
\item \texttt{e(q)} \quad \text{quantile requested}
\item \texttt{e(q_v)} \quad \text{value of the quantile}
\item \texttt{e(r2_p)} \quad \text{pseudo-}R^2$
\item \texttt{e(sum_aadev)} \quad \text{sum of absolute deviations}
\item \texttt{e(sum_rdev)} \quad \text{sum of raw deviations}
\item \texttt{e(sum_w)} \quad \text{sum of weights}
\item \texttt{e(f_r)} \quad \text{density estimate}

\end{itemize}

**Functions**

\begin{itemize}
\item \texttt{e(sample)} \quad \text{marks estimation sample}
\end{itemize}

In addition to the above, the following is stored in \texttt{r}():

**Matrices**

\begin{itemize}
\item \texttt{r(table)} \quad \text{matrix containing the coefficients with their standard errors, test statistics, }p\text{-values, and confidence intervals}
\end{itemize}

Note that results stored in \texttt{r}() are updated when the command is replayed and will be replaced when any \texttt{r}–class command is run after the estimation command.
iqreg stores the following in `e()`:

Scalars
- `e(N)` number of observations
- `e(df_r)` residual degrees of freedom
- `e(q0)` lower quantile requested
- `e(q1)` upper quantile requested
- `e(reps)` number of replications
- `e(r2_p_q0)` lower quantile pseudo-$R^2$
- `e(r2_p_q1)` upper quantile pseudo-$R^2$
- `e(sumrdev0)` lower quantile sum of raw deviations
- `e(sumrdev1)` upper quantile sum of raw deviations
- `e(sumadev0)` lower quantile sum of absolute deviations
- `e(sumadev1)` upper quantile sum of absolute deviations
- `e(rank)` rank of `e(V)`
- `e(convcode)` 0 if converged; otherwise, return code for why nonconvergence

Macros
- `e(cmd)` `iqreg`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(vcetype)` title used to label Std. err.
- `e(properties)` `b V`
- `e(predict)` program used to implement predict
- `e(marginsnotok)` predictions disallowed by margins
- `e(asbalanced)` factor variables fvset as asbalanced
- `e(asobserved)` factor variables fvset as asobserved

Matrices
- `e(b)` coefficient vector
- `e(V)` variance–covariance matrix of the estimators

Functions
- `e(sample)` marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices
- `r(table)` matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

sqreg stores the following in `e()`:

Scalars
- `e(N)` number of observations
- `e(df_r)` residual degrees of freedom requested
- `e(n_q)` number of quantiles requested
- `e(q#)` the quantiles requested
- `e(reps)` number of replications
- `e(r2_p_q#)` pseudo-$R^2$ for q#
- `e(sumrdev#)` sum of raw deviations for q#
- `e(sumadev#)` sum of absolute deviations for q#
- `e(rank)` rank of `e(V)`
- `e(convcode)` 0 if converged; otherwise, return code for why nonconvergence

Macros
- `e(cmd)` `sqreg`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(eqnames)` names of equations
- `e(vcetype)` title used to label Std. err.
- `e(properties)` `b V`
- `e(predict)` program used to implement predict
e(marginsnotok) predictions disallowed by margins
e(asbalanced) factor variables fvset as asbalanced
e(asobserved) factor variables fvset as asobserved

Matrices
e(b) coefficient vector
e(V) variance–covariance matrix of the estimators

Functions
e(sample) marks estimation sample

In addition to the above, the following is stored in r():

Matrices
r(table) matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

bsqreg stores the following in e():

Scalars
e(N) number of observations
e(df_r) residual degrees of freedom
e(q) quantile requested
e(q_v) value of the quantile
e(reps) number of replications
e(r2_p) pseudo-$R^2$
e(sum_adev) sum of absolute deviations
e(sum_rdev) sum of raw deviations
e(rank) rank of e(V)
e(convcode) 0 if converged; otherwise, return code for why nonconvergence

Macros
e(cmd) bsqreg
e(cmdline) command as typed
e(depvar) name of dependent variable
e(properties) b V
e(predict) program used to implement predict
e(marginsnotok) predictions disallowed by margins
e(asbalanced) factor variables fvset as asbalanced
e(asobserved) factor variables fvset as asobserved

Matrices
e(b) coefficient vector
e(V) variance–covariance matrix of the estimators

Functions
e(sample) marks estimation sample

In addition to the above, the following is stored in r():

Matrices
r(table) matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.
Methods and formulas

Methods and formulas are presented under the following headings:

Introduction
Linear programming formulation of quantile regression
Standard errors when residuals are i.i.d.
Pseudo-R²

Introduction

According to Stuart and Ord (1991, 1084), the method of minimum absolute deviations was first proposed by Boscovich in 1757 and was later developed by Laplace; Stigler (1986, 39–55) and Hald (1998, 97–103, 112–116) provide historical details. According to Bloomfield and Steiger (1980), Harris (1950) later observed that the problem of minimum absolute deviations could be turned into the linear programming problem that was first implemented by Wagner (1959). Interest has grown in this method because robust methods and extreme value modeling have become more popular. Statistical and computational properties of minimum absolute deviation estimators are surveyed by Narula and Wellington (1982). Cameron and Trivedi (2005), Hao and Naiman (2007), and Wooldridge (2010) provide excellent introductions to quantile regression methods, while Koenker (2005) gives an in-depth review of the topic.

Linear programming formulation of quantile regression

Define $\tau$ as the quantile to be estimated; the median is $\tau = 0.5$. For each observation $i$, let $\varepsilon_i$ be the residual

$$\varepsilon_i = y_i - x_i' \hat{\beta}_\tau$$

The objective function to be minimized is

$$c_\tau(\varepsilon_i) = (\tau 1 \{\varepsilon_i \geq 0\} + (1 - \tau) 1 \{\varepsilon_i < 0\}) |\varepsilon_i|$$

$$= (\tau 1 \{\varepsilon_i \geq 0\} - (1 - \tau) 1 \{\varepsilon_i < 0\}) \varepsilon_i$$

$$= (\tau - 1 \{\varepsilon_i < 0\}) \varepsilon_i$$

(2)

where $1 \{\cdot\}$ is the indicator function. This function is sometimes referred to as the check function because it resembles a check mark (Wooldridge 2010, 450); the slope of $c_\tau(\varepsilon_i)$ is $\tau$ when $\varepsilon_i > 0$ and is $\tau - 1$ when $\varepsilon_i < 0$, but is undefined for $\varepsilon_i = 0$. Choosing the $\hat{\beta}_\tau$ that minimize $c_\tau(\varepsilon_i)$ is equivalent to finding the $\hat{\beta}_\tau$ that make $x \hat{\beta}_\tau$ best fit the quantiles of the distribution of $y$ conditional on $x$.

This minimization problem is set up as a linear programming problem and is solved with linear programming techniques, as suggested by Armstrong, Frome, and Kung (1979) and described in detail by Koenker (2005). Here $2n$ slack variables, $u_{n \times 1}$ and $v_{n \times 1}$, are introduced, where $u_i \geq 0$, $v_i \geq 0$, and $u_i \times v_i = 0$, reformulating the problem as

$$\min_{\beta_\tau, u, v} \{\tau 1_n' u + (1 - \tau) 1_n' v \mid y - X \beta_\tau = u - v\}$$

where $1_n$ is a vector of 1s. This is a linear objective function on a polyhedral constraint set with $\binom{n}{k}$ vertices, and our goal is to find the vertex that minimizes (2). Each step in the search is described by a set of $k$ observations through which the regression plane passes, called the basis. A step is taken by replacing a point in the basis if the linear objective function can be improved. If this occurs, a line is printed in the iteration log. The definition of convergence is exact in the sense that no amount of added iterations could improve the objective function.
A series of weighted least-squares (WLS) regressions is used to identify a set of observations as a starting basis. The WLS algorithm for $\tau = 0.5$ is taken from Schlossmacher (1973) with a generalization for $0 < \tau < 1$ implied from Hunter and Lange (2000).

### Standard errors when residuals are i.i.d.

The estimator for the VCE implemented in `qreg` assumes that the errors of the model are independent and identically distributed (i.i.d.). When the errors are i.i.d., the large-sample VCE is

$$\text{cov}(\beta_\tau) = \frac{\tau(1 - \tau)}{f_Y^2(\xi_\tau)} \{E(x_i x'_i)\}^{-1}$$

(3)

where $\xi_\tau = F_Y^{-1}(\tau)$ and $F_Y(y)$ is the distribution function of $Y$ with density $f_Y(y)$. See Koenker (2005, 73) for this result. From (3), we see that the regression precision depends on the inverse of the density function, termed the sparsity function, $s_\tau = 1/f_Y(\xi_\tau)$.

While $1/n \sum_{i=1}^n x_i x'_i$ estimates $E(x_i x'_i)$, estimating the sparsity function is more difficult. `qreg` provides several methods to estimate the sparsity function. The different estimators are specified through the suboptions of `vce(iid, denmethod bwidth)`. The suboption `denmethod` specifies the functional form for the sparsity estimator. The default is fitted.

Here we outline the logic underlying the fitted estimator. Because $F_Y(y)$ is the distribution function for $Y$, we have $f_Y(y) = \{dF_Y(y)\}/dy$, $\tau = F_Y(\xi_\tau)$, and $\xi_\tau = F_Y^{-1}(\tau)$. When differentiating the identity $F_Y \{F_Y^{-1}(\tau)\} = \tau$, the sparsity function can be written as $s_\tau = \{F_Y^{-1}(\tau)\}/dt$. Numerically, we can approximate the derivative using the centered difference,

$$\frac{F_Y^{-1}(\tau)}{dt} \approx \frac{F_Y^{-1}(\tau + h) - F_Y^{-1}(\tau - h)}{2h} = \frac{\xi_{\tau+h} - \xi_{\tau-h}}{2h} = \hat{s}_\tau$$

(4)

where $h$ is the bandwidth.

The empirical quantile function is computed by first estimating $\beta_{\tau+h}$ and $\beta_{\tau-h}$, and then computing $\hat{F}_\epsilon^{-1}(\tau + h) = \overline{x} \hat{\beta}_{\tau+h}$ and $\hat{F}_\epsilon^{-1}(\tau - h) = \overline{x} \hat{\beta}_{\tau-h}$, where $\overline{x}$ is the sample mean of the independent variables $x$. These quantities are then substituted into (4).

Alternatively, as the option suggests, `vce(iid, residual)` specifies that `qreg` use the empirical quantile function of the residuals to estimate the sparsity. Here we substitute $\hat{F}_\epsilon$, the distribution of the residuals, for $F_Y$, which only differ by their first moments.

The $k$ residuals associated with the linear programming basis will be zero, where $k$ is the number of regression coefficients. These zero residuals are removed before computing the $\tau + h$ and $\tau - h$ quantiles, $\epsilon_{(\tau+h)} = \hat{F}_\epsilon^{-1}(\tau + h)$ and $\epsilon_{(\tau-h)} = \hat{F}_\epsilon^{-1}(\tau - h)$. The $\hat{F}_\epsilon^{-1}$ estimates are then substituted for $F_Y^{-1}$ in (4).

Each of the estimators for the sparsity function depends on a bandwidth. The `vce()` suboption `bwidth` specifies the bandwidth method to use. The three bandwidth options and their citations are `hsheather` (Hall and Sheather 1988), `bofinger` (Bofinger 1975), and `chamberlain` (Chamberlain 1994).
Their formulas are

\[
h_s = n^{-1/3} \Phi^{-1} \left( 1 - \frac{\alpha}{2} \right)^{2/3} \left[ \frac{3}{2} \times \frac{\phi\{\Phi^{-1}(\tau)\}^2}{2\Phi^{-1}(\tau)^2 + 1} \right]^{1/3}
\]

\[
h_b = n^{-1/5} \left[ \frac{9}{2} \phi\{\Phi^{-1}(\tau)\}^4}{\{2\Phi^{-1}(\tau)^2 + 1\}^2} \right]^{1/5}
\]

\[
h_c = \Phi^{-1} \left( 1 - \frac{\alpha}{2} \right) \sqrt{\frac{\tau(1 - \tau)}{n}}
\]

where \(h_s\) is the Hall–Sheather bandwidth, \(h_b\) is the Bofinger bandwidth, \(h_c\) is the Chamberlain bandwidth, \(\Phi()\) and \(\phi()\) are the standard normal distribution and density functions, \(n\) is the sample size, and \(100(1 - \alpha)\) is the confidence level set by the \texttt{level()} option. Koenker (2005) discusses the derivation of the Hall–Sheather and the Bofinger bandwidth formulas. You should avoid modifying the confidence level when replaying estimates that use the Hall–Sheather or Chamberlain bandwidths because these methods use the confidence level to estimate the coefficient standard errors.

Finally, the \texttt{vce()} suboption \texttt{kernel(kernel)} specifies that \texttt{qreg} use one of several kernel-density estimators to estimate the sparsity function. \texttt{kernel} allows you to choose which kernel function to use, where the default is the Epanechnikov kernel. See \texttt{[R] kdensity} for the functional form of the eight kernels.

The kernel bandwidth is computed using an adaptive estimate of scale

\[
h_k = \min \left( \hat{\sigma}, \frac{r_q}{1.34} \right) \times \left\{ \Phi^{-1}(\tau + h) - \Phi^{-1}(\tau - h) \right\}
\]

where \(h\) is one of \(h_s\), \(h_b\), or \(h_c\); \(r_q\) is the interquartile range; and \(\hat{\sigma}\) is the standard deviation of \(y\); see Silverman (1986, 47) and Koenker (2005, 81) for discussions. Let \(\hat{f}_\epsilon(\epsilon_i)\) be the kernel density estimate for the \(i\)th residual, and then the kernel estimator for the sparsity function is

\[
\hat{s}_\tau = \frac{n h_k}{\sum_{i=1}^{n} \hat{f}_\epsilon(\epsilon_i)}
\]

Finally, substituting your choice of sparsity estimate into (3) results in the i.i.d. variance–covariance matrix

\[
V_n = \hat{s}_\tau^2 \tau(1 - \tau) \left( \sum_{i=1}^{n} x_i x_i' \right)^{-1}
\]

**Pseudo-\(R^2\)**

The pseudo-\(R^2\) is calculated as

\[
1 - \frac{\text{sum of weighted deviations about estimated quantile}}{\text{sum of weighted deviations about raw quantile}}
\]

This is based on the likelihood for a double-exponential distribution \(e^{v_i |\epsilon_i|}\), where \(v_i\) are multipliers

\[
v_i = \begin{cases} 
\tau & \text{if } \epsilon_i > 0 \\
(1 - \tau) & \text{otherwise}
\end{cases}
\]
Minimizing the objective function (2) with respect to $\beta_{\tau}$ also minimizes $\sum_i |\varepsilon_i|v_i$, the sum of weighted least absolute deviations. For example, for the 50th percentile $v_i = 1$, for all $i$, and we have median regression. If we want to estimate the 75th percentile, we weight the negative residuals by 0.25 and the positive residuals by 0.75. It can be shown that the criterion is minimized when 75% of the residuals are negative.

*hausman is not appropriate after `bsqreg`, `isqreg`, or `sqreg`.
†forecast is not appropriate with mi estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, and residuals.

Menu for predict

Statistics > Postestimation

Syntax for predict

For qreg, iqreg, and bsqreg

\texttt{predict [type] newvar [if] [in] [,, [xb|stdp|residuals]]}

For sqreg

\texttt{predict [type] newvar [if] [in] [,, equation(eqno[,eqno]) statistic]}

\begin{tabular}{ll}
\textbf{statistic} & \textbf{Description} \\
\hline
\texttt{xb} & linear prediction; the default \\
\texttt{stdp} & standard error of the linear prediction \\
\texttt{stddp} & standard error of the difference in linear predictions \\
\texttt{residuals} & residuals \\
\end{tabular}

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

\begin{itemize}
\item \texttt{xb}, the default, calculates the linear prediction.
\item \texttt{stdp} calculates the standard error of the linear prediction.
\item \texttt{stddp} is allowed only after you have fit a model using sqreg. The standard error of the difference in linear predictions (x_{1j}b - x_{2j}b) between equations 1 and 2 is calculated.
\item \texttt{residuals} calculates the residuals, that is, y_j - x_jb.
\item \texttt{equation(eqno[,eqno])} specifies the equation to which you are making the calculation.
\end{itemize}

\begin{itemize}
\item equation() is filled in with one \texttt{eqno} for the xb, stdp, and residuals options. equation(#1) would mean that the calculation is to be made for the first equation, equation(#2) would mean the second, and so on. You could also refer to the equations by their names. equation(income) would refer to the equation named income and equation(hours) to the equation named hours.
\item If you do not specify equation(), results are the same as if you had specified equation(#1).
\item To use stddp, you must specify two equations. You might specify equation(#1, #2) or equation(q80, q20) to indicate the 80th and 20th quantiles.
\end{itemize}
margins

Description for margins

margins estimates margins of response for linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]

margins [marginlist] , predict(statistic ...) [options]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xb</td>
<td>linear prediction; the default</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
<tr>
<td>stddp</td>
<td>not allowed with margins</td>
</tr>
<tr>
<td>residuals</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.
estat

Description for estat

estat coefplot plots the estimated coefficients and their confidence intervals (CIs) after sqreg.

Menu for estat

Statistics > Postestimation

Syntax for estat

    estat coefplot [varname] [ , options ]

varname is one of the variables specified when fitting sqreg; the default is the first endogenous variable.

options | Description
---------|----------------
noci     | do not plot the CIs
nools    | do not plot the ordinary least-squares (OLS) estimates

Plot

connect_options | change look of lines or connecting method
marker_options  | change look of markers (color, size, etc.)

CI plot

ciopts(area_options) | affect rendition of the pointwise CIs

Line options

lineopts(cline_options) | affect rendition of reference line identifying the OLS estimates

Y axis, X axis, Titles, Legend, Overall

twoway_options | any options other than by() documented in [G-3] twoway_options

Options for estat

noci removes plots of the pointwise CIs. The default is to plot the CIs.
nools removes the plot of the OLS estimates. The default is to plot the OLS reference line.

connect_options specify how points on a graph are to be connected; [G-3] connect_options.
marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.

ciopts(area_options) affects rendition of the pointwise CIs; see [G-3] area_options.
_lineopts(cline_options) affects rendition of reference line identifying the OLS estimates; see [G-3] _cline_options._

_twoway_options_ are any of the options documented in [G-3] _twoway_options_, excluding by(). These include options for titling the graph (see [G-3] _title_options_) and for saving the graph to disk (see [G-3] _saving_option_).

Remarks and examples

Example 1: Predictions after qreg and iqreg

In example 4 of [R] _qreg_, we fit regressions for the lower and the upper quartile of the price variable. The _predict_ command can be used to obtain the linear prediction after each regression.

```
use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
.qreg price weight length foreign, quantile(.25)
(output omitted)
.predict q25
(option xb assumed; fitted values)
.qreg price weight length foreign, quantile(.75)
(output omitted)
.predict q75
(option xb assumed; fitted values)
```

We can use the variables generated by _predict_ to compute the predicted interquartile range, that is,

```
.generate iqr1 = q75 - q25
```

If we directly perform the interquartile range regression with the _iqreg_ command, we can predict the interquartile range and also the standard error for the prediction.

```
.iqreg price weight length foreign, quantile(.25 .75)
(output omitted)
.predict iqr2
(option xb assumed; fitted values)
.predict stdp, stdp
```
We now plot the predicted interquartile range versus variable length:

```
.scatter iqr2 length
```

As stated in example 5 of [R] qreg, the negative coefficient for the `length` variable means that increases in length imply decreases in the interquartile range and therefore in price dispersion. Consequently, we could have expected a downward trend in the plot, but there is not. This is because the regression output indicates that when we hold the rest of the variables constant, an increase in `length` leads to a decrease in `iqr2`. However, there is a high correlation between `weight` and `length`, which could be masking the effect of `length` on `iqr2`. We can achieve a better visualization by using a contour plot.
We can see the effect by setting a fixed value of `length` on the vertical axis, say, 3,000 lbs. When we move from left to right on the horizontal axis, we see that for small values of `length`, `iqr2` values are shown in red, meaning high values, and when we move toward the right, the graph indicates transition into increasingly smaller values.

Example 2: Coefficients plot after `sqreg`

In example 5 of [R] `qreg`, we simultaneously estimated the quantile regressions at different quantile indexes.

```stata
use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
set seed 1001
sqreg price weight length foreign, q(.25 .5 .75) reps(100)
(output omitted)
```
We can now use \texttt{estat coefplot} to visualize the coefficients at different quantiles. For example, we can type \texttt{estat coefplot weight} to see the trend of the effects of \texttt{weight} on \texttt{price} across quantiles.

```
. estat coefplot weight
```

The resulting graph shows that there is an upward trend in the effects. For reference, the red line shows the OLS estimates.

[U] 20 Estimation and postestimation commands
query — Display system parameters

**Description**

query displays the settings of various Stata parameters.

**Syntax**

```
query [ memory | output | interface | graphics | network | update |
       trace | mata | java | lapack | putdocx | python | rng | sort |
       unicode | other ]
```

**Remarks and examples**

query provides more system information than you will ever want to know. You do not need to understand every line of output that query produces if all you need is one piece of information. Here is what happens when you type query:

```
. query
```

---

**Memory settings**

- `set maxvar 5000 2048-120000; max. vars allowed`
- `set niceness 5 0-10`
- `set min_memory 0 0-1600g`
- `set max_memory . 32m-1600g or .`
- `set segmentsize 32m 1m-32g`
- `set adosize 1000 kilobytes`
- `set max_preservemem 1g 0-1600g`

**Output settings**

- `set doeditbackup` on
The output is broken into several divisions: memory, output, interface, graphics, network, update, trace, Mata, Java, LAPACK, putdocx, Python, RNG, sort, Unicode, and other settings. We will discuss each one in turn.

We generated the output above using Stata/MP for Windows. Here is what happens when we type `query` and we are running Stata/SE for Mac:

```
. query

Memory settings
set maxvar 5000 2048-32767; max. vars allowed
set niceness 5 0-10
set min_memory 0 0-1600g
set max_memory . 32m-1600g or .
set segmentsize 32m 1m-32g
set adosize 1000 kilobytes

Output settings
set more off

Interface settings

Interface settings control how Stata’s interface works.

For more information, see

- `dockable [R] set`
- `floatwindows [R] set`
- `locksplitters [R] set`
- `pinnable [R] set`
- `taskbargroups [R] set`
- `doublebuffer [R] set`
- `revkeyboard [R] set`
- `varkeyboard [R] set`
- `smoothfonts [R] set`
- `linegap [R] set`
- `scrollbufsize [R] set`
- `fastscroll [R] set`
- `reventries [R] set`
- `maxdb [R] db`

Graphics settings

Graphics settings indicate how Stata’s graphics are displayed.

For more information, see

- `graphics [G-2] set graphics`
- `autotabgraphs [R] set`
- `scheme [G-2] set scheme`
- `printcolor [G-2] set printcolor`
- `copycolor [G-2] set printcolor`
- `maxbezierpath [R] set`

Network settings

Network settings determine how Stata interacts with the Internet.

For more information, see [R] netio.

Update settings

Update settings determine how Stata performs updates.

For more information, see [R] update.

Trace settings

Trace settings adjust Stata’s behavior and are particularly useful in debugging code.

For more information, see [P] trace.
**Mata settings**

Mata settings affect Mata’s system parameters.

For more information, see [M-3] mata set.

**Java settings**

Java settings control the Java Runtime Environment.

For more information, see [P] Java utilities.

**LAPACK settings**

LAPACK settings control the Intel MKL LAPACK routines.

For more information, see [M-1] LAPACK.

**putdocx settings**

putdocx settings control how spacing is handled in blocks of text.

For more information, see [RPT] set docx.

**Python settings**

Python settings control the version and search paths of Python.

For more information, see [P] PyStata integration.

**RNG settings**

The RNG settings set Stata’s random-number generators.

For more information, see [R] set rng, [R] set seed (set rngstate), and [R] set rngstream.

**sort settings**

The sort settings affect sort, gsort, and other commands that use sorting as part of their computation.

For more information, see [P] set sortmethod and [P] set sortrngstate.

**Unicode settings**

Unicode settings affect Stata’s localization package for the user interface.

For more information, see [P] set locale_ui and [P] set locale_functions.
Other settings

The other settings are a miscellaneous collection.

For more information, see

```
type    [D] generate
maxiter  [R] set iter
searchdefault [R] search
varabbrev [R] set
emptycells [R] set
fvtrack   [R] set
fvbase    [R] set
processors [R] set
kmp_blocktime [R] set
odbcmgr   [D] odbc
odbcdriver [D] odbc
haverdir  [D] import haver
fredkey   [D] import fred
collect_double [TABLES] set collect_double
dtascomplevel [R] set
reshape_favor [D] reshape
doeditbackup [R] set
```

In general, the parameters displayed by query can be changed by set; see [R] set.

ranksum — Equality tests on unmatched data

Description

ranksum tests the hypothesis that two independent samples (that is, unmatched data) are from populations with the same distribution by using the Wilcoxon rank-sum test, which is also known as the Mann–Whitney two-sample statistic (Wilcoxon 1945; Mann and Whitney 1947).

median performs a nonparametric $k$-sample test on the equality of medians. It tests the null hypothesis that the $k$ samples were drawn from populations with the same median. For two samples, the $\chi^2$ test statistic is computed both with and without a continuity correction.

ranksum and median are for use with unmatched data. For equality tests on matched data, see [R] signrank.

Quick start

Wilcoxon rank-sum test

Test for equality of distributions of $v$ over two groups defined by the levels of $\text{catvar1}$

```stata
ranksum v, by(catvar1)
```

Compute an exact $p$-value for the Wilcoxon rank-sum test

```stata
ranksum v, by(catvar1) exact
```

Estimate the probability that a case from the first level of $\text{catvar1}$ has a greater value of $v$ than a case from the second level of $\text{catvar1}$

```stata
ranksum v, by(catvar1) porder
```

Nonparametric equality-of-medians test

Equality of medians test for $v$ over two or more groups defined by the levels of $\text{catvar2}$

```stata
median v, by(catvar2)
```

Also report Fisher’s exact test

```stata
median v, by(catvar2) exact
```

Same as above, but split cases at the median evenly between the above and below groups

```stata
median v, by(catvar2) exact medianties(split)
```
Menu

ranksum

Statistics > Nonparametric analysis > Tests of hypotheses > Wilcoxon rank-sum test

median

Statistics > Nonparametric analysis > Tests of hypotheses > K-sample equality-of-medians test

Syntax

Wilcoxon rank-sum test

```
ranksum varname [if] [in], by(groupvar) [exact porder]
```

Nonparametric equality-of-medians test

```
median varname [if] [in] [weight], by(groupvar) [median_options]
```

*by(groupvar) is required.

by and collect are allowed with ranksum and median; see [U] 11.1.10 Prefix commands.

fweights are allowed with median; see [U] 11.1.6 weight.
Options for ranksum

by(groupvar) is required. It specifies the name of the grouping variable.

exact specifies that the exact p-value be computed in addition to the approximate p-value. The exact p-value is based on the actual randomization distribution of the test statistic. The approximate p-value is based on a normal approximation to the randomization distribution. By default, the exact p-value is computed for sample sizes \( n = n_1 + n_2 \leq 200 \) because the normal approximation may not be precise in small samples. The exact computation can be suppressed by specifying noexact. For sample sizes larger than 200, you must specify exact to compute the exact p-value. The exact computation is available for sample sizes \( n \leq 1000 \). As the sample size approaches 1,000, the computation takes significantly longer.

porder displays an estimate of the probability that a random draw from the first population is larger than a random draw from the second population.

Options for median

by(groupvar) is required. It specifies the name of the grouping variable.

exact displays the p-value calculated by Fisher’s exact test. For two samples, both one- and two-sided p-values are displayed.

medianties(below|above|drop|split) specifies how values equal to the overall median are to be handled. The median test computes the median for varname by using all observations and then divides the observations into those falling above the median and those falling below the median. When values for an observation are equal to the sample median, they can be dropped from the analysis by specifying medianties(drop); added to the group above or below the median by specifying medianties(above) or medianties(below), respectively; or if there is more than 1 observation with values equal to the median, they can be equally divided into the two groups by specifying medianties(split). If this option is not specified, medianties(below) is assumed.

Remarks and examples

> Example 1

We are testing the effectiveness of a new fuel additive. We run an experiment with 24 cars: 12 cars with the fuel treatment and 12 cars without. We input these data by creating a dataset with 24 observations. mpg records the mileage rating, and treat records 0 if the mileage corresponds to untreated fuel and 1 if it corresponds to treated fuel.
. use https://www.stata-press.com/data/r18/fuel2
. ranksum mpg, by(treat)

Two-sample Wilcoxon rank-sum (Mann-Whitney) test

<table>
<thead>
<tr>
<th>treat</th>
<th>Obs</th>
<th>Rank sum</th>
<th>Expected</th>
</tr>
</thead>
<tbody>
<tr>
<td>Untreated</td>
<td>12</td>
<td>128</td>
<td>150</td>
</tr>
<tr>
<td>Treated</td>
<td>12</td>
<td>172</td>
<td>150</td>
</tr>
<tr>
<td>Combined</td>
<td>24</td>
<td>300</td>
<td>300</td>
</tr>
</tbody>
</table>

Unadjusted variance 300.00
Adjustment for ties -4.04

Adjusted variance 295.96

H0: mpg(treat==Untreated) = mpg(treat==Treated)
z = -1.279
Prob > |z| = 0.2010
Exact prob = 0.2117

Because the total sample is only 24 cars, the exact p-value is computed by default. If the sample size were greater than 200, we would have to specify the exact option if we wanted the exact p-value computed.

Despite the small sample size, the p-value computed using a normal approximation, 0.2010, is similar to the exact p-value, 0.2117. These results indicate that the distributions are not statistically different at a 0.05 significance level.

Similarly, the median test,

. median mpg, by(treat) exact

Median test

<table>
<thead>
<tr>
<th>Greater than the median</th>
<th>Whether car received fuel additive</th>
<th>Untreated</th>
<th>Treated</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>Untreated</td>
<td>7</td>
<td>5</td>
<td>12</td>
</tr>
<tr>
<td>yes</td>
<td>Treated</td>
<td>5</td>
<td>7</td>
<td>12</td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td>12</td>
<td>12</td>
<td>24</td>
</tr>
</tbody>
</table>

Pearson chi2(1) = 0.6667 Pr = 0.414
Fisher's exact = 0.684
1-sided Fisher's exact = 0.342

Continuity corrected:
Pearson chi2(1) = 0.1667 Pr = 0.683

fails to reject the null hypothesis that there is no difference between the fuel with the additive and the fuel without the additive.

Compare these results from these two tests with those obtained from the signrank and signtest where we found significant differences; see \texttt{[R] signrank}. An experiment run on 24 different cars is not as powerful as a before-and-after comparison using the same 12 cars.
ranksum — Equality tests on unmatched data

Stored results

`ranksum` stores the following in `r()`:

Scalars
- `r(N)` sample size
- `r(N_1)` sample size of first group
- `r(N_2)` sample size of second group
- `r(z)` $z$ statistic
- `r(Var_a)` adjusted variance
- `r(group1)` value of variable for first group
- `r(sum_obs)` observed sum of ranks for first group
- `r(sum_exp)` expected sum of ranks for first group
- `r(p)` two-sided $p$-value from normal approximation
- `r(p_l)` lower one-sided $p$-value from normal approximation
- `r(p_u)` upper one-sided $p$-value from normal approximation
- `r(p_exact)` two-sided exact $p$-value
- `r(p_l_exact)` lower one-sided exact $p$-value
- `r(p_u_exact)` upper one-sided exact $p$-value
- `r(porder)` probability that draw from first population is larger than draw from second population

`median` stores the following in `r()`:

Scalars
- `r(N)` sample size
- `r(chi2)` Pearson’s $\chi^2$
- `r(chi2_cc)` continuity-corrected Pearson’s $\chi^2$
- `r(groups)` number of groups compared
- `r(p)` $p$-value for Pearson’s $\chi^2$ test
- `r(p_cc)` continuity-corrected $p$-value
- `r(p_exact)` Fisher’s exact $p$-value
- `r(p1_exact)` one-sided Fisher’s exact $p$-value

Methods and formulas

For a practical introduction to these techniques with an emphasis on examples rather than theory, see Acock (2023), Bland (2015), or Sprent and Smeeton (2007). For a summary of these tests, see Snedecor and Cochran (1989).

Methods and formulas are presented under the following headings:

- `ranksum`
- `median`

ranksum

For the Wilcoxon rank-sum test, there are two independent random variables, $X_1$ and $X_2$, and we test the null hypothesis that $X_1 \sim X_2$. We have a sample of size $n_1$ from $X_1$ and another of size $n_2$ from $X_2$.

The data are then ranked without regard to the sample to which they belong. If the data are tied, averaged ranks are used. Wilcoxon’s test statistic (1945) is the sum of the ranks for the observations in the first sample:

$$ T = \sum_{i=1}^{n_1} R_{1i} $$
Mann and Whitney’s $U$ statistic (1947) is the number of pairs $(X_{1i}, X_{2j})$ such that $X_{1i} > X_{2j}$. These statistics differ only by a constant:

$$U = T - \frac{n_1(n_1 + 1)}{2}$$

Fisher’s principle of randomization provides a method for calculating the distribution of the test statistic. The randomization distribution consists of all the possible values of $T$ resulting from the $\binom{n}{n_1}$ ways to choose $n_1$ ranks from the set of all $n = n_1 + n_2$ observed ranks (untied or tied) and assign them to the first sample. When the exact option is specified (or implied for $n \leq 200$), this distribution is computed using a recursive algorithm whose computational time is proportional to $n^4$. (See Fisher [1935] for the principle of randomization; Wilcoxon, Katti, and Wilcox [1970] for the computation with untied ranks; and Hill and Peto [1971] for the general recursive algorithm.)

$p$-values can also be computed using a normal approximation to the randomization distribution. It is a straightforward exercise to verify that

$$E(T) = \frac{n_1(n + 1)}{2} \quad \text{and} \quad \text{Var}(T) = \frac{n_1n_2s^2}{n}$$

where $s$ is the standard deviation of the combined ranks, $r_i$, for both groups:

$$s^2 = \frac{1}{n - 1} \sum_{i=1}^{n} (r_i - \bar{r})^2$$

This formula for the variance is exact and holds both when there are no ties and when there are ties and we use averaged ranks. (Indeed, the variance formula holds for the randomization distribution of choosing $n_1$ numbers from any set of $n$ numbers.)

For the normal approximation, we calculate

$$z = \frac{T - E(T)}{\sqrt{\text{Var}(T)}}$$

When the porder option is specified, the probability

$$p = \frac{U}{n_1n_2}$$

is computed.

💡 Technical note

We follow the great majority of the literature in naming these tests for Wilcoxon, Mann, and Whitney. However, they were independently developed by several other researchers in the late 1940s and early 1950s. In addition to Wilcoxon, Mann, and Whitney, credit is due to Festinger (1946), Whitfield (1947), Haldane and Smith (1947), and Van der Reyden (1952). Leon Festinger (1919–1989), John Burdon Sanderson Haldane (1892–1964), and Cedric Austen Bardell Smith (1917–2002) are well known for other work, but little seems to be known about Whitfield or van der Reyden. For a detailed study, including information on these researchers, see Berry, Mielke, and Johnston (2012).
The median test examines whether it is likely that two or more samples came from populations with the same median. The null hypothesis is that the samples were drawn from populations with the same median. The alternative hypothesis is that at least one sample was drawn from a population with a different median. The test should be used only with ordinal or interval data.

Assume that there are score values for \( k \) independent samples to be compared. The median test is performed by first computing the median score for all observations combined, regardless of the sample group. Each score is compared with this computed grand median and is classified as being above the grand median, below the grand median, or equal to the grand median. Observations with scores equal to the grand median can be dropped, added to the “above” group, added to the “below” group, or split between the two groups.

Once all observations are classified, the data are cast into a \( 2 \times k \) contingency table, and a Pearson’s \( \chi^2 \) test or Fisher’s exact test is performed.

Henry Berthold Mann (1905–2000) was born in Vienna, Austria, where he completed a doctorate in algebraic number theory. He moved to the United States in 1938 and for several years made his livelihood by tutoring in New York. During this time, he proved a celebrated conjecture in number theory and studied statistics at Columbia with Abraham Wald, with whom he wrote three papers. After the war, he taught at Ohio State and the Universities of Wisconsin and Arizona. In addition to his work in number theory and statistics, he made major contributions to algebra and combinatorics.

Donald Ransom Whitney (1915–2007) studied at Oberlin, Princeton, and Ohio State Universities and worked at the latter throughout his career. His PhD thesis under Henry Mann was on nonparametric statistics. It was this work that produced the test that bears their names.

Title

ratio — Estimate ratios

Description

ratio produces estimates of ratios, along with standard errors.

Quick start

Estimate, standard error, and 95% confidence interval for the ratio of v1 to v2

\texttt{ratio v1\slash v2}

With bootstrap standard errors

\texttt{ratio v1\slash v2, vce(bootstrap)}

Ratios of \(v1\) to \(v2\) and \(v3\) to \(v2\)

\texttt{ratio (v1\slash v2) (v3\slash v2)}

Same as above, but name the ratios \texttt{ratio1} and \texttt{ratio2}

\texttt{ratio (ratio1: v1\slash v2) (ratio2: v3\slash v2)}

Test that \texttt{ratio1} is equal to \texttt{ratio2}

\texttt{test ratio1 = ratio2}

Ratio of \(v1\) to \(v2\) over strata defined by levels of \texttt{svar}

\texttt{ratio v1\slash v2, over(svar)}

Direct standardization across categories \texttt{cvar}, weighting by standardization weight \texttt{wvar}

\texttt{ratio v1\slash v2, stdize(cvar) stdweight(wvar)}

See [U] 11.1.10 Prefix commands.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
Options

stdize(varname) specifies that the point estimates be adjusted by direct standardization across the strata identified by varname. This option requires the stdweight() option.

stdweight(varname) specifies the weight variable associated with the standard strata identified in the stdize() option. The standardization weights must be constant within the standard strata.

nostdrescale prevents the standardization weights from being rescaled within the over() groups. This option requires stdize() but is ignored if the over() option is not specified.

over(varlist) specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in varlist. Only numeric, nonnegative, integer-valued variables are allowed in over(varlist).

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (linearized), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

vce(linearized), the default, uses the linearized or sandwich estimator of variance.

level(#) ; see [R] Estimation options.

noheader prevents the table header from being displayed. This option implies nolegend.

nolegend prevents the table legend identifying the ratios from being displayed.

display_options: vsquish, noemptycells, nolabel, fvwrap(#), fvwrapp(on(style), cformat(%,fmt), and nolstretch; see [R] Estimation options.

The following option is available with ratio but is not shown in the dialog box:

coeflegend; see [R] Estimation options.
Remarks and examples

Example 1

Using the fuel data from example 3 of [R] ttest, we estimate the ratio of mileage for the cars without the fuel treatment (mpg1) to those with the fuel treatment (mpg2).

\[
\text{. use https://www.stata-press.com/data/r18/fuel} \\
\text{. ratio myratio: mpg1/mpg2} \\
\text{Ratio estimation} \quad \text{Number of obs = 12} \\
\text{myratio: mpg1/mpg2} \\
\begin{array}{cccc}
\hline
\text{Ratio} & \text{std. err.} & \text{[95\% conf. interval]} \\
\hline
\text{myratio} & .9230769 & .032493 & .8515603 & .9945936 \\
\hline
\end{array}
\]

Using these results, we can test to see if this ratio is significantly different from one.

```
    . test myratio = 1
    ( 1) myratio = 1
    F( 1, 11) = 5.60
    Prob > F = 0.0373
```

We find that the ratio is different from one at the 5% significance level but not at the 1% significance level.

Example 2

Using state-level census data, we want to test whether the marriage rate is equal to the deathrate.

```
    . use https://www.stata-press.com/data/r18/census2 
    (1980 Census data by state) 
    . ratio (deathrate: death/pop) (marrate: marriage/pop) 
    Ratio estimation \quad \text{Number of obs = 50} 
    deathrate: death/pop 
    marrate: marriage/pop 
    \begin{array}{cccc}
    \hline
    \text{Ratio} & \text{std. err.} & \text{[95\% conf. interval]} \\
    \hline
    \text{deathrate} & .0087368 & .0002052 & .0083244 & .0091492 \\
    \text{marrate} & .0105577 & .0006184 & .009315 & .0118005 \\
    \hline
    \end{array}
    . test deathrate = marrate 
    ( 1) deathrate - marrate = 0 
    F( 1, 49) = 6.93 
    Prob > F = 0.0113
```
Stored results

`ratio` stores the following in `e()`:

Scalars
- `e(N)`: number of observations
- `e(N_over)`: number of subpopulations
- `e(N_stdize)`: number of standard strata
- `e(N_clust)`: number of clusters
- `e(k_eq)`: number of equations in `e(b)`
- `e(df_r)`: sample degrees of freedom
- `e(rank)`: rank of `e(V)`

Macros
- `e(cmd)`: ratio
- `e(cmdline)`: command as typed
- `e(varlist)`: `varlist`
- `e(stdize)`: `varname` from `stdize()`
- `e(stdweight)`: `varname` from `stdweight()`
- `e(wtype)`: weight type
- `e(wexp)`: weight expression
- `e(title)`: title in estimation output
- `e(clustvar)`: name of cluster variable
- `e(over)`: `varlist` from `over()`
- `e(namelist)`: ratio identifiers
- `e(vce)`: `vcetype` specified in `vce()`
- `e(vcetype)`: title used to label Std. err.
- `e(properties)`: `b  V`
- `e(estat_cmd)`: program used to implement `estat`
- `e(marginsnotok)`: predictions disallowed by `margins`

Matrices
- `e(b)`: vector of ratio estimates
- `e(V)`: (co)variance estimates
- `e(N)`: vector of numbers of nonmissing observations
- `e(N_stdsum)`: number of nonmissing observations within the standard strata
- `e(p_stdize)`: standardizing proportions
- `e(error)`: error code corresponding to `e(b)`

Functions
- `e(sample)`: marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices
- `r(table)`: matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

Methods and formulas

Methods and formulas are presented under the following headings:

- The ratio estimator
- Survey data
- The survey ratio estimator
- The standardized ratio estimator
- The poststratified ratio estimator
- The standardized poststratified ratio estimator
- Subpopulation estimation
The ratio estimator

Let \( R = Y/X \) be the ratio to be estimated, where \( Y \) and \( X \) are totals; see [R] total. The estimate for \( R \) is \( \hat{R} = \hat{Y}/\hat{X} \) (the ratio of the sample totals). From the delta method (that is, a first-order Taylor expansion), the approximate variance of the sampling distribution of the linearized \( \hat{R} \) is

\[
V(\hat{R}) \approx \frac{1}{\hat{X}^2} \left\{ V(\hat{Y}) - 2R\text{Cov}(\hat{Y}, \hat{X}) + R^2V(\hat{X}) \right\}
\]

Direct substitution of \( \hat{X}, \hat{R} \), and the estimated variances and covariance of \( \hat{X} \) and \( \hat{Y} \) leads to the following variance estimator:

\[
\hat{V}(\hat{R}) = \frac{1}{\hat{X}^2} \left\{ \hat{V}(\hat{Y}) - 2\hat{R}\text{Cov}(\hat{Y}, \hat{X}) + \hat{R}^2\hat{V}(\hat{X}) \right\}
\]  

(1)

Survey data

See [SVY] Variance estimation, [SVY] Direct standardization, and [SVY] Poststratification for discussions that provide background information for the following formulas.

The survey ratio estimator

Let \( Y_j \) and \( X_j \) be survey items for the \( j \)th individual in the population, where \( j = 1, \ldots, M \) and \( M \) is the size of the population. The associated population ratio for the items of interest is \( R = Y/X \) where

\[
Y = \sum_{j=1}^{M} Y_j \quad \text{and} \quad X = \sum_{j=1}^{M} X_j
\]

Let \( y_j \) and \( x_j \) be the corresponding survey items for the \( j \)th sampled individual from the population, where \( j = 1, \ldots, m \) and \( m \) is the number of observations in the sample.

The estimator \( \hat{R} \) for the population ratio \( R \) is \( \hat{R} = \hat{Y}/\hat{X} \), where

\[
\hat{Y} = \sum_{j=1}^{m} w_jy_j \quad \text{and} \quad \hat{X} = \sum_{j=1}^{m} w_jx_j
\]

and \( w_j \) is a sampling weight. The score variable for the ratio estimator is

\[
z_j(\hat{R}) = \frac{y_j - \hat{R}x_j}{\hat{X}} = \frac{\hat{X}y_j - \hat{Y}x_j}{\hat{X}^2}
\]
The standardized ratio estimator

Let $D_g$ denote the set of sampled observations that belong to the $g$th standard stratum and define $I_{D_g}(j)$ to indicate if the $j$th observation is a member of the $g$th standard stratum; where $g = 1, \ldots, L_D$ and $L_D$ is the number of standard strata. Also, let $\pi_g$ denote the fraction of the population that belongs to the $g$th standard stratum, thus $\pi_1 + \cdots + \pi_{L_D} = 1$. Note that $\pi_g$ is derived from the `stdweight()` option.

The estimator for the standardized ratio is

$$\hat{R}^D = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g}{\hat{X}_g}$$

where

$$\hat{Y}_g = \sum_{j=1}^{m} I_{D_g}(j) w_j y_j$$

and $\hat{X}_g$ is similarly defined. The score variable for the standardized ratio is

$$z_j(\hat{R}^D) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) \frac{\hat{X}_g y_j - \hat{Y}_g x_j}{\hat{X}_g^2}$$

The poststratified ratio estimator

Let $P_k$ denote the set of sampled observations that belong to poststratum $k$, and define $I_{P_k}(j)$ to indicate if the $j$th observation is a member of poststratum $k$, where $k = 1, \ldots, L_P$ and $L_P$ is the number of poststrata. Also, let $M_k$ denote the population size for poststratum $k$. $P_k$ and $M_k$ are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [SVY] svyset.

The estimator for the poststratified ratio is

$$\hat{R}^P = \frac{\hat{Y}^P}{\hat{X}^P}$$

where

$$\hat{Y}^P = \sum_{k=1}^{L_P} M_k \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{M_k} \sum_{j=1}^{m} I_{P_k}(j) w_j y_j$$

and $\hat{X}^P$ is similarly defined. The score variable for the poststratified ratio is

$$z_j(\hat{R}^P) = z_j(\hat{Y}^P) - \hat{R}^P z_j(\hat{X}^P) = \frac{\hat{X}^P z_j(\hat{Y}^P) - \hat{Y}^P z_j(\hat{X}^P)}{(\hat{X}^P)^2}$$

where

$$z_j(\hat{Y}^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{M_k} \left( y_j - \frac{\hat{Y}_k}{M_k} \right)$$

and $z_j(\hat{X}^P)$ is similarly defined.
The standardized poststratified ratio estimator

The estimator for the standardized poststratified ratio is

\[ \hat{R}^{DP} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g}{\hat{X}_g} \]

where

\[ \hat{Y}_g = \sum_{k=1}^{L_p} \frac{M_k}{\hat{M}_k} \hat{Y}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\hat{M}_k} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j) w_j y_j \]

and \( \hat{X}_g \) is similarly defined. The score variable for the standardized poststratified ratio is

\[ z_j(\hat{R}^{DP}) = \sum_{g=1}^{L_D} \pi_g \frac{\hat{X}_g z_j(\hat{Y}_g) - \hat{Y}_g z_j(\hat{X}_g)}{(\hat{X}_g)^2} \]

where

\[ z_j(\hat{Y}_g) = \sum_{k=1}^{L_p} I_{P_k}(j) \frac{M_k}{\hat{M}_k} \left\{ I_{D_g}(j)y_j - \frac{\hat{Y}_{g,k}}{\hat{M}_k} \right\} \]

and \( z_j(\hat{X}_g) \) is similarly defined.

Subpopulation estimation

Let \( S \) denote the set of sampled observations that belong to the subpopulation of interest, and define \( I_S(j) \) to indicate if the \( j \)th observation falls within the subpopulation.

The estimator for the subpopulation ratio is \( \hat{R}^S = \hat{Y}^S / \hat{X}^S \), where

\[ \hat{Y}^S = \sum_{j=1}^{m} I_S(j) w_j y_j \quad \text{and} \quad \hat{X}^S = \sum_{j=1}^{m} I_S(j) w_j x_j \]

Its score variable is

\[ z_j(\hat{R}^S) = I_S(j) \frac{y_j - \hat{R}^S x_j}{\hat{X}^S} = I_S(j) \frac{\hat{Y}^S y_j - \hat{Y}^S x_j}{(\hat{X}^S)^2} \]

The estimator for the standardized subpopulation ratio is

\[ \hat{R}^{DS} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g^S}{\hat{X}_g^S} \]

where

\[ \hat{Y}_g^S = \sum_{j=1}^{m} I_{D_g}(j) I_S(j) w_j y_j \]

and \( \hat{X}_g^S \) is similarly defined. Its score variable is

\[ z_j(\hat{R}^{DS}) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) I_S(j) \frac{\hat{Y}_g^S y_j - \hat{Y}_g^S x_j}{(\hat{X}_g^S)^2} \]
The estimator for the poststratified subpopulation ratio is

$$\hat{R}^{PS} = \frac{\hat{Y}^{PS}}{\hat{X}^{PS}}$$

where

$$\hat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{M_k} \hat{Y}^S_k = \sum_{k=1}^{L_P} \frac{M_k}{M_k} \sum_{j=1}^{m} IP_k(j) IS(j) w_j y_j$$

and $$\hat{X}^{PS}$$ is similarly defined. Its score variable is

$$z_j(\hat{R}^{PS}) = \frac{\hat{X}^{PS} z_j(\hat{Y}^{PS}) - \hat{Y}^{PS} z_j(\hat{X}^{PS})}{(\hat{X}^{PS})^2}$$

where

$$z_j(\hat{Y}^{PS}) = \sum_{k=1}^{L_P} IP_k(j) M_k \left\{ IS(j) y_j - \frac{\hat{Y}^S_k}{M_k} \right\}$$

and $$z_j(\hat{X}^{PS})$$ is similarly defined.

The estimator for the standardized poststratified subpopulation ratio is

$$\hat{R}^{DPS} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}^{PS}}{\hat{X}^{PS}}$$

where

$$\hat{Y}^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{M_k} \hat{Y}^{S,k}_g = \sum_{k=1}^{L_p} \frac{M_k}{M_k} \sum_{j=1}^{m} ID_g(j) IP_k(j) IS(j) w_j y_j$$

and $$\hat{X}^{PS}_g$$ is similarly defined. Its score variable is

$$z_j(\hat{R}^{DPS}) = \sum_{g=1}^{L_D} \pi_g \frac{\hat{X}^{PS} z_j(\hat{Y}^{PS}) - \hat{Y}^{PS} z_j(\hat{X}^{PS})}{(\hat{X}^{PS}_g)^2}$$

where

$$z_j(\hat{Y}^{PS}_g) = \sum_{k=1}^{L_p} IP_k(j) M_k \left\{ ID_g(j) IS(j) y_j - \frac{\hat{Y}^{S,k}_g}{M_k} \right\}$$

and $$z_j(\hat{X}^{PS}_g)$$ is similarly defined.

Remarks and examples

For examples of the use of `test` after `ratio`, see [R] `ratio`.

Also see

[R] `ratio` — Estimate ratios

[U] 20 Estimation and postestimation commands
**Description**

*reg3* estimates a system of structural equations, where some equations contain endogenous variables among the explanatory variables. Estimation is via three-stage least squares (3SLS); see Zellner and Theil (1962). Typically, the endogenous explanatory variables are dependent variables from other equations in the system. *reg3* supports iterated GLS estimation and linear constraints.

*reg3* can also estimate systems of equations by seemingly unrelated regression estimation (SURE), multivariate regression (MVREG), and equation-by-equation ordinary least squares (OLS) or two-stage least squares (2SLS).

**Nomenclature**

Under 3SLS or 2SLS estimation, a *structural equation* is defined as one of the equations specified in the system. A *dependent variable* will have its usual interpretation as the left-hand-side variable in an equation with an associated disturbance term. All dependent variables are explicitly taken to be *endogenous* to the system and are treated as correlated with the disturbances in the system’s equations. Unless specified in an *endog()* option, all other variables in the system are treated as *exogenous* to the system and uncorrelated with the disturbances. The exogenous variables are taken to be *instruments* for the endogenous variables.

**Quick start**

System of equations regressing $y_1$ on $x_1$, $x_2$, and $y_2$ on $x_1$, $x_3$, and $y_1$

```
reg3 (y1 x1 x2 y2) (y2 x1 x3 y1)
```

Same as above, but name equations eq1 and eq2

```
reg3 (eq1: y1 x1 x2 y2) (eq2: y2 x1 x3 y1)
```

Same as above, but specify that $x_1$ is endogenous and add instrumental variable $v_1$

```
reg3 (eq1: y1 x1 x2 y2) (eq2: y2 x1 x3 y1), endog(x1) exog(v1)
```

Same as above, but with iterated estimation

```
reg3 (eq1: y1 x1 x2 y2) (eq2: y2 x1 x3 y1), endog(x1) exog(v1) ireg3
```

Three-stage estimation for systems of simultaneous equations

Model

ireg3 causes reg3 to iterate over the estimated disturbance covariance matrix and parameter estimates until the parameter estimates converge. Although the iteration is usually successful, there is no guarantee that it will converge to a stable point. Under SURE, this iteration converges to the maximum likelihood estimates.

3sls specifies the full 3SLS estimation of the system and is the default for reg3.

2sls causes reg3 to perform equation-by-equation 2SLS on the full system of equations. This option implies dfk, small, and corr(independent).

Cross-equation testing should not be performed after estimation with this option. With 2sls, no covariance is estimated between the parameters of the equations. For cross-equation testing, use 3sls.

ols causes reg3 to perform equation-by-equation OLS on the system—even if dependent variables appear as regressors or the regressors differ for each equation; see [MV] mvreg. ols implies allexog, dfk, small, and corr(independent); nodfk and nosmall may be specified to override dfk and small.

The covariance of the coefficients between equations is not estimated under this option, and cross-equation tests should not be performed after estimation with ols. For cross-equation testing, use sure or 3sls (the default).

sure causes reg3 to perform a SURE of the system—even if dependent variables from some equations appear as regressors in other equations; see [R] sureg. sure is a synonym for allexog.

mvreg is identical to sure, except that the disturbance covariance matrix is estimated with an OLS degrees-of-freedom adjustment—the dfk option. If the regressors are identical for all equations, the parameter point estimates will be the standard MVREG results. If any of the regressors differ, the point estimates are those for SURE with an OLS degrees-of-freedom adjustment in computing the covariance matrix. nodfk and nosmall may be specified to override dfk and small.

\texttt{corr} (correlation) specifies the assumed form of the correlation structure of the equation disturbances and is rarely requested explicitly. For the family of models fit by \texttt{reg3}, the only two allowable correlation structures are unstructured and independent. The default is unstructured.

This option is used almost exclusively to estimate a system of equations by 2SLS or to perform OLS regression with \texttt{reg3} on multiple equations. In these cases, the correlation is set to independent, forcing \texttt{reg3} to treat the covariance matrix of equation disturbances as diagonal in estimating model parameters. Thus, a set of two-stage coefficient estimates can be obtained if the system contains endogenous right-hand-side variables, or OLS regression can be imposed, even if the regressors differ across equations. Without imposing independent disturbances, \texttt{reg3} would estimate the former by 3SLS and the latter by SURE.

Any tests performed after estimation with the independent option will treat coefficients in different equations as having no covariance; cross-equation tests should not be used after specifying \texttt{corr(independent)}.

\texttt{exog(varlist)} specifies additional exogenous variables that are included in none of the system equations. This can occur when the system contains identities that are not estimated. If implicitly exogenous variables from the equations are listed here, \texttt{reg3} will just ignore the additional information. Specified variables will be added to the exogenous variables in the system and used in the first stage as instruments for the endogenous variables. By specifying dependent variables from the structural equations, you can use \texttt{exog()} to override their endogeneity.

\texttt{endog(varlist)} identifies variables in the system that are not dependent variables but are endogenous to the system. These variables must appear in the variable list of at least one equation in the system. Again, the need for this identification often occurs when the system contains identities. For example, a variable that is the sum of an exogenous variable and a dependent variable may appear as an explanatory variable in some equations.

\texttt{inst(varlist)} specifies a full list of all exogenous variables and may not be used with the \texttt{endog()} or \texttt{exog()} options. It must contain a full list of variables to be used as instruments for the endogenous regressors. Like \texttt{exog()}, the list may contain variables not specified in the system of equations. This option can be used to achieve the same results as the \texttt{endog()} and \texttt{exog()} options, and the choice is a matter of convenience. Any variable not specified in the \texttt{varlist} of the \texttt{inst()} option is assumed to be endogenous to the system. As with \texttt{exog()}, including the dependent variables from the structural equations will override their endogeneity.

\texttt{allexog} indicates that all right-hand-side variables are to be treated as exogenous—even if they appear as the dependent variable of another equation in the system. This option can be used to enforce a SURE or MVREG estimation even when some dependent variables appear as regressors.

\texttt{noconstant, constraints(constraints); see \texttt{[R] Estimation options}}.

\texttt{vce(vcetype)} specifies the type of standard error reported, which includes types that are derived from asymptotic theory (unadjusted), that are robust to some kinds of misspecification (robust), and that allow for intragroup correlation (cluster clustvar); see \texttt{[R] vce_option}.

\texttt{vce(unadjusted)}, the default, specifies that an unadjusted (nonrobust) VCE matrix be used; this results in efficient estimates when assuming homoskedasticity.

\texttt{small} specifies that small-sample statistics be computed. It shifts the test statistics from $\chi^2$ and $z$ statistics to $F$ statistics and $t$ statistics. This option is intended primarily to support MVREG. Although the standard errors from each equation are computed using the degrees of freedom for
the equation, the degrees of freedom for the $t$ statistics are all taken to be those for the first equation. This approach poses no problem under MVREG because the regressors are the same across equations.

dfk specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. As an asymptotically justified estimator, \texttt{reg3} by default uses the number of sample observations $n$ as a divisor. When the dfk option is set, a small-sample adjustment is made, and the divisor is taken to be $\sqrt{(n - k_i)(n - k_j)}$, where $k_i$ and $k_j$ are the number of parameters in equations $i$ and $j$, respectively.

dfk2 specifies the use of an alternative divisor in computing the covariance matrix for the equation errors. When the dfk2 option is set, the divisor is taken to be the mean of the residual degrees of freedom from the individual equations.

\begin{itemize}
\item \texttt{level(#)}; see \cite{R} Estimation options.
\item \texttt{first} requests that the first-stage regression results be displayed during estimation.
\item \texttt{nocnsreport}; see \cite{R} Estimation options.
\end{itemize}

\begin{itemize}
\item \texttt{display_options: noc, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#), fvwrappen(style), cformat(\%,fmt), pformat(\%,fmt), sformat(\%,fmt), and nolstretch}; see \cite{R} Estimation options.
\end{itemize}

\begin{itemize}
\item \texttt{optimization_options} control the iterative process that minimizes the sum of squared errors when \texttt{irreg3} is specified. These options are seldom used.
\item \texttt{iterate(#)} specifies the maximum number of iterations. When the number of iterations equals \#, the optimizer stops and presents the current results, even if the convergence tolerance has not been reached. The default is the number set using \texttt{set maxiter}, which is 300 by default.
\item \texttt{trace} adds to the iteration log a display of the current parameter vector.
\item \texttt{log} and \texttt{nolog} specify whether to display the iteration log. The iteration log is displayed by default unless you used \texttt{set iterlog off} to suppress it; see \texttt{set iterlog} in \cite{R} set iter.
\item \texttt{tolerance(#)} specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to \#, the optimization process is stopped. \texttt{tolerance(1e-6)} is the default.
\end{itemize}

The following options are available with \texttt{reg3} but are not shown in the dialog box:

\begin{itemize}
\item \texttt{noheader} suppresses display of the header reporting the estimation method and the table of equation summary statistics.
\item \texttt{notable} suppresses display of the coefficient table.
\item \texttt{nofooter} suppresses display of the footer reporting the list of endogenous and exogenous variables in the model.
\item \texttt{coeflegend}; see \cite{R} Estimation options.
\end{itemize}
Remarks and examples

\texttt{reg3} estimates systems of structural equations where some equations contain endogenous variables among the explanatory variables. Generally, these endogenous variables are the dependent variables of other equations in the system, though not always. The disturbance is correlated with the endogenous variables—violating the assumptions of OLS. Further, because some of the explanatory variables are the dependent variables of other equations in the system, the error terms among the equations are expected to be correlated. \texttt{reg3} uses an instrumental-variables approach to produce consistent estimates and generalized least squares (GLS) to account for the correlation structure in the disturbances across the equations. Good general references on three-stage estimation include Davidson and MacKinnon (1993, 651–661) and Greene (2018, 363–365).

Three-stage least squares can be thought of as producing estimates from a three-step process.

\textbf{Step 1.} Develop instrumented values for all endogenous variables. These instrumented values can simply be considered as the predicted values resulting from a regression of each endogenous variable on all exogenous variables in the system. This stage is identical to the first step in 2SLS and is critical for the consistency of the parameter estimates.

\textbf{Step 2.} Obtain a consistent estimate for the covariance matrix of the equation disturbances. These estimates are based on the residuals from a 2SLS estimation of each structural equation.

\textbf{Step 3.} Perform a GLS-type estimation using the covariance matrix estimated in the second stage and with the instrumented values in place of the right-hand-side endogenous variables.

\section*{Technical note}

The estimation and use of the covariance matrix of disturbances in three-stage estimation is almost identical to the SURE method—\texttt{sureg}. As with SURE, using this covariance matrix improves the efficiency of the three-stage estimator. Even without the covariance matrix, the estimates would be consistent. (They would be 2SLS estimates.) This improvement in efficiency comes with a caveat. All the parameter estimates now depend on the consistency of the covariance matrix estimates. If one equation in the system is misspecified, the disturbance covariance estimates will be inconsistent, and the resulting coefficients will be biased and inconsistent. Alternatively, if each equation is estimated separately by 2SLS (\texttt{[R] regress}), only the coefficients in the misspecified equation are affected.

\section*{Technical note}

If an equation is just identified, the 3SLS point estimates for that equation are identical to the 2SLS estimates. However, as with \texttt{sureg}, even if all equations are just identified, fitting the model via \texttt{reg3} has at least one advantage over fitting each equation separately via \texttt{ivregress}; by using \texttt{reg3}, tests involving coefficients in different equations can be performed easily using \texttt{test} or \texttt{testnl}.

\section*{Example 1}

A simple macroeconomic model relates consumption (\texttt{consump}) to private and government wages paid (\texttt{wagepriv} and \texttt{wagegovt}). Simultaneously, private wages depend on consumption, total government expenditures (\texttt{govt}), and the lagged stock of capital in the economy (\texttt{capital1}). Although this is not a plausible model, it does meet the criterion of being simple. This model could be written as

\[ \texttt{consump} = \beta_0 + \beta_1 \texttt{wagepriv} + \beta_2 \texttt{wagegovt} + \epsilon_1 \]

\[ \texttt{wagepriv} = \beta_3 + \beta_4 \texttt{consump} + \beta_5 \texttt{govt} + \beta_6 \texttt{capital1} + \epsilon_2 \]
If we assume that this is the full system, \texttt{consump} and \texttt{wagepriv} will be endogenous variables, with \texttt{wagegovt}, \texttt{govt}, and \texttt{capital1} exogenous. Data for the U.S. economy on these variables are taken from Klein (1950). This model can be fit with \texttt{reg3} by typing

\begin{verbatim}
use https://www.stata-press.com/data/r18/klein
reg3 (consump wagepriv wagegovt) (wagepriv consump govt capital1)
\end{verbatim}

Endogenous: consump wagepriv
Exogenous: wagegovt govt capital1

Without showing the 2SLS results, we note that the consumption function in this system falls under the conditions noted earlier. That is, the 2SLS and 3SLS coefficients for the equation are identical.

Example 2

Some of the most common simultaneous systems encountered are supply-and-demand models. A simple system could be specified as

\begin{align*}
q_{\text{Demand}} &= \beta_0 + \beta_1 \text{price} + \beta_2 \text{pcompete} + \beta_3 \text{income} + \epsilon_1 \\
q_{\text{Supply}} &= \beta_4 + \beta_5 \text{price} + \beta_6 \text{paw} + \epsilon_2
\end{align*}

Equilibrium condition: quantity = \( q_{\text{Demand}} = q_{\text{Supply}} \)

where

- \text{quantity} is the quantity of a product produced and sold,
- \text{price} is the price of the product,
- \text{pcompete} is the price of a competing product,
- \text{income} is the average income level of consumers, and
- \text{paw} is the price of raw materials used to produce the product.

In this system, price is assumed to be determined simultaneously with demand. The important statistical implications are that price is not a predetermined variable and that it is correlated with the disturbances of both equations. The system is somewhat unusual: quantity is associated with two disturbances. This fact really poses no problem because the disturbances are specified on the behavioral demand and supply equations—two separate entities. Often one of the two equations is rewritten to place price on the left-hand side, making this endogeneity explicit in the specification.
To provide a concrete illustration of the effects of simultaneous equations, we can simulate data for the above system by using known coefficients and disturbance properties. Specifically, we will simulate the data as

\[
\begin{align*}
q_{\text{Demand}} &= 40 - 1.0 \text{price} + 0.25 \text{pcompete} + 0.5 \text{income} + \epsilon_1 \\
q_{\text{Supply}} &= 0.5 \text{price} - 0.75 \text{praw} + \epsilon_2
\end{align*}
\]

where

\[
\begin{align*}
\epsilon_1 &\sim N(0, 3.8) \\
\epsilon_2 &\sim N(0, 2.4)
\end{align*}
\]

For comparison, we can estimate the supply and demand equations separately by OLS. The estimates for the demand equation are

```
use https://www.stata-press.com/data/r18/supDem
regress quantity price pcompete income
```

Examining the coefficients from these regressions, we note that they are not close to the known parameters used to generate the simulated data. In particular, the positive coefficient on price in the demand equation stands out. We constructed our simulated data to be consistent with economic theory—people demand less of a product if its price rises and more if their personal income rises. Although the price coefficient is statistically insignificant, the positive value contrasts starkly with what is predicted from economic price theory and the −1.0 value that we used in the simulation. Likewise, we are disappointed with the insignificance and level of the coefficient on average income. The supply equation has correct signs on the two main parameters, but their levels are different from the known values. In fact, the coefficient on price (0.724675) is different from the simulated parameter (0.5) at the 5% level of significance.
All of these problems are to be expected. We explicitly constructed a simultaneous system of equations that violated one of the assumptions of least squares. Specifically, the disturbances were correlated with one of the regressors—\textit{price}.

Two-stage least squares can be used to address the correlation between regressors and disturbances. Using instruments for the endogenous variable, \textit{price}, 2SLS will produce consistent estimates of the parameters in the system. Let’s use \texttt{ivregress} (see \texttt{[R] ivregress}) to see how our simulated system behaves when fit using 2SLS.

\begin{verbatim}
. ivregress 2sls quantity (price = praw) pcompete income

Endogenous: price
Exogenous: praw pcompete income
\end{verbatim}

We are now much happier with the estimation results. All the coefficients from both equations are close to the true parameter values for the system. In particular, the coefficients are all well within 95% confidence intervals for the parameters. The missing $R^2$ in the demand equation seems unusual; we will discuss that more later.

Finally, this system could be estimated using 3SLS. To demonstrate how large systems might be handled and to avoid multiline commands, we will use global macros (see \texttt{[P] macro}) to hold the specifications for our equations.

\begin{verbatim}
. global demand "(qDemand: quantity price pcompete income)"
. global supply "(qSupply: quantity price praw)"
. reg3 $demand $supply, endog(price)
\end{verbatim}

We must specify \textit{price} as endogenous because it does not appear as a dependent variable in either equation. Without this option, \texttt{reg3} would assume that there are no endogenous variables in the system and produce seemingly unrelated regression (\texttt{sureg}) estimates. The \texttt{reg3} output from our series of commands is
Three-stage least-squares regression

The use of 3SLS over 2SLS is essentially an efficiency issue. The coefficients of the demand equation from 3SLS are close to the coefficients from two-stage least squares, and those of the supply equation are identical. The latter case was mentioned earlier for systems with some exactly identified equations. However, even for the demand equation, we do not expect the coefficients to change systematically. What we do expect from three-stage least squares are more precise estimates of the parameters given the validity of our specification and reg3’s use of the covariances among the disturbances.

Let’s summarize the results. With OLS, we got obviously biased estimates of the parameters. No amount of data would have improved the OLS estimates—they are inconsistent in the face of the violated OLS assumptions. With 2SLS, we obtained consistent estimates of the parameters, and these would have improved with more data. With 3SLS, we obtained consistent estimates of the parameters that are more efficient than those obtained by 2SLS.

Technical note

We noted earlier that the $R^2$ was missing from the two-stage estimates of the demand equation. Now we see that the $R^2$ is negative for the three-stage estimates of the same equation. How can we have a negative $R^2$?

In most estimators, other than least squares, the $R^2$ is no more than a summary measure of the overall in-sample predictive power of the estimator. The computational formula for $R^2$ is $R^2 = 1 - \text{RSS/TSS}$, where RSS is the residual sum of squares (sum of squared residuals) and TSS is the total sum of squared deviations about the mean of the dependent variable. In a standard linear model with a constant, the model from which the TSS is computed is nested within the full model from which RSS is computed—they both have a constant term based on the same data. Thus, it must be that $\text{TSS} \geq \text{RSS}$ and $R^2$ is constrained between 0 and 1.

For 2SLS and 3SLS, some of the regressors enter the model as instruments when the parameters are estimated. However, because our goal is to fit the structural model, the actual values, not the instruments for the endogenous right-hand-side variables, are used to determine $R^2$. The model residuals are computed over a different set of regressors from those used to fit the model. The two-
or three-stage estimates are no longer nested within a constant-only model of the dependent variable, and the residual sum of squares is no longer constrained to be smaller than the total sum of squares.

A negative $R^2$ in 3SLS should be taken for exactly what it is—an indication that the structural model predicts the dependent variable worse than a constant-only model. Is this a problem? It depends on the application. Three-stage least squares applied to our contrived supply-and-demand example produced good estimates of the known true parameters. Still, the demand equation produced an $R^2$ of $-0.854$. How do we feel about our parameter estimates? This should be determined by the estimates themselves, their associated standard errors, and the overall model significance. On this basis, negative $R^2$ and all, we feel pretty good about all the parameter estimates for both the supply and demand equations. Would we want to make predictions about equilibrium quantity by using the demand equation alone? Probably not. Would we want to make these quantity predictions by using the supply equation? Possibly, because based on in-sample predictions, they seem better than those from the demand equations. However, both the supply and demand estimates are based on limited information. If we are interested in predicting quantity, a reduced-form equation containing all our independent variables would usually be preferred.

Technical note

As a matter of syntax, we could have specified the supply-and-demand model on one line without using global macros.

```
. reg3 (quantity price pcompete income) (quantity price praw), endog(price)
```

Endogenous: quantity price
Exogenous: pcompete income praw

However, here `reg3` has been forced to create a unique equation name for the supply equation—2quantity. Both the supply and demand equations could not be designated as quantity, so a number was prefixed to the name for the supply equation.
We could have specified

```
.reg3 (qDemand: quantity price pcompete income) (qSupply: quantity price praw), > endog(price)
```

and obtained the same results and equation labeling as when we used global macros to hold the equation specifications.

Without explicit equation names, `reg3` always assumes that the dependent variable should be used to name equations. When each equation has a different dependent variable, this rule causes no problems and produces easily interpreted result tables. If the same dependent variable appears in more than one equation, however, `reg3` will create a unique equation name based on the dependent variable name. Because equation names must be used for cross-equation tests, you have more control in this situation if explicit names are placed on the equations.

Example 3: Using the full syntax of `reg3`

Klein’s (1950) model of the U.S. economy is often used to demonstrate system estimators. It contains several common features that will serve to demonstrate the full syntax of `reg3`. The Klein model is defined by the following seven relationships:

1. \[ c = \beta_0 + \beta_1 p + \beta_2 L.p + \beta_3 w + \epsilon_1 \]
2. \[ i = \beta_4 + \beta_5 p + \beta_6 L.p + \beta_7 L.k + \epsilon_2 \]
3. \[ wp = \beta_8 + \beta_9 y + \beta_{10} L.y + \beta_{11} yr + \epsilon_3 \]
4. \[ y = c + i + g \]
5. \[ p = y - t - wp \]
6. \[ k = L.k + i \]
7. \[ w = wg + wp \]

Here we have used Stata’s lag operator \( L. \) to represent variables that appear with a one-period lag in our model; see [U] 13.10 Time-series operators.

The variables in the model are listed below. Two sets of variable names are shown. The concise first name uses traditional economics mnemonics, whereas the second name provides more guidance for everyone else. The concise names serve to keep the specification of the model small (and quite understandable to economists).

</table>
Equations (1)–(3) are behavioral and contain explicit disturbances (\(\epsilon_1\), \(\epsilon_2\), and \(\epsilon_3\)). The remaining equations are identities that specify additional variables in the system and their accounting relationships with the variables in the behavioral equations. Some variables are explicitly endogenous by appearing as dependent variables in (1)–(3). Others are implicitly endogenous as linear combinations that contain other endogenous variables (for example, \(w\) and \(p\)). Still other variables are implicitly exogenous by appearing in the identities but not in the behavioral equations (for example, \(wg\) and \(g\)).

Using the concise names, we can fit Klein’s model with the following command:

```
use https://www.stata-press.com/data/r18/klein2
.reg3 (c p L.p w) (i p L.p L.k) (wp y L.y yr), endog(w p y) exog(t wg g)
```

Endogenous: c i wp w p y
Exogenous: L.p L.k L.y yr t wg g

We used the `exog()` option to identify \(t\), \(wg\), and \(g\) as exogenous variables in the system. These variables must be identified because they are part of the system but appear directly in none of the behavioral equations. Without this option, `reg3` would not know they were part of the system and could be used as instrumental variables. The `endog()` option specifying \(w\), \(p\), and \(y\) is also required. Without this information, `reg3` would be unaware that these variables are linear combinations that include endogenous variables. We did not include \(k\) in the `endog()` option because only its lagged value appears in the behavioral equations.
Technical note

Rather than listing additional endogenous and exogenous variables, we could specify the full list of exogenous variables in an `inst()` option,

```
.reg3 (c p L.p w) (i p L.p L.k) (wp y L.y yr), inst(g t wg yr L.p L.k L.y)
```

or equivalently,

```
.reg3 (c p L.p w)
.global conseqn "(c p L.p w)"
.global inveqn "(i p L.p L.k)"
.global wageqn "(wp y L.y yr)"
.global inlist "g t wg yr L.p L.k L.y"
.reg3 $conseqn $inveqn $wageqn, inst($inlist)
```

Macros and explicit equations can also be mixed in the specification

```
.reg3 $conseqn (i p L.p L.k) $wageqn, endog(w p y) exog(t wg g)
```

or

```
.reg3 (c p L.p w) $inveqn (wp y L.y yr), endog(w p y) exog(t wg g)
```

Placing the equation-binding parentheses in the global macros was also arbitrary. We could have used

```
.global consump "c p L.p w"
global invest "i p L.p L.k"
global wagepriv "wp y L.y yr"
.reg3 ($consump) ($invest) ($wagepriv), endog($enlist) exog($exlist) ireg3
```

`reg3` is tolerant of all combinations, and these commands will produce identical output.

Switching to the full variable names, we can fit Klein’s model with the commands below. We will use global macros to store the lists of endogenous and exogenous variables. Again, this is not necessary: these lists could have been typed directly on the command line. However, assigning the lists to local macros makes additional processing easier if alternative models are to be fit. We will also use the `ireg3` option to produce the iterated estimates.

```
.use https://www.stata-press.com/data/r18/kleinfull
.global conseqn "(consump profits L.profits wagetot)"
global inveqn "(invest profits L.profits L.capital)"
global wageqn "(wagepriv totinc L.totinc year)"
global enlist "wagetot profits totinc"
global exlist "taxnetx wagegovt govt"
.reg3 $conseqn $inveqn $wageqn, endog($enlist) exog($exlist) exog($exlist) ireg3
```

Example 4: Constraints with \texttt{reg3}

As a simple example of constraints, (1) above may be rewritten with both wages explicitly appearing (rather than as a variable containing the sum). Using the longer variable names, we have

\[
\text{consump} = \beta_0 + \beta_1 \text{profits} + \beta_2 \text{L.profits} + \beta_3 \text{wagepriv} + \beta_{12} \text{wagegovt} + \epsilon_1
\]

To retain the effect of the identity in (7), we need $\beta_3 = \beta_{12}$ as a constraint on the system. We obtain this result by defining the constraint in the usual way and then specifying its use in \texttt{reg3}. Because \texttt{reg3} is a system estimator, we will need to use the full equation syntax of \texttt{constraint}. The assumption that the following commands are entered after the model above has been estimated. We are simply changing the definition of the consumption equation (\texttt{consump}) and adding a constraint on two of its parameters. The rest of the model definition is carried forward.

. global conseqn "(consump profits L.profits wagepriv wagegovt)"
. constraint define 1 [consump]wagepriv = [consump]wagegovt
. reg3 $conseqn $inveqn $wageqn, endog($enlist) exog($exlist) constr(1) ireg3

Note: additional endogenous variables not in the system have no effect and are ignored (wagetot).

As expected, none of the parameter or standard error estimates has changed from the previous estimates (before the seventh significant digit). We have simply decomposed the total wage variable into its two parts and constrained the coefficients on these parts. The warning about additional endogenous variables was just \texttt{reg3}'s way of letting us know that we had specified some information that was irrelevant to the estimation of the system. We had left the \texttt{wagetot} variable in our \texttt{endog} macro. It does not mean anything to the system to specify \texttt{wagetot} as endogenous because it is no longer in the system. That's fine with \texttt{reg3} and fine for our current purposes.

We can also impose constraints across the equations. For example, the admittedly meaningless constraint of requiring \texttt{profits} to have the same effect in both the consumption and investment equations could be imposed. Retaining the constraint on the wage coefficients, we would estimate this constrained system.
. constraint define 2 [consump]profits = [invest]profits
.reg3 $conseqn $inveqn $wageqn, endog($enlist) exog($exlist) constr(1 2) ireg3
note: additional endogenous variables not in the system have no effect and are ignored (wagetot).

Technical note

Identification in a system of simultaneous equations involves the notion that there is enough information to estimate the parameters of the model given the specified functional form. Under-identification usually manifests itself as one matrix in the 3SLS computations. The most commonly

Technical note

Identification in a system of simultaneous equations involves the notion that there is enough information to estimate the parameters of the model given the specified functional form. Under-identification usually manifests itself as one matrix in the 3SLS computations. The most commonly
Three-stage estimation for systems of simultaneous equations

A violated order condition for 2SLS or 3SLS involves the number of endogenous and exogenous variables. There must be at least as many noncollinear exogenous variables in the remaining system as there are endogenous right-hand-side variables in an equation. This condition must hold for each structural equation in the system.

Put as a set of rules the following:

1. Count the number of right-hand-side endogenous variables in an equation and call this $m_i$.
2. Count the number of exogenous variables in the same equation and call this $k_i$.
3. Count the total number of exogenous variables in all the structural equations plus any additional variables specified in an `exog()` or `inst()` option and call this $K$.
4. If $m_i > (K - k_i)$ for any structural equation $(i)$, then the system is underidentified and cannot be estimated by 3SLS.

We are also possibly in trouble if any of the exogenous variables are linearly dependent. We must have $m_i$ linearly independent variables among the exogenous variables represented by $(K - k_i)$.

The complete conditions for identification involve rank-order conditions on several matrices. For a full treatment, see Theil (1971) or Greene (2018, 363–365).

**Henri Theil (1924–2000)** was born in Amsterdam and awarded a PhD in 1951 by the University of Amsterdam. He researched and taught econometric theory, statistics, microeconomics, macroeconomic modeling, and economic forecasting, and policy at (now) Erasmus University Rotterdam, the University of Chicago, and the University of Florida. Theil’s many specific contributions include work on 2SLS and 3SLS, inequality and concentration, and consumer demand.

### Stored results

`reg3` stores the following in `e()`:  

**Scalars**

- `e(N)` number of observations
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(mss_#)` model sum of squares for equation #
- `e(df_m#)` model degrees of freedom for equation #
- `e(rss_#)` residual sum of squares for equation #
- `e(df_r)` residual degrees of freedom (small)
- `e(r2_#)` $R^2$ for equation #
- `e(F_#)` $F$ statistic for equation # (small)
- `e(rmse_#)` root mean squared error for equation #
- `e(dfk2_adj)` divisor used with VCE when dfk2 specified
- `e(ll)` log likelihood
- `e(N_clust)` number of clusters
- `e(chi2_#)` $\chi^2$ for equation #
- `e(p_#)` $p$-value for model test for equation #
- `e(cons_#)` 1 when equation # has a constant, 0 otherwise
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
Macros
- \texttt{e(cmd)} \texttt{reg3}
- \texttt{e(cmdline)} \texttt{command as typed}
- \texttt{e(depvar)} \texttt{names of dependent variables}
- \texttt{e(exog)} \texttt{names of exogenous variables}
- \texttt{e(endog)} \texttt{names of endogenous variables}
- \texttt{e(eqnames)} \texttt{names of equations}
- \texttt{e(corr)} \texttt{correlation structure}
- \texttt{e(utype)} \texttt{weight type}
- \texttt{e(wexp)} \texttt{weight expression}
- \texttt{e(method)} \texttt{3sls, 2sls, ols, sure, or mvreg}
- \texttt{e(small)} \texttt{small, if specified}
- \texttt{e(dfk)} \texttt{dfk, if specified}
- \texttt{e(clustvar)} \texttt{name of cluster variable}
- \texttt{e(vce)} \texttt{vcetype specified in vce()}
- \texttt{e(vcetype)} \texttt{title used to label Std. err.}
- \texttt{e(properties)} \texttt{b V}
- \texttt{e(predict)} \texttt{program used to implement predict}
- \texttt{e(marginsok)} \texttt{predictions allowed by margins}
- \texttt{e(marginsnotok)} \texttt{predictions disallowed by margins}
- \texttt{e(marginsdefault)} \texttt{default predict() specification for margins}
- \texttt{e(asbalanced)} \texttt{factor variables fvset as asbalanced}
- \texttt{e(asobserved)} \texttt{factor variables fvset as asobserved}

Matrices
- \texttt{e(b)} \texttt{coefficient vector}
- \texttt{e(Cns)} \texttt{constraints matrix}
- \texttt{e(Sigma)} \texttt{\hat{\Sigma} matrix}
- \texttt{e(V)} \texttt{variance–covariance matrix of the estimators}

Functions
- \texttt{e(sample)} \texttt{marks estimation sample}

In addition to the above, the following is stored in \texttt{r()}: Matrices
- \texttt{r(table)} \texttt{matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals}

Note that results stored in \texttt{r()} are updated when the command is replayed and will be replaced when any \texttt{r-class} command is run after the estimation command.

Methods and formulas

The most concise way to represent a system of equations for 3SLS requires thinking of the individual equations and their associated data as being stacked. \texttt{reg3} does not expect the data in this format, but it is a convenient shorthand. The system could then be formulated as

\[
\begin{bmatrix}
  y_1 \\
  y_2 \\
  \vdots \\
  y_M
\end{bmatrix} = \begin{bmatrix}
  Z_1 & 0 & \cdots & 0 \\
  0 & Z_2 & \cdots & 0 \\
  \vdots & \vdots & \ddots & \vdots \\
  0 & 0 & \cdots & Z_M
\end{bmatrix} \begin{bmatrix}
  \beta_1 \\
  \beta_2 \\
  \vdots \\
  \beta_M
\end{bmatrix} + \begin{bmatrix}
  \epsilon_1 \\
  \epsilon_2 \\
  \vdots \\
  \epsilon_M
\end{bmatrix}
\]

In full matrix notation, this is just

\[y = ZB + \epsilon\]

The \textbf{Z} elements in these matrices represent both the endogenous and the exogenous right-hand-side variables in the equations.
Also assume that there will be correlation between the disturbances of the equations so that

\[ E(\epsilon\epsilon') = \Sigma \]

where the disturbances are further assumed to have an expected value of 0; \( E(\epsilon) = 0 \).

The first stage of 3SLS regression requires developing instrumented values for the endogenous variables in the system. These values can be derived as the predictions from a linear regression of each endogenous regressor on all exogenous variables in the system or, more succinctly, as the projection of each regressor through the projection matrix of all exogenous variables onto the regressors. Designating the set of all exogenous variables as \( X \) results in

\[ \hat{z}_i = X(X'X)^{-1}X'z_i \quad \text{for each } i \]

Taken collectively, these \( \hat{Z} \) contain the instrumented values for all the regressors. They take on the actual values for the exogenous variables and first-stage predictions for the endogenous variables. Given these instrumented variables, a generalized least squares (GLS) or Aitken (1935) estimator can be formed for the parameters of the system

\[ \hat{B} = \{ \hat{Z}'(\Sigma^{-1} \otimes I)\hat{Z} \}^{-1} \hat{Z}'(\Sigma^{-1} \otimes I)y \]

All that remains is to obtain a consistent estimator for \( \Sigma \). This estimate can be formed from the residuals of 2SLS estimates of each equation in the system. Alternately, and identically, the residuals can be computed from the estimates formed by taking \( \Sigma \) to be an identity matrix. This maintains the full system of coefficients and allows constraints to be applied when the residuals are computed.

If we take \( E \) to be the matrix of residuals from these estimates, a consistent estimate of \( \Sigma \) is

\[ \hat{\Sigma} = \frac{E'E}{n} \]

where \( n \) is the number of observations in the sample. An alternative divisor for this estimate can be obtained with the \( \text{dfk} \) option as outlined under options.

With the estimate of \( \hat{\Sigma} \) placed into the GLS estimating equation,

\[ \hat{B} = \{ \hat{Z}'(\hat{\Sigma}^{-1} \otimes I)\hat{Z} \}^{-1} \hat{Z}'(\hat{\Sigma}^{-1} \otimes I)y \]

is the 3SLS estimates of the system parameters.

The asymptotic variance–covariance matrix of the estimator is just the standard formulation for a GLS estimator

\[ V_{\hat{B}} = \{ \hat{Z}'(\hat{\Sigma}^{-1} \otimes I)\hat{Z} \}^{-1} \]

Iterated 3SLS estimates can be obtained by computing the residuals from the three-stage parameter estimates, using these to formulate a new \( \hat{\Sigma} \), and recomputing the parameter estimates. This process is repeated until the estimates \( \hat{B} \) converge—if they converge. Convergence is not guaranteed. When estimating a system by SURE, these iterated estimates will be the maximum likelihood estimates for the system. The iterated solution can also be used to produce estimates that are invariant to choice of system and restriction parameterization for many linear systems under full 3SLS.
The exposition above follows the parallel developments in Greene (2018) and Davidson and MacKinnon (1993).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] \_robust}, particularly \texttt{Introduction} and \texttt{Methods and formulas}.

Alexander Craig Aitken (1895–1967) was born in Dunedin, New Zealand. He attended the University of Otago on a full scholarship but left the university to enlist in the New Zealand Expeditionary Force during World War I. He would later reflect on the time he spent in active service and publish two war memoirs.

After returning from the war, he completed his studies at the University of Otago and then worked on his PhD at the University of Edinburgh under E. T. Whittaker. Although he suffered weeks of illness during the course of his postgraduate studies, he managed to write an impressive thesis on data smoothing. He then became a professor of mathematics, and later the Chair of Pure Mathematics, a post he would hold until his retirement in 1965.

Among his many accolades, he was elected a Fellow of the Royal Society of Edinburgh and a Fellow of the Royal Society of Literature, following the publication of his second war memoir. He published many papers on numerical analysis and statistics as well as a couple of books on matrices. Aitken is credited with deriving the generalized least squares estimator, which has been referred to as Aitken’s generalized least squares. Aside from his many academic contributions, he had mental calculating abilities like no other. He is known to have multiplied two 9-digit numbers in less than a minute and could recite up to 707 digits of \(\pi\).

</table>

`*estat ic` is not appropriate after `reg3, 2sls`. 
predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, residuals, and differences between the linear predictions of two equations.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, equation(eqno[,eqno]) statistic]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xb</td>
<td>linear prediction; the default</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
<tr>
<td>residuals</td>
<td>residuals</td>
</tr>
<tr>
<td>difference</td>
<td>difference between the linear predictions of two equations</td>
</tr>
<tr>
<td>stddp</td>
<td>standard error of the difference in linear predictions</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type `predict ... if e(sample) ... if wanted only for the estimation sample.`

Options for predict

```
equation(eqno[,eqno]) specifies to which equation you are referring.
```

equation() is filled in with one `eqno` for the `xb`, `stdp`, and `residuals` options. `equation(#1)` would mean the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named income and `equation(hours)` to the equation named hours.

If you do not specify `equation()`, results are the same as if you specified `equation(#1)`.

difference and `stddp` refer to between-equation concepts. To use these options, you must specify two equations, for example, `equation(#1,#2)` or `equation(income,hours)`. When two equations must be specified, `equation()` is required.

`xb`, the default, calculates the linear prediction (fitted values)—the prediction of $x_j b$ for the specified equation.

`stdp` calculates the standard error of the prediction for the specified equation. It can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`residuals` calculates the residuals.
difference calculates the difference between the linear predictions of two equations in the system. With equation(#1,#2), difference computes the prediction of equation(#1) minus the prediction of equation(#2).

`stddp` is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions \((x_{1j}b - x_{2j}b)\) between equations 1 and 2 is calculated.

For more information on using `predict` after multiple-equation estimation commands, see [R] predict.

**margins**

**Description for margins**

`margins` estimates margins of response for linear predictions and differences between the linear predictions of two equations.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

```
margins [ `marginlist` ] [ , `options` ]
margins [ `marginlist` ] , `predict(statistic ...)` [ `predict(statistic ...)` ... ] [ `options` ]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>default</code></td>
<td>linear predictions for each equation</td>
</tr>
<tr>
<td><code>xb</code></td>
<td>linear prediction for a specified equation</td>
</tr>
<tr>
<td><code>difference</code></td>
<td>difference between the linear predictions of two equations</td>
</tr>
<tr>
<td><code>stddp</code></td>
<td>not allowed with <code>margins</code></td>
</tr>
<tr>
<td><code>residuals</code></td>
<td>not allowed with <code>margins</code></td>
</tr>
<tr>
<td><code>stdd</code></td>
<td>not allowed with <code>margins</code></td>
</tr>
</tbody>
</table>

`xb` defaults to the first equation.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] margins.

**Remarks and examples**

**Example 1: Using predict**

In example 2 of [R] reg3, we fit a simple supply-and-demand model. Here we obtain the fitted supply and demand curves assuming that the exogenous regressors equal their sample means. We first replace each of the three exogenous regressors with their sample means, then we call `predict` to obtain the predictions.
As we would expect based on economic theory, the demand curve slopes downward while the supply curve slopes upward. With the exogenous variables at their mean levels, the equilibrium price and quantity are slightly less than 33 and 13, respectively.

Example 2: Obtaining forecasts

In example 3 of [R] reg3, we fit Klein’s (1950) model of the U.S. economy. That model includes three stochastic equations we fit using reg3 as well as four identities. Here we briefly illustrate how the forecast command can be used to obtain forecasts for all the endogenous variables in the model. For a more detailed discussion of how to forecast with this model, see [TS] forecast.
In Stata, we type

```
use https://www.stata-press.com/data/r18/klein2, clear
reg3 (c p L.p w) (i p L.p L.k) (wp y L.y yr), endog(w p y) exog(t wg g)
(output omitted)
estimates store kleineqs
forecast create kleinmodel
Forecast model kleinmodel started.
forecast estimates kleineqs
    Added estimation results from reg3.
    Forecast model kleinmodel now contains 3 endogenous variables.
forecast identity y = c + i + g
    Forecast model kleinmodel now contains 4 endogenous variables.
forecast identity p = y - t - wp
    Forecast model kleinmodel now contains 5 endogenous variables.
forecast identity k = L.k + i
    Forecast model kleinmodel now contains 6 endogenous variables.
forecast identity w = wg + wp
    Forecast model kleinmodel now contains 7 endogenous variables.
forecast solve, begin(1937)
Computing dynamic forecasts for model kleinmodel.
Starting period:  1937
Ending period:   1941
Forecast prefix:  f_
1937:  ...........................................
1938:  ............................................
1939:  ............................................
1940:  ........................................
1941:  .............................................
Forecast 7 variables spanning 5 periods.
```

Here we have obtained dynamic forecasts for our 7 endogenous variables beginning in 1937. By default, the variables containing the forecasts begin with the prefix `f_`. Next we plot the forecast and actual values of consumption:

```
.tsline c f_c
```

![Graph showing consumption and forecast consumption](image-url)
For more information about producing forecasts, see [TS] forecast.

Methods and formulas

The computational formulas for the statistics produced by predict can be found in [R] predict and [R] regress postestimation.

[R] reg3 — Three-stage estimation for systems of simultaneous equations
[U] 20 Estimation and postestimation commands
regress performs ordinary least-squares linear regression. regress can also perform weighted estimation, compute robust and cluster–robust standard errors, and adjust results for complex survey designs.

### Quick start

Simple linear regression of \( y \) on \( x_1 \)

```
regress y x1
```

Regression of \( y \) on \( x_1, x_2, \) and indicators for categorical variable \( a \)

```
regress y x1 x2 i.a
```

Add the interaction between continuous variable \( x_2 \) and \( a \)

```
regress y x1 c.x2##i.a
```

Fit model for observations where \( v_1 \) is greater than zero

```
regress y x1 x2 i.a if v1>0
```

With cluster–robust standard errors for clustering by levels of \( \text{cvar} \)

```
regress y x1 x2 i.a, vce(cluster cvar)
```

With cluster–robust standard errors for clustering by levels of \( \text{cvar1} \) and \( \text{cvar2} \)

```
regress y x1 x2 i.a, vce(cluster cvar1 cvar2)
```

With bootstrap standard errors

```
regress y x1 x2 i.a, vce(bootstrap)
```

Report standardized coefficients

```
regress y x1 x2 i.a, beta
```

Adjust for complex survey design using \texttt{svyset} data

```
svyset data
svy: regress y x1 x2 i.a
```

Use sampling weight \( w_{\text{var}} \)

```
regress y x1 x2 i.a [pweight=wvar]
```

### Menu

Statistics \( \rightarrow \) Linear models and related \( \rightarrow \) Linear regression
Syntax

```
regress depvar [indepvars] [if] [in] [weight] [, options]
```

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.

`depvar` and `indepvars` may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes, bootstrap, by, collect, fmm, fp, jackknife, mfp, mi estimate, nestreg, rolling, statsby, stepwise, and svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: regress and [FMM] fmm: regress.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] mi estimate.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`aweights` are not allowed with the `jackknife` prefix; see [R] jackknife.

`hascons, tsscons, vce(), beta, noheader, notable, plus, depname(), mse1, and weights` are not allowed with the `svy` prefix; see [SVY] svy.

`aweights, fweights, iweights, and pweights` are allowed; see [U] 11.1.6 weight.

`noheader, notable, plus, mse1, and coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
Options

noconstant; see \[\text{[R]}\] Estimation options.

\texttt{hascons} indicates that a user-defined constant or its equivalent is specified among the independent variables in \texttt{indepvars}. Some caution is recommended when specifying this option, as resulting estimates may not be as accurate as they otherwise would be. Use of this option requires “sweeping” the constant last, so the moment matrix must be accumulated in absolute rather than deviation form. This option may be safely specified when the means of the dependent and independent variables are all reasonable and there is not much collinearity between the independent variables. The best procedure is to view \texttt{hascons} as a reporting option—estimate with and without \texttt{hascons} and verify that the coefficients and standard errors of the variables not affected by the identity of the constant are unchanged.

\texttt{tsscons} forces the total sum of squares to be computed as though the model has a constant, that is, as deviations from the mean of the dependent variable. This is a rarely used option that has an effect only when specified with \texttt{noconstant}. It affects the total sum of squares and all results derived from the total sum of squares.

\texttt{vce(vcetype)} specifies the type of standard error reported, which includes types that are derived from asymptotic theory (\texttt{ols}), that are robust to some kinds of misspecification (\texttt{robust}), that allow for intragroup correlation (\texttt{cluster clustvarlist}), and that use bootstrap or jackknife methods (\texttt{bootstrap}, \texttt{jackknife}); see \[\text{[R]}\] \texttt{vce} option.

\texttt{vce(ols)}, the default, uses the standard variance estimator for ordinary least-squares regression.

\texttt{vce(cluster clustvarlist)} specifies that standard errors allow for intragroup correlation within groups defined by one or more variables in \texttt{clustvarlist}, relaxing the usual requirement that the observations be independent. For example, \texttt{vce(cluster clustvar1)} produces cluster-robust standard errors that allow for observations that are independent across groups defined by \texttt{clustvar1} but not necessarily independent within groups. You could also type \texttt{vce(cluster clustvar1 clustvar2 ... clusterp)} to account for correlation within groups formed by \texttt{p} variables (multiway clustering).

\texttt{regress} also allows the following:

\texttt{vce(hc2 [ clustvar][, dfadjust])} and \texttt{vce(hc3)} specify alternative bias corrections for the robust variance calculation. \texttt{vce(hc2)} and \texttt{vce(hc3)} may not be specified with the \texttt{svy} prefix. In the unclustered case, \texttt{vce(robust)} uses \(\hat{\sigma}_j^2 = \{n/(n-k)\}u_j^2\) as an estimate of the variance of the \(j\)th observation, where \(n\) is the number of observations, \(k\) is the number of regressors, \(u_j\) is the calculated residual, and \(n/(n-k)\) is included to improve the overall estimate’s small-sample properties.

\texttt{vce(hc2)} instead uses \(u_j^2/(1 - h_{jj})\) as the observation’s variance estimate, where \(h_{jj}\) is the diagonal element of the hat (projection) matrix. This estimate is unbiased if the model really is homoskedastic. \texttt{vce(hc2)} tends to produce slightly more conservative confidence intervals. \texttt{vce(hc2 clustvar)} produces estimates that allow for intragroup correlation within groups defined by \texttt{clustvar}. \texttt{dfadjust} computes the Bell and McCaffrey (2002) adjusted degrees of freedom based on \texttt{clustvar}. Note that \texttt{dfadjust} does not affect multiple-imputation results when the command is used with \texttt{mi estimate}. See Methods and formulas for a description of the computation when \texttt{clustvar} is specified.
vce(hc3) uses \( u_j^2/(1 - h_{jj})^2 \) as suggested by Davidson and MacKinnon (1993), who report that this method tends to produce better results when the model really is heteroskedastic. vce(hc3) produces confidence intervals that tend to be more even conservative.

See Davidson and MacKinnon (1993, 554–556) and Angrist and Pischke (2009, 294–308) for more discussion on these two bias corrections.

Reporting level(#); see [R] Estimation options.

beta asks that standardized beta coefficients be reported instead of confidence intervals. The beta coefficients are the regression coefficients obtained by first standardizing all variables to have a mean of 0 and a standard deviation of 1. beta may not be specified with vce(cluster clustvarlist) or the svy prefix.

eform(string) is used only in programs and ado-files that use regress to fit models other than linear regression. eform() specifies that the coefficient table be displayed in exponentiated form as defined in [R] Maximize and that string be used to label the exponentiated coefficients in the table.

depname(varname) is used only in programs and ado-files that use regress to fit models other than linear regression. depname() may be specified only at estimation time. varname is recorded as the identity of the dependent variable, even though the estimates are calculated using depvar. This method affects the labeling of the output—not the results calculated—but could affect subsequent calculations made by predict, where the residual would be calculated as deviations from varname rather than depvar. depname() is most typically used when depvar is a temporary variable (see [P] macro) used as a proxy for varname.

depname() is not allowed with the svy prefix.

clustertable displays a table reporting cluster combinations and the number of clusters per combination. This option is available only when vce(cluster clustvarlist) is specified with more than one variable in clustvarlist to compute multiway cluster–robust standard errors.

display_options: noci, nopvalues, dfci, dfpvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabs, fvwrap(#), fvwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] Estimation options.

dfci specifies that parameter degrees of freedom and confidence intervals be reported in the coefficient table.

dfpvalues specifies that parameter degrees of freedom and p-values be reported in the coefficient table.

The following options are available with regress but are not shown in the dialog box:

noheader suppresses the display of the ANOVA table and summary statistics at the top of the output; only the coefficient table is displayed. This option is often used in programs and ado-files.

notable suppresses display of the coefficient table.

plus specifies that the output table be made extendable. This option is often used in programs and ado-files.
mse1 is used only in programs and ado-files that use `regress` to fit models other than linear regression and is not allowed with the svy prefix. `mse1` sets the mean squared error to 1, forcing the variance–covariance matrix of the estimators to be $(X'X)^{-1}$ (see Methods and formulas below) and affecting calculated standard errors. Degrees of freedom for $t$ statistics is calculated as $n$ rather than $n - k$.

`coeflegend;` see [R] Estimation options.

Remarks and examples

Remarks are presented under the following headings:

- Ordinary least squares
- Treatment of the constant
- Robust standard errors
- Weighted regression
- Video examples

`regress` performs linear regression, including ordinary least squares and weighted least squares. See [U] 27 Overview of Stata estimation commands for a list of other regression commands that may be of interest. For a general discussion of linear regression, see Kutner et al. (2005).

See Stock and Watson (2019) and Wooldridge (2020) for an excellent treatment of estimation, inference, interpretation, and specification testing in linear regression models. See Wooldridge (2010, chap. 4) for a more advanced discussion along the same lines.

See Hamilton (2013, chap. 7) and Cameron and Trivedi (2022, chap. 3) for an introduction to linear regression using Stata. Dohoo, Martin, and Stryhn (2012, 2010) discuss linear regression using examples from epidemiology, and Stata datasets and do-files used in the text are available. Cameron and Trivedi (2022) discuss linear regression using econometric examples with Stata. Mitchell (2021) shows how to use graphics and postestimation commands to understand a fitted regression model.

Chatterjee and Hadi (2012) explain regression analysis by using examples containing typical problems that you might encounter when performing exploratory data analysis. We also recommend Weisberg (2014), who emphasizes the importance of the assumptions of linear regression and problems resulting from these assumptions. Beckett (2020) discusses regression analysis with an emphasis on time-series data. Angrist and Pischke (2009) approach regression as a tool for exploring relationships, estimating treatment effects, and providing answers to public policy questions. For a mathematically rigorous treatment, see Peracchi (2001, chap. 6). Finally, see Plackett (1972) if you are interested in the history of regression. Least squares, which dates back to the 1790s, was discovered independently by Legendre and Gauss.

Ordinary least squares

**Example 1: Basic linear regression**

Suppose that we have data on the mileage rating and weight of 74 automobiles. The variables in our data are mpg, weight, and foreign. The last variable assumes the value 1 for foreign and 0 for domestic automobiles. We wish to fit the model

$$
    mpg = \beta_0 + \beta_1 \text{weight} + \beta_2 \text{foreign} + \epsilon
$$
This model can be fit with `regress` by typing

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight foreign
```

```
Source | SS     df   MS       Number of obs =  74
--------+---------+---------+---------------------------------
Model   | 1619.29 2  809.64  F(2, 71) = 69.75
        |        |         | Prob > F = 0.0000
Residual| 824.17  71 11.61  R-squared = 0.6627
        |        |         | Adj R-squared = 0.6532
Total   | 2443.46 73 33.47  Root MSE = 3.4071
--------+---------+---------+---------------------------------
mpg     | Coefficient Std. err.   t   P>|t|    [95% conf. interval]
--------+---------+---------+--------+---------+-----------------------------
weight  | -.00658  .000637  -10.34 0.000  -.007858  -.0053175
foreign | -1.6500  1.076  -1.53  0.130  -3.7955  -.4954422
_cons   | 41.68    2.166  19.25  0.000  37.36172 45.99768
```

`regress` produces a variety of summary statistics along with the table of regression coefficients. At the upper left, `regress` reports an analysis-of-variance (ANOVA) table. The column headings SS, df, and MS stand for “sum of squares”, “degrees of freedom”, and “mean square”, respectively. In this example, the total sum of squares is 2,443.5: 1,619.3 accounted for by the model and 824.2 left unexplained. Because the regression included a constant, the total sum reflects the sum after removal of means, as does the sum of squares due to the model. The table also reveals that there are 73 total degrees of freedom (counted as 74 observations less 1 for the mean removal), of which 2 are consumed by the model, leaving 71 for the residual.

To the right of the ANOVA table are presented other summary statistics. The $F$ statistic associated with the ANOVA table is 69.75. The statistic has 2 numerator and 71 denominator degrees of freedom. The $F$ statistic tests the hypothesis that all coefficients excluding the constant are zero. The chance of observing an $F$ statistic that large or larger is reported as 0.0000, which is Stata’s way of indicating a number smaller than 0.00005. The $R^2$ for the regression is 0.6627, and the $R^2_a$ adjusted for degrees of freedom ($R^2_a$) is 0.6532. The root mean squared error, labeled Root MSE, is 3.4071. It is the square root of the mean squared error reported for the residual in the ANOVA table.

Finally, Stata produces a table of the estimated coefficients. The first line of the table indicates that the left-hand-side variable is `mpg`. Thereafter follow the estimated coefficients. Our fitted model is

\[
mpg\hat{} = 41.68 - 0.0066\text{weight} - 1.65\text{foreign}
\]

Reported to the right of the coefficients in the output are the standard errors. For instance, the standard error for the coefficient on `weight` is 0.0006371. The corresponding $t$ statistic is $-10.34$, which has a two-sided significance level of 0.000. This number indicates that the significance is less than 0.0005. The 95% confidence interval for the coefficient is $[-0.0079, -0.0053]$.

#### Example 2: Transforming the dependent variable

If we had a graph comparing `mpg` with `weight`, we would notice that the relationship is distinctly nonlinear. This is to be expected because energy usage per distance should increase linearly with weight, but `mpg` is measuring distance per energy used. We could obtain a better model by generating a new variable measuring the number of gallons used per 100 miles (`gp100m`) and then using this new variable in our model:

\[
gp100m = \beta_0 + \beta_1\text{weight} + \beta_2\text{foreign} + \epsilon
\]
We can now fit this model:

```
. generate gp100m = 100/mpg
. regress gp100m weight foreign
```

<table>

Fitting the physically reasonable model increases our $R^2$ to 0.7625.

Example 3: Obtaining beta coefficients

`regress` shares the features of all estimation commands. Among other things, this means that after running a regression, we can use `test` to test hypotheses about the coefficients, `estat vce` to examine the covariance matrix of the estimators, and `predict` to obtain predicted values, residuals, and influence statistics. See [U] 20 Estimation and postestimation commands. Options that affect how estimates are displayed, such as `beta` or `level()`, can be used when replaying results.

Suppose that we meant to specify the `beta` option to obtain beta coefficients (regression coefficients normalized by the ratio of the standard deviation of the regressor to the standard deviation of the dependent variable). Even though we forgot, we can specify the option now:

```
. regress, beta
```

| gp100m  | Coefficient    | Std. err. | t   | P>|t| | Beta     |
|---------|----------------|-----------|-----|------|----------|
| weight  | .0016254       | .0001183  | 13.74| 0.000| .9870255 |
| foreign | .6220535       | .1997381  | 3.11 | 0.003| .2236673 |
| _cons   | -.0734839      | .4019932  | -0.18| 0.855| .         |
Treatment of the constant

By default, `regress` includes an intercept (constant) term in the model. The `noconstant` option suppresses it, and the `hascons` option tells `regress` that the model already has one.

Example 4: Suppressing the constant term

We wish to fit a regression of the weight of an automobile against its length, and we wish to impose the constraint that the weight is zero when the length is zero.

If we simply type `regress weight length`, we are fitting the model

\[ \text{weight} = \beta_0 + \beta_1 \text{length} + \epsilon \]

Here a length of zero corresponds to a weight of \( \beta_0 \). We want to force \( \beta_0 \) to be zero or, equivalently, estimate an equation that does not include an intercept:

\[ \text{weight} = \beta_1 \text{length} + \epsilon \]

We do this by specifying the `noconstant` option:

```plaintext
. regress weight length, noconstant

Source | SS df MS
--------|------|-----
Model   | 703869302 1 703869302
Residual| 14892897.8 73 204012.299
Total   | 718762200 74 9713002.7

F(1, 73) = 3450.13  Prob > F = 0.0000
R-squared = 0.9793  Adj R-squared = 0.9790
Root MSE = 451.68

weight | Coefficient Std. err. t P>|t| [95% conf. interval]
--------|-------------|------|-----|----------------------
length  | 16.29829 .2774752 58.74 0.000 15.74528 16.8513
```

In our data, length is measured in inches and weight in pounds. We discover that each inch of length adds 16 pounds to the weight.
Sometimes there is no need for Stata to include a constant term in the model. Most commonly, this occurs when the model contains a set of mutually exclusive indicator variables. hascons is a variation of the noconstant option—it tells Stata not to add a constant to the regression because the regression specification already has one, either directly or indirectly.

For instance, we now refit our model of weight as a function of length and include separate constants for foreign and domestic cars by specifying bn.foreign. bn.foreign is factor-variable notation for “no base for foreign” or “include all levels of variable foreign in the model”; see [U] 11.4.3 Factor variables.

```
. regress weight length bn.foreign, hascons

Source | SS      df    MS
----------|----------|--------
Model    | 39647744.7 2  19823872.3
Residual | 4446433.7  71  62625.8268
----------|----------|--------
Total    | 44094178.4 73  604029.841

weight | Coefficient Std. err.    t     P>|t|     [95% conf. interval]
--------|-----------------|--------|------|------------------------|------------------------|
length  | 31.44455        1.601234 19.64  0.000 28.25178               34.63732
foreign |                |        |      |                        |                        |
Domestic| -2850.25        315.9691 -9.02  0.000 -3480.274             -2220.225
Foreign | -2983.927       275.1041 -10.85 0.000 -3532.469             -2435.385

Technical note

There is a subtle distinction between the hascons and noconstant options. We can most easily reveal it by refitting the last regression, specifying noconstant rather than hascons:

```
. regress weight length bn.foreign, noconstant

Source | SS       df    MS
----------|----------|--------
Model    | 714315766 3  238105255
Residual | 4446433.7 71  62625.8268
----------|----------|--------
Total    | 718762200 74  9713002.7

weight | Coefficient Std. err.    t     P>|t|     [95% conf. interval]
--------|-----------------|--------|------|------------------------|------------------------|
length  | 31.44455        1.601234 19.64  0.000 28.25178               34.63732
foreign |                |        |      |                        |                        |
Domestic| -2850.25        315.9691 -9.02  0.000 -3480.274             -2220.225
Foreign | -2983.927       275.1041 -10.85 0.000 -3532.469             -2435.385

Comparing this output with that produced by the previous regress command, we see that they are almost, but not quite, identical. The parameter estimates and their associated statistics—the second half of the output—are identical. The overall summary statistics and the ANOVA table—the first half of the output—are different, however.

In the first case, the $R^2$ is shown as 0.8992; here it is shown as 0.9938. In the first case, the $F$ statistic is 316.54; now it is 3,802.03. The numerator degrees of freedom is different as well. In the first case, the numerator degrees of freedom is 2; now the degrees of freedom is 3. Which is correct?
Both are. Specifying the hascons option causes `regress` to adjust the ANOVA table and its associated statistics for the explanatory power of the constant. The regression in effect has a constant; it is just written in such a way that a separate constant is unnecessary. No such adjustment is made with the noconstant option.

## Technical note

When the hascons option is specified, `regress` checks to make sure that the model does in fact have a constant term. If `regress` cannot find a constant term, it automatically adds one. Fitting a model of `weight` on `length` and specifying the hascons option, we obtain

```
. regress weight length, hascons
note: option hascons false.
```

Even though we specified hascons, `regress` included a constant, anyway. It also added a note to our output: “note: option hascons false”.

## Technical note

Even if the model specification effectively includes a constant term, we need not specify the hascons option. `regress` is always on the lookout for collinear variables and omits them from the model. For instance,

```
. regress weight length bn.foreign
note: i.foreign omitted because of collinearity.
```

```
Source | SS      | df | MS       | Number of obs = 74
Model   | 39647744.7 | 2  | 19823872.3 | F(2, 71) = 316.54
Residual| 4446433.7  | 71 | 62625.8268 | Prob > F = 0.0000
Total   | 44094178.4 | 73 | 604029.841 | Adj R-squared = 0.8963

weight | Coefficient | Std. err. | t | P>|t| | [95% conf. interval]

_foreign | Domestic | 133.6775 | 77.47615 | 1.73 | 0.089 | -20.80555 | 288.1605
Foreign | 0 (omitted) |
_cons | -2983.927 | 275.1041 | -10.85 | 0.000 | -3532.469 | -2435.385
```
Robust standard errors

`regress` with the `vce(robust)` option substitutes a robust variance matrix calculation for the conventional calculation, or if `vce(cluster clustvarlist)` is specified, allows relaxing the assumption of independence within groups. How this method works is explained in [U] 20.22 Obtaining robust variance estimates. Below, we show how well this approach works.

Example 5: Heteroskedasticity and robust standard errors

Specifying the `vce(robust)` option is equivalent to requesting White-corrected standard errors in the presence of heteroskedasticity. We use the automobile data and, in the process of looking at the energy efficiency of cars, analyze a variable with considerable heteroskedasticity.

We will examine the amount of energy—measured in gallons of gasoline—that the cars in the data need to move 1,000 pounds of their weight 100 miles. We are going to examine the relative efficiency of foreign and domestic cars.

```
. generate gpmw = ((1/mpg)/weight)*100*1000
. summarize gpmw
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>gpmw</td>
<td>74</td>
<td>1.682184</td>
<td>.2426311</td>
<td>1.09553</td>
<td>2.30521</td>
</tr>
</tbody>
</table>

In these data, the engines consume between 1.10 and 2.31 gallons of gas to move 1,000 pounds of the car’s weight 100 miles. If we ran a regression with conventional standard errors of `gpmw` on `foreign`, we would obtain

```
. regress gpmw foreign
```

```
Source | SS   | df | MS | Number of obs = 74
-------|------|----|----|------------------|
Model  | .936705572 | 1  | .936705572 | F(1, 72) = 20.07
Residual | .36079459  | 72 | .046677703 | Prob > F = 0.0000
Total  | 4.29750017 | 73 | .058869865 | R-squared = 0.2180
```

```
gpmw | Coefficient | Std. err. | t     | P>|t|    | [95% conf. interval]
-----|-------------|-----------|------|-------|------------------|
foreign | .2461526 | .0549487 | 4.48 | 0.000 | .1366143 , .3556909 |
_cons    | 1.609004  | .0299608 | 53.70 | 0.000 | 1.549278 , 1.66873  |
```

`regress` with the `vce(robust)` option, on the other hand, reports

```
. regress gpmw foreign, vce(robust)
```

```
Linear regression Number of obs = 74
F(1, 72) = 13.13
Prob > F = 0.0005
R-squared = 0.2180
Root MSE = .21605
```

```
gpmw | Robust Coefficient | std. err. | t     | P>|t|    | [95% conf. interval]
-----|--------------------|-----------|------|-------|------------------|
foreign | .2461526 | .0679238 | 3.62 | 0.001 | .1107489 , .3815563 |
_cons    | 1.609004 | .0234535 | 68.60 | 0.000 | 1.56225 , 1.665758 |
```

The point estimates are the same (foreign cars need one-quarter gallon more gas), but the standard errors differ by roughly 20%. Conventional regression reports the 95% confidence interval as [0.14, 0.36], whereas the robust standard errors make the interval [0.11, 0.38].
Which is right? Notice that `gpmw` is a variable with considerable heteroskedasticity:

```
. tabulate foreign, summarize(gpmw)
```

<table>
<thead>
<tr>
<th>Car origin</th>
<th>Summary of gpmw</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Mean</td>
<td>Std. dev.</td>
<td>Freq.</td>
</tr>
<tr>
<td>Domestic</td>
<td>1.6090039</td>
<td>.16845182</td>
<td>52</td>
</tr>
<tr>
<td>Foreign</td>
<td>1.8551565</td>
<td>.30186861</td>
<td>22</td>
</tr>
<tr>
<td>Total</td>
<td>1.6821844</td>
<td>.24263113</td>
<td>74</td>
</tr>
</tbody>
</table>

Thus, here we favor the robust standard errors. In [U] 20.22 Obtaining robust variance estimates, we show another example using linear regression where it makes little difference whether we specify `vce(robust)`. The linear-regression assumptions were true, and we obtained nearly linear-regression results. The advantage of the robust estimate is that in neither case did we have to check assumptions.

Technical note

`regress` purposefully suppresses displaying the ANOVA table when `vce(robust)` is specified. This is done because the sums of squares are no longer appropriate for use in the usual hypothesis tests, even though computationally the sums of squares remain the same. In the nonrobust setting, the $F$ statistic reported by `regress` is defined in terms of the sums of squares, as in ANOVA. When `vce(robust)` is specified, the ANOVA test is not valid, and the $F$ statistic corresponds to a Wald test based on the robustly estimated variance matrix.

Some references give formulas for the $F$ statistic in terms of either $R^2$ or the root MSE. It is not appropriate to use those formulas for the $F$ statistic with robust standard errors because the $R^2$ and root MSE are calculated from the sums of squares. Moreover, the root MSE can no longer be used as an estimate for $\sigma$ because there is no longer a single $\sigma$ to estimate—the variance of the residual varies observation by observation. However, `regress` continues to report the $R^2$ and the root MSE in the robust setting because those statistics are still usable in other settings. In particular, $R^2$ remains valid as a goodness-of-fit statistic.

Example 6: Alternative robust standard errors

The `vce(hc2)` and `vce(hc3)` options modify the robust variance calculation. In the context of linear regression without clustering, the idea behind the robust calculation is somehow to measure $\sigma_j^2$, the variance of the residual associated with the $j$th observation, and then to use that estimate to improve the estimated variance of $\hat{\beta}$. Because residuals have (theoretically and practically) mean 0, one estimate of $\sigma_j^2$ is the observation’s squared residual itself—$u_j^2$. A finite-sample correction could improve that by multiplying $u_j^2$ by $n/(n-k)$, and, as a matter of fact, `vce(robust)` uses $\{n/(n-k)\}u_j^2$ as its estimate of the residual’s variance.

`vce(hc2)` and `vce(hc3)` use alternative estimators of the observation-specific variances. For instance, if the residuals are homoskedastic, we can show that the expected value of $u_j^2$ is $\sigma^2(1-h_{jj})$, where $h_{jj}$ is the $j$th diagonal element of the projection (hat) matrix. $h_{jj}$ has average value $k/n$, so $1-h_{jj}$ has average value $1-k/n = (n-k)/n$. Thus, the default robust estimator $\hat{\sigma}_j = \{n/(n-k)\}u_j^2$ amounts to dividing $u_j^2$ by the average of the expectation.
vce(hc2) divides $u_j^2$ by $1 - h_{jj}$ itself, so it should yield better estimates if the residuals really are homoskedastic. vce(hc3) divides $u_j^2$ by $(1 - h_{jj})^2$ and has no such clean interpretation. Davidson and MacKinnon (1993) show that $u_j^2/(1 - h_{jj})^2$ approximates a more complicated estimator that they obtain by jackknifing (MacKinnon and White 1985). Angrist and Pischke (2009) also illustrate the relative merits of these adjustments.

Here are the results of refitting our efficiency model using vce(hc2) and vce(hc3):

```
. regress gpmw foreign, vce(hc2)

Example 7: Standard errors for clustered data

The vce(cluster clustvarlist) and vce(hc2 clustvar) options relax the assumption of independence. Below, we have 28,534 observations on 4,711 women aged 14–46 years. Data were collected on these women between 1968 and 1988. We are going to fit a classic earnings model, and we begin by ignoring that the majority of the women in the dataset have multiple observations.
. use https://www.stata-press.com/data/r18/regsmpl, clear
(NLS women 14-26 in 1968)

. regress ln_wage age c.age#c.age tenure

Source | SS df MS
-------|--------|------
Model   | 1054.52501 3 351.508335
Residual | 5360.43962 28,097 .190783344
Total   | 6414.96462 28,100 .228290556

F(3, 28097) = 1842.45 Prob > F = 0.0000
R-squared = 0.1644 Adj R-squared = 0.1643

Number of obs = 28,101

ln_wage | Coefficient Std. err. t P>|t| [95% conf. interval]
-------|--------|------|------|------------------|------|------|
age    | .0752172 .0034736 21.65 0.000 .0684088 .0820257
       |-.0010851 .0000575 -18.86 0.000 -.0011979 -.0009724
       | .0390877 .0007743 50.48 0.000 .0375699 .0406054
       | .3339821 .0504413 6.62 0.000 .2351148 .4328495

The number of observations in our model is 28,101 because Stata drops observations that have a missing value for one or more of the variables in the model. We can be reasonably certain that the standard errors reported above are meaningless. Without a doubt, a woman with higher-than-average wages in one year typically has higher-than-average wages in other years, and so the residuals are not independent. One way to deal with this is to use cluster–robust standard errors. We do this by specifying vce(cluster id) or vce(hc2 id), which treat only observations with different person ids as truly independent:

. regress ln_wage age c.age#c.age tenure, vce(cluster id)

Linear regression Number of obs = 28,101
F(3, 4698) = 748.82 Prob > F = 0.0000
R-squared = 0.1644 Root MSE = .43679
(Std. err. adjusted for 4,699 clusters in idcode)

| ln_wage | Robust Coefficient std. err. t P>|t| [95% conf. interval] |
|---------|----------|--------|------|------------------|------|------|---|---|
| age     | .0752172 .0045711 16.45 0.000 .0662557 .0841788
| c.age#c.age | -.0010851 .0000778 -13.94 0.000 -.0012377 -.0009325
| tenure  | .0390877 .0014425 27.10 0.000 .0362596 .0419157
| _cons   | .3339821 .0641918 5.20 0.000 .208136 .4598282

For comparison, we focus on the tenure coefficient, which in economics jargon can be interpreted as the rate of return for keeping your job. The 95% confidence interval we previously estimated—an interval we do not believe—is [0.038, 0.041]. The robust interval is twice as wide, being [0.036, 0.042]. For this example, vce(hc2 id) gives standard errors similar to vce(cluster id).
Another possible way to account for the lack of independence is to fit a random-effects model. Here is the random-effects result:

```
.xtreg ln_wage age c.age#c.age tenure, re
```

Random-effects GLS regression
Number of obs = 28,101
Group variable: idcode Number of groups = 4,699
R-squared:  
Within = 0.1370  
Between = 0.2154  
Overall = 0.1608
Wald chi2(3) = 4717.05
corr(u_i, X) = 0 (assumed)

| ln_wage | Coefficient | Std. err. | z    | P>|z| | [95% conf. interval] |
|---------|-------------|-----------|------|-----|-----------------------|
| age     | 0.0568296   | 0.0026958 | 21.08| 0.000| 0.0515459 to 0.0621132 |
| c.age#c.age | -0.0007566   | 0.0000447 | -16.93| 0.000| -0.0008441 to -0.000669 |
| tenure  | 0.0260135   | 0.0007477 | 34.79| 0.000| 0.0245481 to 0.0274789 |
| _cons   | 0.6136792   | 0.0394611 | 15.55| 0.000| 0.5363368 to 0.6910216 |

Robust regression estimated the 95% interval [0.036, 0.042], and xtreg (see [XT] xtreg) estimates [0.025, 0.027]. Which is better? The random-effects regression estimator assumes a lot. We can check some of these assumptions by performing a Hausman test. Using estimates (see [R] estimates store), we store the random-effects estimation results, and then we run the required fixed-effects regression to perform the test.

```
.estimates store random
.xtreg ln_wage age c.age#c.age tenure, fe
```

Fixed-effects (within) regression
Number of obs = 28,101
Group variable: idcode Number of groups = 4,699
R-squared:  
Within = 0.1375  
Between = 0.2066  
Overall = 0.1568
F(3, 23399) = 1243.00
corr(u_i, Xb) = 0.1380

| ln_wage | Coefficient | Std. err. | t    | P>|t| | [95% conf. interval] |
|---------|-------------|-----------|------|-----|-----------------------|
| age     | 0.0522751   | 0.002783  | 18.78| 0.000| 0.0468202 to 0.05773  |
| c.age#c.age | -0.0006717   | 0.0004614 | -14.56| 0.000| -.0007621 to -.0005813 |
| tenure  | 0.021738    | 0.00799   | 27.21| 0.000| 0.020172 to 0.023304  |
| _cons   | 0.687178    | 0.0405944 | 16.93| 0.000| 0.6076103 to 0.7667456 |

F test that all u_i=0: F(6998, 23399) = 7.98

| sigma_u | .38743138  |
| sigma_e | .29674679  |
| rho     | .6302569   | (fraction of variance due to u_i) |

Prob > chi2 = 0.0000

The Hausman test casts grave suspicions on the random-effects model we just fit, so we should be careful in interpreting those results.

Meanwhile, our robust regression results still stand, as long as we are careful about the interpretation. The correct interpretation is that, if the data collection were repeated (on women sampled the same way as in the original sample), and if we were to refit the model, 95% of the time we would expect the estimated coefficient on tenure to be in the range \([0.036, 0.042]\).

Even with robust regression, we must be careful about going beyond that statement. Here the Hausman test is probably picking up something that differs within and between person, which would cast doubt on our robust regression model in terms of interpreting \([0.036, 0.042]\) to contain the rate of return for keeping a job, economywide, for all women, without exception.

Let’s take this example a bit further by also recognizing workers with the same education level, grade, may be more alike than those with different education levels. Here we will use multiway clustering (Cameron, Gelbach, and Miller 2008) to account for correlations within individuals over years and within education levels, assuming observations from different people and different education level are independent.

| _cons      | .334631     | .2769961  | 1.21 | 0.243 | -.2473162 - .9165782 |

Cluster combinations formed by idcode and grade.

With the clustertable option, the output includes a table that describes the cluster combinations and reports the number of levels for each cluster combination. We clustered on two variables, so there are three cluster combinations, and, in general, for $p$ cluster variables, there are $p^2 - 1$ cluster combinations. The $t$-statistic degrees of freedom is chosen from the cluster combination that has the smallest number of levels. In this case, we have $19 - 1 = 18$ degrees of freedom, and the Wald test $F$ statistic, computed from the cluster–robust VCE, has a denominator degrees of freedom of 18. The 95% confidence interval for tenure increases slightly to [0.035, 0.043]. Yet the confidence intervals here are not strictly comparable; this model is fit to two fewer observations because of missing values in the cluster variable grade, and we conjecture that observations are correlated within grade.
Weighted regression

`regress` can perform weighted and unweighted regression. We indicate the weight by specifying the `[weight]` qualifier.

Example 8: Using means as regression variables

We have census data recording the deathrate (`drate`) and median age (`medage`) for each state. The data also record the region of the country in which each state is located and the overall population of the state:

```stata
use https://www.stata-press.com/data/r18/census9
(1980 Census data by state)
describe
Contains data from https://www.stata-press.com/data/r18/census9.dta
    Observations: 50 1980 Census data by state

<table>
<thead>
<tr>
<th>Variable</th>
<th>Storage</th>
<th>Display</th>
<th>Value</th>
<th>Variable label</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>str13</td>
<td>%-13s</td>
<td>State</td>
<td></td>
</tr>
<tr>
<td>state2</td>
<td>str2</td>
<td>%-2s</td>
<td>Two-letter state abbreviation</td>
<td></td>
</tr>
<tr>
<td>drate</td>
<td>int</td>
<td>%9.0g</td>
<td>Deathrate</td>
<td></td>
</tr>
<tr>
<td>pop</td>
<td>long</td>
<td>%12.0gc</td>
<td>Population</td>
<td></td>
</tr>
<tr>
<td>medage</td>
<td>float</td>
<td>%9.2f</td>
<td>Median age</td>
<td></td>
</tr>
<tr>
<td>region</td>
<td>byte</td>
<td>%-8.0g</td>
<td>cenreg</td>
<td>Census region</td>
</tr>
</tbody>
</table>
```

We can use factor variables to include dummy variables for region. Because the variables in the regression reflect means rather than individual observations, the appropriate method of estimation is analytically weighted least squares (Davidson and MacKinnon 2004, 261–262), where the weight is total population:

```stata
regress drate medage i.region [aweight=pop]
(sum of wgt is 225,907,472)

<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>Number of obs = 50</th>
</tr>
</thead>
<tbody>

<td>Root MSE = 5.246</td>
</tr>
</tbody>
</table>

| drate | Coefficient | Std. err. | t | P>|t| | [95% conf. interval] |
|-------|-------------|-----------|---|------|---------------------|
| medage | 4.283183 | .5393329 | 7.94 | 0.000 | 3.196911 | 5.369455 |
| region N Cntrl | .3138738 | 2.456431 | 0.13 | 0.899 | -4.633632 | 5.26138 |
| South | -1.438452 | 2.320244 | -0.62 | 0.538 | -6.111663 | 3.234758 |
| West | -10.90629 | 2.681349 | -4.07 | 0.000 | -16.30681 | -5.505777 |

| _cons | -39.14727 | 17.23613 | -2.27 | 0.028 | -73.86262 | -4.431915 |
```

To weight the regression by population, we added the qualifier `[aweight=pop]` to the end of the `regress` command. Stata informed us that the sum of the weight is $2.2591 \times 10^8$; there were approximately 226 million people residing in the United States according to our 1980 data.
In the weighted regression, we see that the coefficient on West is statistically significant but that the coefficients on N Cntrl and South are not. We use testparm to test the joint significance of the region variable. Because we fit a weighted regression, testparm uses the appropriately weighted variance–covariance matrix.

```
. testparm i.region
 ( 1) 2.region = 0
 ( 2) 3.region = 0
 ( 3) 4.region = 0
 F(  3,  45) =  9.84
  Prob > F =  0.0000
```

The results indicate that the region variables are jointly significant. Note that we could have performed this same test by typing contrast region. You may prefer to use the contrast command because, in addition to the joint test, you can perform other tests such as comparisons of each region’s mean to the grand mean; see [R] contrast for more information.

`regress` also accepts frequency weights (fweights). Frequency weights are appropriate when the data do not reflect cell means but instead represent replicated observations. Specifying aweights or fweights will not change the parameter estimates, but it will change the corresponding significance levels.

For instance, if we specified [fweight=pop] in the weighted regression example above—which would be statistically incorrect—Stata would treat the data as if the data represented 226 million independent observations on death rates and median age. The data most certainly do not represent that—they represent 50 observations on state averages.

With aweights, Stata treats the number of observations on the process as the number of observations in the data. When we specify fweights, Stata treats the number of observations as if it were equal to the sum of the weights; see Methods and formulas below.

**Technical note**

A frequent inquiry sent to StataCorp Technical Services is to describe the effect of specifying [aweight=exp] with `regress` in terms of transformation of the dependent and independent variables. The mechanical answer is that typing

```
. regress y x1 x2 [aweight=n]
```

is equivalent to fitting the model

$$y_j \sqrt{n_j} = \beta_0 \sqrt{n_j} + \beta_1 x_{1j} \sqrt{n_j} + \beta_2 x_{2j} \sqrt{n_j} + u_j \sqrt{n_j}$$

This regression will reproduce the coefficients and covariance matrix produced by the aweighted regression. The mean squared errors (estimates of the variance of the residuals) will, however, be different. The transformed regression reports $s_t^2$, an estimate of $\text{Var}(u_j \sqrt{n_j})$. The aweighted regression reports $s_a^2$, an estimate of $\text{Var}(u_j \sqrt{n_j} \sqrt{N/\sum_k n_k})$, where $N$ is the number of observations. Thus,

$$s_a^2 = \frac{N}{\sum_k n_k} s_t^2 = \frac{s_t^2}{\bar{n}}$$  \hspace{1cm} (1)

The logic for this adjustment is as follows: Consider the model

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + u$$
Assume that, were this model fit on individuals, \( \text{Var}(u) = \sigma_u^2 \), a constant. Assume that individual data are not available; what is available are averages \((\bar{y}_j, \bar{x}_{1j}, \bar{x}_{2j})\) for \( j = 1, \ldots, N \), and each average is calculated over \( n_j \) observations. Then it is still true that

\[
\bar{y}_j = \beta_0 + \beta_1 \bar{x}_{1j} + \beta_2 \bar{x}_{2j} + \bar{u}_j
\]

where \( \bar{u}_j \) is the average of \( n_j \) mean 0, variance \( \sigma_u^2 \) deviates and has variance \( \sigma_u^2 / n_j \). Thus, multiplying through by \( \sqrt{n_j} \) produces

\[
\bar{y}_j \sqrt{n_j} = \beta_0 \sqrt{n_j} + \beta_1 \bar{x}_{1j} \sqrt{n_j} + \beta_2 \bar{x}_{2j} \sqrt{n_j} + \bar{u}_j \sqrt{n_j}
\]

and \( \text{Var}(\bar{u}_j \sqrt{n_j}) = \sigma_u^2 \). The mean squared error, \( s_t^2 \), reported by fitting this transformed regression is an estimate of \( \sigma_u^2 \). The coefficients and covariance matrix could also be obtained by \texttt{aweight regress}. The only difference would be in the reported mean squared error, which from (1) is \( \sigma_u^2 / \bar{n} \). On average, each observation in the data reflects the averages calculated over \( \bar{n} = \sum_k n_k / N \) individuals, and thus this reported mean squared error is the average variance of an observation in the dataset. We can retrieve the estimate of \( \sigma_u^2 \) by multiplying the reported mean squared error by \( \bar{n} \).

More generally, \texttt{aweight}s are used to solve general heteroskedasticity problems. In these cases, we have the model

\[
y_j = \beta_0 + \beta_1 x_{1j} + \beta_2 x_{2j} + u_j
\]

and the variance of \( u_j \) is thought to be proportional to \( a_j \). If the variance is proportional to \( a_j \), it is also proportional to \( \alpha a_j \), where \( \alpha \) is any positive constant. Not quite arbitrarily, but with no loss of generality, we could choose \( \alpha = \sum_k (1/a_k) / N \), the average value of the inverse of \( a_j \). We can then write \( \text{Var}(u_j) = k\alpha a_j \sigma^2 \), where \( k \) is the constant of proportionality that is no longer a function of the scale of the weights.

Dividing this regression through by the \( \sqrt{a_j} \),

\[
y_j / \sqrt{a_j} = \beta_0 / \sqrt{a_j} + \beta_1 x_{1j} / \sqrt{a_j} + \beta_2 x_{2j} / \sqrt{a_j} + u_j / \sqrt{a_j}
\]

produces a model with \( \text{Var}(u_j / \sqrt{a_j}) = k\alpha \sigma^2 \), which is the constant part of \( \text{Var}(u_j) \). This variance is a function of \( \alpha \), the average of the reciprocal weights; if the weights are scaled arbitrarily, then so is this variance.

We can also fit this model by typing

\[
\texttt{. regress y x1 x2 [aweight=1/a]}
\]

This input will produce the same estimates of the coefficients and covariance matrix; the reported mean squared error is, from (1), \( \{N / \sum_k (1/a_k)\} k\alpha \sigma^2 = k \sigma^2 \). This variance is independent of the scale of \( a_j \).
Stored results

regress stores the following in e():

Scalars
- e(N): number of observations
- e(mss): model sum of squares
- e(df_m): model degrees of freedom
- e(rss): residual sum of squares
- e(df_r): residual degrees of freedom
- e(r2): \( R^2 \)
- e(r2_a): adjusted \( R^2 \)
- e(F): \( F \) statistic
- e(rmse): root mean squared error
- e(ll): log likelihood under additional assumption of i.i.d. normal errors
- e(ll_0): log likelihood, constant-only model
- e(N_clust): number of clusters
- e(rank): rank of e(V)

Macros
- e(cmd): regress
- e(cmdline): command as typed
- e(depvar): name of dependent variable
- e(wtype): weight type
- e(wexp): weight expression
- e(model): ols
- e(title): title in estimation output when vce() is not ols
- e(clustvar): names of cluster variables
- e(cluster#): cluster combination #
- e(vce): vcetype specified in vce()
- e(vcetype): title used to label Std. err.
- e(properties): b V
- e(estat_cmd): program used to implement estat
- e(predict): program used to implement predict
- e(marginsok): predictions allowed by margins
- e(asbalanced): factor variables fvset as asbalanced
- e(asobserved): factor variables fvset as asobserved

Matrices
- e(b): coefficient vector
- e(V): variance–covariance matrix of the estimators
- e(beta): standardized coefficients
- e(V_modelbased): model-based variance
- e(adj_df): adjusted degrees of freedom when vce(hc2, dfadjust) is specified
- e(kcluster): cluster sizes, multiway clustering

Functions
- e(sample): marks estimation sample

In addition to the above, the following is stored in r():

Matrices
- r(table): matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.
Methods and formulas

Methods and formulas are presented under the following headings:

- Coefficient estimation and ANOVA table
- Weighted regression
- A general notation for the robust variance calculation
- Robust calculation for regress

Coefficient estimation and ANOVA table

Variables printed in lowercase and not boldfaced (for example, x) are scalars. Variables printed in lowercase and boldfaced (for example, x) are column vectors. Variables printed in uppercase and boldfaced (for example, X) are matrices.

Let X denote the matrix of observations on the right-hand-side variables, y the vector of observations on the left-hand-side variables. Define A as X′X and a as X′y. The coefficient vector b is defined as A−1a. Although not shown in the notation, unless hascons is specified, A and a are accumulated in deviation form and the constant is calculated separately. This comment applies to all statistics listed below.

The total sum of squares, TSS, equals y′y if there is no intercept and y′y − (1′y)2/n otherwise. The degrees of freedom is n − c, where n is the number of observations and c = 1 if there is a constant in the regression and 0 otherwise.

The residual sum of squares, RSS, is defined as (y − Xb)′(y − Xb). The degrees of freedom is n − k, where n is the number of observations and k is the number of right-hand-side variables (including the constant).

The model sum of squares, MSS, equals TSS − RSS. The degrees of freedom is k − c.

The mean squared error, s2, is defined as RSS/(n − k). The root mean squared error is s, its square root.

The F statistic with k − c and n − k degrees of freedom is defined as

\[ F = \frac{\text{MSS}}{(k-c)s^2} \]

The R² is defined as R² = 1 − RSS/TSS.

The adjusted R² is defined as R²_a = 1 − (1 − R²)(n − c)/(n − k).

The conventional estimate of variance is s²A−1. The calculation of variance estimates when robust variance estimates are specified is described below.

Weighted regression

Let v be a column vector of weights specified by the user. Let w be a column vector of normalized weights, w = {v/(1′v)}(1′1). For fweights, w = v. For historical reasons, iweights are treated like fweights when robust standard errors are not specified. Instead, when vce(robust), vce(cluster clustvarlist), vce(hc2), or vce(hc3) is specified, iweights are treated like aweights.

If the user specifies weights, the number of observations, n, in the above formulas is defined as 1′w. For iweights, this is truncated to an integer. The sum of the weights is 1′v. X′X, X′y, and y′y are replaced in the above formulas by X′DX, X′Dy, and y′Dy, respectively, where D is a diagonal matrix whose diagonal elements are the elements of w.
A general notation for the robust variance calculation

Put aside all context of linear regression and the notation that goes with it—we will return to it. First, we are going to establish a notation for describing robust variance calculations.

The calculation formula for the robust variance calculation is

\[
\hat{V} = q_c \hat{V} \left( \sum_{k=1}^{M} u_k^{(G')'} u_k^{(G)} \right) \hat{V}
\]

where

\[
u_k^{(G)} = \sum_{j \in G_k} w_j u_j
\]

\(G_1, G_2, \ldots, G_M\) are the clusters specified by `vce(cluster clustvarlist)` when `clustvarlist` contains only one variable, and \(w_j\) are the user-specified weights, normalized if `aweights` or `pweights` are specified and equal to 1 if no weights are specified.

For `fweights` without clusters, the variance formula is

\[
\hat{V} = q_c \hat{V} \left( \sum_{j=1}^{N} w_j u_j' u_j \right) \hat{V}
\]

which is the same as expanding the dataset and making the calculation on the unweighted data.

If `vce(cluster clustvarlist)` is not specified, \(M = N\), and each cluster contains 1 observation. The inputs into this calculation are

- \(\hat{V}\), which is typically a conventionally calculated variance matrix;
- \(u_j, j = 1, \ldots, N\), a row vector of scores; and
- \(q_c\), a constant finite-sample adjustment.

Thus, we can now describe how estimators apply the robust calculation formula by defining \(\hat{V}, u_j,\) and \(q_c\).

Two definitions are popular enough for \(q_c\) to deserve a name. The regression-like formula for \(q_c\) (Fuller et al. 1986) is

\[
q_c = \frac{N - 1}{N - k} \frac{M}{M - 1}
\]

where \(M\) is the number of clusters and \(N\) is the number of observations. For weights, \(N\) refers to the sum of the weights if weights are frequency weights and the number of observations in the dataset (ignoring weights) in all other cases. Also note that, weighted or not, \(M = N\) when `vce(cluster clustvarlist)` is not specified, and then \(q_c = N/(N - k)\).

The asymptotic-like formula for \(q_c\) is

\[
q_c = \frac{M}{M - 1}
\]

where \(M = N\) if `vce(cluster clustvarlist)` is not specified.

See [U] 20.22 Obtaining robust variance estimates and [P] _robust for a discussion of the robust variance estimator and a development of these formulas.
Robust calculation for regress

For `regress`, \( \hat{V} = A^{-1} \). The other terms are `vce(robust)`, but not `vce(hc2)` or `vce(hc3)`,

\[
\mathbf{u}_j = (y_j - x_j \mathbf{b}) x_j
\]

and \( q_c \) is given by its regression-like definition. `vce(hc2)`,

\[
\mathbf{u}_j = \frac{1}{\sqrt{1 - h_{jj}}} (y_j - x_j \mathbf{b}) x_j
\]

where \( q_c = 1 \) and \( h_{jj} = x_j (X'X)^{-1} x_j' \). `vce(hc3)`,

\[
\mathbf{u}_j = \frac{1}{1 - h_{jj}} (y_j - x_j \mathbf{b}) x_j
\]

where \( q_c = 1 \) and \( h_{jj} = x_j (X'X)^{-1} x_j' \). `vce(hc2 clustvar)`,

\[
\mathbf{u}_j = (y_j - X_j \mathbf{b})' (I_{G_j} - H_{jj})^{-\frac{1}{2}} X_j
\]

where \( q_c = 1 \), \( H_{jj} = X_j (X'X)^{-1} X_j' \) for cluster \( j \) of size \( G_j \), \( G_j \times k \) data matrix \( X_j \), and \( G_j \times 1 \) vector \( y_j \). \((I_{G_j} - H_{jj})^{-\frac{1}{2}}\) is the inverse of the symmetric square root of \((I_{G_j} - H_{jj})\) (Bell and McCaffrey 2002).

`vce(hc2 [clustvar], dfadjust)` directs `regress` to compute the adjusted degrees of freedom described by Imbens and Kolesár (2016). Define the \( N \times M \) matrix \( \mathbf{G} \) such that the \( j \)th column is

\[
(I_N - H)_j' (I_{G_j} - H_{jj})^{-\frac{1}{2}} X_j (X'X)^{-1} e_l
\]

where \( j = 1, \ldots, M \), \( e_l \) is a unary vector for the \( l \)th regressor, \( l = 1, \ldots, k \), and \((I_N - H)_j\) is the \( G_j \times N \) subset of the \( N \times N \) matrix \((I_N - H)\) for cluster \( j \). The Bell and McCaffrey (2002) adjusted degrees of freedom for the \( l \)th regressor is

\[
K_l = \frac{\text{tr}(G'G)^2}{\text{tr}[(G'G)^2]} = \left( \sum_{i=1}^{M} \lambda_i \right)^2 / \sum_{i=1}^{M} \lambda_i^2
\]

where \( \text{tr}(\cdot) \) is the trace function and \( \lambda_i \) are the eigenvalues of \( G'G \).
When $M$ is large, or when there are no clusters and $M = N$, computing the eigenvalues can be time consuming. We define

$$a_j = (I - H_{jj})^{-\frac{1}{2}} X_j (X'X)^{-1} e_{L,k}$$
$$b_j = H_{jj}a_j$$
$$A = (a_1', a_2', \ldots, a_M')' = (A_1, A_2, \ldots, A_M)'$$
$$B = (b_1, \ldots, b_M) = \begin{pmatrix}
B_{1,1} & B_{1,2} & \cdots & B_{1,M} \\
\vdots & \vdots & \ddots & \vdots \\
B_{N,1} & B_{N,2} & \cdots & B_{N,M}
\end{pmatrix}$$

for $j = 1, \ldots, M$ and $H_j = X (X'X)^{-1} X'_j$. Then $G'G = \text{diag}(A) - B'B$ (Kolesár 2021).

We now express the adjusted degrees of freedom as

$$K_l = \frac{\left( \sum_{j=1}^M A_j - \sum_{i=1}^N \sum_{j=1}^M B_{ij}^2 \right)^2}{\sum_{j=1}^M A_j^2 - 2 \sum_{j=1}^M A_j \sum_{i=1}^N \sum_{j=1}^M B_{ij}^2 + \sum_{j=1}^N \sum_{j=1}^M \sum_{j=1}^M (b'_j b_{j2})^2}$$

which can be computed efficiently in Mata and using QR decomposition. For example, by decomposing $X = QR$, where $Q$ is $n \times k$ and orthonormal and $R$ is $k \times k$ and upper triangular, we can rewrite the matrix $B$ so that it has dimension $k \times M$ instead of $N \times M$.

When weights are specified, we use the weighted covariate matrix $\tilde{X} = \text{diag}(w)^{\frac{1}{2}} X$ and its corresponding projection matrix $\tilde{H}$, as well as the cluster covariance matrices $\tilde{X}_j$, their projection matrices $\tilde{H}_{jj}$, and weighted residuals $\tilde{\varepsilon}_j = \text{diag}(w)^{\frac{1}{2}} \tilde{\varepsilon}_j$. When frequency weights are specified without clusters, we substitute $1/\sqrt{1 - h_{jj}}$ with $1/\sqrt{w_j - \tilde{h}_{jj}}$, where $j = 1, \ldots, N$. Also, when there are no clusters, the weights are included in the degrees-of-freedom algebra

$$K_l = \frac{\left( \sum_{j=1}^N w_j A_j - \sum_{i=1}^k \sum_{j=1}^N B_{ij}^2 \right)^2}{\sum_{j=1}^N w_j A_j^2 - 2 \sum_{j=1}^N A_j \sum_{i=1}^k \sum_{j=1}^N B_{ij}^2 + \sum_{j=1}^N \sum_{j=1}^N \sum_{j=1}^N (b'_j b_{j2})^2}$$

Here we substituted $k$ for $N$ in the row dimension of $B$ as it is when using QR decomposition to perform the computations.

With weights, the $\text{vce(hc2 clustvar)}$ computation discussed above is modified to

$$u_j = \left( \text{diag}(w_j)^{\frac{1}{2}} (y_j - X_jb) \right)' \left( I - \tilde{H}_{jj} \right)^{-\frac{1}{2}} \tilde{X}_j$$
$$= \left( \tilde{y}_j - \tilde{X}_j b \right)' \left( I - \tilde{H}_{jj} \right)^{-\frac{1}{2}} \tilde{X}_j$$
Multiway clustering

When you type `vce(cluster clustvarlist)` with more than one variable, the variance–covariance estimator uses multiway cluster–robust variance estimation. This is carried out by estimating the robust VCE for all combinations of the specified cluster variables and summing. For \( p \) cluster variables, there will be \( P = 2^p - 1 \) cluster variable combinations. Let \( V_i \) be the \( i \)th robust VCE, \( i = 1, \ldots, P \). Define \( S_j \), \( j = 1, \ldots, p \), as the set of indices \( i \) involving \( j \) cluster variables. The size, or cardinality, of \( S_j \) is \(|S_j| = \binom{p}{j}\) and \( \sum_{j=1}^{p} \binom{p}{j} = 2^p - 1 \). For example, for \( p = 4 \), \(|S_1| = \binom{4}{1} = 4\), \(|S_2| = \binom{4}{2} = 6\), \(|S_3| = \binom{4}{3} = 4\), and \(|S_4| = \binom{4}{4} = 1\). The multiway cluster–robust VCE is then

\[
V_* = \sum_{j=1}^{P} (-1)^{j-1} \sum_{i \in S_j} V_i
\]

You are more likely to cluster on two or, maybe, three variables. In the case of two cluster variables, the computation would be

\[
V_* = V_1 + V_2 - V_{12}
\]

where \( V_1 \) corresponds to the variance–covariance computation clustering at the level of the first cluster, \( V_2 \) corresponds to the second level, and \( V_{12} \) corresponds to the variance–covariance computation for the group formed by the intersection of both clustering levels.

An eigendecomposition on \( V_* \) ensures the matrix to be positive semidefinite. Let the columns of matrix \( U \) contain the eigenvectors of \( V_* \) and the vector contain \( u \), its eigenvalues. If \( V_* \) is not positive definite, some of the elements of \( u \) will be less than 0. Let \( u_+ \) contain all the nonnegative elements of \( u \) and zeros where \( u_i < 0 \). The matrix \( V_+ = U \cdot \text{diag}(u_+) \cdot U' \) will then be positive semidefinite.

Acknowledgments

The robust estimate of variance was first implemented in Stata by Mead Over of the Center for Global Development, Dean Jolliffe of the World Bank, and Andrew Foster of the Department of Economics at Brown University (Over, Jolliffe, and Foster 1996).
The history of regression is long and complicated: the books by Stigler (1986) and Hald (1998) are devoted largely to the story. Legendre published first on least squares in 1805. Gauss published later in 1809, but he had the idea earlier. Gauss, and especially Laplace, tied least squares to a normal errors assumption. The idea of the normal distribution can itself be traced back to De Moivre in 1733. Laplace discussed a variety of other estimation methods and error assumptions over his long career, while linear models long predate either innovation. Most of this work was linked to problems in astronomy and geodesy.

A second wave of ideas started when Galton used graphical and descriptive methods on data bearing on heredity to develop what he called regression. His term reflects the common phenomenon that characteristics of offspring are positively correlated with those of parents but with regression slope such that offspring “regress toward the mean”. Galton’s work was rather intuitive: contributions from Pearson, Edgeworth, Yule, and others introduced more formal machinery, developed related ideas on correlation, and extended application into the biological and social sciences. So most of the elements of regression as we know it were in place by 1900.

Pierre-Simon Laplace (1749–1827) was born in Normandy and was early recognized as a remarkable mathematician. He weathered a changing political climate well enough to rise to Minister of the Interior under Napoleon in 1799 (although only for 6 weeks) and to be made a Marquis by Louis XVIII in 1817. He made many contributions to mathematics and physics, his two main interests being theoretical astronomy and probability theory (including statistics). Laplace transforms are named for him.

Adrien-Marie Legendre (1752–1833) was born in Paris (or possibly in Toulouse) and educated in mathematics and physics. He worked in number theory, geometry, differential equations, calculus, function theory, applied mathematics, and geodesy. The Legendre polynomials are named for him. His main contribution to statistics is as one of the discoverers of least squares. He died in poverty, having refused to bow to political pressures.

Johann Carl Friedrich Gauss (1777–1855) was born in Braunschweig (Brunswick), now in Germany. He studied there and at Göttingen. His doctoral dissertation at the University of Helmstedt was a discussion of the fundamental theorem of algebra. He made many fundamental contributions to geometry, number theory, algebra, real analysis, differential equations, numerical analysis, statistics, astronomy, optics, geodesy, mechanics, and magnetism. An outstanding genius, Gauss worked mostly in isolation in Göttingen.

Francis Galton (1822–1911) was born in Birmingham, England, into a well-to-do family with many connections: he and Charles Darwin were first cousins. After an unsuccessful foray into medicine, he became independently wealthy at the death of his father. Galton traveled widely in Europe, the Middle East, and Africa, and became celebrated as an explorer and geographer. His pioneering work on weather maps helped in the identification of anticyclones, which he named. From about 1865, most of his work was centered on quantitative problems in biology, anthropology, and psychology. In a sense, Galton (re)invented regression, and he certainly named it. Galton also promoted the normal distribution, correlation approaches, and the use of median and selected quantiles as descriptive statistics. He was knighted in 1909.

## Postestimation commands

The following postestimation commands are of special interest after `regress`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dfbeta</td>
<td>DFBETA influence statistics</td>
</tr>
<tr>
<td>estat hettest</td>
<td>tests for heteroskedasticity</td>
</tr>
<tr>
<td>estat imtest</td>
<td>information matrix test</td>
</tr>
<tr>
<td>estat ovtest</td>
<td>Ramsey regression specification-error test for omitted variables</td>
</tr>
<tr>
<td>estat szroeter</td>
<td>Szroeter’s rank test for heteroskedasticity</td>
</tr>
<tr>
<td>estat vif</td>
<td>variance inflation factors for the independent variables</td>
</tr>
<tr>
<td>estat esize</td>
<td>$\eta^2$, $\varepsilon^2$, and $\omega^2$ effect sizes</td>
</tr>
<tr>
<td>estat moran</td>
<td>Moran’s test of residual correlation with nearby residuals</td>
</tr>
<tr>
<td>lassogof</td>
<td>calculate goodness-of-fit predictions</td>
</tr>
</tbody>
</table>

These commands are not appropriate with `svy` estimation results.
The following standard postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contrast</td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td>estat ic</td>
<td>Akaike’s, consistent Akaike’s, corrected Akaike’s, and Schwarz’s Bayesian information criteria (AIC, CAIC, AICc, and BIC)</td>
</tr>
<tr>

</tbody>
</table>

*forecast, hausman, and lrtest are not appropriate with svy estimation results. forecast is also not appropriate with mi estimation results.
Predictions

Description for predict

predict creates a new variable containing predictions such as linear predictions, residuals, standardized residuals, Studentized residuals, Cook’s distance, leverage, probabilities, expected values, DFBETAs for varname, standard errors, COVRATIOS, DFITS, and Welsch distances.

Menu for predict

Unstarred statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when if e(sample) is not specified.

rstandard, rstudent, Cook’s leverage, dfbeta(), stdp, stdf, stdr, covratio, dfits, and welsh are not available if any vce() other than vce(ols) was specified with regress.

xb, residuals, score, and stdp are the only options allowed with svy estimation results.

where a and b may be numbers or variables; a missing (a ≥ .) means −∞, and b missing (b ≥ .) means +∞; see [U] 12.2.1 Missing values.
Options for predict

xb, the default, calculates the linear prediction.

residuals calculates the residuals.

score is equivalent to residuals in linear regression.

rstandard calculates the standardized residuals.

rstudent calculates the Studentized (jackknifed) residuals.

cooksd calculates the Cook’s D influence statistic (Cook 1977).

leverage or hat calculates the diagonal elements of the projection (“hat”) matrix.

pr(\{a, b\}) calculates \( \Pr\{a < x_j \mathbf{b} + u_j < b\} \), the probability that \( y_j | x_j \) would be observed in the interval \((a, b)\).

\( a \) and \( b \) may be specified as numbers or variable names; \( lb \) and \( ub \) are variable names;

pr(20,30) calculates \( \Pr\{20 < x_j \mathbf{b} + u_j < 30\}\);

pr(lb,ub) calculates \( \Pr\{lb < x_j \mathbf{b} + u_j < ub\} \); and

pr(20,ub) calculates \( \Pr\{20 < x_j \mathbf{b} + u_j < ub\} \).

\( a \) missing \((a \geq .)\) means \(-\infty\); pr(.,30) calculates \( \Pr\{-\infty < x_j \mathbf{b} + u_j < 30\}\);

pr(lb,.) calculates \( \Pr\{-\infty < x_j \mathbf{b} + u_j < 30\} \) in observations for which \( lb \geq . \)

and calculates \( \Pr\{lb < x_j \mathbf{b} + u_j < 30\} \) elsewhere.

\( b \) missing \((b \geq .)\) means \(+\infty\); pr(20,.) calculates \( \Pr\{+\infty > x_j \mathbf{b} + u_j > 20\} \);

pr(20,ub) calculates \( \Pr\{+\infty > x_j \mathbf{b} + u_j > 20\} \) in observations for which \( ub \geq . \)

and calculates \( \Pr\{20 < x_j \mathbf{b} + u_j < ub\} \) elsewhere.

e(\{a, b\}) calculates \( E(x_j \mathbf{b} + u_j | a < x_j \mathbf{b} + u_j < b) \), the expected value of \( y_j | x_j \) conditional on

\( y_j | x_j \) being in the interval \((a, b)\), meaning that \( y_j | x_j \) is truncated. \( a \) and \( b \) are specified as they

are for pr().

ystar(\{a, b\}) calculates \( E(y_j^*), \) where \( y_j^* = a \) if \( x_j \mathbf{b} + u_j \leq a, y_j^* = b \) if \( x_j \mathbf{b} + u_j \geq b, \) and

\( y_j^* = x_j \mathbf{b} + u_j \) otherwise, meaning that \( y_j^* \) is censored. \( a \) and \( b \) are specified as they are for pr().

dfbeta(varname) calculates the DFBETA for varname, the difference between the regression coefficient

when the \( j \)th observation is included and excluded, said difference being scaled by the estimated

standard error of the coefficient. varname must have been included among the regressors in the

previously fitted model. The calculation is automatically restricted to the estimation subsample.

stdp calculates the standard error of the prediction, which can be thought of as the standard error of

the predicted expected value or mean for the observation’s covariate pattern. The standard error

of the prediction is also referred to as the standard error of the fitted value.

stdf calculates the standard error of the forecast, which is the standard error of the point prediction

for 1 observation. It is commonly referred to as the standard error of the future or forecast value.

By construction, the standard errors produced by stdf are always larger than those produced by

stdp; see Methods and formulas.

stdr calculates the standard error of the residuals.

covratio calculates COVRATIO (Belsley, Kuh, and Welsch 1980), a measure of the influence of the

\( j \)th observation based on considering the effect on the variance–covariance matrix of the estimates.

The calculation is automatically restricted to the estimation subsample.
dfits calculates DFITS (Welsch and Kuh 1977) and attempts to summarize the information in the leverage versus residual-squared plot into one statistic. The calculation is automatically restricted to the estimation subsample.

welsch calculates Welsch distance (Welsch 1982) and is a variation on dfits. The calculation is automatically restricted to the estimation subsample.

Remarks and examples for predict

Remarks are presented under the following headings:

- Terminology
- Fitted values and residuals
- Prediction standard errors
- Prediction with weighted data
- Leverage statistics
- Standardized and Studentized residuals
- DFITS, Cook’s Distance, and Welsch Distance
- COVRATIO

Terminology

Many of these commands concern identifying influential data in linear regression. This is, unfortunately, a field that is dominated by jargon, codified and partially begun by Belsley, Kuh, and Welsch (1980). In the words of Chatterjee and Hadi (1986, 416), “Belsley, Kuh, and Welsch’s book, *Regression Diagnostics*, was a very valuable contribution to the statistical literature, but it unleashed on an unsuspecting statistical community a computer speak (à la Orwell), the likes of which we have never seen.” Things have only gotten worse since then. Chatterjee and Hadi’s (1986, 1988) own attempts to clean up the jargon did not improve matters (see Hoaglin and Kempthorne [1986], Velleman [1986], and Welsch [1986]). We apologize for the jargon, and for our contribution to the jargon in the form of inelegant command names, we apologize most of all.

Model sensitivity refers to how estimates are affected by subsets of our data. Imagine data on $y$ and $x$, and assume that the data are to be fit by the regression $y_i = \alpha + \beta x_i + \epsilon_i$. The regression estimates of $\alpha$ and $\beta$ are $a$ and $b$, respectively. Now imagine that the estimated $a$ and $b$ would be different if a small portion of the dataset, perhaps even one observation, were deleted. As a data analyst, you would like to think that you are summarizing tendencies that apply to all the data, but you have just been told that the model you fit is unduly influenced by one point or just a few points and that, as a matter of fact, there is another model that applies to the rest of the data—a model that you have ignored. The search for subsets of the data that, if deleted, would change the results markedly is a predominant theme of this entry.

There are three key issues in identifying model sensitivity to individual observations, which go by the names *residuals*, *leverage*, and *influence*. In our $y_i = a + bx_i + \epsilon_i$ regression, the residuals are, of course, $\epsilon_i$—they reveal how much our fitted value $\hat{y}_i = a + bx_i$ differs from the observed $y_i$. A point $(x_i, y_i)$ with a corresponding large residual is called an outlier. Say that you are interested in outliers because you somehow think that such points will exert undue influence on your estimates. Your feelings are generally right, but there are exceptions. A point might have a huge residual and yet not affect the estimated $b$ at all. Nevertheless, studying observations with large residuals almost always pays off.

$(x_i, y_i)$ can be an outlier in another way—just as $y_i$ can be far from $\hat{y}_i$, $x_i$ can be far from the center of mass of the other $x$’s. Such an “outlier” should interest you just as much as the more traditional outliers. Picture a scatterplot of $y$ against $x$ with thousands of points in some sort of mass...
at the lower left of the graph and one point at the upper right of the graph. Now, run a regression line through the points—the regression line will come close to the point at the upper right of the graph and may in fact, go through it. That is, this isolated point will not appear as an outlier as measured by residuals because its residual will be small. Yet this point might have a dramatic effect on our resulting estimates in the sense that, were you to delete the point, the estimates would change markedly. Such a point is said to have high leverage. Just as with traditional outliers, a high leverage point does not necessarily have an undue effect on regression estimates, but if it does not, it is more the exception than the rule.

Now, all of this is a most unsatisfactory state of affairs. Points with large residuals may, but need not, have a large effect on our results, and points with small residuals may still have a large effect. Points with high leverage may, but need not, have a large effect on our results, and points with low leverage may still have a large effect. Can you not identify the influential points and simply have the computer list them for you? You can, but you will have to define what you mean by “influential”.

“Influential” is defined with respect to some statistic. For instance, you might ask which points in your data have a large effect on your estimated \( a \), which points have a large effect on your estimated \( b \), which points have a large effect on your estimated standard error of \( b \), and so on, but do not be surprised when the answers to these questions are different. In any case, obtaining such measures is not difficult—all you have to do is fit the regression excluding each observation one at a time and record the statistic of interest which, in the day of the modern computer, is not too onerous. Moreover, you can save considerable computer time by doing algebra ahead of time and working out formulas that will calculate the same answers as if you ran each of the regressions. (Ignore the question of pairs of observations that, together, exert undue influence, and triples, and so on, which remains largely unsolved and for which the brute force fit-every-possible-regression procedure is not a viable alternative.)

Fitted values and residuals

Typing `predict` *newvar* with no options creates *newvar* containing the fitted values. Typing `predict` *newvar*, resid creates *newvar* containing the residuals.

Example 1

Continuing with example 1 from [R] `regress`, we wish to fit the following model:

\[
\text{mpg} = \beta_0 + \beta_1 \text{weight} + \beta_2 \text{foreign} + \epsilon
\]

```stata
use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress mpg weight foreign
Source | SS df MS Number of obs = 74
------ | --- --- ------ --------
Model | 1619.2877 2 809.643849 F(2, 71) = 69.75 Prob > F = 0.0000
Residual | 824.171761 71 11.608053 R-squared = 0.6627
| Adj R-squared = 0.6627
Total | 2443.45946 73 33.472047 Root MSE = 3.4071

mpg | Coefficient Std. err. t P>|t| [95% conf. interval]
----- | ---------- ---------- ------ -------- ------------------
weight | -.0065879 .0006371 -10.34 0.000 -.0078583 -.0053175
foreign | -1.650029 1.075994 -1.53 0.130 -3.7955 .4954422
_cons | 41.6797 2.165547 19.25 0.000 37.36172 45.99768
```
That done, we can now obtain the predicted values from the regression. We will store them in a new variable called `pmpg` by typing `predict pmpg`. Because `predict` produces no output, we will follow that by summarizing our predicted and observed values.

```
. predict pmpg
(option xb assumed; fitted values)
. summarize pmpg mpg
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>pmpg</td>
<td>74</td>
<td>21.2973</td>
<td>4.709779</td>
<td>9.794333</td>
<td>29.82151</td>
</tr>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
</tbody>
</table>

Example 2: Out-of-sample predictions

We can just as easily obtain predicted values from the model by using a wholly different dataset from the one on which the model was fit. The only requirement is that the data have the necessary variables, which here are `weight` and `foreign`.

Using the data on two new cars (the Pontiac Sunbird and the Volvo 260) from `newautos.dta`, we can obtain out-of-sample predictions (or forecasts) by typing

```
. use https://www.stata-press.com/data/r18/newautos, clear
(Regress postestimation — Postestimation tools for regress)
. predict pmpg
(option xb assumed; fitted values)
. list, divider
```

<table>
<thead>
<tr>
<th>make</th>
<th>weight</th>
<th>foreign</th>
<th>pmpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pont. Sunbird</td>
<td>2690</td>
<td>Domestic</td>
<td>23.95829</td>
</tr>
<tr>
<td>Volvo 260</td>
<td>3170</td>
<td>Foreign</td>
<td>19.14607</td>
</tr>
</tbody>
</table>

The Pontiac Sunbird has a predicted mileage rating of 23.96 mpg, whereas the Volvo 260 has a predicted rating of 19.15 mpg. In comparison, the actual mileage ratings are 24 for the Pontiac and 17 for the Volvo.

Prediction standard errors

`predict` can calculate the standard error of the forecast (`stdf` option), the standard error of the prediction (`stdp` option), and the standard error of the residual (`stdr` option). It is easy to confuse `stdf` and `stdp` because both are often called the prediction error. Consider the prediction $\hat{y}_j = x_j b$, where $b$ is the estimated coefficient (column) vector and $x_j$ is a (row) vector of independent variables for which you want the prediction. First, $\hat{y}_j$ has a variance due to the variance of the estimated coefficient vector $b$.

$$\text{Var}(\hat{y}_j) = \text{Var}(x_j b) = s^2 h_j$$

where $h_j = x_j (X'X)^{-1} x_j'$ and $s^2$ is the mean squared error of the regression. Do not panic over the algebra—just remember that $\text{Var}(\hat{y}_j) = s^2 h_j$, whatever $s^2$ and $h_j$ are. `stdp` calculates this quantity. This is the error in the prediction due to the uncertainty about $b$.

If you are about to hand this number out as your forecast, however, there is another error. According to your model, the true value of $y_j$ is given by

$$y_j = x_j b + \epsilon_j = \hat{y}_j + \epsilon_j$$
and thus the \( \text{Var}(y_j) = \text{Var}(\hat{y}_j) + \text{Var}(\epsilon_j) = s^2 h_j + s^2 \), which is the square of \( \text{stdf} \). \( \text{stdf} \), then, is the sum of the error in the prediction plus the residual error.

\( \text{stdr} \) has to do with an analysis-of-variance decomposition of \( s^2 \), the estimated variance of \( y \). The standard error of the prediction is \( s^2 h_j \), and therefore \( s^2 h_j + s^2(1 - h_j) = s^2 \) decomposes \( s^2 \) into the prediction and residual variances.

Example 3: Standard error of the forecast

Returning to our model of mpg on weight and foreign, we previously predicted the mileage rating for the Pontiac Sunbird and Volvo 260 as 23.96 and 19.15 mpg, respectively. We now want to put a standard error around our forecast. Remember, the data for these two cars were in newautos.dta:

```stata
use https://www.stata-press.com/data/r18/newautos, clear
predict pmpg
predict se_pmpg, stdf
list, divider
```

<table>
<thead>
<tr>
<th>make</th>
<th>weight</th>
<th>foreign</th>
<th>pmpg</th>
<th>se_pmpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pont. Sunbird</td>
<td>2690</td>
<td>Domestic</td>
<td>23.9583</td>
<td>3.4628</td>
</tr>
<tr>
<td>Volvo 260</td>
<td>3170</td>
<td>Foreign</td>
<td>19.1461</td>
<td>3.5259</td>
</tr>
</tbody>
</table>

Thus, an approximate 95% confidence interval for the mileage rating of the Volvo 260 is \( 19.15 \pm 2 \cdot 3.53 = [12.09, 26.21] \).

Prediction with weighted data

`predict` can be used after frequency-weighted (`fweight`) estimation, just as it is used after unweighted estimation. The technical note below concerns the use of `predict` after analytically weighted (`aweight`) estimation.

Technical note

After analytically weighted estimation, `predict` is willing to calculate only the prediction (no options), residual (`residual` option), standard error of the prediction (`stdp` option), and diagonal elements of the projection matrix (`hat` option). For analytically weighted estimation, the standard error of the forecast and residuals, the standardized and Studentized residuals, and Cook’s \( D \) are not statistically well-defined concepts.

Leverage statistics

In addition to providing fitted values and the associated standard errors, the `predict` command can also be used to generate various statistics used to detect the influence of individual observations. This section provides a brief introduction to leverage (hat) statistics, and some of the following subsections discuss other influence statistics produced by `predict`. 
Example 4: Diagonal elements of projection matrix

The diagonal elements of the projection matrix, obtained by the hat option, are a measure of distance in explanatory variable space. leverage is a synonym for hat.

. use https://www.stata-press.com/data/r18/auto, clear
   (1978 automobile data)
. regress mpg weight foreign
   (output omitted)
. predict xdist, hat
. summarize xdist, detail

<table>

75% .0494002 Largest Std. dev. .0207624
90% .0693432 .099715 Variance .0004311
95% .0880814 .099715 Skewness 1.159745
99% .1003283 .1003283 Kurtosis 4.083313

Some 5% of our sample has an xdist measure in excess of 0.08. Let’s force them to reveal their identities:

. list foreign make mpg if xdist>.08, divider

<table>
<thead>
<tr>
<th>foreign</th>
<th>make</th>
<th>mpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>Ford Fiesta</td>
<td>28</td>
</tr>
<tr>
<td>Domestic</td>
<td>Linc. Continental</td>
<td>12</td>
</tr>
<tr>
<td>Domestic</td>
<td>Linc. Mark V</td>
<td>12</td>
</tr>
<tr>
<td>Domestic</td>
<td>Plym. Champ</td>
<td>34</td>
</tr>
<tr>
<td>Foreign</td>
<td>Peugeot 604</td>
<td>14</td>
</tr>
</tbody>
</table>

To understand why these cars are on this list, we must remember that the explanatory variables in our model are weight and foreign and that xdist measures distance in this metric. The Ford Fiesta and the Plymouth Champ are the two lightest domestic cars in our data. The Lincolns are the two heaviest domestic cars, and the Peugeot is the heaviest foreign car.

See lvr2plot in [R] regress postestimation diagnostic plots for information on a leverage-versus-squared-residual plot.

Standardized and Studentized residuals

The terms standardized and Studentized residuals have meant different things to different authors. In Stata, predict defines the standardized residual as $\hat{e}_s = e_i / \left(s \sqrt{1 - h_i}\right)$ and the Studentized residual as $r_i = e_i / \left(s_i \sqrt{1 - h_i}\right)$, where $s_i$ is the root mean squared error of a regression with the $i$th observation removed. Stata’s definition of the Studentized residual is the same as the one given in Bollen and Jackman (1990, 264) and is what Chatterjee and Hadi (1988, 74) call the “externally Studentized” residual. Stata’s “standardized” residual is the same as what Chatterjee and Hadi (1988, 74) call the “internally Studentized” residual.
Standardized and Studentized residuals are attempts to adjust residuals for their standard errors. Although the $\epsilon_i$ theoretical residuals are homoskedastic by assumption (that is, they all have the same variance), the calculated $e_i$ are not. In fact,

$$\text{Var}(e_i) = \sigma^2(1 - h_i)$$

where $h_i$ are the leverage measures obtained from the diagonal elements of hat matrix. Thus, observations with the greatest leverage have corresponding residuals with the smallest variance.

Standardized residuals use the root mean squared error of the regression for $\sigma$. Studentized residuals use the root mean squared error of a regression omitting the observation in question for $\sigma$. In general, Studentized residuals are preferable to standardized residuals for purposes of outlier identification. Studentized residuals can be interpreted as the $t$ statistic for testing the significance of a dummy variable equal to 1 in the observation in question and 0 elsewhere (Belsley, Kuh, and Welsch 1980). Such a dummy variable would effectively absorb the observation and so remove its influence in determining the other coefficients in the model. Caution must be exercised here, however, because of the simultaneous testing problem. You cannot simply list the residuals that would be individually significant at the 5% level—their joint significance would be far less (their joint significance level would be far greater).

Example 5: Standardized and Studentized residuals

In the Terminology section of Remarks and examples for predict, we distinguished residuals from leverage and speculated on the impact of an observation with a small residual but large leverage. If we adjust the residuals for their standard errors, however, the adjusted residual would be (relatively) larger and perhaps large enough so that we could simply examine the adjusted residuals. Taking our price on weight and foreign##c.mpg model from example 1 of [R] regress postestimation diagnostic plots, we can obtain the in-sample standardized and Studentized residuals by typing

```stata
use https://www.stata-press.com/data/r18/auto, clear
regress price weight foreign##c.mpg
predict esta if e(sample), rstandard
predict estu if e(sample), rstudent
```

In the lvr2plot section of [R] regress postestimation diagnostic plots, we discovered that the VW Diesel has the highest leverage in our data, but a corresponding small residual. The standardized and Studentized residuals for the VW Diesel are

```stata
list make price esta estu if make=="VW Diesel"
```

<table>
<thead>
<tr>
<th>make</th>
<th>price</th>
<th>esta</th>
<th>estu</th>
</tr>
</thead>
<tbody>
<tr>
<td>VW Diesel</td>
<td>5,397</td>
<td>.6142691</td>
<td>.6114758</td>
</tr>
</tbody>
</table>
```

The Studentized residual of 0.611 can be interpreted as the $t$ statistic for including a dummy variable for VW Diesel in our regression. Such a variable would not be significant.
DFITS, Cook’s Distance, and Welsch Distance

DFITS (Welsch and Kuh 1977), Cook’s Distance (Cook 1977), and Welsch Distance (Welsch 1982) are three attempts to summarize the information in the leverage versus residual-squared plot into one statistic. That is, the goal is to create an index that is affected by the size of the residuals—outliers—and the size of $h_i$—leverage. Viewed mechanically, one way to write DFITS (Bollen and Jackman 1990, 265) is

$$DFITS_i = r_i \sqrt{\frac{h_i}{1 - h_i}}$$

where $r_i$ are the Studentized residuals. Thus, large residuals increase the value of DFITS, as do large values of $h_i$. Viewed more traditionally, DFITS is a scaled difference between predicted values for the $i$th case when the regression is fit with and without the $i$th observation, hence the name.

The mechanical relationship between DFITS and Cook’s Distance, $D_i$ (Bollen and Jackman 1990, 266), is

$$D_i = \frac{1}{k} \frac{s^2_{(i)}}{s^2} DFITS^2_i$$

where $k$ is the number of variables (including the constant) in the regression, $s$ is the root mean squared error of the regression, and $s_{(i)}$ is the root mean squared error when the $i$th observation is omitted. Viewed more traditionally, $D_i$ is a scaled measure of the distance between the coefficient vectors when the $i$th observation is omitted.

The mechanical relationship between DFITS and Welsch’s Distance, $W_i$ (Chatterjee and Hadi 1988, 123), is

$$W_i = DFITS_i \sqrt{n - 1}$$

The interpretation of $W_i$ is more difficult because it is based on the empirical influence curve. Although DFITS and Cook’s distance are similar, the Welsch distance measure includes another normalization by leverage.

Belsley, Kuh, and Welsch (1980, 28) suggest that DFITS values greater than $2\sqrt{k/n}$ deserve more investigation, and so values of Cook’s distance greater than $4/n$ should also be examined (Bollen and Jackman 1990, 265–266). Through similar logic, the cutoff for Welsch distance is approximately $3\sqrt{k}$ (Chatterjee and Hadi 1988, 124).

Example 6: DFITS influence measure

Continuing with our model of price on weight and foreign##c.mpg, we can obtain the DFITS influence measure:

```
. predict e if e(sample), resid
. predict dfits, dfits
```

We did not specify `if e(sample)` in computing the DFITS statistic. DFITS is available only over the estimation sample, so specifying `if e(sample)` would have been redundant. It would have done no harm, but it would not have changed the results.

Our model has $k = 5$ independent variables ($k$ includes the constant) and $n = 74$ observations; following the $2\sqrt{k/n}$ cutoff advice, we type
. list make price e dfits if abs(dfits) > 2*sqrt(5/74), divider

<table>
<thead>
<tr>
<th>make</th>
<th>price</th>
<th>e</th>
<th>dfits</th>
</tr>
</thead>
<tbody>
<tr>
<td>12. Cad. Eldorado</td>
<td>14,500</td>
<td>7271.96</td>
<td>.9564455</td>
</tr>
<tr>
<td>13. Cad. Seville</td>
<td>15,906</td>
<td>5036.348</td>
<td>1.356619</td>
</tr>
<tr>
<td>24. Ford Fiesta</td>
<td>4,389</td>
<td>3164.872</td>
<td>.5724172</td>
</tr>
<tr>
<td>27. Linc. Mark V</td>
<td>13,594</td>
<td>3109.193</td>
<td>.5200413</td>
</tr>
<tr>
<td>28. Linc. Versailles</td>
<td>13,466</td>
<td>6560.912</td>
<td>.8760136</td>
</tr>
<tr>
<td>42. Plym. Arrow</td>
<td>4,647</td>
<td>-3312.968</td>
<td>-.9384231</td>
</tr>
</tbody>
</table>

We calculate Cook’s distance and list the observations greater than the suggested $4/n$ cutoff:

. predict cooks if e(sample), cooks
. list make price e cooks if cooks > 4/74, divider

<table>
<thead>
<tr>
<th>make</th>
<th>price</th>
<th>e</th>
<th>cooks</th>
</tr>
</thead>
<tbody>
<tr>
<td>12. Cad. Eldorado</td>
<td>14,500</td>
<td>7271.96</td>
<td>.1492676</td>
</tr>
<tr>
<td>13. Cad. Seville</td>
<td>15,906</td>
<td>5036.348</td>
<td>.3328515</td>
</tr>
<tr>
<td>24. Ford Fiesta</td>
<td>4,389</td>
<td>3164.872</td>
<td>.0638815</td>
</tr>
<tr>
<td>28. Linc. Versailles</td>
<td>13,466</td>
<td>6560.912</td>
<td>.1308004</td>
</tr>
<tr>
<td>42. Plym. Arrow</td>
<td>4,647</td>
<td>-3312.968</td>
<td>.1700736</td>
</tr>
</tbody>
</table>

Here we used if e(sample) because Cook’s distance is not restricted to the estimation sample by default. It is worth comparing this list with the preceding one.

Finally, we use Welsch distance and the suggested $3\sqrt{k}$ cutoff:

. predict wd, welsch
. list make price e wd if abs(wd) > 3*sqrt(5), divider

<table>
<thead>
<tr>
<th>make</th>
<th>price</th>
<th>e</th>
<th>wd</th>
</tr>
</thead>
<tbody>
<tr>
<td>12. Cad. Eldorado</td>
<td>14,500</td>
<td>7271.96</td>
<td>8.394372</td>
</tr>
<tr>
<td>13. Cad. Seville</td>

</table>

Here we did not need to specify if e(sample) because welsch automatically restricts the prediction to the estimation sample.

\section*{COVRATIO}

COVRATIO (Belsley, Kuh, and Welsch 1980) measures the influence of the $i$th observation by considering the effect on the variance–covariance matrix of the estimates. The measure is the ratio of the determinants of the covariances matrix, with and without the $i$th observation. The resulting formula is

$$
\text{COVRATIO}_i = \frac{1}{1-h_i} \left( \frac{n-k-\hat{c}_{s_i}^2}{n-k-1} \right)^k
$$

where $\hat{c}_{s_i}$ is the standardized residual.
For noninfluential observations, the value of COVRATIO is approximately 1. Large values of the residuals or large values of leverage will cause deviations from 1, although if both are large, COVRATIO may tend back toward 1 and therefore not identify such observations (Chatterjee and Hadi 1988, 139).

Belsley, Kuh, and Welsch (1980) suggest that observations for which

$$|\text{COVRATIO}_i - 1| \geq \frac{3k}{n}$$

are worthy of further examination.

Example 7: COVRATIO influence measure

Using our model of price on weight and foreign##c.mpg, we can obtain the COVRATIO measure and list the observations outside the suggested cutoff by typing

```
predict covr, covratio
.list make price e covr if abs(covr-1) >= 3*5/74, divider
```

<table>
<thead>
<tr>
<th>make</th>
<th>price</th>
<th>e</th>

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.
DFBETA influence statistics

Description for dfbeta

dfbeta will calculate one, more than one, or all the DFBETAs after regress. Although predict will also calculate DFBETAs, predict can do this for only one variable at a time. dfbeta is a convenience tool for those who want to calculate DFBETAs for multiple variables. The names for the new variables created are chosen automatically and begin with the letters _dfbeta_.

Menu for dfbeta

Statistics > Linear models and related > Regression diagnostics > DFBETAs

Syntax for dfbeta

dfbeta [ indepvar [ indepvar [...] ] ] [ , stub(name) ]

Option for dfbeta

stub(name) specifies the leading characters dfbeta uses to name the new variables to be generated. The default is stub(_dfbeta_).

Remarks and examples for dfbeta

DFBETAs are perhaps the most direct influence measure of interest to model builders. DFBETAs focus on one coefficient and measure the difference between the regression coefficient when the \(i\)th observation is included and excluded, the difference being scaled by the estimated standard error of the coefficient. Belsley, Kuh, and Welsch (1980, 28) suggest observations with \(|\text{DFBETA}_i| > 2/\sqrt{n}\) as deserving special attention, but it is also common practice to use 1 (Bollen and Jackman 1990, 267), meaning that the observation shifted the estimate at least one standard error.

Example 8: DFBETAs influence measure; the dfbeta() option

Using our model of \(\text{price}\) on \(\text{weight}\) and \(\text{foreign##c.mpg}\), let’s first ask which observations have the greatest impact on the determination of the coefficient on \(1.\text{foreign}\). We will use the suggested \(2/\sqrt{n}\) cutoff:

```
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
```
The Cadillac Seville shifted the coefficient on 1.foreign 0.82 standard deviations!

Now let us ask which observations have the greatest effect on the mpg coefficient:

```
. predict dmpg, dfbeta(mpg)
. list make price mpg dmpg if abs(dmpg) > 2/sqrt(74), divider
```

<table>
<thead>
<tr>
<th>make</th>
<th>price</th>
<th>mpg</th>
<th>dmpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cad. Eldorado</td>
<td>14,500</td>
<td>14</td>
<td>-.5970351</td>
</tr>
<tr>
<td>Cad. Seville</td>
<td>15,906</td>
<td>21</td>
<td>1.134269</td>
</tr>
<tr>
<td>Linc. Versailles</td>
<td>13,466</td>
<td>14</td>
<td>-.6069287</td>
</tr>
<tr>
<td>Plym. Arrow</td>
<td>4,647</td>
<td>28</td>
<td>-.8925859</td>
</tr>
<tr>
<td>Plym. Champ</td>
<td>4,425</td>
<td>34</td>
<td>.3186909</td>
</tr>
</tbody>
</table>

Once again, we see the Cadillac Seville heading the list, indicating that our regression results may be dominated by this one car.

---

**Example 9: DFBETAs influence measure; the dfbeta command**

We can use `predict, dfbeta()` or the `dfbeta` command to generate the DFBETAs. `dfbeta` makes up names for the new variables automatically and, without arguments, generates the DFBETAs for all the variables in the regression:

```
. dfbeta
Generating DFBETA variables ...
  _dfbeta_1: DFBETA weight
  _dfbeta_2: DFBETA 1.foreign
  _dfbeta_3: DFBETA mpg
  _dfbeta_4: DFBETA 1.foreign#c.mpg
```

dfbeta created four new variables in our dataset: _dfbeta_1, containing the DFBETAs for weight; _dfbeta_2, containing the DFBETAs for mpg; and so on. Had we wanted only the DFBETAs for mpg and weight, we might have typed

```
. dfbeta mpg weight
Generating DFBETA variables ...
  _dfbeta_5: DFBETA weight
  _dfbeta_6: DFBETA mpg
```
In the example above, we typed `dfbeta mpg weight` instead of `dfbeta`; if we had typed `dfbeta` followed by `dfbeta mpg weight`, here is what would have happened:

```
. dfbeta
Generating DFBETA variables ...
   _dfbeta_7: DFBETA weight
   _dfbeta_8: DFBETA 1.foreign
   _dfbeta_9: DFBETA mpg
   _dfbeta_10: DFBETA 1.foreign#c.mpg
. dfbeta mpg weight
Generating DFBETA variables ...
   _dfbeta_11: DFBETA weight
   _dfbeta_12: DFBETA mpg
```

dfbeta would have made up different names for the new variables. dfbeta never replaces existing variables—it instead makes up a different name, so we need to pay attention to dfbeta’s output.

## Tests for violation of assumptions

### Description for estat hettest

`estat hettest` performs three versions of the Breusch–Pagan (1979) and Cook–Weisberg (1983) test for heteroskedasticity. All three versions of this test present evidence against the null hypothesis that $t = 0$ in $\text{Var}(e) = \sigma^2 \exp(zt)$. In the *normal* version, performed by default, the null hypothesis also includes the assumption that the regression disturbances are independent-normal draws with variance $\sigma^2$. The normality assumption is dropped from the null hypothesis in the *iid* and *fstat* versions, which respectively produce the score and $F$ tests discussed in *Methods and formulas*. If `varlist` is not specified, the fitted values are used for $z$. If `varlist` or the `rhs` option is specified, the variables specified are used for $z$.

### Menu for estat

Statistics > Postestimation

### Syntax for estat hettest

```
estat hettest [varlist] [, rhs [normal|iid|fstat] mtest[(spec)]]
```

`collect` is allowed with `estat hettest`; see [U] 11.1.10 Prefix commands.

### Options for estat hettest

- `rhs` specifies that tests for heteroskedasticity be performed for the right-hand-side (explanatory) variables of the fitted regression model. The `rhs` option may be combined with a `varlist`.

- `normal`, the default, causes `estat hettest` to compute the original Breusch–Pagan/Cook–Weisberg test, which assumes that the regression disturbances are normally distributed.

- `iid` causes `estat hettest` to compute the $N \times R^2$ version of the score test that drops the normality assumption.

- `fstat` causes `estat hettest` to compute the $F$-statistic version that drops the normality assumption.
mtest\( [\text{spec}] \) specifies that multiple testing be performed. The argument specifies how \( p \)-values are adjusted. The following specifications, \text{spec}, are supported:

- \text{bonferroni}: Bonferroni’s multiple testing adjustment
- \text{holm}: Holm’s multiple testing adjustment
- \text{sidak}: Šidák’s multiple testing adjustment
- \text{noadjust}: no adjustment is made for multiple testing

mtest may be specified without an argument. This is equivalent to specifying mtest(noadjust); that is, tests for the individual variables should be performed with unadjusted \( p \)-values. By default, estat hettest does not perform multiple testing. mtest may not be specified with \text{iid} or \text{fstat}.

**Description for estat imtest**

estat imtest performs an information matrix test for the regression model and an orthogonal decomposition into tests for heteroskedasticity, skewness, and kurtosis due to Cameron and Trivedi (1990); White’s test for homoskedasticity against unrestricted forms of heteroskedasticity (1980) is available as an option. White’s test is usually similar to the first term of the Cameron–Trivedi decomposition.

**Menu for estat**
Statistics > Postestimation

**Syntax for estat imtest**

```
estat imtest [ , preserve white ]
```

collect is allowed with estat imtest; see [U] 11.1.10 Prefix commands.

**Options for estat imtest**

- **preserve** specifies that the data in memory be preserved, all variables and cases that are not needed in the calculations be dropped, and at the conclusion the original data be restored. This option is costly for large datasets. However, because estat imtest has to perform an auxiliary regression on \( k(k+1)/2 \) temporary variables, where \( k \) is the number of regressors, it may not be able to perform the test otherwise.

- **white** specifies that White’s original heteroskedasticity test also be performed.

**Description for estat ovtest**

estat ovtest performs two versions of the Ramsey (1969) regression specification-error test (RESET) for omitted variables. This test amounts to fitting \( y = xb + zt + u \) and then testing \( t = 0 \). If the \text{rhs} option is not specified, powers of the fitted values are used for \( z \). If \text{rhs} is specified, powers of the individual elements of \( x \) are used.
Menu for estat
Statistics > Postestimation

Syntax for estat ovtest

```bash
estat ovtest [, rhs]
```

collect is allowed with estat ovtest; see [U] 11.1.10 Prefix commands.

Option for estat ovtest

`rhs` specifies that powers of the right-hand-side (explanatory) variables be used in the test rather than powers of the fitted values.

Description for estat szroeter

`estat szroeter` performs Szroeter’s rank test for heteroskedasticity for each of the variables in `varlist` or for the explanatory variables of the regression if `rhs` is specified.

Menu for estat
Statistics > Postestimation

Syntax for estat szroeter

```bash
estat szroeter [ varlist ] [, rhs mtest(spec) ]
```

Either `varlist` or `rhs` must be specified.

Options for estat szroeter

`rhs` specifies that tests for heteroskedasticity be performed for the right-hand-side (explanatory) variables of the fitted regression model. The `rhs` option may be combined with a `varlist`.

`mtest(spec)` specifies that multiple testing be performed. The argument specifies how $p$-values are adjusted. The following specifications, `spec`, are supported:

- `bonferroni` Bonferroni’s multiple testing adjustment
- `holm` Holm’s multiple testing adjustment
- `sidak` Šidák’s multiple testing adjustment
- `noadj` no adjustment is made for multiple testing

`estat szroeter` always performs multiple testing. By default, it does not adjust the $p$-values.
Remarks and examples for estat hettest, estat imtest, estat ovtest, and estat szroeter

We introduce some regression diagnostic commands that are designed to test for certain violations that rvfplot (see [R] regress postestimation diagnostic plots) less formally attempts to detect. estat ovtest provides Ramsey’s test for omitted variables—a pattern in the residuals. estat hettest provides a test for heteroskedasticity—the increasing or decreasing variation in the residuals with fitted values, with respect to the explanatory variables, or with respect to yet other variables. The score test implemented in estat hettest (Breusch and Pagan 1979; Cook and Weisberg 1983) performs a score test of the null hypothesis that $b = 0$ against the alternative hypothesis of multiplicative heteroskedasticity. estat szroeter provides a rank test for heteroskedasticity, which is an alternative to the score test computed by estat hettest. Finally, estat imtest computes an information matrix test, including an orthogonal decomposition into tests for heteroskedasticity, skewness, and kurtosis (Cameron and Trivedi 1990). The heteroskedasticity test computed by estat imtest is similar to the general test for heteroskedasticity that was proposed by White (1980). Cameron and Trivedi (2022, chap. 3) discuss most of these tests and provides more examples.

Example 10: estat ovtest, estat hettest, estat szroeter, and estat imtest

We use our model of price on weight and foreign##c.mpg.

```stata
. use https://www.stata-press.com/data/r18/auto, clear
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
. estat ovtest
Ramsey RESET test for omitted variables
Omitted: Powers of fitted values of price
H0: Model has no omitted variables
F(3, 66) = 7.77
Prob > F = 0.0002
. estat hettest
Breusch-Pagan/Cook-Weisberg test for heteroskedasticity
Assumption: Normal error terms
Variable: Fitted values of price
H0: Constant variance
     chi2(1) = 6.50
     Prob > chi2 = 0.0108
```

Testing for heteroskedasticity in the right-hand-side variables is requested by specifying the `rhs` option. By specifying the `mtest(bonferroni)` option, we request that tests be conducted for each of the variables, with a Bonferroni adjustment for the $p$-values to accommodate our testing multiple hypotheses.
. estat hettest, rhs mtest(bonf)

Breusch-Pagan/Cook-Weisberg test for heteroskedasticity
Assumption: Normal error terms
H0: Constant variance

We find evidence for omitted variables, heteroskedasticity, and nonnormal skewness.

So, why bother with the various graphical commands when the tests seem so much easier to interpret? In part, it is a matter of taste: both are designed to uncover the same problem, and both are, in fact, going about it in similar ways. One is based on a formal calculation, whereas the other is based on personal judgment in evaluating a graph. On the other hand, the tests are seeking evidence of specific problems, whereas judgment is more general. The careful analyst will use both.

We performed the omitted-variable test first. Omitted variables are a more serious problem than heteroskedasticity or the violations of higher moment conditions tested by estat imtest. If this
were not a manual, having found evidence of omitted variables, we would never have run the \texttt{estat hettest}, \texttt{estat szroeter}, and \texttt{estat imtest} commands, at least not until we solved the omitted-variable problem.

\section*{Technical note}

\texttt{estat ovtest} and \texttt{estat hettest} both perform two flavors of their respective tests. By default, \texttt{estat ovtest} looks for evidence of omitted variables by fitting the original model augmented by $\hat{y}^2$, $\hat{y}^3$, and $\hat{y}^4$, which are the fitted values from the original model. Under the assumption of no misspecification, the coefficients on the powers of the fitted values will be zero. With the \texttt{rhs} option, \texttt{estat ovtest} instead augments the original model with powers (second through fourth) of the explanatory variables (except for dummy variables).

\texttt{estat hettest}, by default, looks for heteroskedasticity by modeling the variance as a function of the fitted values. If, however, we specify a variable or variables, the variance will be modeled as a function of the specified variables. In our example, if we had, a priori, some reason to suspect heteroskedasticity and that the heteroskedasticity is a function of a car’s weight, then using a test that focuses on weight would be more powerful than the more general tests such as White’s test or the first term in the Cameron–Trivedi decomposition test.

\texttt{estat hettest}, by default, computes the original Breusch–Pagan/Cook–Weisberg test, which includes the assumption of normally distributed errors. Koenker (1981) derived an $N \times R^2$ version of this test that drops the normality assumption. Wooldridge (2020, 270) gives an $F$-statistic version that does not require the normality assumption.

\section*{Stored results for \texttt{estat hettest}, \texttt{estat imtest}, and \texttt{estat ovtest}}

\texttt{estat hettest} stores the following results for the (multivariate) score test in \texttt{r()}:\[\]

\textbf{Scalars}\[\]
- $r(\text{chi2})$: $\chi^2$ test statistic
- $r(\text{df})$: #df for the asymptotic $\chi^2$ distribution under $H_0$
- $r(p)$: $p$-value

\texttt{estat hettest}, \texttt{fstat} stores results for the (multivariate) score test in \texttt{r()}:\[\]

\textbf{Scalars}\[\]
- $r(F)$: test statistic
- $r(\text{df}_m)$: #df of the test for the $F$ distribution under $H_0$
- $r(\text{df}_r)$: #df of the residuals for the $F$ distribution under $H_0$
- $r(p)$: $p$-value

\texttt{estat hettest} (if \texttt{mtest} is specified) and \texttt{estat szroeter} store the following in \texttt{r()}:\[\]

\textbf{Matrices}\[\]
- $r(\text{mtest})$: a matrix of test results, with rows corresponding to the univariate tests
- $\text{mtest}[,,1]$: $\chi^2$ test statistic
- $\text{mtest}[,,2]$: #df
- $\text{mtest}[,,3]$: unadjusted $p$-value
- $\text{mtest}[,,4]$: adjusted $p$-value (if an \texttt{mtest()} adjustment method is specified)

\textbf{Macros}\[\]
- $r(\text{mtmethod})$: adjustment method for $p$-value
estat imtest stores the following in r():

Scalars
- \( r(chi2_t) \): IM-test statistic \( = r(chi2_h) + r(chi2_s) + r(chi2_k) \)
- \( r(df_t) \): df for limiting \( \chi^2 \) distribution under \( H_0 \) \( = r(df_h) + r(df_s) + r(df_k) \)
- \( r(chi2_h) \): heteroskedasticity test statistic
- \( r(chi2_s) \): skewness test statistic
- \( r(chi2_k) \): kurtosis test statistic
- \( r(chi2_w) \): White’s heteroskedasticity test (if white specified)
- \( r(df_h), r(df_s), r(df_k), r(df_w) \): df for limiting \( \chi^2 \) distribution under \( H_0 \)

estat ovtest stores the following in r():

Scalars
- \( r(p) \): two-sided \( p \)-value
- \( r(F) \): \( F \) statistic
- \( r(df) \): degrees of freedom
- \( r(df_r) \): residual degrees of freedom

Variance inflation factors

Description for estat vif

estat vif calculates the centered or uncentered variance inflation factors (VIFs) for the independent variables specified in a linear regression model.

Menu for estat

Statistics > Postestimation

Syntax for estat vif

estat vif [, uncentered]

Option for estat vif

uncentered requests the computation of the uncentered variance inflation factors. The uncentered VIFs are often used to detect the collinearity of the regressors with the constant. uncentered must be specified if the regression model did not include a constant term because centered VIFs are not appropriate for these models.

Remarks and examples for estat vif

Problems arise in regression when the predictors are highly correlated. In this situation, there may be a significant change in the regression coefficients if you add or delete an independent variable. The estimated standard errors of the fitted coefficients are inflated, or the estimated coefficients may not be statistically significant even though a statistical relation exists between the dependent and independent variables.
Data analysts rely on these facts to check informally for the presence of multicollinearity. `estat vif`, another command for use after `regress`, calculates the variance inflation factors and tolerances for each of the independent variables.

The output shows the variance inflation factors together with their reciprocals. Some analysts compare the reciprocals with a predetermined tolerance. In the comparison, if the reciprocal of the VIF is smaller than the tolerance, the associated predictor variable is removed from the regression model. However, most analysts rely on informal rules of thumb applied to the VIF; see Chatterjee and Hadi (2012). According to these rules, there is evidence of multicollinearity if

1. The largest VIF is greater than 10 (some choose a more conservative threshold value of 30).
2. The mean of all the VIFs is considerably larger than 1.

### Example 11: estat vif

We examine a regression model fit using the ubiquitous automobile dataset:

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress price mpg rep78 trunk headroom length turn displ gear_ratio
```

```
Source | SS df MS Number of obs = 69

The results are mixed. Although we have no VIFs greater than 10, the mean VIF is greater than 1, though not considerably so. We could continue the investigation of collinearity, but given that other authors advise that collinearity is a problem only when VIFs exist that are greater than 30 (contradicting our rule above), we will not do so here.
Example 12: estat vif, with strong evidence of multicollinearity

This example comes from a dataset described in Kutner, Nachtsheim, and Neter (2004, 257) that examines body fat as modeled by caliper measurements on the triceps, midarm, and thigh.

```
. use https://www.stata-press.com/data/r18/bodyfat
(Body fat)
. regress bodyfat tricep thigh midarm
```

```

Note how the coefficients change and how the estimated standard errors for each of the regression coefficients become much smaller. The calculated value of $R^2$ for the overall regression for the subset model does not appreciably decline when we remove the correlated predictor. Removing an independent variable from the model is one way to deal with multicollinearity. Other methods include ridge regression, weighted least squares, and restricting the use of the fitted model to data that follow the same pattern of multicollinearity. In economic studies, it is sometimes possible to estimate the regression coefficients from different subsets of the data by using cross-section and time series.

All examples above demonstrated the use of centered VIFs. As pointed out by Belsley (1991), the centered VIFs may fail to discover collinearity involving the constant term. One solution is to use the uncentered VIFs instead. According to the definition of the uncentered VIFs, the constant is viewed as a legitimate explanatory variable in a regression model, which allows one to obtain the VIF value for the constant term.

Example 13: estat vif, with strong evidence of collinearity with the constant term

Consider the extreme example in which one of the regressors is highly correlated with the constant. We simulate the data and examine both centered and uncentered VIF diagnostics after fitted regression model as follows.

```stata
. use https://www.stata-press.com/data/r18/extreme_collin
. regress y one x z
```

```

Mean VIF | 1.02
According to the values of the centered VIFs (1.03, 1.03, 1.00), no harmful collinearity is detected in the model. However, by the construction of these simulated data, we know that one is highly collinear with the constant term. As such, the large values of uncentered VIFs for one (402.94) and _cons (401.26) reveal high collinearity of the variable one with the constant term.

Measures of effect size

Description for estat esize

estat esize calculates effect sizes for linear models after regress or anova. By default, estat esize reports $\eta^2$ estimates (Kerlinger and Lee 2000), which are equivalent to $R^2$ estimates. If the option epsilon is specified, estat esize reports $\epsilon^2$ estimates (Grissom and Kim 2012). If the option omega is specified, estat esize reports $\omega^2$ estimates (Grissom and Kim 2012). Both $\epsilon^2$ and $\omega^2$ are adjusted $R^2$ estimates. Confidence intervals for $\eta^2$ estimates are estimated by using the noncentral $F$ distribution (Smithson 2001). See Kline (2013) or Thompson (2006) for further information.

Menu for estat

Statistics > Postestimation

Syntax for estat esize

estat esize [, epsilon omega level(#)]

collect is allowed with estat esize; see [U] 11.1.10 Prefix commands.

Options for estat esize

epsilon specifies that the $\epsilon^2$ estimates of effect size be reported. The default is $\eta^2$ estimates.

omega specifies that the $\omega^2$ estimates of effect size be reported. The default is $\eta^2$ estimates.

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.
Remarks and examples for estat esize

Whereas p-values are used to assess the statistical significance of a result, measures of effect size are used to assess the practical significance of a result. Effect sizes can be broadly categorized as “measures of group differences” (the \( d \) family) and “measures of association” (the \( r \) family); see Ellis (2010, table 1.1). The \( d \) family includes estimators such as Cohen’s \( D \), Hedges’s \( G \), and Glass’s \( \Delta \) (also see \([R] \) esize). The \( r \) family includes estimators such as the point-biserial correlation coefficient, \( \eta^2 \), \( \epsilon^2 \), and \( \omega^2 \). For an introduction to the concepts and calculation of effect sizes, see Kline (2013) or Thompson (2006). For a more detailed discussion, see Kirk (1996), Ellis (2010), Cumming (2012), Grissom and Kim (2012), and Kelley and Preacher (2012).

Example 14: Calculating effect sizes for a linear regression model

Suppose we fit a linear regression model for low-birthweight infants.

\[
\text{. use https://www.stata-press.com/data/r18/lbw (Hosmer & Lemeshow data)}
\]

\[
\text{. regress bwt smoke i.race}
\]

</tr>
<tr>
<td>race</td>
<td>.0908394</td>
<td>2</td>
<td>.0233037 .1700334</td>
</tr>
</tbody>
</table>

Note: Eta-squared values for individual model terms are partial.

The overall model effect size is 0.124. This means that roughly 12.4% of the variation in \( bwt \) is explained by the model. The partial effect size for \texttt{smoke} is 0.077. This means that roughly 7.7% of the variation in \( bwt \) is explained by \texttt{smoke} after you remove the variation explained by all other terms.
The omega option causes `estat esize` to report $\omega^2$ and partial $\omega^2$.

```
estat esize, omega
```

</tbody>
</table>

Note: Eta-squared values for individual model terms are partial.

Technical note

$\eta^2$ was developed in the context of analysis of variance. Thus, the published research on the calculation of confidence intervals focuses on cases where the numerator degrees of freedom are relatively small (for example, df < 20).

Some combinations of the $F$ statistic, numerator degrees of freedom, and denominator degrees of freedom yield confidence limits that do not contain the corresponding estimated value for an $\eta^2$. This problem is most commonly observed for larger numerator degrees of freedom.

Nothing in the literature suggests alternative methods for constructing confidence intervals in such cases; therefore, we recommend cautious interpretation of confidence intervals for $\eta^2$ when the numerator degrees of freedom are greater than 20.

Methods and formulas

See Hamilton (2013, chap. 7), Kohler and Kreuter (2012, sec. 9.3), or Baum (2006, chap. 5) for an overview of using Stata to perform regression diagnostics. See Peracchi (2001, chap. 8) for a mathematically rigorous discussion of diagnostics.

Methods and formulas are presented under the following headings:

predict

Special-interest postestimation commands

predict

Assume that you have already fit the regression model

$$y = Xb + e$$

where $X$ is $n \times k$.

Denote the previously estimated coefficient vector by $b$ and its estimated variance matrix by $V$. predict works by recalling various aspects of the model, such as $b$, and combining that information with the data currently in memory. Let $x_j$ be the $j$th observation currently in memory, and let $s^2$ be the mean squared error of the regression.

If the user specified weights in regress, then $X'X$ in the following formulas is replaced by $X'DX$, where $D$ is defined in Weighted regression under Methods and formulas in [R] regress.

Let $V = s^2(X'X)^{-1}$. Let $k$ be the number of independent variables including the intercept, if any, and let $y_j$ be the observed value of the dependent variable.

The predicted value (xb option) is defined as $\hat{y}_j = x_j b$.

Let $\ell_j$ represent a lower bound for an observation $j$ and $u_j$ represent an upper bound. The probability that $y_j|x_j$ would be observed in the interval $(\ell_j, u_j)$—the pr($\ell$, $u$) option—is

$$P(\ell_j, u_j) = Pr(\ell_j < x_j b + e_j < u_j) = \Phi \left( \frac{u_j - \hat{y}_j}{s} \right) - \Phi \left( \frac{\ell_j - \hat{y}_j}{s} \right)$$

where for the pr($\ell$, $u$), e($\ell$, $u$), and ystar($\ell$, $u$) options, $\ell_j$ and $u_j$ can be anywhere in the range $(-\infty, +\infty)$.
The option \( e(\ell, u) \) computes the expected value of \( y_j|\mathbf{x}_j \) conditional on \( y_j|\mathbf{x}_j \) being in the interval \((\ell_j, u_j)\), that is, when \( y_j|\mathbf{x}_j \) is truncated. It can be expressed as

\[
E(\ell_j, u_j) = E(\mathbf{x}_j \mathbf{b} + e_j \mid \ell_j < \mathbf{x}_j \mathbf{b} + e_j < u_j) = \hat{y}_j - s \frac{\phi \left( \frac{u_j - \hat{y}_j}{s} \right) - \phi \left( \frac{\ell_j - \hat{y}_j}{s} \right)}{\Phi \left( \frac{u_j - \hat{y}_j}{s} \right) - \Phi \left( \frac{\ell_j - \hat{y}_j}{s} \right)}
\]

where \( \phi \) is the normal density and \( \Phi \) is the cumulative normal.

You can also compute \( ystar(\ell, u) \)—the expected value of \( y_j|\mathbf{x}_j \), where \( y_j \) is assumed censored at \( \ell_j \) and \( u_j \):

\[
y^*_j = \begin{cases} 
\ell_j & \text{if } \mathbf{x}_j \mathbf{b} + e_j \leq \ell_j \\
\mathbf{x}_j \mathbf{b} + e_j & \text{if } \ell_j < \mathbf{x}_j \mathbf{b} + e_j < u_j \\
u_j & \text{if } \mathbf{x}_j \mathbf{b} + e_j \geq u_j 
\end{cases}
\]

This computation can be expressed in several ways, but the most intuitive formulation involves a combination of the two statistics just defined:

\[
y^*_j = P(-\infty, \ell_j) \ell_j + P(\ell_j, u_j) E(\ell_j, u_j) + P(u_j, +\infty) u_j
\]

A diagonal element of the projection matrix (\texttt{hat}) or (\texttt{leverage}) is given by

\[
h_j = \mathbf{x}_j (\mathbf{X}' \mathbf{X})^{-1} \mathbf{x}'_j
\]

The \textit{standard error of the prediction} (the \texttt{stdp} option) is defined as \( s_{p_j} = \sqrt{\mathbf{x}_j \mathbf{V} \mathbf{x}'_j} \)
and can also be written as \( s_{p_j} = s \sqrt{h_j} \).

The \textit{standard error of the forecast} (\texttt{stdf}) is defined as \( s_{f_j} = s \sqrt{1 + h_j} \).

The \textit{standard error of the residual} (\texttt{stadr}) is defined as \( s_{r_j} = s \sqrt{1 - h_j} \).

The \textit{residuals} (\texttt{residuals}) are defined as \( \hat{e}_j = y_j - \hat{y}_j \).

The \textit{standardized residuals} (\texttt{rstandard}) are defined as \( \hat{e}_{s_j} = \hat{e}_j / s_{r_j} \).

The \textit{Studentized residuals} (\texttt{rstudent}) are defined as

\[
r_j = \frac{\hat{e}_j}{s_{(j)} \sqrt{1 - h_j}}
\]

where \( s_{(j)} \) represents the root mean squared error with the \( j \)th observation removed, which is given by

\[
s^2_{(j)} = \frac{s^2(n - k)}{n - k - 1} - \frac{\hat{e}_j^2}{(n - k - 1)(1 - h_j)}
\]

where \( n \) is the number of observations and \( k \) is the number of right-hand-side variables (including the constant).

Cook’s \( D \) (\texttt{cooksD}) is given by

\[
D_j = \frac{\hat{e}_{s_j}^2 (s_{p_j} / s_{r_j})^2}{k} = \frac{h_j \hat{e}_j^2}{ks^2(1 - h_j)^2}
\]
DFITS (dfits) is given by
\[ \text{DFITS}_j = r_j \sqrt{\frac{h_j}{1 - h_j}} \]

Welsch distance (welsch) is given by
\[ W_j = \frac{r_j \sqrt{h_j(n - 1)}}{1 - h_j} \]

COVRATIO (covratio) is given by
\[ \text{COVRATIO}_j = \frac{1}{1 - h_j} \left( \frac{n - k - \hat{e}_{s,j}^2}{n - k - 1} \right)^k \]

The DFBETAs (dfbeta) for a particular regressor \( x_i \) are given by
\[ \text{DFBETA}_j = \frac{r_j u_j}{\sqrt{U^2(1 - h_j)}} \]

where \( u_j \) are the residuals obtained from a regression of \( x_i \) on the remaining \( x \)'s and \( U^2 = \sum_j u_j^2 \).

**Special-interest postestimation commands**

The omitted-variable test (Ramsey 1969) reported by `estat ovtest` fits the regression \( y_i = x_i b + z_i t + u_i \) and then performs a standard \( F \) test of \( t = 0 \). The default test uses \( z_i = (\hat{y}_1^2, \hat{y}_1^3, \hat{y}_1^4) \). If `rhs` is specified, \( z_i = (x_1^2, x_1^3, x_1^4, x_2^2, \ldots, x_m^4) \). In either case, the variables are normalized to have minimum 0 and maximum 1 before powers are calculated.

The test for heteroskedasticity (Breusch and Pagan 1979; Cook and Weisberg 1983) models \( \text{Var}(e_i) = \sigma^2 \exp(zt) \), where \( z \) is a variable list specified by the user, the list of right-hand-side variables, or the fitted values \( x \hat{\beta} \). The test is of \( t = 0 \). Mechanically, `estat hettest` fits the augmented regression \( \hat{e}_i^2 / \hat{\sigma}^2 = a + z_i t + v_i \).

The original Breusch–Pagan/Cook–Weisberg version of the test assumes that the \( e_i \) are normally distributed under the null hypothesis which implies that the score test statistic \( S \) is equal to the model sum of squares from the augmented regression divided by 2. Under the null hypothesis, \( S \) has the \( \chi^2 \) distribution with \( m \) degrees of freedom, where \( m \) is the number of columns of \( z \).

Koenker (1981) derived a score test of the null hypothesis that \( t = 0 \) under the assumption that the \( e_i \) are independent and identically distributed (i.i.d.). Koenker showed that \( S = N \ast R^2 \) has a large-sample \( \chi^2 \) distribution with \( m \) degrees of freedom, where \( N \) is the number of observations and \( R^2 \) is from the augmented regression and \( m \) is the number of columns of \( z \). `estat hettest, iid` produces this version of the test.

Wooldridge (2020, 270) showed that an \( F \) test of \( t = 0 \) in the augmented regression can also be used under the assumption that the \( e_i \) are i.i.d. `estat hettest, fstat` produces this version of the test.

Szroeter’s class of tests for homoskedasticity against the alternative that the residual variance increases in some variable \( x \) is defined in terms of
\[ H = \frac{\sum_{i=1}^n h(x_i)e_i^2}{\sum_{i=1}^n e_i^2} \]
where $h(x)$ is some weight function that increases in $x$ (Szroeter 1978). $H$ is a weighted average of the $h(x)$, with the squared residuals serving as weights. Under homoskedasticity, $H$ should be approximately equal to the unweighted average of $h(x)$. Large values of $H$ suggest that $e^2$ tends to be large where $h(x)$ is large; that is, the variance indeed increases in $x$, whereas small values of $H$ suggest that the variance actually decreases in $x$. estat szroeter uses $h(x_i) = \text{rank}(x_i$ in $x_1 \ldots x_n)$; see Judge et al. [1985, 452] for details.

The methods and formulas for estat szroeter are described in [R] test.

estat imtest performs the information matrix test for the regression model, as well as an orthogonal decomposition into tests for heteroskedasticity $\delta_1$, nonnormal skewness $\delta_2$, and nonnormal kurtosis $\delta_3$ (Cameron and Trivedi 1990; Long and Trivedi 1993). The decomposition is obtained via three auxiliary regressions. Let $e$ be the regression residuals, $\hat{\sigma}^2$ be the maximum likelihood estimate of $\sigma^2$ in the regression, $n$ be the number of observations, $X$ be the set of $k$ variables specified with estat imtest, and $R^2_{un}$ be the uncentered $R^2$ from a regression. $\delta_1$ is obtained as $nR^2_{un}$ from a regression of $e^2 - \hat{\sigma}^2$ on the cross products of the variables in $X$. $\delta_2$ is computed as $nR^2_{un}$ from a regression of $e^3 - 3\hat{\sigma}^2e$ on $X$. Finally, $\delta_3$ is obtained as $nR^2_{un}$ from a regression of $e^4 - 6\hat{\sigma}^2e^2 - 3\hat{\sigma}^4$ on $X$. $\delta_1$, $\delta_2$, and $\delta_3$ are asymptotically $\chi^2$ distributed with $1/2k(k+1)$, $K$, and 1 degree of freedom. The information test statistic $\delta = \delta_1 + \delta_2 + \delta_3$ is asymptotically $\chi^2$ distributed with $1/2k(k+3)$ degrees of freedom. White’s test for heteroskedasticity is computed as $nR^2$ from a regression of $\hat{u}^2$ on $X$ and the cross products of the variables in $X$. This test statistic is usually close to $\delta_1$.

estat vif calculates the centered variance inflation factor (VIF$_c$) (Chatterjee and Hadi 2012, 248–251) for $x_j$, given by

$$\text{VIF}_c(x_j) = \frac{1}{1 - \hat{R}^2_j}$$

where $\hat{R}^2_j$ is the square of the centered multiple correlation coefficient that results when $x_j$ is regressed against all other explanatory variables, including the constant.

The uncentered variance inflation factor (VIF$_{uc}$) (Belsley 1991, 28–29) for $x_j$ is given by

$$\text{VIF}_{uc}(x_j) = \frac{1}{1 - \tilde{R}^2_j}$$

where $\tilde{R}^2_j$ is the square of the uncentered multiple correlation coefficient that results when $x_j$ is regressed against all other explanatory variables and a constant of 1. If the original regression model was fit without a constant, the constant would also be omitted from the regression of $x_j$.

The methods and formulas for estat esize are described in Methods and formulas of [R] esize.

Acknowledgments

estat ovtest and estat hettst are based on programs originally written by Richard Goldstein. estat imtest, estat szroeter, and the current version of estat hettst were written by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands. estat imtest is based in part on code written by J. Scott Long of the Department of Sociology at Indiana University, coauthor of the Stata Press book Regression Models for Categorical and Limited Dependent Variables, and author of the Stata Press book The Workflow of Data Analysis Using Stata.

**Description**

The following postestimation commands are of special interest after `regress`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rvfplot</code></td>
<td>residual-versus-fitted plot</td>
</tr>
<tr>
<td><code>avplot</code></td>
<td>added-variable plot</td>
</tr>
<tr>
<td><code>avplots</code></td>
<td>all added-variables plots in one image</td>
</tr>
<tr>
<td><code>cprplot</code></td>
<td>component-plus-residual plot</td>
</tr>
<tr>
<td><code>acprplot</code></td>
<td>augmented component-plus-residual plot</td>
</tr>
<tr>
<td><code>rvpplot</code></td>
<td>residual-versus-predictor plot</td>
</tr>
<tr>
<td><code>lvr2plot</code></td>
<td>leverage-versus-squared-residual plot</td>
</tr>
</tbody>
</table>

These commands are not appropriate with `svy` estimation results.

For a discussion of the terminology used in this entry, see the Terminology section of Remarks and examples for `predict` in [R] `regress postestimation`.

**rvfplot**

**Description for rvfplot**

`rvfplot` graphs a residual-versus-fitted plot, a graph of the residuals against the fitted values.

**Menu for rvfplot**

Statistics > Linear models and related > Regression diagnostics > Residual-versus-fitted plot

**Syntax for rvfplot**

```
rvfplot [, rvfplot_options]
```

<table>
<thead>
<tr>
<th>rvfplot_options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>marker_options</code></td>
<td>change look of markers (color, size, etc.)</td>
</tr>
<tr>
<td><code>marker_label_options</code></td>
<td>add marker labels; change look or position</td>
</tr>
</tbody>
</table>

Add plots

```
addplot(plot)
```

Y axis, X axis, Titles, Legend, Overall

```
twoway_options
```

any options other than by() documented in [G-3] `twoway_options`
### Options for rvfplot

*marker_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker_options*.

*marker_label_options* specify if and how the markers are to be labeled; see [G-3] *marker_label_options*.

*Add plots*

*addplot(plot)* provides a way to add plots to the generated graph. See [G-3] *addplot_option*.

*Y axis, X axis, Titles, Legend, Overall*

*twoway_options* are any of the options documented in [G-3] *twoway_options*, excluding by(). These include options for titling the graph (see [G-3] *title_options*) and for saving the graph to disk (see [G-3] *saving_option*).

### Remarks and examples for rvfplot

rvfplot graphs the residuals against the fitted values.

#### Example 1

Using auto.dta described in [U] 1.2.2 Example datasets, we will use *regress* to fit a model of price on weight, mpg, foreign, and the interaction of foreign with mpg. We specify foreign##c.mpg to obtain the interaction of foreign with mpg; see [U] 11.4.3 Factor variables.

```stata
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress price weight foreign##c.mpg
```

<table>

Once we have fit a model, we may use any of the regression diagnostics commands. `rvfplot` (read residual-versus-fitted plot) graphs the residuals against the fitted values:

```
.rvfplot, yline(0)
```

![Residuals vs. Fitted Values](image)

All the diagnostic plot commands allow the `graph twoway` and `graph twoway scatter` options; we specified a `yline(0)` to draw a line across the graph at $y = 0$; see `[G-2] graph twoway scatter`.

In a well-fitted model, there should be no pattern to the residuals plotted against the fitted values—something not true of our model. Ignoring the two outliers at the top center of the graph, we see curvature in the pattern of the residuals, suggesting a violation of the assumption that `price` is linear in our independent variables. We might also have seen increasing or decreasing variation in the residuals—heteroskedasticity. Any pattern whatsoever indicates a violation of the least-squares assumptions.
**avplot**

**Description for avplot**

`avplot` graphs an added-variable plot (a.k.a. partial-regression leverage plot, partial regression plot, or adjusted partial residual plot) after `regress`. `indepvar` may be an independent variable (a.k.a. predictor, carrier, or covariate) that is currently in the model or not.

**Menu for avplot**

Statistics > Linear models and related > Regression diagnostics > Added-variable plot

**Syntax for avplot**

```
avplot  indepvar [ ,  avplot_options ]
```

- `avplot_options` Description
  - **Plot**
    - `marker_options` change look of markers (color, size, etc.)
    - `marker_label_options` add marker labels; change look or position
  - **Reference line**
    - `rlopts(cline_options)` affect rendition of the reference line
  - **Add plots**
    - `addplot(plot)` add other plots to the generated graph
  - **Y axis, X axis, Titles, Legend, Overall**
    - `twoway_options` any options other than by() documented in [G-3] `twoway_options`

**Options for avplot**

- **Plot**
  - `marker_options` affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] `marker_options`.
  - `marker_label_options` specify if and how the markers are to be labeled; see [G-3] `marker_label_options`.
- **Reference line**
  - `rlopts(cline_options)` affects the rendition of the reference line. See [G-3] `cline_options`.
- **Add plots**
  - `addplot(plot)` provides a way to add plots to the generated graph. See [G-3] `addplot_option`.
- **Y axis, X axis, Titles, Legend, Overall**
  - `twoway_options` are any of the options documented in [G-3] `twoway_options`, excluding by(). These include options for titling the graph (see [G-3] `title_options`) and for saving the graph to disk (see [G-3] `saving_option`).
Remarks and examples for avplot

avplot graphs an added-variable plot, also known as the partial-regression leverage plot.

One of the wonderful features of one-regressor regressions (regressions of \( y \) on one \( x \)) is that we can graph the data and the regression line. There is no easier way to understand the regression than to examine such a graph. Unfortunately, we cannot do this when we have more than one regressor. With two regressors, it is still theoretically possible—the graph must be drawn in three dimensions, but with three or more regressors no graph is possible.

The added-variable plot is an attempt to project multidimensional data back to the two-dimensional world for each of the original regressors. This is, of course, impossible without making some concessions. Call the coordinates on an added-variable plot \( y \) and \( x \). The added-variable plot has the following properties:

- There is a one-to-one correspondence between \((x_i, y_i)\) and the \(i\)th observation used in the original regression.
- A regression of \( y \) on \( x \) has the same coefficient and standard error (up to a degree-of-freedom adjustment) as the estimated coefficient and standard error for the regressor in the original regression.
- The “outlierness” of each observation in determining the slope is in some sense preserved.

It is equally important to note the properties that are not listed. The \( y \) and \( x \) coordinates of the added-variable plot cannot be used to identify functional form, or, at least, not well (see Mallows [1986]). In the construction of the added-variable plot, the relationship between \( y \) and \( x \) is forced to be linear.

Example 2

Let’s use the same model as we used in example 1.

```stata
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
```

We can now examine the added-variable plot for mpg.

```stata
. avplot mpg
```

```
coef = 263.18749, se = 110.79612, t = 2.38
```

![Added-variable plot](image)

---

\[
\begin{align*}
\text{e( price | X )} & \text{ -50510} \\
\text{e( mpg | X )} & \text{ 2000} \\
\text{coef} & \text{ 263.18749, se} \text{ 110.79612, t} \text{ 2.38}
\end{align*}
\]
This graph suggests a problem in determining the coefficient on mpg. Were this a one-regressor regression, the two points at the top-left corner and the one at the top right would cause us concern, and so it does in our more complicated multiple-regressor case. To identify the problem points, we retyped our command, modifying it to read `avplot mpg, mlabel(make)`, and discovered that the two cars at the top left are the Cadillac Eldorado and the Lincoln Versailles; the point at the top right is the Cadillac Seville. These three cars account for 100% of the luxury cars in our data, suggesting that our model is misspecified. By the way, the point at the lower right of the graph, also cause for concern, is the Plymouth Arrow, our data entry error.

Technical note

Stata’s `avplot` command can be used with regressors already in the model, as we just did, or with potential regressors not yet in the model. In either case, `avplot` will produce the correct graph. The name “added-variable plot” is unfortunate in the case when the variable is already among the list of regressors but is, we think, still preferable to the name “partial-regression leverage plot” assigned by Belsley, Kuh, and Welsch (1980, 30) and more in the spirit of the original use of such plots by Mosteller and Tukey (1977, 271–279). Welsch (1986, 403), however, disagrees: “I am sorry to see that Chatterjee and Hadi [1986] endorse the term ‘added-variable plot’ when $X_j$ is part of the original model” and goes on to suggest the name “adjusted partial residual plot”.

avplots

Description for avplots

`avplots` graphs all the added-variable plots in one image.

Menu for avplots

Statistics > Linear models and related > Regression diagnostics > Added-variable plot

Options for avplots

*marker_options* affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] *marker_options*. *marker_label_options* specify if and how the markers are to be labeled; see [G-3] *marker_label_options*. *combine_options* are any of the options documented in [G-2] *graph combine*. These include options for titling the graph (see [G-3] *title_options*) and for saving the graph to disk (see [G-3] *saving_option*).

*Reference line*

*rlopts(cline_options)* affects the rendition of the reference line. See [G-3] *cline_options*.

*Y axis, X axis, Titles, Legend, Overall*

*twoway_options* are any of the options documented in [G-3] *twoway_options*, excluding by(). These include options for titling the graph (see [G-3] *title_options*) and for saving the graph to disk (see [G-3] *saving_option*).

Remarks and examples for avplots

Example 3

In example 2, we used *avplot* to examine the added-variable plot for *mpg* in our regression of *price* on *weight* and *foreign##c.mpg*. Now, let’s use *avplots* to graph an added-variable plot for every regressor in the data.

```
. avplots
```

![Graphs showing added-variable plots for different regressors.](image)

```plaintext
coef = 4.6135886, se = .7254961, t = 6.36

coef = 11240.331, se = 2751.6808, t = 4.08

coef = 263.18749, se = 110.79612, t = 2.38

coef = -307.21656, se = 108.53072, t = -2.83
```
cprplot

Description for cprplot

cprplot graphs a component-plus-residual plot (a.k.a. partial residual plot) after `regress`. `indepvar` must be an independent variable that is currently in the model.

Menu for cprplot

Statistics > Linear models and related > Regression diagnostics > Component-plus-residual plot

</tbody>
</table>

Options for cprplot

**Plot**

`marker_options` affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] `marker_options`.

`marker_label_options` specify if and how the markers are to be labeled; see [G-3] `marker_label_options`.

**Reference line**

`rlopts(cline_options)` affects the rendition of the reference line. See [G-3] `cline_options`. 
Options

lowess adds a lowess smooth of the plotted points to assist in detecting nonlinearities.

lsopts(lowess_options) affects the rendition of the lowess smooth. For an explanation of these options, especially the bwidth() option, see [R] lowess. Specifying lsopts() implies the lowess option.

mspline adds a median spline of the plotted points to assist in detecting nonlinearities.

msopts(mspline_options) affects the rendition of the spline. For an explanation of these options, especially the bands() option, see [G-2] graph twoway mspline. Specifying msopts() implies the mspline option.

Add plots

addplot(plot) provides a way to add other plots to the generated graph. See [G-3] addplot_option.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

Remarks and examples for cprplot

Added-variable plots are successful at identifying outliers, but they cannot be used to identify functional form. The component-plus-residual plot (Ezekiel 1924; Larsen and McCleary 1972) is another attempt at projecting multidimensional data into a two-dimensional form, but with different properties. Although the added-variable plot can identify outliers, the component-plus-residual plot cannot. It can, however, be used to examine the functional form assumptions of the model. Both plots have the property that a regression line through the coordinates has a slope equal to the estimated coefficient in the regression model.

Example 4

We illustrate component-plus-residual plots using a variation of auto.dta.

```stata
use https://www.stata-press.com/data/r18/auto1 (Automobile models)
regress price mpg weight
```

| _cons       | 2197.9      | 3190.768  | 0.69 | 0.493| -4164.311 8560.11  |
In fact, we know that the effects of mpg in this model are nonlinear—if we added mpg squared to the model, its coefficient would have a \( t \) statistic of 2.38, the \( t \) statistic on mpg would become \(-2.48\), and weight’s effect would become about one-third of its current value and become statistically insignificant. Pretend that we do not know this.

The component-plus-residual plot for mpg is

\[
\text{cprplot mpg, mspline msopts(bands(13))}
\]

We are supposed to examine the above graph for nonlinearities or, equivalently, ask if the regression line, which has slope equal to the estimated effect of mpg in the original model, fits the data adequately. To assist our eyes, we added a median spline. Perhaps some people may detect nonlinearity from this graph, but we assert that if we had not previously revealed the nonlinearity of mpg and if we had not added the median spline, the graph would not overly bother us.
acprplot

Description for acprplot

acprplot graphs an augmented component-plus-residual plot (a.k.a. augmented partial residual plot) as described by Mallows (1986). This seems to work better than the component-plus-residual plot for identifying nonlinearities in the data.

Menu for acprplot

Statistics > Linear models and related > Regression diagnostics > Augmented component-plus-residual plot

Syntax for acprplot

```
acprplot indepvar [, acprplot_options]
```

</tbody>
</table>

Options for acprplot

- **Plot**: `marker_options` affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] `marker_options`.
- `marker_label_options` specify if and how the markers are to be labeled; see [G-3] `marker_label_options`.
- **Reference line**: `rlopts(cline_options)` affects the rendition of the reference line. See [G-3] `cline_options`.
- **Options**: `lowess` adds a lowess smooth of the plotted points to assist in detecting nonlinearities.
lsopts(lowess_options) affects the rendition of the lowess smooth. For an explanation of these options, especially the bwidth() option, see [R] lowess. Specifying lsopts() implies the lowess option.

mspline adds a median spline of the plotted points to assist in detecting nonlinearities.

msopts(mspline_options) affects the rendition of the spline. For an explanation of these options, especially the bands() option, see [G-2] graph twoway mspline. Specifying msopts() implies the mspline option.

Add plots

addplot(plot) provides a way to add other plots to the generated graph. See [G-3] addplot_option.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

Remarks and examples for acprplot

In the cprplot section above, we discussed the component-plus-residual plot. Mallows (1986) proposed an augmented component-plus-residual plot that is often more sensitive to detecting nonlinearity.

Example 5

Let’s compare the augmented component-plus-residual plot with the component-plus-residual plot of example 4.

. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. regress price weight foreign##c.mpg
   (output omitted)
. acprplot mpg, mspline msopts(bands(13))

It does do somewhat better.
rvpplot

Description for rvpplot

rvpplot graphs a residual-versus-predictor plot (a.k.a. independent variable plot or carrier plot), a graph of the residuals against the specified predictor.

Menu for rvpplot

Statistics > Linear models and related > Regression diagnostics > Residual-versus-predictor plot

Syntax for rvpplot

rvpplot indepvar [, rvpplot_options]

rvpplot_options Description

Plot
marker_options change look of markers (color, size, etc.)
marker_label_options add marker labels; change look or position

Add plots
addplot(plot) add plots to the generated graph

Y axis, X axis, Titles, Legend, Overall
twoway_options any options other than by() documented in [G-3] twoway_options

Options for rvpplot

Plot
marker_options affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.

marker_label_options specify if and how the markers are to be labeled; see [G-3] marker_label_options.

Add plots
addplot(plot) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

Y axis, X axis, Titles, Legend, Overall
twoway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).
Remarks and examples for rvpplot

The residual-versus-predictor plot is a simple way to look for violations of the regression assumptions. If the assumptions are correct, there should be no pattern on the graph.

➤ Example 6

Let’s use our model of price on mpg and weight.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
. rvpplot mpg, yline(0)
```

![Residual-versus-predictor plot](image)

Remember, any pattern counts as a problem, and in this graph, we see that the variation in the residuals decreases as mpg increases.
lvr2plot

Description for lvr2plot

lvr2plot graphs a leverage-versus-squared-residual plot (a.k.a. L-R plot).

Menu for lvr2plot

Statistics  >  Linear models and related  >  Regression diagnostics  >  Leverage-versus-squared-residual plot

Syntax for lvr2plot

lvr2plot [ , lvr2plot_options ]

lvr2plot_options          Description

Plot
   marker_options          change look of markers (color, size, etc.)
   marker_label_options    add marker labels; change look or position

Add plots
   addplot( plot )          add other plots to the generated graph

Y axis, X axis, Titles, Legend, Overall
   twoway_options           any options other than by() documented in [G-3] twoway_options

Options for lvr2plot

--- Plot ---

   marker_options affects the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.

   marker_label_options specify if and how the markers are to be labeled; see [G-3] marker_label_options.

--- Add plots ---

   addplot( plot ) provides a way to add other plots to the generated graph. See [G-3] addplot_option.

--- Y axis, X axis, Titles, Legend, Overall ---

   twoway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).
Remarks and examples for lvr2plot

One of the most useful diagnostic graphs is provided by lvr2plot (leverage-versus-residual-squared plot), a graph of leverage against the (normalized) residuals squared.

Example 7

We illustrate lvr2plot using our model in example 1.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. regress price weight foreign##c.mpg
(output omitted)
. lvr2plot
```

The lines on the chart show the average values of leverage and the (normalized) residuals squared. Points above the horizontal line have higher-than-average leverage; points to the right of the vertical line have larger-than-average residuals.

One point immediately catches our eye, and four more make us pause. The point at the top of the graph has high leverage and a smaller-than-average residual. The other points that bother us all have higher-than-average leverage, two with smaller-than-average residuals and two with larger-than-average residuals.

A less pretty but more useful version of the above graph specifies that make be used as the symbol (see [G-3] marker_label_options):
The VW Diesel, Plymouth Champ, Plymouth Arrow, and Peugeot 604 are the points that cause us the most concern. When we further examine our data, we discover that the VW Diesel is the only diesel in our data and that the data for the Plymouth Arrow were entered incorrectly into the computer. No such simple explanations were found for the Plymouth Champ and Peugeot 604.

Methods and formulas

See Hamilton (2013, 209–214) and Kohler and Kreuter (2012, sec. 9.3) for a discussion of these diagnostic graphs.

The lvr2plot command plots leverage against the squares of the normalized residuals. The normalized residuals are defined as $\hat{e}_{nj} = \hat{e}_j / (\sum_i \hat{e}_i^2)^{1/2}$.

Postestimation commands

The following postestimation commands for time series are available for `regress`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat archlm</code></td>
<td>test for ARCH effects in the residuals</td>
</tr>
<tr>
<td><code>estat bgodfrey</code></td>
<td>Breusch–Godfrey test for higher-order serial correlation</td>
</tr>
<tr>
<td><code>estat durbinalt</code></td>
<td>Durbin’s alternative test for serial correlation</td>
</tr>
<tr>
<td><code>estat dwatson</code></td>
<td>Durbin–Watson $d$ statistic to test for first-order serial correlation</td>
</tr>
<tr>
<td><code>estat sbcusum</code></td>
<td>perform cumulative sum test for parameter stability</td>
</tr>
<tr>
<td><code>estat sbknown</code></td>
<td>perform tests for a structural break with a known break date</td>
</tr>
<tr>
<td><code>estat sbsingle</code></td>
<td>perform tests for a structural break with an unknown break date</td>
</tr>
</tbody>
</table>

These commands provide regression diagnostic tools specific to time series. You must `tsset` your data before using these commands; see `[TS] tsset`.

`estat archlm`

Description for `estat archlm`

`estat archlm` performs Engle’s Lagrange multiplier (LM) test for the presence of autoregressive conditional heteroskedasticity.

Menu for estat

Statistics > Postestimation

Syntax for `estat archlm`

```
estat archlm [, archlm_options]
```

<table>
<thead>
<tr>
<th>archlm_options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>lags(numlist)</code></td>
<td>test <code>numlist</code> lag orders</td>
</tr>
<tr>
<td><code>force</code></td>
<td>allow test after <code>regress, vce(robust)</code></td>
</tr>
</tbody>
</table>

`collect` is allowed; see `[U] 11.1.10 Prefix commands`.

2483
Options for estat archlm

lags(numlist) specifies a list of numbers, indicating the lag orders to be tested. The test will be performed separately for each order. The default is order one.

force allows the test to be run after regress, vce(robust). The command will not work if the vce(cluster clustvar) option is specified with regress; see [R] regress.

estat bgodfrey

Description for estat bgodfrey

estat bgodfrey performs the Breusch–Godfrey test for higher-order serial correlation in the disturbance. This test does not require that all the regressors be strictly exogenous.

Menu for estat

Statistics > Postestimation

Syntax for estat bgodfrey

estat bgodfrey [ , bgodfrey_options ]

bgodfrey_options Description

lags(numlist) test numlist lag orders
nomiss0 do not use Davidson and MacKinnon’s approach
small obtain p-values using the F or t distribution

collect is allowed; see [U] 11.1.10 Prefix commands.

Options for estat bgodfrey

lags(numlist) specifies a list of numbers, indicating the lag orders to be tested. The test will be performed separately for each order. The default is order one.

nomiss0 specifies that Davidson and MacKinnon’s approach (1993, 358), which replaces the missing values in the initial observations on the lagged residuals in the auxiliary regression with zeros, not be used.

small specifies that the p-values of the test statistics be obtained using the F or t distribution instead of the default χ² or normal distribution.
estat durbinalt

Description for estat durbinalt

  estat durbinalt performs Durbin’s alternative test for serial correlation in the disturbance. This test does not require that all the regressors be strictly exogenous.

Menu for estat

  Statistics > Postestimation

Syntax for estat durbinalt

  estat durbinalt [ , durbinalt_options ]

<table>
<thead>
<tr>
<th>durbinalt_options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lags(numlist)</td>
<td>test numlist lag orders</td>
</tr>
<tr>
<td>nomiss0</td>
<td>do not use Davidson and MacKinnon’s approach</td>
</tr>
<tr>
<td>robust</td>
<td>compute standard errors using the robust/sandwich estimator</td>
</tr>
<tr>
<td>small</td>
<td>obtain p-values using the F or t distribution</td>
</tr>
<tr>
<td>force</td>
<td>allow test after regress, vce(robust) or after newey</td>
</tr>
</tbody>
</table>

collect is allowed; see [U] 11.1.10 Prefix commands.

Options for estat durbinalt

  lags(numlist) specifies a list of numbers, indicating the lag orders to be tested. The test will be performed separately for each order. The default is order one.

  nomiss0 specifies that Davidson and MacKinnon’s approach (1993, 358), which replaces the missing values in the initial observations on the lagged residuals in the auxiliary regression with zeros, not be used.

  robust specifies that the Huber/White/sandwich robust estimator for the variance–covariance matrix be used in Durbin’s alternative test.

  small specifies that the p-values of the test statistics be obtained using the F or t distribution instead of the default $\chi^2$ or normal distribution. This option may not be specified with robust, which always uses an $F$ or a $t$ distribution.

  force allows the test to be run after regress, vce(robust) and after newey (see [R] regress and [TS] newey). The command will not work if the vce(cluster clustvar) option is specified with regress.
estat dwatson

Description for estat dwatson

estat dwatson computes the Durbin–Watson $d$ statistic (Durbin and Watson 1950) to test for first-order serial correlation in the disturbance when all the regressors are strictly exogenous.

Menu for estat

Statistics > Postestimation

Syntax for estat dwatson

```
estat dwatson
```

collect is allowed; see [U] 11.1.10 Prefix commands.

Remarks and examples

The Durbin–Watson test is used to determine whether the error term in a linear regression model follows an AR(1) process. For the linear model

$$y_t = x_t \beta + u_t$$

the AR(1) process can be written as

$$u_t = \rho u_{t-1} + \epsilon_t$$

In general, an AR(1) process requires only that $\epsilon_t$ be independent and identically distributed (i.i.d.). The Durbin–Watson test, however, requires $\epsilon_t$ to be distributed $N(0, \sigma^2)$ for the statistic to have an exact distribution. Also, the Durbin–Watson test can be applied only when the regressors are strictly exogenous. A regressor $x$ is strictly exogenous if $\text{Corr}(x_s, u_t) = 0$ for all $s$ and $t$, which precludes the use of the Durbin–Watson statistic with models where lagged values of the dependent variable are included as regressors.

The null hypothesis of the test is that there is no first-order autocorrelation. The Durbin–Watson $d$ statistic can take on values between 0 and 4 and under the null $d$ is equal to 2. Values of $d$ less than 2 suggest positive autocorrelation ($\rho > 0$), whereas values of $d$ greater than 2 suggest negative autocorrelation ($\rho < 0$). Calculating the exact distribution of the $d$ statistic is difficult, but empirical upper and lower bounds have been established based on the sample size and the number of regressors. Extended tables for the $d$ statistic have been published by Savin and White (1977). For example, suppose you have a model with 30 observations and three regressors (including the constant term). For a test of the null hypothesis of no autocorrelation versus the alternative of positive autocorrelation, the lower bound of the $d$ statistic is 1.284, and the upper bound is 1.567 at the 5% significance level. You would reject the null if $d < 1.284$, and you would fail to reject if $d > 1.567$. A value falling within the range (1.284, 1.567) leads to no conclusion about whether or not to reject the null hypothesis.

When lagged dependent variables are included among the regressors, the past values of the error term are correlated with those lagged variables at time $t$, implying that they are not strictly exogenous regressors. The inclusion of covariates that are not strictly exogenous causes the $d$ statistic to be biased toward the acceptance of the null hypothesis. Durbin (1970) suggested an alternative test for models with lagged dependent variables and extended that test to the more general AR($p$) serial correlation process

$$u_t = \rho_1 u_{t-1} + \cdots + \rho_p u_{t-p} + \epsilon_t$$

where $\epsilon_t$ is i.i.d. with variance $\sigma^2$ but is not assumed or required to be normal for the test.
The null hypothesis of Durbin’s alternative test is

\[ H_0 : \rho_1 = 0, \ldots, \rho_p = 0 \]

and the alternative is that at least one of the \( \rho \)'s is nonzero. Although the null hypothesis was originally derived for an AR\((p)\) process, this test turns out to have power against MA\((p)\) processes as well. Hence, the actual null of this test is that there is no serial correlation up to order \( p \) because the MA\((p)\) and the AR\((p)\) models are locally equivalent alternatives under the null. See Godfrey (1988, 113–115) for a discussion of this result.

Durbin’s alternative test is in fact a LM test, but it is most easily computed with a Wald test on the coefficients of the lagged residuals in an auxiliary OLS regression of the residuals on their lags and all the covariates in the original regression. Consider the linear regression model

\[ y_t = \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + u_t \] (1)

in which the covariates \( x_1 \) through \( x_k \) are not assumed to be strictly exogenous and \( u_t \) is assumed to be i.i.d. and to have finite variance. The process is also assumed to be stationary. (See Wooldridge [2020, sec. 11.1] for a discussion of stationarity.) Estimating the parameters in (1) by OLS obtains the residuals \( \hat{u}_t \). Next another OLS regression is performed of \( \hat{u}_t \) on \( \hat{u}_{t-1}, \ldots, \hat{u}_{t-p} \) and the other regressors,

\[ \hat{u}_t = \gamma_1 \hat{u}_{t-1} + \cdots + \gamma_p \hat{u}_{t-p} + \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + \epsilon_t \] (2)

where \( \epsilon_t \) stands for the random-error term in this auxiliary OLS regression. Durbin’s alternative test is then obtained by performing a Wald test that \( \gamma_1, \ldots, \gamma_p \) are jointly zero. The test can be made robust to an unknown form of heteroskedasticity by using a robust VCE estimator when estimating the regression in (2). When there are only strictly exogenous regressors and \( p = 1 \), this test is asymptotically equivalent to the Durbin–Watson test.

The Breusch–Godfrey test is also an LM test of the null hypothesis of no autocorrelation versus the alternative that \( u_t \) follows an AR\((p)\) or MA\((p)\) process. Like Durbin’s alternative test, it is based on the auxiliary regression (2), and it is computed as \( NR^2 \), where \( N \) is the number of observations and \( R^2 \) is the simple \( R^2 \) from the regression. This test and Durbin’s alternative test are asymptotically equivalent. The test statistic \( NR^2 \) has an asymptotic \( \chi^2 \) distribution with \( p \) degrees of freedom. It is valid with or without the strict exogeneity assumption but is not robust to conditional heteroskedasticity, even if a robust VCE is used when fitting (2).

In fitting (2), the values of the lagged residuals will be missing in the initial periods. As noted by Davidson and MacKinnon (1993), the residuals will not be orthogonal to the other covariates in the model in this restricted sample, which implies that the \( R^2 \) from the auxiliary regression will not be zero when the lagged residuals are left out. Hence, Breusch and Godfrey’s \( NR^2 \) version of the test may overreject in small samples. To correct this problem, Davidson and MacKinnon (1993) recommend setting the missing values of the lagged residuals to zero and running the auxiliary regression in (2) over the full sample used in (1). This small-sample correction has become conventional for both the Breusch–Godfrey and Durbin’s alternative test, and it is the default for both commands. Specifying the \( \text{nomiss0} \) option overrides this default behavior and treats the initial missing values generated by regressing on the lagged residuals as missing. Hence, \( \text{nomiss0} \) causes these initial observations to be dropped from the sample of the auxiliary regression.

Durbin’s alternative test and the Breusch–Godfrey test were originally derived for the case covered by \texttt{regress} without the \texttt{vce(robust)} option. However, after \texttt{regress}, \texttt{vce(robust)} and \texttt{newey}, Durbin’s alternative test is still valid and can be invoked if the \texttt{robust} and \texttt{force} options are specified.
Example 1: tests for serial correlation

Using data from Klein (1950), we first fit an OLS regression of consumption on the government wage bill:

```
. use https://www.stata-press.com/data/r18/klein
. tsset yr
  Time variable: yr, 1920 to 1941
  Delta: 1 unit
. regress consump wagegovt
```

```
Source | SS df MS
-------+---------------------------------------------------------------------
Model   | 532.567711 1 532.567711 F(1, 20) = 17.72 Prob > F = 0.0004
Residual| 601.207167 20 30.0603584 R-squared = 0.4697
         |                                     Adj R-squared = 0.4432
Total   | 1133.77488 21 53.9892799 Root MSE = 5.4827
```

| consump     | Coefficient | Std. err. | t | P>|t| | [95% conf. interval] |
|-------------|-------------|-----------|---|-----|---------------------|
| wagegovt    | 2.50744     | .5957173  | 4.21| 0.000| 1.264796 3.750085   |
| _cons       | 40.84699    | 3.192183  | 12.80| 0.000| 34.18821 47.50577   |

If we assume that wagegov is a strictly exogenous variable, we can use the Durbin–Watson test to check for first-order serial correlation in the errors.

```
. estat dwatson
Durbin-Watson d-statistic( 2, 22) = .3217998
```

The Durbin–Watson $d$ statistic, 0.32, is far from the center of its distribution ($d = 2.0$). Given 22 observations and two regressors (including the constant term) in the model, the lower 5% bound is about 0.997, much greater than the computed $d$ statistic. Assuming that wagegov is strictly exogenous, we can reject the null of no first-order serial correlation. Rejecting the null hypothesis does not necessarily mean an AR process; other forms of misspecification may also lead to a significant test statistic. If we are willing to assume that the errors follow an AR(1) process and that wagegov is strictly exogenous, we could refit the model using arima or prais and model the error process explicitly; see [TS] arima and [TS] prais.

If we are not willing to assume that wagegov is strictly exogenous, we could instead use Durbin’s alternative test or the Breusch–Godfrey to test for first-order serial correlation. Because we have only 22 observations, we will use the small option.

```
. estat durbinalt, small
Durbin's alternative test for autocorrelation

lags(p) | F | df | Prob > F   |
--------|---|----|------------|
1       | 35.035 | ( 1, 19 ) | 0.0000 |
```

H0: no serial correlation
. estat bgodfrey, small

Breusch–Godfrey LM test for autocorrelation

<table>
<thead>
<tr>
<th>lags(p)</th>
<th>F</th>
<th>df</th>
<th>Prob &gt; F</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>14.264</td>
<td>( 1, 19 )</td>
<td>0.0013</td>
</tr>
</tbody>
</table>

H0: no serial correlation

Both tests strongly reject the null of no first-order serial correlation, so we decide to refit the model with two lags of consump included as regressors and then rerun estat durbinalt and estat bgodfrey. Because the revised model includes lagged values of the dependent variable, the Durbin–Watson test is not applicable.

H0: no serial correlation

Although wagegovt and the constant term are no longer statistically different from zero at the 5% level, the output from estat durbinalt and estat bgodfrey indicates that including the two lags of consump has removed any serial correlation from the errors.
Engle (1982) suggests an LM test for checking for autoregressive conditional heteroskedasticity (ARCH) in the errors. The $p$th-order ARCH model can be written as

$$\sigma_t^2 = E(u_t^2|u_{t-1}, \ldots, u_{t-p})$$

$$= \gamma_0 + \gamma_1 u_{t-1}^2 + \cdots + \gamma_p u_{t-p}^2$$

To test the null hypothesis of no autoregressive conditional heteroskedasticity (that is, $\gamma_1 = \cdots = \gamma_p = 0$), we first fit the OLS model (1), obtain the residuals $\hat{u}_t$, and run another OLS regression on the lagged residuals:

$$\hat{u}_t^2 = \gamma_0 + \gamma_1 \hat{u}_{t-1}^2 + \cdots + \gamma_p \hat{u}_{t-p}^2 + \epsilon$$

The test statistic is $NR^2$, where $N$ is the number of observations in the sample and $R^2$ is the $R^2$ from the regression in (3). Under the null hypothesis, the test statistic follows a $\chi^2_p$ distribution.

Example 2: estat archlm

We refit the original model that does not include the two lags of consump and then use estat archlm to see if there is any evidence that the errors are autoregressive conditional heteroskedastic.

```
. regress consump wagegovt
Source | SS       df       MS
------ | --------- ----- -----
Model  | 532.567711 1  532.567711
Residual | 601.207167 20  30.0603584
Total  | 1133.77488 21  53.9892799

H0: no ARCH effects vs. H1: ARCH(p) disturbance

estat archlm shows the results for tests of ARCH(1), ARCH(2), and ARCH(3) effects, respectively. At the 5% significance level, all three tests reject the null hypothesis that the errors are not autoregressive conditional heteroskedastic. See [TS] arch for information on fitting ARCH models.
Stored results

estat archlm stores the following in r():

Scalars
- r(N): number of observations
- r(k): number of regressors
- r(N_gaps): number of gaps

Macros
- r(lags): lag order

Matrices
- r(arch): test statistic for each lag order
- r(df): degrees of freedom
- r(p): two-sided p-values

estat bgodfrey stores the following in r():

Scalars
- r(N): number of observations
- r(k): number of regressors
- r(N_gaps): number of gaps

Macros
- r(lags): lag order

Matrices
- r(chi2): $\chi^2$ statistic for each lag order
- r(F): $F$ statistic for each lag order (small only)
- r(df_r): residual degrees of freedom (small only)
- r(df): degrees of freedom
- r(p): two-sided p-values

estat durbinalt stores the following in r():

- r(k): number of regressors
- r(N_gaps): number of gaps
- r(dw): Durbin–Watson statistic
Methods and formulas

Consider the regression

\[ y_t = \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + u_t \] (4)

in which some of the covariates are not strictly exogenous. In particular, some of the \( x_{it} \) may be lags of the dependent variable. We are interested in whether the \( u_t \) are serially correlated.

The Durbin–Watson \( d \) statistic reported by \texttt{estat dwatson} is

\[
d = \frac{\sum_{t=1}^{n-1} (\hat{u}_{t+1} - \hat{u}_t)^2}{\sum_{t=1}^{n} \hat{u}_t^2}
\]

where \( \hat{u}_t \) represents the residual of the \( t \)th observation.

To compute Durbin’s alternative test and the Breusch–Godfrey test against the null hypothesis that there is no \( p \)th order serial correlation, we fit the regression in (4), compute the residuals, and then fit the following auxiliary regression of the residuals \( \hat{u}_t \) on \( p \) lags of \( \hat{u}_t \) and on all the covariates in the original regression in (4):

\[
\hat{u}_t = \gamma_1 \hat{u}_{t-1} + \cdots + \gamma_p \hat{u}_{t-p} + \beta_1 x_{1t} + \cdots + \beta_k x_{kt} + \epsilon
\] (5)

Durbin’s alternative test is computed by performing a Wald test to determine whether the coefficients of \( \hat{u}_{t-1}, \ldots, \hat{u}_{t-p} \) are jointly different from zero. By default, the statistic is assumed to be distributed \( \chi^2(p) \). When \texttt{small} is specified, the statistic is assumed to follow an \( F(p, N - p - k) \) distribution. The reported \( p \)-value is a two-sided \( p \)-value. When \texttt{robust} is specified, the Wald test is performed using the Huber/White/sandwich estimator of the variance–covariance matrix, and the test is robust to an unspecified form of heteroskedasticity.

The Breusch–Godfrey test is computed as \( N R^2 \), where \( N \) is the number of observations in the auxiliary regression (5) and \( R^2 \) is the \( R^2 \) from the same regression (5). Like Durbin’s alternative test, the Breusch–Godfrey test is asymptotically distributed \( \chi^2(p) \), but specifying \texttt{small} causes the \( p \)-value to be computed using an \( F(p, N - p - k) \).

By default, the initial missing values of the lagged residuals are replaced with zeros, and the auxiliary regression is run over the full sample used in the original regression of (4). Specifying the \texttt{nomiss0} option causes these missing values to be treated as missing values, and the observations are dropped from the sample.

Engle’s LM test for ARCH(\( p \)) effects fits an OLS regression of \( \hat{u}_t^2 \) on \( \hat{u}_{t-1}^2, \ldots, \hat{u}_{t-p}^2 \):

\[
\hat{u}_t^2 = \gamma_0 + \gamma_1 \hat{u}_{t-1}^2 + \cdots + \gamma_p \hat{u}_{t-p}^2 + \epsilon
\]

The test statistic is \( n R^2 \) and is asymptotically distributed \( \chi^2(p) \).

Acknowledgment

The original versions of \texttt{estat archlm}, \texttt{estat bgodfrey}, and \texttt{estat durbinalt} were written by Christopher F. Baum of the Department of Economics at Boston College and author of the Stata Press books \textit{An Introduction to Modern Econometrics Using Stata} and \textit{An Introduction to Stata Programming} and coauthor of the Stata Press book \textit{Environmental Econometrics Using Stata}.

Description

rerir reports three statistics that assess two-way interactions in an additive model of relative risk. The statistics are of interest for determining how two risk factors interact to produce a positive result for the outcome of interest. The estimates of the interactions themselves are reported as excess relative risks (ERRs). Statistics reported for the interaction are the relative excess risk due to interaction (RERI), attributable proportion (AP), and synergy index (SI); rerir supports binomial generalized linear, Poisson, negative binomial, logistic, Cox, parametric survival, and interval-censored parametric and semiparametric survival models.

Quick start

Report ERRs, RERI, AP, and SI for the interaction of exposures exp1 and exp2 from a binomial generalized linear model for y fit by binreg
rerir binreg y exp1 exp2

Same as above, but use poisson to fit the model
rerir poisson y exp1 exp2

Same as above, but report incidence-rate ratios for the interactions rather than ERRs
rerir poisson y exp1 exp2, irr

Same as above, but include the covariate x, and specify noisily to view the full Poisson model
rerir poisson y exp1 exp2 x, irr noisily

Same as above, but report ERRs for the interactions as well as incidence-rate ratios for the full model
rerir poisson y exp1 exp2 x, irr err noisily

Fit a Cox model using stset data stratified by svar, and report ERRs, RERI, AP, and SI for the interactions of exp1 and exp2
rerir stcox exp1 exp2, strata(svar)

Same as above, but fit a Weibull model
rerir streg exp1 exp2, strata(svar) distribution(weibull)

Fit a Weibull model with interval-censored survival data, with variables t1 and t2 giving lower and upper endpoints for the censoring interval, and report ERRs, RERI, AP, and SI for the interactions
rerir stintreg exp1 exp2, distribution(weibull) interval(t1 t2)
Syntax

reri cmd depvar var1 var2 [control_vars] [if] [in] [weight]
[ , options cmd_options]

cmd defines the estimation command to be executed and may be one of the following:

binreg, logistic, nbreg, poisson, stcox, stintcox, stintreg, and streg

depvar is required for all except stcox, stintcox, stintreg, and streg, which do not allow
depvar.

var1 and var2 are binary variables (integer valued and nonnegative) whose interactions are to be
tested for additivity.

var1 and var2 cannot be factor variables, but control_vars may contain factor variables; see [U] 11.4.3 Factor variables.
cmd_options are any options allowed by cmd, except options or, hr, rd, and vce(jackknife1) are not allowed
when cmd is binreg.
When cmd is poisson, vce(robust) is used by default when depvar is 0/1.
bootstrap, by, collect, jackknife, and statsby are allowed; see [U] 11.1.10 Prefix commands.
Weights are allowed if cmd allows them; see [U] 11.1.6 weight.
All postestimation commands behave as they would after cmd; see the postestimation manual entry for cmd.

Options

table

baselevel1(#) and baselevel2(#) specify base levels for var1 and var2, respectively, the two
variables that give the interactions of interest.

If var1 and var2 are 0/1 variables, then by default, the RERI statistic is a test of whether the ERR of
interaction 01 (01 meaning var1 = 0 and var2 = 1) plus the ERR of interaction 10 equals the ERR
of interaction 11. In shorthand notation, we say we are testing 01 + 10 = 11 on the ERR scale.

Specifying baselevel1(#) or baselevel2(#) allows the base levels of the interactions to be changed. For example, with 0/1 variables, baselevel1(1) sets the base level for var1 to 1, and
RERI tests whether 11 + 00 = 01.

If baselevel1(#) is not specified, the base level of var1 is the default base level of the factor
variable i.var1. The default base level is the smallest of the two values of var1, unless the
default has been changed by fvset. This is similarly true for baselevel2(\#) and \textit{var2}. See [U] 11.4.3.2 \textbf{Base levels} and [R] \textbf{fvset}. Note that base levels cannot be set using factor-variable notation when specifying \textit{var1} and \textit{var2}.

goisily displays all output from \textit{cmd}.

\textbf{err} specifies that the coefficients of the interactions be displayed as ERRs. This is the default. ERR is equal to relative risk minus one. See \textbf{Remarks and examples} below.

\textit{coef\_type} specifies an alternative scale for the coefficients of the interactions instead of ERRs. Allowed \textit{coef\_type} depends on \textit{cmd} and can be \textit{rr}, \textit{or}, \textit{irr}, or \textit{hr}, whichever is allowed by \textit{cmd}. In addition, \textit{coef\_type} can be \textit{coef}, which displays the interaction terms as unscaled coefficients.

For \textit{binreg}, \textit{coef\_type} \textit{rr} displays the interactions as relative-risk ratios. The other models fit by \textit{binreg} using options \textit{or}, \textit{hr}, and \textit{rd} are not available with \textit{reri}. For \textit{logistic}, \textit{coef\_type} \textit{or} displays the interactions as odds ratios. For \textit{poisson} and \textit{nbreg}, \textit{coef\_type} \textit{irr} displays the interactions as incidence-rate ratios. For \textit{stcox}, \textit{stintcox}, \textit{stintreg}, and \textit{streg}, \textit{coef\_type} \textit{hr} displays the interactions as hazard ratios. For the survival-time commands, \textit{nohr} may be used as a synonym for \textit{coef}.

When \textit{noisily} is specified, \textit{err} and a \textit{coef\_type} may be specified simultaneously. In this case, the table of interactions displayed by \textit{reri} reports ERRs, and the coefficient table produced by \textit{cmd} displays coefficients on the \textit{coef\_type} scale.

\textbf{level(\#)} specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by \textbf{set level}; see [R] \textbf{level}.

\textbf{nofvlabel} specifies that numeric values rather than \textit{value labels} be displayed in the legend and \textit{cmd} output.

\textbf{nolegend} suppresses the display of the legend for the interactions.

\section*{Remarks and examples}

Remarks are presented under the following headings:

\begin{itemize}
\item \textbf{Introduction}
\item Additive versus multiplicative interactions
\item Incidence-rate ratios, hazard ratios, and odds ratios
\end{itemize}

\section*{Introduction}

\textit{reri} reports three statistics that assess additive interactions of relative risk: RERI, AP, and SI (Lash et al. 2021). These measures are typically of interest when working with epidemiologic data. When one assesses the effect of multiple exposures on an outcome, determining whether one exposure modifies the effect of another can be an important piece of the puzzle.

When there are two exposures that affect an outcome, we often want to model how the exposures interact. That is, for binary exposures \textit{A} and \textit{B}, we want to model the risk of a positive outcome for subjects having both \textit{A} and \textit{B} compared with subjects having only \textit{A} and those having only \textit{B}.

Typically, a multiplicative model for the interaction is fit to the data: the risk for those with \textit{A} and \textit{B} is hypothesized to equal the risk for only \textit{A} times the risk for only \textit{B}. If the risk for \textit{A} and \textit{B} equals the multiplicative risk, then we say there is no interaction of \textit{A} and \textit{B}. If the risk is greater than the multiplicative risk, we say there is a positive interaction of \textit{A} and \textit{B}. Multiplicative models
are computationally convenient because they are simple to specify, and it is easy to test whether the interaction term is greater (or less) than multiplicative.

Inherent to this model is the hypothesis that the risk is multiplicative. For many biological processes, however, an additive model of risk may model the process better than a multiplicative one (see, for example, Andersson et al. [2005]). That is, the risk for subjects with A and B is hypothesized to equal the risk for only A plus the risk for only B. For this hypothesis, we want to look at how much the risk for A and B is greater (or less) than the additive risk.

The RERI statistic is this risk difference formulated using relative risks. A RERI statistic that is 0 means the risk is additive. One that is positive means the risk is superadditive, and one that is negative means the risk is subadditive. The test of statistical significance of the RERI statistic is straightforward, but it is not as simple as the test for the multiplicative model (see Methods and formulas).

Besides the RERI statistic, there are two other related statistics for additive models: AP and SI. The AP is the proportion of risk of A and B due to the superadditivity of exposures A and B. The SI recasts the RERI statistic as a ratio, rather than a difference.

Let’s formally define these statistics. Let \( p_{A+B} \) be the probability of having a positive outcome for subjects positive for binary exposure A and positive for binary exposure B. Define \( p_{A-B} \), \( p_{A+B-} \), and \( p_{A-B-} \) similarly. An additive model for the probabilities is

\[
\begin{align*}
p_{A+B} &= p_{A-B} + (p_{A-B} - p_{A-B-}) + (p_{A+B} - p_{A-B-}) \\
\end{align*}
\]

Said in words, the probability of a positive outcome for \( A+B \) equals the probability for the base category \( A-B \) plus the amounts that probabilities for \( A-B+ \) and \( A+B- \) exceed the probability for the base category.

If we divide this equation by \( p_{A-B-} \) and note that \( p_{A+B+}/p_{A-B-} = RR_{A+B+} \), the relative risk for \( A+B+ \) (and similarly for \( RR_{A-B+} \) and \( RR_{A+B-} \)), we get

\[
RR_{A+B+} = RR_{A-B+} + RR_{A+B-} - 1
\]

ERR is defined as \( ERR = RR - 1 \). In terms of ERR, the additive model becomes

\[
ERR_{A+B+} = ERR_{A-B+} + ERR_{A+B-}
\]

The RERI statistic is defined as

\[
RERI = ERR_{A+B+} - ERR_{A-B+} - ERR_{A+B-}
\]

Hence, RERI is 0 for a perfectly additive model. If it is negative, the effect of the \( A+B+ \) interaction is less than additive (subadditive). If positive, the effect is more than additive (superadditive).

AP is simply RERI scaled by the relative risk (not ERR) of \( A+B+ \). That is,

\[
AP = \frac{RERI}{RR_{A+B+}}
\]

When AP is positive, it represents the proportion of risk of \( A+B+ \) due to the superadditivity of exposures A and B (that is, the amount greater than additivity). Note that it is a proportion of risk, not relative risk, as one can see by multiplying both numerator and denominator by the reference probability \( p_{A-B-} \).

The SI is a ratio measure:

\[
SI = \frac{ERR_{A+B+}}{ERR_{A-B+} + ERR_{A+B-}}
\]
The SI is 1, rather than 0, for a perfectly additive model. It is < 1 for a subadditive model and > 1 for a superadditive model. Note that because ERRs can be negative (they are always ≥ −1), the SI can be negative, making interpretation difficult. The SI is intended as a measure for cases in which all ERRs of the model are positive, but this will not always be the case. ERRs will be determined by the data and the specification of the model. See Knol et al. (2011) and example 4 for discussions about negative ERRs.

Additive versus multiplicative interactions

Typically, interactions are fit and tested by specifying main effects and interactions of the main effects (Rothman, Greenland, and Walker 1980). Suppose $x_{A+}$ is a 0/1 variable that is 1 when exposure $A$ is positive and 0 when it is negative. The variable $x_{B+}$ is defined similarly for exposure $B$. Let $x_{A+B+}$ be the 0/1 variable that is 1 when both $A$ and $B$ are positive and 0 otherwise.

When we specify a model and include terms

$$b_1 x_{A+} + b_2 x_{B+} + b_3 x_{A+B+}$$

we call $b_1 x_{A+}$ and $b_2 x_{B+}$ main effects and $b_3 x_{A+B+}$ their interaction. The test of the interaction is the test of $b_3 = 0$.

It is a model of interaction that is additive in these terms. However, when the statistics of interest are risk ratios, odds ratios, or hazard ratios, the model is generally called multiplicative because it is multiplicative in these statistics. The risk ratios (or odds ratios or hazard ratios) are given by the exponentiated coefficients; that is, $RR_{A+} = e^{b_1}$, $RR_{B+} = e^{b_2}$, etc. The risk ratio for $A+B+$ is $RR_{A+B+} = e^{b_1} e^{b_2} e^{b_3}$. If the interaction is multiplicative, $e^{b_3} = 1$ and

$$RR_{A+B+} = RR_{A+} \times RR_{B+}$$

As mentioned earlier, many biological processes more closely follow an additive model of risk than a multiplicative one. The additive model of ERR is

$$ERR_{A+B+} = ERR_{A-B+} + ERR_{A+B-}$$

Note that unlike the multiplicative model with main effects, the three states in the additive model, $A−B+$, $A+B−$, and $A+B+$, are disjoint.

reri is called with the syntax

reri cmd depvar var1 var2 ...

reri uses var1 and var2 to create the three terms for the additive model using factor-variable notation. Suppose var1 is $xa$, a 0/1 variable, indicating whether a subject has exposure $A$. Suppose var2 is $xb$ for exposure $B$. Then, the terms needed to test for additive ERR are, in factor-variable notation,

$$0.xa#1.xb 1.xa#0.xb 1.xa#1.xb$$

reri creates these terms and calls cmd to fit the model. Then, it uses nlcom to calculate the RERI, AP, and SI statistics and their standard errors. See Methods and formulas.
Incidence-rate ratios, hazard ratios, and odds ratios

Incidence rates and hazards are measures of risk. An incidence rate is a probability adjusted for time at risk. A hazard is a conditional probability when the distribution is discrete and an incremental conditional probability when the distribution is continuous (Kalbfleisch and Prentice 2002). Hence, incidence-rate ratios and hazard ratios are measures of relative risk. So using RERI, AP, and SI statistics with models that estimate incidence-rate ratios (poisson and nbreg) or hazard ratios (stcox, stintcox, streg, stintreg) presents no difficulties.

Odds ratios, however, are different. As is well known, the odds ratio approximates the risk ratio in the population when the prevalence of the outcome in the population is low (see, for example, Greenland and Thomas [1982]). So if your data are from a case–control study and the population prevalence of a positive outcome is low, then odds ratios from a logistic regression will approximate the risk ratios in the population, and the RERI, AP, and SI statistics are appropriate. On the other hand, if the population prevalence is high, the odds ratio is typically a poor approximation to the risk ratio (unless it is close to 1), and interpretation of the RERI, AP, and SI statistics may be problematic (see, for example, Skrondal [2003]).

If the study you are analyzing is a cohort study, observational study, or a randomized controlled trial with a binary outcome, you can estimate risk directly rather than fitting a logistic regression. A binomial model of risk or a Poisson model can be fit (using an appropriate variance estimator; see Cummings [2009] and example 2).

If time to outcome is measured, then a survival model may be fit, and there are no issues interpreting the RERI and SI statistics. Interpreting the AP statistic is a little trickier because it relates to the hazard at a point in time rather than risk in a population, so the proportion is the proportion of the hazard at a given time.

Example 1: Binomial model of risk

We have simulated data on birth defects that mimic the results from Brender et al. (2013), an observational study of birth defects. Three binary outcomes are included in these data and are tube, palate, and heart, representing neural tube defects, palate defects, and heart defects, respectively. Predictors of birth defects are two measures of nitrate intake: drug, with values 0/1, indicating nitrosatable drug exposure; and nitrate, also with values 0/1, representing either low or high daily consumption of nitrates from drinking water.

We load the dataset and describe it.
We first examine the outcome tube. We want to see whether the interactions of the two predictors drug and nitrate follow an additive model of risk. Because this is an observational study, a binomial model of risk is appropriate, and we can fit it using \texttt{binreg}.

The syntax of \texttt{reri} is \texttt{reri cmd depvar var1 var2}, where \texttt{var1} and \texttt{var2} are the binary predictors of interest. Note that \texttt{var1} and \texttt{var2} are specified without using factor-variable notation. \texttt{reri} will create the interactions automatically. Here’s the result:

```
. reri binreg tube drug nitrate
```

```
Fitting \texttt{binreg} ...
Interaction of \texttt{drug} and \texttt{nitrate} on an additive scale
Model: Binomial generalized linear  Number of observations = 1,284

Observations: 1,367 Simulated prenatal nitrate intake and birth defects data
Variables: 6 4 Oct 2022 16:05 (_dta has notes)
```

We first examine the outcome tube. We want to see whether the interactions of the two predictors drug and nitrate follow an additive model of risk. Because this is an observational study, a binomial model of risk is appropriate, and we can fit it using \texttt{binreg}.

The syntax of \texttt{reri} is \texttt{reri cmd depvar var1 var2}, where \texttt{var1} and \texttt{var2} are the binary predictors of interest. Note that \texttt{var1} and \texttt{var2} are specified without using factor-variable notation. \texttt{reri} will create the interactions automatically. Here’s the result:

```
. reri binreg tube drug nitrate
```

```

Note: \texttt{P>|z|} for synergy index (SI) is for test \texttt{H0: SI = 1}.

Note that the interactions created by \texttt{reri} represent disjoint groups in the data. The \texttt{--} interaction is for \texttt{drug} = No and \texttt{nitrate} = High. The \texttt{+-} and \texttt{++} interactions are defined similarly as shown in the legend. The interaction \texttt{--} is, of course, the reference category.

By default, \texttt{reri} displays the model coefficients for the \texttt{--}, \texttt{+-}, and \texttt{++} interactions as \texttt{ERR}, which is relative risk minus one. So \texttt{ERR} greater than 0 means that relative risk is greater than 1. If the model is additive, we would have

\[
\text{ERR}_{++} = \text{ERR}_{--} + \text{ERR}_{+-}
\]
The RERI statistic is the difference between the two sides of this equation:

\[ \text{RERI} = \text{ERR}_{++} - \text{ERR}_{-+} - \text{ERR}_{+-} \]

The estimates are \( \text{ERR}_{-+} = 0.116 \) and \( \text{ERR}_{+-} = 0.239 \), so \( \text{ERR}_{++} + \text{ERR}_{-+} = 0.355 \). The estimate of \( \text{ERR}_{++} \) is 0.777, which is greater than \( \text{ERR}_{-+} + \text{ERR}_{+-} \). So the model is superadditive. The RERI statistic is 0.422, the difference between 0.777 and 0.355.

The \( p \)-value for RERI is a test of the null hypothesis \( \text{RERI} = 0 \). That is, a small \( p \)-value provides evidence to reject the additive model for the interactions. In this case, \( p = 0.352 \), so we do not have enough evidence to reject the additive model, despite the observed superadditivity.

\[ \text{AP} = \frac{\text{RERI}}{\text{RR}_{++}} \]

It is the proportion of risk for the ++ interaction that is due to the risk that is above additive. In this case, AP is 0.238 or 23.8%. Its \( p \)-value is a test of the null hypothesis \( \text{AP} = 0 \). This null hypothesis is equivalent to the null hypothesis \( \text{RERI} = 0 \), so \( p \)-values will be similar.

\[ \text{SI} = \frac{\text{ERR}_{++}}{\text{ERR}_{-+} + \text{ERR}_{+-}} \]

It is how many times larger (or smaller) is \( \text{ERR}_{++} = 0.777 \) than \( \text{ERR}_{-+} + \text{ERR}_{+-} = 0.355 \). In this example, it is about twice as large, or more precisely, 2.19 times as large. The null hypothesis is \( \text{SI} = 1 \), rather than 0. The SI is a rather odd statistic because it is a test of an additive model using a multiplicative scale!

\text{reri} can optionally display the interaction coefficients from binreg as relative risk (that is, risk ratios) rather than ERR. This is done by specifying the \text{rr} option. We do so and also specify the \text{noisily} option to see the output from binreg.

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.

We see the output of binreg followed by the output of reri. In this case, reri displays the interaction coefficients as risk ratios, matching the output of binreg. Risk ratios are just ERRs plus one, so point estimates and confidence intervals for the interactions are just shifted by one from the previous results, and standard errors and p-values are unchanged. The RERI, AP, and SI statistics are all exactly the same as they were in the previous results.

For comparison, we can fit a binreg model specifying the interaction in the standard manner: main effects for drug and nitrate and a single interaction term for drug = Yes and nitrate = High.

```
. binreg tube drug##nitrate, rr

Note: _cons estimates baseline risk.
This model is not as easy to interpret as the previous ones and shows no evidence that drug, nitrate, or their interaction has any effect on neural tube defects. However, the previous model fit with disjoint interactions provided strong evidence that the relative risk of neural tube defects was greater for the ++ group when compared with the reference group; in that model, the risk ratio for the ++ group was greater than 1, and the p-value was 0.012.

Note that when running binreg directly, we must specify the rr model option. When reri calls binreg, it automatically fits an rr model. Specifying rr with reri is merely a display option; it reports relative risk rather than ERR.

Technical note

As mentioned earlier, when reri is called with, say,

```
  reri cmd y x1 x2 ...
```

it creates disjoint interactions and runs

```
  cmd y 0.x1#1.x2 1.x1#0.x2 1.x1#1.x2 ...
```

(assuming that x1 and x2 are 0/1 and that 0 is taken as the base category for both).

If reri gives an error message and you cannot figure out the reason why, run

```
  cmd y 0.x1#1.x2 1.x1#0.x2 1.x1#1.x2 ...
```

and see whether this gives any problems such as dropped terms or dropped observations.

Example 2: Poisson model

We continue with our previous example. We again fit a model for the outcome tube, representing neural tube birth defects. Our predictors, as in the previous example, are drug (nitrosatable drug exposure) and nitrate (drinking water nitrate intake). The only difference is that we specify poisson rather than binreg.

```
  . reri poisson tube drug nitrate
```

Fitting poisson ...

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.
We see that the reported point estimates for the interactions, RERI, AP, and SI are identical to the ones estimated when we used binreg. The standard errors are almost the same, differing only in the fourth significant digit.

When the outcome is 0/1, *reri poisson* by default reports standard errors calculated using *vce(robust)*. This is because when the outcome is 0/1, the distribution is binomial (Bernoulli), not Poisson, and *vce(robust)* gives standard errors that are valid in this case. The other *vcetypes* allowed with *poisson* are available and can be selected by specifying the *vce()* option with *reri*. See [R] *poisson* and [R] *vce_option*.

*binreg* by default fits models using iterated, reweighted least-squares optimization and uses the expected information matrix for the variance estimator. *poisson* uses maximum likelihood optimization. Point estimates will theoretically be the same but will have numerical differences because of the different optimizers used. Different variance estimators are used, so slight differences, as we observed here, are to be expected.

One advantage of using *poisson* with *reri* rather than *binreg* is that maximum likelihood optimization is more robust than iterated, reweighted least-squares optimization. There can be convergence problems with iterated, reweighted least squares when maximum likelihood will converge without any difficulty.

*binreg* does have an *ml* option for maximum likelihood optimization. We can also specify *vce(robust)* to reproduce the results given by *poisson*.

```
. reri binreg tube drug nitrate, ml vce(robust)

| Synergy ind.  | 2.190483   | 2.035131  | 0.84 | 0.399| .3545735 13.53235 |
```

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.

*reri binreg* with *ml* and *vce(robust)* gives the same results as *reri poisson*. But if we want maximum likelihood with the robust variance estimator, we might as well just use *reri poisson*.

Example 3: Logistic model

We continue with the previous example. These data were simulated to mimic an observational study with full data from several sites over a set period of time. So risk ratios can be estimated directly. But let’s pretend it was a case–control study. The outcomes, birth defects, have low prevalences, so odds ratios from a logistic regression should be good approximations to the risk ratios.
We specify logistic with \texttt{reri}:

\begin{verbatim}
  . reri logistic tube drug nitrate
Fitting \texttt{logistic} ...
Interaction of \texttt{drug} and \texttt{nitrate} on an additive scale
Model: Logistic
  Number of observations  = 1,284

| drug#nitrate | ERR  | Std. err. | z     | P>|z|  | [95% conf. interval] |
|--------------|------|-----------|-------|------|---------------------|
| - +          | .141003 | .1933785 | 0.78  | 0.436 | -.1814898 - .590577 |
| + -          | .2965734 | .3085999 | 1.09  | 0.275 | -.1867932 1.067251  |
| + +          | 1.080139 | .6495028 | 2.35  | 0.019 | .1280107 2.835939  |

RERI .642563 .691611 0.93 0.353 -.7129695 1.998096
Attr. prop. .3089038 .2594074 1.19 0.234 -.1995252 .817329
Synergy ind. 2.468459 2.456832 0.91 0.364 .3509409 17.36273

Note: P>|z| for synergy index (SI) is for test \texttt{H0: SI = 1}. The ERRs reported are the odds ratios minus one. Calculating ERR using odds ratios assumes that the odds ratios are approximations to the risk ratios.

Here we see that RERI = 0.643, AP = 0.309, and SI = 2.47. When we used \texttt{poisson} and \texttt{binreg}, we got RERI = 0.422, AP = 0.238, and SI = 2.19. Results are similar but not that close numerically.

If we have data from an observational study, a cohort, or a randomized controlled trial, we can estimate risk ratios directly, and we should do so using \texttt{poisson} or \texttt{binreg}. If it is a case-control study, we have no choice but to use \texttt{logistic}.

Example 4: Negative ERRs

We present data from \texttt{example 2} in \texttt{[ST] stcox}. The data represent 48 participants in a cancer drug trial. Some receive treatment (\texttt{drug} = 1) and some receive a placebo (\texttt{drug} = 0). The data contain the participants' age and time until death. It has already been \texttt{stset} and is ready to be analyzed using a survival model.

We load the dataset, \texttt{describe} it, and run \texttt{st} to see the survival-time settings.

The age of the participants ranges from 47 to 67 years. Median age is 56. Second, we create the variable older with older = 1 representing those with ages > 56 and older = 0 those with ages ≤ 56. We give it a value label as well.

. generate older = cond(age > 56, 1, 0)
. label define older_lbl 0 "age<=56" 1 "age>56"
. label values older older_lbl
Now, we run reri stcox:

. reri stcox drug older

Fitting stcox ...  

Interaction of drug and older on an additive scale

Model: Cox proportional hazards  Number of observations = 48

|          | ERR       | Std. err. | z     | P>|z|  | [95% conf. interval] |
|----------|-----------|-----------|-------|------|---------------------|
| drug#older |          |           |       |      |                     |
| - +       | .6268459  | .768877   | 1.03  | 0.303| -.3557603 3.108141  |
| + -       | -.9158604 | .0532904  | -3.91 | 0.000| -.9756843 -.7088514 |
| + +       | -.7313977 | .1392912  | -2.53 | 0.011| -.9027935 -.2577947 |

|          | ERR       | Std. err. | z     | P>|z|  | [95% conf. interval] |
|----------|-----------|-----------|-------|------|---------------------|
| RERI     | -.4423833 | .7436483  | -0.59 | 0.552| -1.899907 1.015141  |
| Attr. prop. | -1.646983 | 2.711232  | -0.61 | 0.544| -6.960901 3.666935 |
| Synergy ind. | 2.530662  | 6.713001  | 0.35  | 0.726| .0139727 458.3401  |

Notes: P>|z| for synergy index (SI) is for test H0: SI = 1.

Some estimates of excess relative risk are not positive.

The ERR is negative for the + - (drug = 1 and older = 0) and ++ (drug = 1 and older = 1) interactions. This means the relative risk is less than one.

The RERI, AP, and SI statistics were designed for models in which the - +, + -, and ++ interactions each have positive ERRs. That is, values of 1 for the predictors are hypothesized to be associated with increased risk. Clearly, this is not true here. drug = 1 is hypothesized to be associated with decreased risk. We incorrectly specified the model for reri. drug = 0 should be the category hypothesized for a positive ERR.

We can correct this by specifying the option baselevel1(1), which tells reri to use drug = 1 as the base level for the first predictor.

. reri stcox drug older, baselevel1(1)

Fitting stcox ...  

Interaction of drug and older on an additive scale

Model: Cox proportional hazards  Number of observations = 48

|          | ERR       | Std. err. | z     | P>|z|  | [95% conf. interval] |
|----------|-----------|-----------|-------|------|---------------------|
| drug#older |          |           |       |      |                     |
| - +       | 2.192339  | 1.962714  | 1.89  | 0.059| -.0433052 9.652331  |
| + -       | 10.885    | 7.527446  | 3.91  | 0.000| 2.434872 40.12572 |
| + +       | 18.33507  | 12.94706  | 4.42  | 0.000| 4.20437 70.83291  |

|          | ERR       | Std. err. | z     | P>|z|  | [95% conf. interval] |
|----------|-----------|-----------|-------|------|---------------------|
| RERI     | 5.257728  | 8.484262  | 0.62  | 0.535| -11.37112 21.88658 |
| Attr. prop. | .271927   | .3309285  | 0.82  | 0.411| -.376681 .920535  |
| Synergy ind. | 1.402049  | .677738   | 0.70  | 0.484| .5436253 3.615984 |

Note: P>|z| for synergy index (SI) is for test H0: SI = 1.
The ERRs are now all positive, and the model is easy to interpret. The RERI statistic is 5.26, so the effects are superadditive. But the RERI statistic has a $p$-value of 0.535, so we cannot reject the additive model.

The message of this example is clear. If you have negative ERRs, first check that you correctly specified the hypothesized direction of effects. If the model is correctly specified and there are negative ERRs (not close to 0), then the RERI, AP, and SI statistics may not be useful descriptors for the observed effects.

Stored results

`reri` stores the following in `r()`:

Scalars
- $r(N)$: number of observations
- $r(reri)$: RERI
- $r(ap)$: AP
- $r(si)$: SI
- $r(level)$: confidence level

Matrices
- $r(reri_table)$: table of results

The `e()` and `r()` stored results from `cmd` are returned as well.

Methods and formulas

The RERI statistic is

$$\text{RERI} = \text{ERR}_{A^+B^+} - \text{ERR}_{A^-B^+} - \text{ERR}_{A^+B^-}$$

where ERR = RR - 1 is the ERR and RR denotes relative risk. Here $A^+B^+$ refers to subjects positive for exposure $A$ and positive for exposure $B$, with $A^-B^+$ and $A^+B^-$ defined similarly.

The AP is

$$\text{AP} = \frac{\text{RERI}}{\text{RR}_{A^+B^+}}$$

The SI is

$$\text{SI} = \frac{\text{ERR}_{A^+B^+}}{\text{ERR}_{A^-B^+} + \text{ERR}_{A^+B^-}}$$

When incidence-rate ratios, odds ratios, or hazard ratios are estimated rather than risk ratios, they are used in the calculation in place of relative risk.

Standard errors are calculated by `nlcom` using the “delta method”. See `Methods and formulas` in [R] `nlcom` for details. The standard error for the SI is calculated by first calculating the standard error for the logarithm of SI and then transforming the result back to the SI scale.
Acknowledgment

reri is based on the ic package written by Niels Henrik Bruun of the Aalborg University Hospital, Morten Fenger-Grøn of Jyske Bank, and Anders Prior of Aarhus University (2017).

#review — Review previous commands

## Description

The `#review` command displays the last few lines typed at the terminal.

## Syntax

```stata
#review [#1 [ #2 ]]
```

## Remarks and examples

`#review` (pronounced pound-review) is a Stata preprocessor command. `#commands` do not generate a return code or generate ordinary Stata errors. The only error message associated with `#commands` is “unrecognized #command”.

The `#review` command displays the last few lines typed at the terminal. If no arguments follow `#review`, the last 20 lines typed at the terminal are displayed. The first argument specifies the number of lines to be reviewed, so `#review 10` displays the last 10 lines typed. The second argument specifies the number of lines to be displayed, so `#review 10 5` displays five lines, starting at the 10th previous line.

Stata reserves a buffer for `#review` lines and stores as many previous lines in the buffer as will fit, rolling out the oldest line to make room for the newest. Requests to `#review` lines no longer stored will be ignored. Only lines typed at the terminal are placed in the `#review` buffer. See [U] 10.5 Editing previous lines in Stata.

### Example 1

Typing `#review` by itself will show the last 20 lines you typed at the terminal:

```stata
. #review
20 webuse auto
19 describe
18 notes
17 * comments go into the #review buffer, too
16 tabulate rep78
15 codebook foreign
14 regress mpg weight i.foreign
13 generate gp100m = 100/mpg
12 label variable gp100m "Gallons per 100 miles"
11 tabulate rep78, summarize(gp100m)
10 ttest gp100m, by(foreign)
9 regress gp100m weight i.foreign
8 regress, beta
7 margins foreign
6 generate gpmw = ((100/mpg)/weight)*1000
5 summarize gpmw
4 twoway scatter price gpmw
3 regress gpmw i.foreign
2 regress gpmw i.foreign, vce(robust)
1 #review
. -
```

2511
Typing `#review 15 2` shows the 15th and 14th previous lines:

```
. #review 15 2
15 regress mpg weight i.foreign
14 generate gp100m = 100/mpg
```

`-`
ROC analysis quantifies the accuracy of diagnostic tests or other evaluation modalities used to discriminate between two states or conditions, which are here referred to as normal and abnormal or control and case. The discriminatory accuracy of a diagnostic test is measured by its ability to correctly classify known normal and abnormal subjects. For this reason, we often refer to the diagnostic test as a classifier. The analysis uses the ROC curve, a graph of the sensitivity versus 1 − specificity of the diagnostic test. The sensitivity is the fraction of positive cases that are correctly classified by the diagnostic test, whereas the specificity is the fraction of negative cases that are correctly classified. Thus the sensitivity is the true-positive rate, and the specificity is the true-negative rate.

There are six ROC commands:

<table>
<thead>
<tr>
<th>Command</th>

<td>roctab</td>
<td>[R] roctab</td>
<td>Nonparametric ROC analysis</td>
</tr>
</tbody>
</table>

Postestimation commands are available after rocfit and rocreg; see [R] rocfit postestimation and [R] rocreg postestimation.

Both nonparametric and parametric (semiparametric) methods have been suggested for generating the ROC curve. The roctab command performs nonparametric ROC analysis for a single classifier. roccomp extends the nonparametric ROC analysis function of roctab to situations where we have multiple diagnostic tests of interest to be compared and tested. The rocgold command also provides ROC analysis for multiple classifiers. rocgold compares each classifier’s ROC curve to a “gold standard” ROC curve and makes adjustments for multiple comparisons in the analysis. Both rocgold and roccomp also allow parametric estimation of the ROC curve through a binormal fit. In a binormal fit, both the control and the case populations are normal.

The rocfit command also estimates the ROC curve of a classifier through a binormal fit. Unlike roctab, roccomp, and rocgold, rocfit is an estimation command. In postestimation, graphs of the ROC curve and confidence bands can be produced. Additional tests on the parameters can also be conducted.

ROC analysis can be interpreted as a two-stage process. First, the control distribution of the classifier is estimated, assuming a normal model or using a distribution-free estimation technique. The classifier is standardized using the control distribution to 1 − percentile value, the false-positive rate. Second, the ROC curve is estimated as the case distribution of the standardized classifier values.

Covariates may affect both stages of ROC analysis. The first stage may be affected, yielding a covariate-adjusted ROC curve. The second stage may also be affected, producing multiple covariate-specific ROC curves.
The `rocreg` command performs ROC analysis under both types of covariate effects. Both parametric (semiparametric) and nonparametric methods may be used by `rocreg`. Like `rocfit`, `rocreg` is an estimation command and provides many postestimation capabilities.

The global performance of a diagnostic test is commonly summarized by the area under the ROC curve (AUC). This area can be interpreted as the probability that the result of a diagnostic test of a randomly selected abnormal subject will be greater than the result of the same diagnostic test from a randomly selected normal subject. The greater the AUC, the better the global performance of the diagnostic test. Each of the ROC commands provides computation of the AUC.

Citing a lack of clinical relevance for the AUC, other ROC summary measures have been suggested. These include the partial area under the ROC curve for a given false-positive rate \( t \) [\( \text{pAUC}(t) \)]. This is the area under the ROC curve from the false-positive rate of 0 to \( t \). The ROC value at a particular false-positive rate and the false-positive rate for a particular ROC value are also useful summary measures for the ROC curve. These three measures are directly estimated by `rocreg` during the model fit or postestimation stages. Point estimates of ROC value are computed by the other ROC commands, but no standard errors are reported.

References

**Description**

`roccomp` and `rocgold` are used to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data.

The two variables `refvar` and `classvar` must be numeric. The reference variable indicates the true state of the observation, such as diseased and nondiseased or normal and abnormal, and must be coded as 0 and 1. The rating or outcome of the diagnostic test or test modality is recorded in `classvar`, which must be at least ordinal, with higher values indicating higher risk.

`roccomp` tests the equality of two or more ROC areas obtained from applying two or more test modalities to the same sample or to independent samples. `roccomp` expects the data to be in wide form when comparing areas estimated from the same sample and in long form for areas estimated from independent samples.

`rocgold` independently tests the equality of the ROC area of each of several test modalities, specified by `classvar`, against a “gold standard” ROC curve, `goldvar`. For each comparison, `rocgold` reports the raw and the Bonferroni-adjusted $p$-value. Optionally, Šídák’s adjustment for multiple comparisons can be obtained.

See [R] `rocfit` and [R] `rocreg` for commands that fit maximum-likelihood ROC models.

### Quick start

Equality of AUCs for rating $v1$ of true state `true` between samples defined by `catvar`

```
roccomp true v1, by(catvar)
```

Equality of AUCs for ratings $v1$ and $v2$ for the same sample

```
roccomp true v1 v2
```

Same as above, but plot ROC curves without reporting summary statistics and test of equality

```
roccomp true v1 v2, graph
```

Same as above, but plot $v1$ with a dashed line and $v2$ with a solid line

```
roccomp true v1 v2, graph plot1opts(lpattern(dash)) ///
          plot2opts(lpattern(solid))
```

Use contrast matrix `mymat` to compare ROC areas for $v1$, $v2$, $v3$, and $v4$

```
matrix mymat = (1,0,-1,0 \ 0,1,0,-1)
roccomp true v1 v2 v3 v4, test(mymat)
```

Test equality of ROC area for $v1$ against a “gold standard” $gold$

```
rocgold true gold v1
```
Menu

roccomp

Statistics > Epidemiology and related > ROC analysis > Test equality of two or more ROC areas

rocgold

Statistics > Epidemiology and related > ROC analysis > Test equality of ROC area against gold standard

Syntax

Test equality of ROC areas

```
roccomp refvar classvar [classvars] [if] [in] [weight] [, roccomp_options]
```

Test equality of ROC area against a standard ROC curve

```
rocgold refvar goldvar classvar [classvars] [if] [in] [weight] [, rocgold_options]
```

## Options

<table>
<thead>
<tr>
<th>Main</th>
<th>by(varname) (roccomp only) is required when comparing independent ROC areas. The by() variable identifies the groups to be compared.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>sidak (rocgold only) requests that the p-value be adjusted for the effect of multiple comparisons by using Šidák’s method. Bonferroni’s adjustment is reported by default.</td>
</tr>
<tr>
<td></td>
<td>test(matname) specifies the contrast matrix to be used when comparing ROC areas. By default, the null hypothesis that all areas are equal is tested.</td>
</tr>
<tr>
<td></td>
<td>graph produces graphical output of the ROC curve.</td>
</tr>
<tr>
<td></td>
<td>norefline suppresses plotting the 45-degree reference line from the graphical output of the ROC curve.</td>
</tr>
<tr>
<td></td>
<td>separate is meaningful only with roccomp and specifies that each ROC curve be placed on its own graph rather than one curve on top of the other.</td>
</tr>
<tr>
<td></td>
<td>summary reports the area under the ROC curve, its standard error, and its confidence interval. This option is needed only when also specifying graph.</td>
</tr>
</tbody>
</table>
binormal specifies that the areas under the ROC curves to be compared should be estimated using the binormal distribution assumption. By default, areas to be compared are computed using the trapezoidal rule.

\texttt{line#opts(line_options)} affect the rendition of the line representing the \#th ROC curve drawn using the binormal distribution assumption; see \texttt{[G-3] line_options}. These lines are drawn only if the \texttt{binormal} option is specified.

\texttt{level(#)} specifies the confidence level, as a percentage, for the confidence intervals. The default is \texttt{level(95)} or as set by \texttt{set level}; see \texttt{[R] level}.

\texttt{plot#opts(plot_options)} affect the rendition of the \#th ROC curve—the curve’s plotted points connected by lines. The \texttt{plot_options} can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see \texttt{[G-3] marker_options}, \texttt{[G-3] marker_label_options}, and \texttt{[G-3] cline_options}.

For \texttt{rocgold}, \texttt{plot1opts()} are applied to the ROC for the gold standard.

\texttt{rlopts(cline_options)} affects the rendition of the reference line; see \texttt{[G-3] cline_options}.

\texttt{twoway_options} are any of the options documented in \texttt{[G-3] twoway_options}. These include options for titling the graph (see \texttt{[G-3] title_options}), options for saving the graph to disk (see \texttt{[G-3] saving_option}), and the \texttt{by()} option (see \texttt{[G-3] by_option}).

**Remarks and examples**

Remarks are presented under the following headings:

- **Introduction**
- **Comparing areas under the ROC curve**
- **Correlated data**
- **Independent data**
- **Comparing areas with a gold standard**

**Introduction**

\texttt{roccomp} provides comparison of the ROC curves of multiple classifiers. \texttt{rocgold} compares the ROC curves of multiple classifiers with a single “gold standard” classifier. Adjustment of inference for multiple comparisons is also provided by \texttt{rocgold}.

Comparing areas under the ROC curve

The area under multiple ROC curves can be compared by using \texttt{roccomp}. The command syntax is slightly different if the ROC curves are correlated (that is, different diagnostic tests are applied to the same sample) or independent (that is, diagnostic tests are applied to different samples).

Correlated data

\textgreater \textit{Example 1}

Hanley and McNeil (1983) presented data from an evaluation of two computer algorithms designed to reconstruct CT images from phantoms. We will call these two algorithms’ modalities 1 and 2. A sample of 112 phantoms was selected; 58 phantoms were considered normal, and the remaining 54 were abnormal. Each of the two modalities was applied to each phantom, and the resulting images were rated by a reviewer using a six-point scale: 1 = definitely normal, 2 = probably normal, 3 = possibly normal, 4 = possibly abnormal, 5 = probably abnormal, and 6 = definitely abnormal. Because each modality was applied to the same sample of phantoms, the two sets of outcomes are correlated.

We list the first 7 observations:

\begin{verbatim}
   use https://www.stata-press.com/data/r18/ct
   (Reconstruction of CT images)
   . list in 1/7, sep(0)

    mod1  mod2  status
   -------------
     1.  2    1   0
     2.  5    5   1
     3.  2    1   0
     4.  2    3   0
     5.  5    6   1
     6.  2    2   0
     7.  3    2   0

    The data are in wide form, which is required when dealing with correlated data. Each observation corresponds to one phantom. The variable \texttt{mod1} identifies the rating assigned for the first modality, and \texttt{mod2} identifies the rating assigned for the second modality. The true status of the phantoms is given by \texttt{status}=0 if they are normal and \texttt{status}=1 if they are abnormal. The observations with at least one missing rating were dropped from the analysis.

    We plot the two ROC curves and compare their areas.

   . roccomp status mod1 mod2, graph

    Area
    -----
    mod1 112 0.8828 0.0317 0.82067 0.94498
    mod2 112 0.9302 0.0256 0.88005 0.98042

    H0: area(mod1) = area(mod2)
    chisq(1) = 2.31  Prob>chisq = 0.1282
\end{verbatim}
By default, `roccomp`, with the `graph` option specified, plots the ROC curves on the same graph. Optionally, the curves can be plotted side by side, each on its own graph, by also specifying `separate`.

For each curve, `roccomp` reports summary statistics and provides a test for the equality of the area under the curves, using an algorithm suggested by DeLong, DeLong, and Clarke-Pearson (1988).

Although the area under the ROC curve for modality 2 is larger than that of modality 1, the $\chi^2$ test yielded a $p$-value of 0.1282, suggesting that there is no significant difference between these two areas.

The `roccomp` command can also be used to compare more than two ROC areas. To illustrate this, we modified the previous dataset by including a fictitious third modality.

```
. use https://www.stata-press.com/data/r18/ct2
(Reconstruction of CT images)
. roccomp status mod1 mod2 mod3, graph summary

</table>
```

$H_0$: area(mod1) = area(mod2) = area(mod3)

$\chi^2(2) = 6.54$  $\Prob(\chi^2) = 0.0381$
By default, roccomp tests whether the areas under the ROC curves are all equal. Other comparisons can be tested by creating a contrast matrix and specifying `test(matname)`, where `matname` is the name of the contrast matrix.

For example, assume that we are interested in testing whether the area under the ROC for `mod1` is equal to that of `mod3`. To do this, we can first create an appropriate contrast matrix and then specify its name with the `test()` option.

Of course, this is a trivial example because we could have just specified

`. roccomp status mod1 mod3`

without including `mod2` to obtain the same test results. However, for illustration, we will continue with this example.

The contrast matrix must have its number of columns equal to the number of `classvars` (that is, the total number of ROC curves) and a number of rows less than or equal to the number of `classvars`, and the elements of each row must add to zero.

`. matrix C=(1,0,-1)
. roccomp status mod1 mod2 mod3, test(C)

</tr>
</tbody>
</table>

H0: Comparison as defined by contrast matrix: C
chi2(1) = 3.43  Prob>chi2 = 0.0642

Other contrasts could be made. For example, we could test if mod3 is different from at least one of the other two by first creating the following contrast matrix:

. matrix C=(-1,0,1 \
     0,-1,1)
. mat list C

C[2,3]                 c1   c2   c3
r1  -1  0   1
r2   0 -1   1

Independent data

Example 2

In example 1, we noted that because each test modality was applied to the same sample of phantoms, the classification outcomes were correlated. Now, assume that we have collected the same data presented by Hanley and McNeil (1983), except that we applied the first test modality to one sample of phantoms and the second test modality to a different sample of phantoms. The resulting measurements are now considered independent.

Here are a few of the observations.

. use https://www.stata-press.com/data/r18/ct3
(Reconstruction of CT images)
. list in 1/7, sep(0)

<table>
<thead>
<tr>
<th>pop</th>
<th>status</th>
<th>rating</th>
<th>mod</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>12</td>
<td>0</td>

<td>19</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>7.</td>
<td>3</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

The data are in long form, which is required when dealing with independent data. The data consist of 24 observations: 6 observations corresponding to abnormal phantoms and 6 to normal phantoms evaluated using the first modality, and similarly 6 observations corresponding to abnormal phantoms and 6 to normal phantoms evaluated using the second modality. The number of phantoms corresponding to each observation is given by the pop variable. Once again, we have frequency-weighted data. The variable mod identifies the modality, and rating is the assigned classification.
We can better view our data by using the `table` command.

```
table (mod status) (rating) [fw=pop], totals(mod mod#status mod#rating)
```

<table>
<thead>
<tr>
<th>Modality</th>
<th>Rating</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>Total</th>
</tr>
</thead>
<tbody>

<td>Total</td>
<td>34</td>
<td>21</td>
<td>10</td>
<td>22</td>
<td>15</td>
<td>10</td>
<td>112</td>
</tr>
</tbody>
</table>

The `status` variable indicates the true status of the phantoms: `status = 0` if they are normal and `status = 1` if they are abnormal.

We now compare the areas under the two ROC curves.

```

Comparing areas with a gold standard

The area under multiple ROC curves can be compared with a gold standard using `rocgold`. The command syntax is similar to that of `roccomp`. The tests are corrected for the effect of multiple comparisons.

Example 3

We will use the same data (presented by Hanley and McNeil [1983]) as in the `roccomp` examples. Let’s assume that the first modality is considered to be the standard against which both the second and third modalities are compared.

We want to plot and compare both the areas of the ROC curves of `mod2` and `mod3` with `mod1`. Because we consider `mod1` to be the gold standard, it is listed first after the reference variable in the `rocgold` command line.

```
. use https://www.stata-press.com/data/r18/ct2
   (Reconstruction of CT images)
. rocgold status mod1 mod2 mod3, graph summary
```

<table>
<thead>
<tr>
<th></th>
<th>ROC area</th>
<th>Std. err.</th>
<th>chi2</th>
<th>df</th>
<th>Pr&gt;chi2</th>
<th>Bonferroni Pr&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>mod1 (standard)</td>
<td>0.8828</td>
<td>0.0317</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>mod2</td>
<td>0.9302</td>
<td>0.0256</td>
<td>2.3146</td>
<td>1</td>
<td>0.1282</td>
<td>0.2563</td>
</tr>
<tr>
<td>mod3</td>
<td>0.9240</td>
<td>0.0241</td>
<td>5.2480</td>
<td>1</td>
<td>0.0220</td>
<td>0.0439</td>
</tr>
</tbody>
</table>

Equivalently, we could have done this in two steps by using the `roccomp` command.

```
. roccomp status mod1 mod2, graph summary
. roccomp status mod1 mod3, graph summary
```
Stored results

roccomp stores the following in r():

Scalars
\( r(N_g) \)  number of groups
\( r(p) \)  \( p \)-value for \( \chi^2 \) test
Matrices
\( r(V) \)  variance–covariance matrix

rocgold stores the following in r():

Scalars
\( r(N_g) \)  number of groups
Matrices
\( r(V) \)  variance–covariance matrix
\( r(chi2) \)  \( \chi^2 \) vector
\( r(p) \)  vector of \( p \)-values for \( \chi^2 \) tests
\( r(p_adj) \)  vector of adjusted \( p \)-values
\( r(df) \)  \( \chi^2 \) degrees-of-freedom vector

Methods and formulas

Assume that we applied a diagnostic test to each of \( N_n \) normal and \( N_a \) abnormal subjects. Further assume that the higher the outcome value of the diagnostic test, the higher the risk of the subject being abnormal. Let \( \hat{\theta} \) be the estimated area under the curve, and let \( X_i, i = 1, 2, \ldots, N_a \) and \( Y_j, j = 1, 2, \ldots, N_n \) be the values of the diagnostic test for the abnormal and normal subjects, respectively.

Areas under ROC curves are compared using an algorithm suggested by DeLong, DeLong, and Clarke-Pearson (1988). Let \( \hat{\theta} = (\hat{\theta}^1, \hat{\theta}^2, \ldots, \hat{\theta}^k) \) be a vector representing the areas under \( k \) ROC curves. See Methods and formulas in [R] roctab for the definition of these area estimates.

For the \( r \)th area, define
\[
V_{10}^r(X_i) = \frac{1}{N_n} \sum_{j=1}^{N_n} \psi(X_i^r, Y_j^r)
\]
and for each normal subject, \( j \), define
\[
V_{01}^r(Y_j) = \frac{1}{N_n} \sum_{i=1}^{N_n} \psi(X_i^r, Y_j^r)
\]
where
\[
\psi(X^r, Y^r) = \begin{cases} 
1 & Y^r < X^r \\
\frac{1}{2} & Y^r = X^r \\
0 & Y^r > X^r
\end{cases}
\]
Define the \( k \times k \) matrix \( S_{10} \) such that the \( (r, s) \)th element is
\[
S_{10}^{r,s} = \frac{1}{N_a - 1} \sum_{i=1}^{N_a} \{V_{10}^r(X_i) - \hat{\theta}^r\} \{V_{10}^s(X_i) - \hat{\theta}^s\}
\]
and \( S_{01} \) such that the \( (r, s) \)th element is
\[
S_{01}^{r,s} = \frac{1}{N_n - 1} \sum_{j=1}^{N_n} \{V_{01}^r(Y_i) - \hat{\theta}^r\} \{V_{01}^s(Y_i) - \hat{\theta}^s\}
\]
Then, the covariance matrix is
\[ S = \frac{1}{N_a} S_{10} + \frac{1}{N_n} S_{01} \]

Let \( L \) be a contrast matrix defining the comparison, so that
\[ (\hat{\theta} - \theta)'L'(LL')^{-1}L(\hat{\theta} - \theta) \]
has a \( \chi^2 \) distribution with degrees of freedom equal to the rank of \( LSL' \).

[R] **roctab** — Nonparametric ROC analysis
**Description**

rocfit fits maximum-likelihood ROC models assuming a binormal distribution of the latent variable.

The two variables refvar and classvar must be numeric. The reference variable indicates the true state of the observation, such as diseased and nondiseased or normal and abnormal, and must be coded as 0 and 1. The rating or outcome of the diagnostic test or test modality is recorded in classvar, which must be at least ordinal, with higher values indicating higher risk.

See [R] roc for other commands designed to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data.

**Quick start**

Binary true state, true, as a function of classification variable class

rocfit true class

Same as above, but with frequency weights wvar

rocfit true class [fweight = wvar]

Specify that class is continuous and generate v1 containing classification groups

rocfit true class, continuous(3) generate(v1)

**Menu**

Statistics > Epidemiology and related > ROC analysis > Parametric ROC analysis without covariates
Syntax

```
rocfit refvar classvar [ if ] [ in ] [ weight ] [ , rocfit_options ]
```

```
rocfit_options          Description

Model
  continuous(#)         divide classvar into # groups of approximately equal length
  generate(newvar)      create newvar containing classification groups

SE
  vce(vcetype)         vcetype may be oim or opg

Reporting
  level(#)             set confidence level; default is level(95)

Maximization
  maximize_options     control the maximization process; seldom used
```

collect and fp are allowed; see [U] 11.1.10 Prefix commands.

fweights are allowed; see [U] 11.1.6 weight.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

- `continuous(#)` specifies that the continuous `classvar` be divided into # groups of approximately equal length. This option is required when `classvar` takes on more than 20 distinct values.

- `continuous(.)` may be specified to indicate that `classvar` be used as it is, even though it could have more than 20 distinct values.

- `generate(newvar)` specifies the new variable that is to contain values indicating the groups produced by `continuous(#)`.

- `vce(vcetype)` specifies the type of standard error reported. `vcetype` may be either oim or opg; see [R] vce_option.

- `level(#)`; see [R] Estimation options.

- `maximize_options`: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

  Setting the optimization type to technique(bhhh) resets the default `vcetype` to vce(opg).
Remarks and examples

Dorfman and Alf (1969) developed a generalized approach for obtaining maximum likelihood estimates of the parameters for a smooth fitting ROC curve. The most commonly used method for ordinal data, and the one implemented here, is based upon the binormal model; see Pepe (2003), Pepe, Longton, and Janes (2009), and Janes, Longton, and Pepe (2009) for methods of ROC analysis for continuous data, including methods for adjusting for covariates.

The model assumes the existence of an unobserved, continuous, latent variable that is normally distributed (perhaps after a monotonic transformation) in both the normal and abnormal populations with means \( \mu_n \) and \( \mu_a \) and variances \( \sigma_n^2 \) and \( \sigma_a^2 \), respectively. The model further assumes that the \( K \) categories of the rating variable result from partitioning the unobserved latent variable by \( K - 1 \) fixed boundaries. The method fits a straight line to the empirical ROC points plotted using normal probability scales on both axes. Maximum likelihood estimates of the line’s slope and intercept and the \( K - 1 \) boundaries are obtained simultaneously. See Methods and formulas for details.

The intercept from the fitted line is a measurement of \((\mu_a - \mu_n)/\sigma_a\), and the slope measures \(\sigma_n/\sigma_a\).

Thus, the intercept is the standardized difference between the two latent population means, and the slope is the ratio of the two standard deviations. The null hypothesis that there is no difference between the two population means is evaluated by testing that the intercept = 0, and the null hypothesis that the variances in the two populations are equal is evaluated by testing that the slope = 1.

Example 1

We use Hanley and McNeil’s (1982) dataset, described in example 1 of [R] roctab, to fit a smooth ROC curve assuming a binormal model.

```
. use https://www.stata-press.com/data/r18/hanley
  (Tomographic images)
. rocfit disease rating
  Fitting binormal model:
Iteration 0:  Log likelihood = -123.68069
Iteration 1:  Log likelihood = -123.64867
Iteration 2:  Log likelihood = -123.64855
Iteration 3:  Log likelihood = -123.64855
Binormal model of disease on rating  Number of obs = 109
  Goodness-of-fit chi2(2) = 0.21
  Prob > chi2 = 0.9006
  Log likelihood = -123.64855

| Coefficient | Std. err. | z     | P>|z|   | [95% conf. interval] |
|-------------|-----------|-------|-------|----------------------|
| intercept   | 1.656782  | 0.310456 | 5.34  | 0.000  | 1.048300  | 2.265265  |
| slope (*)   | 0.713002  | 0.215882 | -1.33 | 0.184  | 0.289881  | 1.136123  |

| /cut2       | 0.463215  | 0.167235 | 2.77  | 0.006  | 0.135441  | 0.790990  |
| /cut3       | 0.766860  | 0.174808 | 4.39  | 0.000  | 0.424243  | 1.109477  |
| /cut4       | 1.797938  | 0.299581 | 6.00  | 0.000  | 1.210770  | 2.385106  |
```
rocfit outputs the MLE for the intercept and slope of the fitted regression line along with, here, four boundaries (because there are five ratings) labeled /cut1 through /cut4. Also rocfit computes and reports four indices based on the fitted ROC curve: the area under the curve (labeled ROC area), $\delta (m)$ (labeled delta(m)), $d_e$ (labeled d(e)), and $d_a$ (labeled d(a)). More information about these indices can be found in Methods and formulas and in Erdreich and Lee (1981).

(*) z test for slope==1

rocfit stores the following in e():

Scalars
- `e(N)` number of observations
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(ll)` log likelihood
- `e(chi2_gf)` goodness-of-fit $\chi^2$
- `e(df_gf)` goodness-of-fit degrees of freedom
- `e(p_gf)` $p$-value for goodness-of-fit test
- `e(area)` area under the ROC curve
- `e(se_area)` standard error for the area under the ROC curve
- `e(deltam)` delta(m)
- `e(se_delm)` standard area for delta(m)
- `e(de)` d(e) index
- `e(se_de)` standard error for d(e) index
- `e(da)` d(a) index
- `e(se_da)` standard error for d(a) index
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

Macros
- `e(cmd)` rocfit
- `e(cmdline)` command as typed
- `e(depvar)` `refvar` and `classvar`
- `e(vtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(chi2type)` GOF: type of model $\chi^2$ test
- `e(vcetype)` `vcetype` specified in `vce()`
- `e(properties)` `b V`
In addition to the above, the following is stored in `r()`: 

Matrices
- `r(table)`
  - matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

## Methods and formulas

Dorfman and Alf (1969) developed a general procedure for obtaining maximum likelihood estimates of the parameters of a smooth-fitting ROC curve. The most common method, and the one implemented in Stata, is based upon the binormal model.

The model assumes that there is an unobserved continuous latent variable that is normally distributed in both the normal and abnormal populations. The idea is better explained with the following illustration:

The latent variable is assumed to be normally distributed for both the normal and abnormal subjects, perhaps after a monotonic transformation, with means \( \mu_n \) and \( \mu_a \) and variances \( \sigma_n^2 \) and \( \sigma_a^2 \), respectively.

This latent variable is assumed to be partitioned into the \( k \) categories of the rating variable by \( k - 1 \) fixed boundaries. In the above figure, the \( k = 5 \) categories of the rating variable identified on the bottom result from the partition of the four boundaries \( Z_1 \) through \( Z_4 \).

Let \( R_j \) for \( j = 1, 2, \ldots, k \) indicate the categories of the rating variable, let \( i = 1 \) if the subject belongs to the normal group, and let \( i = 2 \) if the subject belongs to the abnormal group.
Then,

\[ p(R_j | i = 1) = F(Z_j) - F(Z_{j-1}) \]

where \( Z_k = (x_k - \mu_n) / \sigma_n \), \( F \) is the cumulative normal distribution, \( F(Z_0) = 0 \), and \( F(Z_k) = 1 \). Also,

\[ p(R_j | i = 2) = F(bZ_j - a) - F(bZ_{j-1} - a) \]

where \( b = \sigma_n / \sigma_a \) and \( a = (\mu_a - \mu_n) / \sigma_a \).

The parameters \( a, b \) and the \( k - 1 \) fixed boundaries \( Z_j \) are simultaneously estimated by maximizing the log-likelihood function

\[ \log L = \sum_{i=1}^{2} \sum_{j=1}^{k} r_{ij} \log \{ p(R_j | i) \} \]

where \( r_{ij} \) is the number of \( R_j \)'s in group \( i \).

The area under the fitted ROC curve is computed as

\[ \Phi \left( \frac{a}{\sqrt{1 + b^2}} \right) \]

where \( \Phi \) is the standard normal cumulative distribution function.

Point estimates for the ROC curve indices are as follows:

\[ \delta(m) = \frac{a}{b} \quad d_c = \frac{2a}{b+1} \quad d_a = \frac{a \sqrt{2}}{\sqrt{1 + b^2}} \]

Variances for these indices are computed using the delta method.

The \( \delta(m) \) estimates \((\mu_a - \mu_n)/\sigma_n\), \( d_c \) estimates \(2(\mu_a - \mu_n)/(\sigma_a - \sigma_n)\), and \( d_a \) estimates \(\sqrt{2}(\mu_a - \mu_n)/(\sigma_a^2 - \sigma_n^2)^2\).

Simultaneous confidence bands for the entire curve are obtained, as suggested by Ma and Hall (1993), by first obtaining Working–Hotelling (1929) confidence bands for the fitted straight line in normal probability coordinates and then transforming them back to ROC coordinates.

Description for rocplot

rocplot plots the fitted ROC curve and simultaneous confidence bands.

Menu for rocplot

Statistics > Epidemiology and related > ROC analysis > ROC curves after rocfit

Syntax for rocplot

rocplot [, rocplot_options]

rocplot_options Description

Main
confband display confidence bands
norefline suppress plotting the reference line
level(#) set confidence level; default is level(95)

Plot
plotopts(plot_options) affect rendition of the ROC points

Fit line
lineopts(cline_options) affect rendition of the fitted ROC line

CI plot
ciopts(area_options) affect rendition of the confidence bands

Reference line
rlopts(cline_options) affect rendition of the reference line

Add plots
addplot(plot) add other plots to the generated graph

Y axis, X axis, Titles, Legend, Overall
twoway_options any options other than by() documented in [G-3] twoway_options

plot_options Description

marker_options change look of markers (color, size, etc.)
marker_label_options add marker labels; change look or position
cline_options change look of the line
Options for rocplot

**Main**

- `confband` specifies that simultaneous confidence bands be plotted around the ROC curve.
- `norefline` suppresses plotting the 45-degree reference line from the graphical output of the ROC curve.
- `level(#)` specifies the confidence level, as a percentage, for the confidence bands. The default is `level(95)` or as set by `set level`; see 

**Plot**

- `plotopts(plot_options)` affects the rendition of the plotted ROC points, including the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected. For the full list of available `plot_options`, see [G-3] `marker_options`, [G-3] `marker_label_options`, and [G-3] `cline_options`.

**Fit line**

- `lineopts(cline_options)` affects the rendition of the fitted ROC line; see [G-3] `cline_options`.

**CI plot**

- `ciopts(area_options)` affects the rendition of the confidence bands; see [G-3] `area_options`.

**Reference line**

- `rlopts(cline_options)` affects the rendition of the reference line; see [G-3] `cline_options`.

**Add plots**

- `addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] `addplot_option`.

**Y axis, X axis, Titles, Legend, Overall**

- `twoway_options` are any of the options documented in [G-3] `twoway_options`, excluding by(). These include options for titling the graph (see [G-3] `title_options`) and for saving the graph to disk (see [G-3] `saving_option`).

Remarks and examples

Remarks are presented under the following headings:

- Using lincom and test
- Using rocplot

Using lincom and test

`intercept`, `slope`, and `/cut#`, shown in example 1 of [R] `rocfit`, are equation names and not variable names, so they need to be referenced as described in `Special syntaxes after multiple-equation estimation` of [R] `test`. For example, instead of typing

```
.test intercept
intercept not found
r(111);
```
you should type

```
.test [intercept]_cons
( 1) [intercept]_cons = 0
  chi2( 1) = 28.48
  Prob > chi2 = 0.0000
```

### Using rocplot

> Example 1

In example 1 of [R] `rocfit`, we fit a ROC curve by typing `rocfit disease rating`.

In the output table for our model, we are testing whether the variances of the two latent populations are equal by testing that the slope = 1.

We plot the fitted ROC curve.

```
. rocplot, confband
```

![ROC curve plot](image)

Area under curve = 0.9113  se(area) = 0.0295

[U] 20 Estimation and postestimation commands
Description

The `rocreg` command is used to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data under the presence of covariates.

The two variables `refvar` and `classvar` must be numeric. The reference variable indicates the true state of the observation—such as diseased and nondiseased or normal and abnormal—and must be coded as 0 and 1. The `refvar` coded as 0 can also be called the control population, while the `refvar` coded as 1 comprises the case population. The rating or outcome of the diagnostic test or test modality is recorded in `classvar`, which must be ordinal, with higher values indicating higher risk.

`rocreg` can fit three models: a nonparametric model, a parametric probit model that uses the bootstrap for inference, and a parametric probit model fit using maximum likelihood.

Quick start

**Nonparametric estimation with bootstrap resampling**

Area under the ROC curve for test classifier `v1` and true state `true` using seed 20547

```
rocreg true v1, bseed(20547)
```

Add `v2` as an additional classifier

```
rocreg true v1 v2, bseed(20547)
```

Same as above, but estimate ROC value for a false-positive rate of 0.7

```
rocreg true v1 v2, bseed(20547) roc(.7)
```

Covariate stratification of controls by categorical variable `a` using seed 121819

```
rocreg true v1 v2, bseed(121819) ctrlcov(a)
```

Linear control covariate adjustment with binary variable `b` and continuous variable `x`

```
rocreg true v1 v2, bseed(121819) ctrlcov(b x) ctrlmodel(linear)
```

**Parametric estimation**

Area under the ROC curve for test classifier `v1` and true state `true` by estimating equations using seed 200512

```
rocreg true v1, probit bseed(200512)
```

And save results to `myfile.dta` for use by `rocregplot`

```
rocreg true v1, probit bseed(200512) bsave(myfile)
```
Add \( v2 \) as a classifier and \( x \) as a control covariate in a linear control covariate-adjustment model

\[
\text{rocreg true v1 v2, probit bseed(200512) ctrlcov(x) ctrlmodel(linear)}
\]

Also treat \( x \) as a ROC covariate

\[
\text{rocreg true v1 v2, probit bseed(200512) ctrlcov(x) ctrlmodel(linear) roccov(x)}
\]

Estimate AUC by maximum likelihood instead of bootstrap resampling

\[
\text{rocreg true v1, probit ml}
\]
Syntax

Perform nonparametric analysis of ROC curve under covariates, using bootstrap

rocreg refvar classvar [ classvars ] [ if ] [ in ] [ , np_options ]

Perform parametric analysis of ROC curve under covariates, using bootstrap

rocreg refvar classvar [ classvars ] [ if ] [ in ], probit [ probit_options ]

Perform parametric analysis of ROC curve under covariates, using maximum likelihood

rocreg refvar classvar [ classvars ] [ if ] [ in ] [ weight ], probit ml [ probit_ml_options ]

np_options Description

Model

auc estimate total area under the ROC curve; the default
roc(numlist) estimate ROC for given false-positive rates
invroc(numlist) estimate false-positive rates for given ROC values
pauc(numlist) estimate partial area under the ROC curve (pAUC) up to each false-positive rate
cluster(varname) variable identifying resampling clusters
ctrlcov(varlist) adjust control distribution for covariates in varlist
ctrlmodel(strata|linear) stratify or regress on covariates; default is ctrlmodel(strata)
pvc(empirical|normal) use empirical or normal distribution percentile value estimates; default is pvc(empirical)
tiecorrected adjust for tied observations; not allowed with pvc(normal)

Bootstrap

nobootstrap do not perform bootstrap, just output point estimates
bseed(#) random-number seed for bootstrap
breps(#) number of bootstrap replications; default is breps(1000)
bootcc perform case–control (stratified on refvar) sampling rather than cohort sampling in bootstrap
nobstrata ignore covariate stratification in bootstrap sampling
nodots suppress bootstrap replication dots

Reporting

level(#) set confidence level; default is level(95)
### Description

**Model**

- **`probit`**: fit the probit model
- **`roccov(varlist)`**: covariates affecting ROC curve
- **`fprpts(#)`**: number of false-positive rate points to use in fitting ROC curve; default is `fprpts(10)`
- **`ctrlfprall`**: fit ROC curve at each false-positive rate in control population
- **`cluster(varname)`**: variable identifying resampling clusters
- **`ctrlcov(varlist)`**: adjust control distribution for covariates in `varlist`
- **`ctrlmodel(strata|linear)`**: stratify or regress on covariates; default is `ctrlmodel(strata)`
- **`pvc(empirical|normal)`**: use empirical or normal distribution percentile value estimates; default is `pvc(empirical)`
- **`tiecorrected`**: adjust for tied observations; not allowed with `pvc(normal)`

**Bootstrap**

- **`nobootstrap`**: do not perform bootstrap, just output point estimates
- **`bseed(#)`**: random-number seed for bootstrap
- **`breps(#)`**: number of bootstrap replications; default is `breps(1000)`
- **`bootcc`**: perform case–control (stratified on `refvar`) sampling rather than cohort sampling in bootstrap
- **`nobstrata`**: ignore covariate stratification in bootstrap sampling
- **`nodots`**: suppress bootstrap replication dots
- **`bsave(filename,...)`**: save bootstrap replicates from parametric estimation
- **`bfile(filename)`**: use bootstrap replicates dataset for estimation replay

**Reporting**

- **`level(#)`**: set confidence level; default is `level(95)`

*`probit` is required.*
**probit_ml_options**

*probit and ml are required.

fweights, iweights, and pweights are allowed with maximum likelihood estimation; see [U] 11.1.6 weight.

collect is allowed; see [U] 11.1.10 Prefix commands.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

Options are presented under the following headings:

* Options for nonparametric ROC estimation, using bootstrap
* Options for parametric ROC estimation, using bootstrap
* Options for parametric ROC estimation, using maximum likelihood

### Options for nonparametric ROC estimation, using bootstrap

- auc estimates the total area under the ROC curve. This is the default summary statistic.
- roc(numlist) estimates the ROC corresponding to each of the false-positive rates in numlist. The values of numlist must be in the range (0,1).
- invroc(numlist) estimates the false-positive rates corresponding to each of the ROC values in numlist. The values of numlist must be in the range (0,1).
- pauc(numlist) estimates the partial area under the ROC curve up to each false-positive rate in numlist. The values of numlist must in the range (0,1).
- cluster(varname) specifies the variable identifying resampling clusters.
- ctrlcov(varlist) specifies the covariates to be used to adjust the control population.
- ctrlmodel(strata|linear) specifies how to model the control population of classifiers on ctrlcov(). When ctrlmodel(linear) is specified, linear regression is used. The default is ctrlmodel(strata); that is, the control population of classifiers is stratified on the control variables.
pvc(empirical | normal) determines how the percentile values of the control population will be calculated. When pvc(normal) is specified, the standard normal cumulative distribution function (CDF) is used for calculation. Specifying pvc(empirical) will use the empirical CDFs of the control population classifiers for calculation. The default is pvc(empirical).

tiecorrected adjusts the percentile values for ties. For each value of the classifier, one half the probability that the classifier equals that value under the control population is added to the percentile value. tiecorrected is not allowed with pvc(normal).

Bootstrap

nobootstrap specifies that bootstrap standard errors not be calculated.

bseed(#) specifies the random-number seed to be used in the bootstrap.

breps(#) sets the number of bootstrap replications. The default is breps(1000).

bootcc performs case–control (stratified on refvar) sampling rather than cohort bootstrap sampling.

nobstrata ignores covariate stratification in bootstrap sampling.

nodots suppresses bootstrap replication dots.

Reporting

level(#) specifies the reporting level; see [R] Estimation options.

Options for parametric ROC estimation, using bootstrap

Model

probit fits the probit model. This option is required and implies parametric estimation.

roccov(varlist) specifies the covariates that will affect the ROC curve.

fprpts(#) sets the number of false-positive rate points to use in modeling the ROC curve. These points form an equispaced grid on (0,1). The default is fprpts(10).

ctrlfprall models the ROC curve at each false-positive rate in the control population.

cluster(varname) specifies the variable identifying resampling clusters.

ctrlcov(varlist) specifies the covariates to be used to adjust the control population.

ctrlmodel(strata | linear) specifies how to model the control population of classifiers on ctrlcov(). When ctrlmodel(linear) is specified, linear regression is used. The default is ctrlmodel(strata); that is, the control population of classifiers is stratified on the control variables.

pvc(empirical | normal) determines how the percentile values of the control population will be calculated. When pvc(normal) is specified, the standard normal CDF is used for calculation. Specifying pvc(empirical) will use the empirical CDFs of the control population classifiers for calculation. The default is pvc(empirical).

tiecorrected adjusts the percentile values for ties. For each value of the classifier, one half the probability that the classifier equals that value under the control population is added to the percentile value. tiecorrected is not allowed with pvc(normal).

Bootstrap

nobootstrap specifies that bootstrap standard errors not be calculated.
bseed(#) specifies the number of bootstrap replications. The default is breps(1000).

bootcc performs case–control (stratified on refvar) sampling rather than cohort bootstrap sampling.

nobstrata ignores covariate stratification in bootstrap sampling.

dots suppresses bootstrap replication dots.

bsave(filename, ...) saves bootstrap replicates from parametric estimation in the given filename with specified options (that is, replace). bsave() is only allowed with parametric analysis using bootstrap.

bfile(filename) specifies to use the bootstrap replicates dataset for estimation replay. bfile() is only allowed with parametric analysis using bootstrap.

---

level(#) ; see [R] Estimation options.

---

**Options for parametric ROC estimation, using maximum likelihood**

---

**Model**

probit fits the probit model. This option is required and implies parametric estimation.

ml fits the probit model by maximum likelihood estimation. This option is required and must be specified with probit.

roccov(varlist) specifies the covariates that will affect the ROC curve.

cluster(varname) specifies the variable used for clustering.

ctrlcov(varlist) specifies the covariates to be used to adjust the control population.

---

level(#) ; see [R] Estimation options.

display_options: noomitted, cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

---

**Maximization**

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used. The technique(bhhh) option is not allowed.

---

**Remarks and examples**

Remarks are presented under the following headings:

- Introduction
- ROC statistics
- Covariate-adjusted ROC curves
- Parametric ROC curves: Estimating equations
- Parametric ROC curves: Maximum likelihood
**Introduction**

Receiver operating characteristic (ROC) analysis provides a quantitative measure of the accuracy of diagnostic tests to discriminate between two states or conditions. These conditions may be referred to as normal and abnormal, nondiseased and diseased, or control and case. We will use these terms interchangeably. The discriminatory accuracy of a diagnostic test is measured by its ability to correctly classify known control and case subjects.

The analysis uses the ROC curve, a graph of the sensitivity versus $1 - \text{specificity}$ of the diagnostic test. The sensitivity is the fraction of positive cases that are correctly classified by the diagnostic test, whereas the specificity is the fraction of negative cases that are correctly classified. Thus, the sensitivity is the true-positive rate, and the specificity is the true-negative rate. We also call $1 - \text{specificity}$ the false-positive rate.

These rates are functions of the possible outcomes of the diagnostic test. At each outcome, a decision will be made by the user of the diagnostic test to classify the tested subject as either normal or abnormal. The true-positive and false-positive rates measure the probability of correct classification or incorrect classification of the subject as abnormal. Given the classification role of the diagnostic test, we will refer to it as the classifier.

Using this basic definition of the ROC curve, Pepe (2000) and Pepe (2003) describe how ROC analysis can be performed as a two-stage process. In the first stage, the control distribution of the classifier is estimated. The specificity is then determined as the percentiles of the classifier values calculated based on the control population. The false-positive rates are calculated as $1 - \text{specificity}$. In the second stage, the ROC curve is estimated as the cumulative distribution of the case population’s “false-positive” rates, also known as the survival function under the case population of the previously calculated percentiles. We use the terms ROC value and true-positive value interchangeably.

This formulation of ROC curve analysis provides simple, nonparametric estimates of several ROC curve summary parameters: area under the ROC curve, partial area under the ROC curve, ROC value for a given false-positive rate, and false-positive rate (also known as invROC) for a given ROC value. In the next section, we will show how to use rocreg to compute these estimates with bootstrap inference. There we will also show how rocreg complements the other nonparametric Stata ROC commands roctab and roccomp.

Other factors beyond condition status and the diagnostic test may affect both stages of ROC analysis. For example, a test center may affect the control distribution of the diagnostic test. Disease severity may affect the distribution of the standardized diagnostic test under the case population. Our analysis of the ROC curve in these situations will be more accurate if we take these covariates into account.

In a nonparametric ROC analysis, covariates may only affect the first stage of estimation; that is, they may be used to adjust the control distribution of the classifier. In a parametric ROC analysis, it is assumed that ROC follows a normal distribution, and thus covariates may enter the model at both stages; they may be used to adjust the control distribution and to model ROC as a function of these covariates and the false-positive rate. In parametric models, both sets of covariates need not be distinct but, in fact, they are often the same.

To model covariate effects on the first stage of ROC analysis, Janes and Pepe (2009) propose a covariate-adjusted ROC curve. We will demonstrate the covariate adjustment capabilities of rocreg in Covariate-adjusted ROC curves.

To account for covariate effects at the second stage, we assume a parametric model. Particularly, the ROC curve is a generalized linear model of the covariates. We will thus have a separate ROC curve for each combination of the relevant covariates. In Parametric ROC curves: Estimating equations, we show how to fit the model with estimating equations and bootstrap inference using rocreg.
This method, documented as the “pdf” approach in Alonzo and Pepe (2002), works well with weak assumptions about the control distribution.

Also in Parametric ROC curves: Estimating equations, we show how to fit a constant-only parametric model (involving no covariates) of the ROC curve with weak assumptions about the control distribution. The constant-only model capabilities of rocreg in this context will be compared with those of rocfit. roccomp has the binormal option, which will allow it to compute area under the ROC curve according to a normal ROC curve, equivalent to that obtained by rocfit. We will compare this functionality with that of rocreg.

In Parametric ROC curves: Maximum likelihood, we demonstrate maximum likelihood estimation of the ROC curve model with rocreg. There we assume a normal linear model for the classifier on the covariates and case–control status. This method is documented in Pepe (2003). We will also demonstrate how to use this method with no covariates, and we will compare rocreg under the constant-only model with rocfit and roccomp.

The rocregplot command is used repeatedly in this entry. This command provides graphical output for rocreg and is documented in [R] rocregplot.

ROC statistics

roctab computes the ROC curve by calculating the false-positive rate and true-positive rate empirically at every value of the input classifier. It makes no distributional assumptions about the case or control distributions. We can get identical behavior from rocreg by using the default option settings.

Example 1: Nonparametric ROC, AUC

Hanley and McNeil (1982) presented data from a study in which a reviewer was asked to classify, using a five-point scale, a random sample of 109 tomographic images from patients with neurological problems. The rating scale was as follows: 1 is definitely normal, 2 is probably normal, 3 is questionable, 4 is probably abnormal, and 5 is definitely abnormal. The true disease status was normal for 58 of the patients and abnormal for the remaining 51 patients.
Here we list 9 of the 109 observations:

```
. use https://www.stata-press.com/data/r18/hanley
     (Tomographic images)
. list disease rating in 1/9

<table>
<thead>
<tr>
<th>disease</th>
<th>rating</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1 5</td>
</tr>
<tr>
<td>2</td>
<td>0 1</td>
</tr>
<tr>
<td>3</td>
<td>1 5</td>
</tr>
<tr>
<td>4</td>
<td>0 4</td>
</tr>
<tr>
<td>5</td>
<td>0 1</td>
</tr>
<tr>
<td>6</td>
<td>0 3</td>
</tr>
<tr>
<td>7</td>
<td>1 5</td>
</tr>
<tr>
<td>8</td>
<td>0 5</td>
</tr>
<tr>
<td>9</td>
<td>0 1</td>
</tr>
</tbody>
</table>
```

For each observation, disease identifies the true disease status of the subject (0 is normal, 1 is abnormal), and rating contains the classification value assigned by the reviewer.

We run roctab on these data, specifying the graph option so that the ROC curve is rendered. We then calculate the false-positive and true-positive rates of the ROC curve by using rocreg. We graph the rates with rocregplot. Because we focus on rocreg output later, for now we use the quietly prefix to omit the output of rocreg. Both graphs are combined using graph combine (see [G-2] graph combine) for comparison. To ease the comparison, we specify the aspectratio(1) option in roctab; this is the default aspect ratio in rocregplot.

```
. roctab disease rating, graph aspectratio(1) name(a) nodraw title("roctab")
. quietly rocreg disease rating
. rocregplot, name(b) nodraw legend(off) title("rocreg")
. graph combine a b
```

Both roctab and rocreg compute the same false-positive rate and ROC values. The stairstep line connection style of the graph on the right emphasizes the empirical nature of its estimates. The control distribution of the classifier is estimated using the empirical CDF estimate. Similarly, the ROC curve, the distribution of the resulting case observation false-positive rate values, is estimated using the empirical CDF. Note the footnote in the roctab plot. By default, roctab will estimate the area
under the ROC curve (AUC) using a trapezoidal approximation to the estimated false-positive rate and true-positive rate points.

The AUC can be interpreted as the probability that a randomly selected member of the case population will have a larger classifier value than a randomly selected member of the control population. It can also be viewed as the average ROC value, averaged uniformly over the (0,1) false-positive rate domain (Pepe 2003).

The nonparametric estimator of the AUC (DeLong, DeLong, and Clarke-Pearson 1988; Hanley and Hajian-Tilaki 1997) used by rocreg is equivalent to the sample mean of the percentile values of the case observations. Thus to calculate the nonparametric AUC estimate, we only need to calculate the percentile values of the case observations with respect to the control distribution.

This estimate can differ from the trapezoidal approximation estimate. Under discrete classification data, like we have here, there may be ties between classifier values from case to control. The trapezoidal approximation uses linear interpolation between the classifier values to correct for ties. Correcting the nonparametric estimator involves adding a correction term to each observation’s percentile value, which measures the probability that the classifier is equal to (instead of less than) the observation’s classifier value.

The tie-corrected nonparametric estimate (trapezoidal approximation) is used when we think the true ROC curve is smooth. This means that the classifier we measure is a discretized approximation of a true latent and a continuous classifier.

We now recompute the ROC curve of rating for classifying disease and calculate the AUC. Specifying the tiecorrected option allows tie correction to be used in the rocreg calculation. Under nonparametric estimation, rocreg bootstraps to obtain standard errors and confidence intervals for requested statistics. We use the default 1,000 bootstrap replications to obtain confidence intervals for our parameters. This is a reasonable lower bound to the number of replications (Mooney and Duval 1993) required for estimating percentile confidence intervals. By specifying the summary option in roctab, we will obtain output showing the trapezoidal approximation of the AUC estimate, along with standard error and confidence interval estimates for the trapezoidal approximation suggested by DeLong, DeLong, and Clarke-Pearson (1988).
The estimates of AUC match well. The standard error from \texttt{roctab} is close to the bootstrap standard error calculated by \texttt{rocreg}. The bootstrap standard error generalizes to the more complex models that we consider later, whereas the \texttt{roctab} standard-error calculation does not.

The AUC can be used to compare different classifiers. It is the most popular summary statistic for comparisons (Pepe, Longton, and Janes 2009). \texttt{roccomp} will compute the trapezoidal approximation of the AUC and graph the ROC curves of multiple classifiers. Using the DeLong, DeLong, and Clarke-Pearson (1988) covariance estimates for the AUC estimate, \texttt{roccomp} performs a Wald test of the null hypothesis that all classifier AUC values are equal. \texttt{rocreg} has similar capabilities.

\textbf{Example 2: Nonparametric ROC, AUC, multiple classifiers}

Hanley and McNeil (1983) presented data from an evaluation of two computer algorithms designed to reconstruct CT images from phantoms. We will call these two algorithms modalities 1 and 2. A sample of 112 phantoms was selected; 58 phantoms were considered normal, and the remaining 54 phantoms were considered abnormal. The data were analyzed using the \texttt{rocreg} command with the \texttt{tiecorrected} option and the \texttt{asymptotic normal} option for the standard error calculation. The bootstrap standard error was also calculated using the \texttt{bootstrap} command. The results show that the AUC is close to 1, indicating excellent classification performance.

The \texttt{roccomp} command was used to compare the two algorithms using the DeLong, DeLong, and Clarke-Pearson (1988) covariance estimates for the AUC estimate. The test showed that there was no significant difference between the two algorithms, with a p-value of 0.34.

Confidence intervals for the AUC were calculated using the \texttt{roctab} command with the \texttt{asymptotic normal} option for the standard error calculation. The confidence intervals were (0.83, 0.95) for modality 1 and (0.82, 0.95) for modality 2, indicating that both algorithms have excellent classification performance.

The ROC curves were graphed using the \texttt{roccomp} command, which showed that both algorithms have excellent classification performance, with the area under the ROC curve close to 1.
were abnormal. Each of the two modalities was applied to each phantom, and the resulting images were rated by a reviewer using a six-point scale: 1 is definitely normal, 2 is probably normal, 3 is possibly normal, 4 is possibly abnormal, 5 is probably abnormal, and 6 is definitely abnormal. Because each modality was applied to the same sample of phantoms, the two sets of outcomes are correlated.

We list the first seven observations:

```
use https://www.stata-press.com/data/r18/ct, clear
(Reconstruction of CT images)
list in 1/7, sep(0)
```

<table>
<thead>
<tr>
<th>mod1</th>
<th>mod2</th>

</tr>
<tr>
<td>2</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

Each observation corresponds to one phantom. The mod1 variable identifies the rating assigned for the first modality, and the mod2 variable identifies the rating assigned for the second modality. The true status of the phantoms is given by status==0 if they are normal and status==1 if they are abnormal. The observations with at least one missing rating were dropped from the analysis.

A fictitious dataset was created from this true dataset, adding a third test modality. We will use roccomp to compute the AUC statistic for each modality in these data and compare the AUC of the three modalities. We obtain the same behavior from rocreg. As before, the tiecorrected option is specified so that the AUC is calculated with the trapezoidal approximation.

H0: All classifiers have equal AUC values
Ha: At least one classifier has a different AUC value
P-value: .0339546 Test based on bootstrap (N) assumptions.

We see that the AUC estimates are equivalent, and the standard errors are quite close as well. The p-value for the tests of equal AUC under rocreg leads to similar inference as the p-value from roccomp. The Wald test performed by rocreg uses the joint bootstrap estimate variance matrix of the three AUC estimators rather than the DeLong, DeLong, and Clarke-Pearson (1988) variance estimate used by roccomp.

roccomp is used here on potentially correlated classifiers that are recorded in wide-format data. It can also be used on long-format data to compare independent classifiers. Further details can be found in [R] roccomp.

Citing the AUC’s lack of clinical relevance, there is argument against using it as a key summary statistic of the ROC curve (Pepe 2003; Cook 2007). Pepe, Longton, and Janes (2009) suggest using the estimate of the ROC curve itself at a particular point, or the estimate of the false-positive rate at a given ROC value, also known as invROC.
Recall from example 1 how nonparametric rocreg graphs look, with the stairstep pattern in the ROC curve. In an ideal world, the graph would be a smooth one-to-one function, and it would be trivial to map a false-positive rate to its corresponding true-positive rate and vice versa.

However, smooth ROC curves can only be obtained by assuming a parametric model that uses linear interpolation between observed false-positive rates and between observed true-positive rates, and rocreg is certainly capable of that; see example 1 of [R] rocregplot. However, under nonparametric estimation, the mapping between false-positive rates and true-positive rates is not one to one, and estimates tend to be less reliable the further you are from an observed data point. This is somewhat mitigated by using tie-corrected rates (the tiecorrected option).

When we examine continuous data, the difference between the tie-corrected estimates and the standard estimates becomes negligible, and the empirical estimate of the ROC curve becomes close to the smooth ROC curve obtained by linear interpolation. So the nonparametric ROC and invROC estimates work well.

Fixing one rate value of interest can be difficult and subjective (Pepe 2003). A compromise measure is the partial area under the ROC curve (pAUC) (McClish 1989; Thompson and Zucchini 1989). This is the integral of the ROC curve from 0 and above to a given false-positive rate (perhaps the largest clinically acceptable value). Like the AUC estimate, the nonparametric estimate of the pAUC can be written as a sample average of the case observation percentiles, but with an adjustment based on the prescribed maximum false-positive rate (Dodd and Pepe 2003). A tie correction may also be applied so that it reflects the trapezoidal approximation.

We cannot compare rocreg with roctab or roccomp on the estimation of pAUC, because pAUC is not computed by the latter two.

Example 3: Nonparametric ROC, other statistics

To see how rocreg estimates ROC, invROC, and pAUC, we will examine a new study. Wieand et al. (1989) examined a pancreatic cancer study with two continuous classifiers, here called y1 (CA 19-9) and y2 (CA 125). This study was also examined in Pepe, Longton, and Janes (2009). The indicator of cancer in a subject is recorded as d. The study was a case–control study, stratifying participants on disease status.

We list the first five observations:

```
. use https://research.fredhutch.org/content/dam/stripe/diagnostic-biomarkers-
   > statistical-center/files/wiedat2b.dta, clear
   (S. Wieand - Pancreatic cancer diagnostic marker data)
. list in 1/5

+-----+-----+-----+
| y1  | y2  | d   |
+-----+-----+-----+
| 28  | 13.3| no  |
| 15.5| 11.1| no  |
| 8.2 | 16.7| no  |
| 3.4 | 12.6| no  |
| 17.3| 7.4 | no  |
+-----+-----+-----+
```

We will estimate the ROC curves at a large value (0.7) and a small value (0.2) of the false-positive rate. These values are specified in roc(). The false-positive rate for ROC or sensitivity value of 0.6 will also be estimated by specifying invroc(). Percentile confidence intervals for these parameters are displayed in the graph obtained by rocregplot after rocreg. The pAUC statistic will be calculated for the false-positive rate of 0.5, which is specified as an argument to the pauc() option. Following Pepe, Longton, and Janes (2009), we use a stratified bootstrap, sampling separately from the case
and control populations by specifying the `bootcc` option. This reflects the case–control nature of the study.

All four statistics can be estimated simultaneously by `rocreg`. For clarity, however, we will estimate each statistic with a separate call to `rocreg`. `rocregplot` is used after estimation to graph the ROC and false-positive rate estimates. The display of the individual, observation-specific false-positive rate and ROC values will be omitted in the plot. This is accomplished by specifying `msymbol(i)` in our `plot1opts()` and `plot2opts()` options to `rocregplot`.

In this study, we see that classifier \( y_1 \) (CA 19-9) is a uniformly better test than is classifier \( y_2 \) (CA 125) until high levels of false-positive rate and sensitivity or ROC value are reached. At the high level of false-positive rate, 0.7, the ROC value does not significantly differ between the two classifiers. This can be seen in the plot by the overlapping confidence intervals.

We also find significant evidence supporting the hypothesis that the pAUC for \( y_1 \) up to a false-positive rate of 0.5 differs from the area of the same region under the ROC curve of \( y_2 \).

### Covariate-adjusted ROC curves

When covariates affect the control distribution of the diagnostic test, thresholds for the test being classified as abnormal may be chosen that vary with the covariate values. These conditional thresholds will be more accurate than the marginal thresholds that would normally be used, because they take into account the specific distribution of the diagnostic test under the given covariate values as opposed to the marginal distribution over all covariate values.

By using these covariate-specific thresholds, we are essentially creating new classifiers for each covariate-value combination, and thus we are creating multiple ROC curves. As explained in Pepe (2003), when the case and control distributions of the covariates are the same, the marginal ROC curve will always be bound above by these covariate-specific ROC curves. So using conditional thresholds will never provide a less powerful test diagnostic in this case.
In the marginal ROC curve calculation, the classifiers are standardized to percentiles according to the control distribution, marginalized over the covariates. Thus, the ROC curve is the CDF of the standardized case observations. The covariate-adjusted ROC curve is the CDF of one minus the conditional control percentiles for the case observations, and the marginal ROC curve is the CDF of one minus the marginal control percentiles for the case observations (Pepe and Cai 2004). Thus, the standardization of classifier to false-positive rate value is conditioned on the specific covariate values under the covariate-adjusted ROC curve.

The covariate-adjusted ROC curve (Janes and Pepe 2009) at a given false-positive rate $t$ is equivalent to the expected value of the covariate-specific ROC at $t$ over all covariate combinations. When the covariates in question do not affect the case distribution of the classifier, the covariate-specific ROC will have the same value at each covariate combination. So here the covariate-adjusted ROC is equivalent to the covariate-specific ROC, regardless of covariate values.

When covariates do affect the case distribution of the classifier, users of the diagnostic test would likely want to model the covariate-specific ROC curves separately. Tools to do this can be found in the parametric modeling discussion in the following two sections. Regardless, the covariate-adjusted ROC curve can serve as a meaningful summary of covariate-adjusted accuracy.

Also note that the ROC summary statistics defined in the previous section have covariate-adjusted analogs. These analogs are estimated in a similar manner as under the marginal ROC curve (Janes, Longton, and Pepe 2009). The options for their calculation in rocreg are identical to those given in the previous section. Further details can be found in Methods and formulas.

Example 4: Nonparametric ROC, linear covariate adjustment

Norton et al. (2000) studied data from a neonatal audiology study on three tests to identify hearing impairment in newborns. These data were also studied in Janes, Longton, and Pepe (2009). Here we list 5 of the 5,058 observations.

The classifiers $y_1$ (DPOAE 65 at 2 kHz), $y_2$ (TEOAE 80 at 2 kHz), and $y_3$ (ABR) and the hearing impairment indicator $d$ are recorded along with some relevant covariates. The infant’s age is recorded in months as currage, and the infant’s gender is indicated by male. Over 90% of the newborns were tested in each ear (ear), so we will cluster on infant ID (id).

Following the strategy of Janes, Longton, and Pepe (2009), we will first perform ROC analysis for the classifiers while adjusting for the covariate effects of the infant’s gender and age. This is done by specifying these variables in the ctrlcov() option. We adjust using a linear regression rule, by specifying ctrlmodel(linear). This means that when a user of the diagnostic test chooses a threshold conditional on the age and gender covariates, they assume that the diagnostic test classifier has some linear dependence on age and gender and equal variance as their levels vary. Our cluster adjustment is made by specifying the cluster() option.
We will focus on the first classifier. The percentile, or specificity, values are calculated empirically by default, and thus so are the false-positive rates, \((1 - \text{specificity})\). Also by default, the ROC curve values are empirically defined by the false-positive rates. To draw the ROC curve, we again use `rocregplot`.

The AUC is calculated by default. For brevity, we specify the `nobootstrap` option so that bootstrap sampling is not performed. The AUC point estimate will be sufficient for our purposes.

Our covariate control adjustment model shows that `currage` has a negative effect on `y1` (DPOAE 65 at 2 kHz) under the control population. At the 0.001 significance level, we reject that its contribution to `y1` is zero, and the point estimate has a negative sign. This result does not directly tell us about the effect of `currage` on the ROC curve of `y1` as a classifier of `d`. None of the case observations are used in the linear regression, so information on `currage` for abnormal cases is not used in the model. This result does show us how to calculate false-positive rates for tests that use thresholds conditional on a child’s sex and current age. We will see how `currage` affects the ROC curve when `y1` is used as a classifier and conditional thresholds are used based on `male` and `currage` in the following section, *Parametric ROC curves: Estimating equations.*

### Technical note

Under this nonparametric estimation, `rocreg` saved the false-positive rate for each observation’s `y1` values in the utility variable `_fpr_y1`. The true-positive rates are stored in the utility variable `_roc_y1`. For other models, say with classifier `yname`, these variables would be named `_fpr_yname` and `_roc_yname`. They will also be overwritten with each call of `rocreg`. The variables `_roc_*` and `_fpr_*` are usually for internal `rocreg` use only and are overwritten with each call of `rocreg`. They are only created for nonparametric models or parametric models that do not involve ROC covariates. In these models, covariates may only affect the first stage of estimation, the control distribution, and not the ROC curve itself. In parametric models that allow ROC covariates, different covariate values would lead to different ROC curves.

To see how the covariate-adjusted ROC curve estimate differs from the standard marginal estimate, we will reestimate the ROC curve for classifier `y1` without covariate adjustment. We rename these variables before the new estimation and then draw an overlaid `twoway line` (see [G-2] graph `twoway line`) plot to compare the two.

Though they are close, particularly in AUC, there are clearly some points of difference between the estimates. So the covariate-adjusted ROC curve may be useful here.

In our examples thus far, we have used the empirical CDF estimator to estimate the control distribution. rocreg allows some flexibility here. The pvc(normal) option may be specified to calculate the percentile values according to a Gaussian distribution of the control.

Covariate adjustment in rocreg may also be performed with stratification instead of linear regression. Under the stratification method, the unique values of the stratified covariates each define separate parameters for the control distribution of the classifier. A user of the diagnostic test chooses a threshold based on the control distribution conditioned on the unique covariate value parameters.

We will demonstrate the use of normal percentile values and covariate stratification in our next example.
Example 5: Nonparametric ROC, covariate stratification

The hearing test study of Stover et al. (1996) examined the effectiveness of negative signal-to-noise ratio, $nsnr$, as a classifier of hearing loss. The test was administered under nine different settings, corresponding to different frequency, $xf$, and intensity, $xl$, combinations. Here we list 10 of the 1,848 observations.

Hearing loss is represented by $d$. The covariate $xd$ is a measure of the degree of hearing loss. We will use this covariate in later analysis, because it only affects the case distribution of the classifier. Multiple measurements are taken for each individual, $id$, so we will cluster by individual.

We evaluate the effectiveness of $nsnr$ using $xf$ and $xl$ as stratification covariates with `rocreg`; the default method of covariate adjustment.

As mentioned before, the default false-positive rate calculation method in `rocreg` estimates the conditional control distribution of the classifiers empirically. For comparison, we will also estimate a separate ROC curve using false-positive rates assuming the conditional control distribution is normal. This behavior is requested by specifying the `pvc(normal)` option. Using the `rocregplot` option `name()` to store the ROC plots and using the `graph combine` command, we are able to compare the Gaussian and empirical ROC curves side by side. As before, for brevity we specify the `nobootstrap` option to suppress bootstrap sampling.

On cursory visual inspection, we see little difference between the two curves. The AUC values are close as well. So it is sensible to assume that we have Gaussian percentile values for control standardization.

Parametric ROC curves: Estimating equations

We now assume a parametric model for covariate effects on the second stage of ROC analysis. Particularly, the ROC curve is a probit model of the covariates. We will thus have a separate ROC curve for each combination of the relevant covariates.

Under weak assumptions about the control distribution of the classifier, we can fit this model by using estimating equations as described in Alonzo and Pepe (2002). This method can be also be used without covariate effects in the second stage, assuming a parametric model for the single (constant only) ROC curve. Covariates may still affect the first stage of estimation, so we parametrically model the single covariate-adjusted ROC curve (from the previous section). The marginal ROC curve, involving no covariates in either stage of estimation, can be fit parametrically as well.
In addition to the Alonzo and Pepe (2002) explanation, further details are given in Pepe, Longton, and Janes (2009); Janes, Longton, and Pepe (2009); Pepe (2003); and Janes and Pepe (2009).

The parametric models that we consider assume that the ROC curve is a cumulative distribution function $g$ invoked with input of a linear polynomial in the corresponding quantile function invoked on the false-positive rate $u$. In this context, we assume that $g$ corresponds to a standard normal cumulative distribution function, $\Phi$. So the corresponding quantile function is $\Phi^{-1}$. The constant intercept of the polynomial may depend on covariates, but the slope term $\alpha$ (the quantile coefficient) may not.

\[
\text{ROC}(u) = g\{x'\beta + \alpha g^{-1}(u)\}
\]

The first step of the algorithm involves the choice of false-positive rates to use in the parametric fit. These are typically a set of equispaced points spanning the interval $(0,1)$. Alonzo and Pepe (2002) examined the effect of fitting large and small sets of points, finding that relatively small sets could be used with little loss of efficiency. Alternatively, the set can be formed by using the observed false-positive rates in the data (Pepe 2003). Further details on the algorithm are provided in Methods and formulas.

Under parametric estimation, all the summary measures we defined earlier, except the AUC, are not calculated until postestimation. In models with covariates, each covariate combination would yield a different ROC curve and thus different summary parameters, so no summary parameters are initially estimated. In marginal parametric models (where there are no ROC covariates, but there are potentially control covariates), we will calculate the AUC and leave the other measures for postestimation; see [R] rocreg postestimation. As with the other parameters, we bootstrap for standard errors and inference.

We will now demonstrate how rocreg performs the Alonzo and Pepe (2002) algorithm using the previous section’s examples and others.

**Example 6: Parametric ROC, linear covariate adjustment**

We return to the neonatal audiology study with gender and age covariates (Norton et al. 2000), which we discussed in example 4. Janes, Longton, and Pepe (2009) suspected the current age of the infant would play a role in the case distribution of the classifier $y_1$ (DPOAE 65 at 2 kHz). They postulated a probit link between the ROC curve and the covariate-adjusted false-positive rates. We follow their investigation and reach similar results.

In example 4, we saw the results of adjusting for the currage and male variables in the control population for classifier $y_1$. Now, we see how currage affects the ROC curve when $y_1$ is used with thresholds conditioned on male and currage.

We specify the covariates that should affect the ROC curve in the roccov() option. By default, rocreg will choose 10 equally spaced false-positive rates in the $(0,1)$ interval as fitting points. The fprpts() option allows the user to specify more or fewer points. We specify the bsave() option with the nnh2y1 dataset so that we can use the bootstrap resamples in postestimation.

Note how the number of clusters—here infants—changes from the covariate control adjustment model fit to the ROC model. The control fit is limited to control cases and thus fewer infants. The ROC is fit on all the data, so the variance is adjusted for all clustering on all infants.

With a 0.05 level of statistical significance, we cannot reject the null hypothesis that currage has no effect on the ROC curve at a given false-positive rate. This is because each of our 95% bootstrap confidence intervals contains 0. This corresponds with the finding in Janes, Longton, and Pepe (2009) where the reported 95% intervals each contained 0. We cannot reject that the intercept parameter \( \beta_0 \), reported as _cons in the main table, is 0 at the 0.05 level either. The slope parameter \( \alpha \), reported
as _cons in the probit table, is close to 1 and cannot be rejected as being 1 at the 0.05 level. Under the assumption that the ROC coefficients except \( \alpha \) are 0 and that \( \alpha = 1 \), the ROC curve at false-positive rate \( u \) is equal to \( u \). In other words, we cannot reject that the false-positive rate is equal to the true-positive rate, and so the test is noninformative. Further investigation of the results requires postestimation; see [R] rocreg postestimation.

The fitting point set can be formed by using the observed false-positive rates (Pepe 2003). Our next example will illustrate this.

#### Example 7: Parametric ROC, covariate stratification

We return to the hearing test study of Stover et al. (1996), which we discussed in example 5. Pepe (2003) suspected that intensity, \( xd \), would play a role in the case distribution of the negative signal-to-noise ratio (nsnr) classifier. A ROC regression was fit with covariate adjustment for \( xf \) and \( xl \) with stratification, and for ROC covariates \( xf \), \( xl \), and \( xd \). There is no prohibition against the same covariate being used in the first and second stages of ROC calculation. The false-positive rate fitting point set was composed of all observed false-positive rates in the control data.

We fit the model with rocreg here. Using observed false-positive rates as the fitting point set can make the dataset very large, so fitting the model is computationally intensive. We demonstrate the fitting algorithm without precise confidence intervals, focusing instead on the coefficient estimates and standard errors. We will thus perform only 50 bootstrap replications, a reasonable number to obtain accurate standard error estimates (Mooney and Duval 1993). The number of replications is specified in the `brep()` option.

The ROC covariates are specified in roccov(). We specify that all observed false-positive rates in the control observations be used as fitting points with the `ctrlfprall` option. The `nobstrata` option specifies that the bootstrap is not stratified. The covariate stratification in the first stage of estimation does not affect the resampling. We will return to this example in postestimation, so we save the bootstrap results in the `nsnrf` dataset with the `bsave()` option.

We obtain results similar to those reported in Pepe (2003, 159). We find that the coefficients for xl and xd differ from 0 at the 0.05 level of significance. So over certain covariate combinations, we can have a variety of informative tests using nsnr as a classifier.

As mentioned before, when there are no covariates, rocreg can still fit a parametric model for the ROC curve of a classifier by using the Alonzo and Pepe (2002) method. roccomp and rocfit can fit marginal probit models as well. We will compare the behavior of rocreg with that of roccomp and rocfit for probit models without covariates.

When the binormal option is specified, roccomp calculates the AUC for input classifiers according to the maximum likelihood algorithm of rocfit. The rocfit algorithm expects discrete classifiers but can slice continuous classifiers into discrete partitions. Further, the case and control distributions are both assumed normal. Actually, the observed classification values are taken as discrete indicators of the latent normally distributed classification values. This method is documented in Dorfman and Alf (1969).
Alonzo and Pepe (2002) compared their estimating equations probability density function method (with empirical estimation of the false-positive rates) to the maximum likelihood approach of Dorfman and Alf (1969) and found that they had similar efficiency and mean squared error. So we should expect `rocfit` and `rocreg` to give similar results when fitting a simple probit model.

Example 8: Parametric ROC, marginal model

We return to the Hanley and McNeil (1982) data. We will fit a probit model to the ROC curve, assuming that the `rating` variable is a discrete indicator of an underlying latent normal random variable in both the case and control populations of `disease`. We invoke `rocfit` with the default options. `rocreg` is invoked with the `probit` option. The percentile values are calculated empirically. Because there are fewer categories than 10, there will be fewer than 10 false-positive rates that trigger a different true-positive rate value. So for efficiency, we invoke `rocreg` with the `ctrlfprall` option.

We see that the intercept and slope parameter estimates are close. The intercept (cons in the main table) is clearly nonzero. Under rocreg, the slope (cons in the probit table) and its percentile and bias-corrected confidence intervals are close to those of rocfit. The area under the ROC curve for each of the rocreg and rocfit estimators also matches closely.

Now, we will compare the parametric fit of rocreg under the constant probit model with roccomp.

Example 9: Parametric ROC, marginal model, multiple classifiers

We now use the fictitious dataset generated from Hanley and McNeil (1983). To fit a probit model using roccomp, we specify the binormal option. Our specification of rocreg remains the same as before.

rocregplot is used to render the model produced by rocreg. We specify several graph options to both roccomp and rocregplot to ease comparison. When the binormal option is specified along with graph, roccomp will draw the binormal fitted lines in addition to connected line plots of the empirical false-positive and true-positive rates.

In this plot, we overlay scatterplots of the empirical false-positive rates (because percentile value calculation defaulted to pvc(empirical)) and the parametric true-positive rates.

**H0**: All classifiers have equal AUC values

**Ha**: At least one classifier has a different AUC value

**P-value**: 0.0599896 Test based on bootstrap (N) assumptions.

```
. rocregplot, title(rocreg) nodraw name(b)
> plot1opts(msymbol(o)) plot2opts(msymbol(s)) plot3opts(msymbol(t))
```
We see differing true-positive rate values in the scattered points, which is expected because `roccomp` gives the empirical estimate and `rocreg` gives the parametric estimate. However, the estimated curves and areas under the ROC curve look similar. Using the Wald test based on the bootstrap covariance, `rocreg` rejects the null hypothesis that each test has the same AUC at the 0.1 significance level. `roccomp` formulates the asymptotic covariance using the `rocfit` estimates of AUC. Examination of its output leads to rejection of the null hypothesis that the AUCs are equal across each test at the 0.05 significance level.

**Parametric ROC curves: Maximum likelihood**

The Alonzo and Pepe (2002) method of fitting a parametric model to the ROC curve is powerful because it can be generally applied, but that can be a limitation as well. Whenever we invoke the method and want anything other than point estimates of the parameters, we must perform bootstrap resampling.

An alternative is to use maximum likelihood inference to fit the ROC curve. This method can save computational time by avoiding the bootstrap.

`rocreg` implements maximum likelihood estimation for ROC curve analysis when both the case and control populations are normal. Particularly, the classifier is a normal linear model on certain covariates, and the covariate effect and variance of the classifier may change between the case and control populations. This model is defined in Pepe (2003, 145).

\[
y = z' \beta_0 + Dx' \beta_1 + \sigma(D) \epsilon
\]

Our error term, \(\epsilon\), is a standard normal random variable. The variable \(D\) is our true status variable, being 1 for the case population observations and 0 for the control population observations. The variance function \(\sigma\) is defined as

\[
\sigma(D) = \sigma_0(D = 0) + \sigma_1(D = 1)
\]

This provides two variance parameters in the model and does not depend on covariate values.
Suppose a covariate $x_i$ is present in $z$ and $x$. The coefficient $\beta_{1i}$ represents the interaction effect of the $x_i$ and $D$. It is the extra effect that $x_i$ has on classifier $y$ under the case population, $D = 1$, beyond the main effect $\beta_{0i}$. These $\beta_1$ coefficients are directly related to the ROC curve of $y$.

Under this model, the ROC curve is derived to be

$$\text{ROC}(u) = \Phi \left[ \frac{1}{\sigma_1} \{ x' \beta_1 + \sigma_0 \Phi^{-1}(u) \} \right]$$

For convenience, we reparameterize the model at this point, creating the parameters $\beta_i = \sigma_i^{-1} \beta_{1i}$ and $\alpha = \sigma_i^{-1} \sigma_0$. We refer to $\beta_0$ as the constant intercept, $\text{i}_\text{cons}$. The parameter $\alpha$ is referred to as the constant slope, $\text{s}_\text{cons}$.

$$\text{ROC}(u) = \Phi \{ x' \beta + \alpha \Phi^{-1}(u) \}$$

We may interpret the final coefficients as the standardized linear effect of the ROC covariate on the classifier under the case population. The marginal effect of the covariate on the classifier in the control population is removed, and it is rescaled by the case population standard deviation of the classifier when all ROC covariate effects are removed. An appreciable effect on the classifier by a ROC covariate in this measure leads to an appreciable effect on the classifier’s ROC curve by the ROC covariate.

The advantage of estimating the control coefficients $\beta_0$ is similar to the gains of estimating the covariate control models in the estimating equations ROC method and nonparametric ROC estimation. This model would similarly apply when evaluating a test that is conditioned on control covariates.

Again, we note that under parametric estimation, all the summary measures we defined earlier except the AUC are not calculated until postestimation. In models with covariates, each covariate combination would yield a different ROC curve and thus different summary parameters, so no summary parameters are estimated initially. In marginal parametric models, we will calculate the AUC and leave the other measures for postestimation. There is a simple closed-form formula for the AUC under the probit model. Using this formula, the delta method can be invoked for inference on the AUC. Details on AUC estimation for probit marginal models are found in Methods and formulas.

We will demonstrate the maximum likelihood method of rocreg by revisiting the models of the previous section.

Example 10: Maximum likelihood ROC, single classifier

Returning to the hearing test study of Stover et al. (1996), we use a similar covariate grouping as before. The frequency $xf$ and intensity $xl$ are control covariates ($z$), while all three covariates $xf$, $xl$, and hearing loss degree $xd$ are case covariates ($x$). In example 7, we fit this model using the Alonzo and Pepe (2002) method. Earlier we stratified on the control covariates and estimated the conditioned control distribution of $\text{nsnr}$ empirically. Now, we assume a normal linear model for $\text{nsnr}$ on $xf$ and $xl$ under the control population.

We fit the model by specifying the control covariates in the $\text{ctrlcov()}$ option and the case covariates in the $\text{roccov()}$ option. The $\text{ml}$ option tells rocreg to perform maximum likelihood estimation.
We find the results are similar to those of example 7. Frequency (xf) and intensity (xl) have a negative effect on the classifier nsnr in the control population. The negative control effect is mitigated for xf in the case population, but the effect for xl is even more negative there. Hearing loss severity, xd, has a positive effect on nsnr in the case population, and it is undefined in the control population.

The ROC coefficients are shown in the ROC Model table. Each are different from 0 at the 0.05 level. At this level, we also cannot conclude that the variances differ from case to control populations,
because 1 is in the 95% confidence interval for \( \text{s}_\text{cons} \), the ratio of the case to control standard deviation parameters.

Both frequency \((x_f)\) and hearing loss severity \((x_d)\) make a positive contribution to the ROC curve and thus make the test more powerful. Intensity \((x_l)\) has a negative effect on the ROC curve and weakens the test. We previously saw in example 5 that the control distribution appears to be normal, so using maximum likelihood to fit this model is a reasonable approach.

This model was also fit in Pepe (2003, 147). Pepe used separate least-squares estimates for the case and control samples. We obtain similar results for the coefficients, but the maximum likelihood fitting yields slightly different standard deviations by considering both case and control observations concurrently. In addition, a misprint in Pepe (2003, 147) reports a coefficient of \(-4.91\) for \(x_l\) in the case population instead of \(-3.19\) as reported by Stata.

Inference on multiple classifiers using the Alonzo and Pepe (2002) estimating equation method is performed by fitting each model separately and bootstrapping to determine the dependence of the estimates. Using the maximum likelihood method, we also fit each model separately. We use \texttt{suest} (see \texttt{[R] suest}) to estimate the joint variance–covariance of our parameter estimates.

For our models, we can view the score equation for each model as an estimating equation. The estimate that solves the estimating equation (that makes the score 0) is asymptotically normal with a variance matrix that can be estimated using the inverse of the squared scores. By stacking the score equations of the separate models, we can estimate the variance matrix for all the parameter estimates by using this rule. This is an informal explanation; further details can be found in \texttt{[R] suest} and in the references Rogers (1993); White (1982 and 1996).

Now, we will examine a case with multiple classification variables.

\textbf{Example 11: Maximum likelihood ROC, multiple classifiers}

We return to the neonatal audiology study with gender and age covariates (Norton et al. 2000). In example 6, we fit a model with \texttt{male} and \texttt{currage} as control covariates, and \texttt{currage} as a ROC covariate for the classifier \(y_1\) (DPOAE 65 at 2 kHz). We will refit this model, extending it to include the classifier \(y_2\) (TEOAE 80 at 2 kHz).

Both classifiers have similar results. The results for $y_1$ show the same direction as the estimating equation results in example 6. However, we can now reject the null hypothesis that the ROC $\text{currage}$ coefficient is 0 at the 0.05 level.

In example 6, we could not reject that the slope parameter $s\_\text{cons}$ was 1 and that the constant intercept or ROC coefficient for current age was 0. The resulting ROC curve implied a noninformative test using $y_1$ as a classifier. This is not the case with our current results. As $\text{currage}$ increases, we expect a steeper ROC curve and thus a more powerful test, for both classifiers $y_1$ (DPOAE 65 at 2 kHz) and $y_2$ (TEOAE 80 at 2 kHz).

In example 10, the clustering of observations within infant $\text{id}$ was adjusted in the individual fit of $\text{nsnr}$. In our current example, the adjustment for the clustering of observations within $\text{id}$ is performed during concurrent estimation, as opposed to during the individual classifier fits (as in example 10). This adjustment, performed by $\text{suest}$, is still accurate.

Now, we will fit constant probit models and compare rocreg with rocfit and roccomp with the binormal option. Our first applications of rocfit and roccomp are taken directly from examples 8 and 9. The Dorfman and Alf (1969) algorithm that rocfit works with uses discrete classifiers or uses slicing to make a classifier discrete. So we are applying the maximum likelihood method of rocreg on discrete classification data here, where it expects continuous data. We expect to see some discrepancies, but we do not find great divergence in the estimates. After revisiting examples 8 and 9, we will fit a probit model with a continuous classifier and no covariates using rocreg, and we will compare the results with those from rocfit.

Example 12: Maximum likelihood ROC, marginal model

Using the Hanley and McNeil (1982) data, discussed in example 1 and in example 8, we fit a constant probit model of the classifier rating with true status disease. rocreg is invoked with the ml option and compared with rocfit.

We find that both the intercept and the slope are estimated as higher with the maximum likelihood method under rocreg than with rocfit. The AUC (ROC area in rocfit) is close for both commands. We find that the standard errors of each of these estimates is slightly lower under rocreg than rocfit as well.

Both rocfit and rocreg suggest that the slope parameter of the ROC curve (slope in rocfit and s_cons in rocreg) is not significantly different from 1. Thus, we cannot reject that the classifier has the same variance in both case and control populations. There is, however, significant evidence that the intercepts (i_cons in rocreg and intercept in rocfit) differ from 0. Because of the positive direction of the intercept estimates, the ROC curve for rating as a classifier of disease suggests that rating provides an informative test. This is also suggested by the high AUC, which is significantly different from 0.5, that is, a flip of a coin.

<td>0.9376</td>
<td>0.9453</td>
</tr>
</tbody>
</table>

Each classifier has a higher estimated AUC under rocreg than roccomp. Each curve appears to be raised and smoothed in the rocreg fit as compared with roccomp. They are different, but not drastically different. The inference on whether the curve areas are the same is similar to example 9. We reject equality at the 0.10 level under rocreg and at the 0.05 level under roccomp.

Each intercept is significantly different from 0 at the 0.05 level and is estimated in a positive direction. Though all but classifier mod2 has 1 in their slope confidence intervals, the high intercepts suggest steep ROC curves and powerful tests.

Also note that the false-positive and true-positive rate points are calculated empirically in the roccomp graph and parametrically in rocreg. In example 9, the false-positive rates calculated by rocreg were calculated empirically, similar to roccomp. But in this example, the rates are calculated based on normal percentiles.

Now, we will generate an example to compare rocfit and rocreg under maximum likelihood estimation of a continuous classifier.

Example 14: Maximum likelihood ROC, graphical comparison with rocfit

We generate 500 realizations of a population under threat of disease. One quarter of the population has the disease. A classifier \(x\) is measured, which has a control distribution of \(N(1, 3)\) and a case distribution of \(N(1 + 5, 2)\). We will invoke rocreg with the ml option on this generated data. We specify the continuous() option for rocfit and invoke it on the data as well. The continuous() option tells rocfit how many discrete slices to partition the data into before fitting.
For comparison of the two curves, we will use the \texttt{rocfit} postestimation command, \texttt{rocplot}; see \texttt{[R] rocfit postestimation}. This command graphs the empirical false-positive and true-positive rates with an overlaid fit of the binormal curve estimated by \texttt{rocfit}. \texttt{rocplot} also supports an \texttt{addplot()} option. We use the saved variables from \texttt{rocreg} in this option to overlay a line plot of the \texttt{rocreg} fit.

(*) z test for slope==1

. rocplot, plotopts(msymbol(i)) lineopts(lpattern(dash))
> norefline addplot(line _roc_x _fpr_x, sort(_fpr_x _roc_x))
> lpattern(solid)) aspectratio(1) legend(off)

We find that the curves are close. As before, the rocfit estimates are lower for the slope and intercept than under rocreg. The AUC estimates are close. Though the slope confidence interval contains 1, a high ROC intercept suggests a steep ROC curve and thus a powerful test.
Stored results

Nonparametric rocreg stores the following in e():

Scalars
- e(N) number of observations
- e(N_strata) number of covariate strata
- e(N_clust) number of clusters
- e(level) confidence level for bootstrap CIs
- e(rank) rank of e(V)

Macros
- e(cmd) rocreg
- e(cmdline) command as typed
- e(classvars) classification variable list
- e(refvar) status variable, reference variable
- e(ctrlmodel) covariate-adjustment specification
- e(ctrlcov) covariate-adjustment variables
- e(pvc) percentile value calculation method
- e(title) title in estimation output
- e(tiecorrected) tiecorrected, if specified
- e(nobootstrap) nobootstrap, if specified
- e(rngstate) random-number state used in bootstrap, if bootstrap was performed
- e(breps) number of bootstrap resamples, if bootstrap performed
- e(bootcc) bootcc, if specified
- e(nobstrata) nobstrata, if specified
- e(clustvar) name of cluster variable
- e(exp#) expression for the #th statistic
- e(roc) false-positive rates where ROC was estimated
- e(invroc) ROC values where false-positive rates were estimated
- e(pauc) false-positive rates where pAUC was estimated
- e(auc) indicates that AUC was calculated
- e(vce) bootstrap
- e(properties) b V (or b if bootstrap not performed)

Matrices
- e(b) coefficient vector
- e(V) variance–covariance matrix of the estimators
- e(b.bs) bootstrap estimates
- e(reps) number of nonmissing results
- e(bias) estimated biases
- e(se) estimated standard errors
- e(z0) median biases
- e(ci_normal) normal-approximation confidence intervals
- e(ci_percentile) percentile confidence intervals
- e(ci_bc) bias-corrected confidence intervals

Functions
- e(sample) marks estimation sample

In addition to the above, the following is stored in r():

Matrices
- r(table) matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.
Parametric, bootstrap `rocreg` stores the following in `e()`: 

Scalars 
- `e(N)` number of observations 
- `e(N_strata)` number of covariate strata 
- `e(N_clust)` number of clusters 
- `e(level)` confidence level for bootstrap CIs 
- `e(rank)` rank of `e(V)`

Macros 
- `e(cmd)` `rocreg` 
- `e(cmdline)` command as typed 
- `e(classvars)` classification variable list 
- `e(refvar)` status variable, reference variable 
- `e(ctrlmodel)` covariate-adjustment specification 
- `e(ctrlcov)` covariate-adjustment variables 
- `e(pvc)` percentile value calculation method 
- `e(title)` title in estimation output 
- `e(tiecorrected)` tiecorrected, if specified 
- `e(probit)` probit, if specified 
- `e(roccov)` ROC covariates 
- `e(fprpts)` number of points used as false-positive rate fit points 
- `e(ctrlfprall)` indicates whether all observed false-positive rates were used as fit points 
- `e(nobootstrap)` nobootstrap, if specified 
- `e(rngstate)` random-number state used in bootstrap 
- `e(breps)` number of bootstrap resamples 
- `e(bootcc)` bootcc, if specified 
- `e(nobstrata)` nobstrata, if specified 
- `e(clustvar)` name of cluster variable 
- `e(exp#)` expression for the #th statistic 
- `e(vce)` bootstrap 
- `e(properties)` b V (or b if nobootstrap is specified) 
- `e(predict)` program used to implement predict

Matrices 
- `e(b)` coefficient vector 
- `e(V)` variance–covariance matrix of the estimators 
- `e(b_bs)` bootstrap estimates 
- `e(reps)` number of nonmissing results 
- `e(bias)` estimated biases 
- `e(se)` estimated standard errors 
- `e(z0)` median biases 
- `e(ci_normal)` normal-approximation confidence intervals 
- `e(ci_percentile)` percentile confidence intervals 
- `e(ci_bc)` bias-corrected confidence intervals

Functions 
- `e(sample)` marks estimation sample 

In addition to the above, the following is stored in `r()`:

Matrices 
- `r(table)` matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.
Parametric maximum likelihood rocreg stores the following in e():

Scalars
- e(N) number of observations
- e(N_clust) number of clusters
- e(rank) rank of e(V)

Macros
- e(cmd) rocreg
- e(cmdline) command as typed
- e(classvars) classification variable list
- e(refvar) status variable
- e(ctrlmodel) linear
- e(ctrlcov) control population covariates
- e(roccov) ROC covariates
- e(probit) probit, if specified
- e(pvc) normal
- e(vtype) weight type
- e(wexp) weight expression
- e(title) title in estimation output
- e(clustvar) name of cluster variable
- e(vce) cluster if clustering used
- e(vcetype) robust if multiple classifiers or clustering used
- e(ml) ml if specified
- e(predict) program used to implement predict

Matrices
- e(b) coefficient vector
- e(V) variance–covariance matrix of the estimators

Functions
- e(sample) marks estimation sample

In addition to the above, the following is stored in r():

Matrices
- r(table) matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

Methods and formulas

Assume that we applied a diagnostic test to each of \(N_0\) control and \(N_1\) case subjects. Further assume that the higher the outcome value of the diagnostic test, the higher the risk of the subject being abnormal. Let \(y_{1i}, i = 1, 2, \ldots, N_1\), and \(y_{0j}, j = 1, 2, \ldots, N_0\), be the values of the diagnostic test for the case and control subjects, respectively. The true status variable \(D\) identifies an observation as case \(D = 1\) or control \(D = 0\). The CDF of the classifier \(Y\) is \(F\). Conditional on \(D\), we write the CDF as \(F_D\).

Methods and formulas are presented under the following headings:

- ROC statistics
- Covariate-adjusted ROC curves
- Parametric ROC curves: Estimating equations
- Parametric ROC curves: Maximum likelihood
ROC statistics

We obtain these definitions and their estimates from Pepe (2003) and Pepe, Longton, and Janes (2009). The false-positive and true-positive rates at cutoff $c$ are defined as

$$\text{FPR}(y) = P(Y \geq y | D = 0)$$

$$\text{TPR}(y) = P(Y \geq y | D = 1)$$

The true-positive rate, or ROC value at false-positive rate $u$, is given by

$$\text{ROC}(u) = P(1 - F_0(Y) \leq u | D = 1)$$

When $Y$ is continuous, the false-positive rate can be written as

$$\text{FPR}(y) = 1 - F_0(y)$$

The empirical CDF for the sample $z_1, \ldots, z_n$ is given by

$$\hat{F}(z) = \sum_{i=1}^{n} \frac{I(z < z_i)}{n}$$

The empirical estimates $\hat{\text{FPR}}$ and $\hat{\text{ROC}}$ both use this empirical CDF estimator.

The area under the ROC curve is defined as

$$\text{AUC} = \int_{0}^{1} \text{ROC}(u) \, du$$

The partial area under the ROC curve for false-positive rate $a$ is defined as

$$\text{pAUC}(a) = \int_{0}^{a} \text{ROC}(u) \, du$$

The nonparametric estimate for the AUC is given by

$$\hat{\text{AUC}} = \sum_{i=1}^{N_1} \frac{1 - \hat{\text{FPR}}(y_{1i})}{N_1}$$

The nonparametric estimate of pAUC is given by

$$\hat{\text{pAUC}}(a) = \sum_{i=1}^{N_1} \max \left\{ 1 - \hat{\text{FPR}}(y_{1i}) - (1 - a), 0 \right\} \frac{N_1}{N_0}$$

For discrete classifiers, a correction term is subtracted from the false-positive rate estimate so that the $\hat{\text{AUC}}$ and $\hat{\text{pAUC}}$ estimates correspond with a trapezoidal approximation to the area of the ROC curve.

$$\text{FPR}^c(y) = 1 - \hat{F}_0(y) - \frac{1}{2} \sum_{j=1}^{N_0} \frac{I(y = y_{0j})}{N_0}$$

In the nonparametric estimation of the ROC curve, all inference is performed using the bootstrap command (see [R] bootstrap). rocreg also allows users to calculate the ROC curve and related statistics by assuming a normal control distribution. So these formulas are updated by replacing $F_0$ by $\Phi$ (with adjustment of the marginal mean and variance of the control distribution).
Covariate-adjusted ROC curves

Suppose we observe covariate vector $Z$ in addition to the classifier $Y$. Let $Z_{1i}, i = 1, 2, \ldots, N_1$, and $Z_{0j}, j = 1, 2, \ldots, N_0$, be the values of the covariates for the case and control subjects, respectively.

The covariate-adjusted ROC curve is defined by Janes and Pepe (2009) as

$$AROC(t) = E \{ ROC(t | Z_0) \}$$

It is calculated by replacing the marginal control CDF estimate, $\hat{F}_0$, with the conditional control CDF estimate, $\hat{F}_{0Z}$. If we used a normal control CDF, then we would replace the marginal control mean and variance with the conditional control mean and variance. The formulas of the previous section can be updated for covariate-adjustment by making this substitution of the conditional CDF for the marginal CDF in the false-positive rate calculation.

Because the calculation of the ROC value is now performed based on the conditionally calculated false-positive rate, no further conditioning is made in its calculation under nonparametric estimation.

rocreg supports covariate adjustment with stratification and linear regression. Under stratification, separate parameters are estimated for the control distribution at each level of the covariates. Under linear regression, the classifier is regressed on the covariates over the control distribution, and the resulting coefficients serve as parameters for $\hat{F}_{0Z}$.

Parametric ROC curves: Estimating equations

Under nonparametric estimation of the ROC curve with covariate adjustment, no further conditioning occurs in the ROC curve calculation beyond the use of covariate-adjusted false-positive rates as inputs.

Under parametric estimation of the ROC curve, we can relax this restriction. We model the ROC curve as a cumulative distribution function $g$ (standard normal $\Phi$) invoked with input of a linear polynomial in the corresponding quantile function (here $\Phi^{-1}$) invoked on the false-positive rate $u$. The constant intercept of the polynomial may depend on covariates; the slope term $\alpha$ (quantile coefficient) may not.

$$ROC(u) = g\{x'\beta + \alpha g^{-1}(u)\}$$

Pepe (2003) notes that having a binormal ROC ($g = \Phi$) is equivalent to specifying that some monotone transformation of the data exists to make the case and control classifiers normally distributed. This specification applies to the marginal case and control.

Under weak assumptions about the control distribution of the classifier, we can fit this model by using estimating equations (Alonzo and Pepe 2002). The method can be used without covariate effects in the second stage, assuming a parametric model for the single ROC curve. Using the Alonzo and Pepe (2002) method, the covariate-adjusted ROC curve may be fit parametrically. The marginal ROC curve, involving no covariates in either stage of estimation, can be fit parametrically as well. In addition to the Alonzo and Pepe (2002) explanation, further details are given in Pepe, Longton, and Janes (2009); Janes, Longton, and Pepe (2009); Pepe (2003); and Janes and Pepe (2009).

The algorithm can be described as follows:

1. Estimate the false-positive rates of the classifier $fpr$. These may be computed in any fashion outlined so far: covariate-adjusted, empirically, etc.

2. Determine a set of $n_p$ false-positive rates to use as fitting points $f_1, \ldots, f_{n_p}$. These may be an equispaced grid on $(0, 1)$ or the set of observed false-positive rates from part 1.
3. Expand the case observation portion of the data to include a subobservation for each fitting point. So there are now $N_1(n_p - 1)$ additional observations in the data.

4. Generate a new dummy variable $u$. For subobservation $j$, $u = I(f_{pr} \leq f_j)$.

5. Generate a new variable $\textit{quant}$ containing the quantiles of the false-positive rate fitting points. For subobservation $j$, $\textit{quant} = g^{-1}(f_j)$.

6. Perform a binary regression (probit, $g = \Phi$) of $f_{pr}$ on the covariates $\mathbf{x}$ and quantile variable $\textit{quant}$.

The coefficients of part 6 are the coefficients of the ROC model. The coefficients of the covariates coincide naturally with estimates of $\beta$, and the $\alpha$ parameter is estimated by the coefficient on $\textit{quant}$. Because the method is so general and makes few distributional assumptions, bootstrapping must be performed for inference. If multiple classifiers are to be fit, the algorithm is performed separately for each in each bootstrap, and the bootstrap is used to estimate covariances.

We mentioned earlier that in parametric estimation, the AUC was the only summary parameter that could be estimated initially. This is true when we fit the marginal probit model because there are no covariates in part 6 of the algorithm.

To calculate the AUC statistic under a marginal probit model, we use the formula

$$AUC = \Phi \left( \frac{\beta_0}{\sqrt{1 + \alpha^2}} \right)$$

Alternatively, the AUC for the probit model can be calculated as $pAUC(1)$ in postestimation. Under both models, bootstrapping is performed for inference on the AUC.

**Parametric ROC curves: Maximum likelihood**

`rocreg` supports another form of parametric ROC estimation: maximum likelihood with a normally distributed classifier. This method assumes that the classifier is a normal linear model on certain covariates, and the covariate effect and variance of the classifier may change between the case and control populations. The model is defined in Pepe (2003, 145).

$$y = \mathbf{z}'\beta_0 + D\mathbf{x}'\beta_1 + \sigma(D)\epsilon$$

Our error term, $\epsilon$, is a standard normal random variable. The variable $D$ is our true status variable, being 1 for the case population observations and 0 for the control population observations. The variance function $\sigma$ is defined as

$$\sigma(D) = \sigma_0(D = 0) + \sigma_1(D = 1)$$

This provides two variance parameters in the model and does not depend on covariate values.

Under this model, the ROC curve is easily derived to be

$$\text{ROC}(u) = \Phi \left[ \frac{1}{\sigma_1} \left\{ \mathbf{x}'\beta_1 + \sigma_0 \Phi^{-1}(u) \right\} \right]$$

We reparameterize the model, creating the parameters $\beta_i = \sigma_i^{-1}\beta_1$ and $\alpha = \sigma_1^{-1}\sigma_0$. We refer to $\beta_0$ as the constant intercept, `_cons`. The parameter $\alpha$ is referred to as the constant slope, s._cons.

$$\text{ROC}(u) = \Phi \{ \mathbf{x}'\beta + \alpha \Phi^{-1}(u) \}$$
The original model defining the classifier $y$ leads to the following single observation likelihoods for $D = 0$ and $D = 1$:

$$L(\beta_0, \beta_1, \sigma_1, \sigma_0, | D = 0, y, z, x) = \frac{1}{\sqrt{2\pi\sigma_0}} \exp\left(-\frac{(y - z'\beta_0)^2}{2\sigma_0^2}\right)$$

$$L(\beta_0, \beta_1, \sigma_1, \sigma_0, | D = 1, y, z, x) = \frac{1}{\sqrt{2\pi\sigma_1}} \exp\left(-\frac{(y - z'\beta_0 - x'\beta_1)^2}{2\sigma_1^2}\right)$$

These can be combined to yield the observation-level log likelihood:

$$\ln L(\beta_0, \beta_1, \sigma_1, \sigma_0, | D, y, z, x) = -\frac{\ln 2\pi}{2} - I(D = 0) \left\{ \ln \sigma_0 + \frac{(y - z'\beta_0)^2}{2\sigma_0^2} \right\} - I(D = 1) \left\{ \ln \sigma_1 + \frac{(y - z'\beta_0 - x'\beta_1)^2}{2\sigma_1^2} \right\}$$

When there are multiple classifiers, each classifier is fit separately with maximum likelihood. Then, the results are combined by stacking the scores and using the sandwich variance estimator. For more information, see [R] suest and the references White (1982); Rogers (1993); and White (1996).

**Acknowledgments**

We thank Margaret S. Pepe, Holly Janes, and Gary Longton (retired) of the Fred Hutchinson Cancer Research Center for providing the inspiration for the rocreg command and for illuminating many useful datasets for its documentation.

predict

Description for predict

Use of predict after fitting a parametric model with rocreg allows calculation of all the ROC curve summary statistics for covariate-specific ROC curves. The ROC values for given false-positive rates, false-positive rate for given ROC values, area under the ROC curve (AUC), and partial areas under the ROC curve (pAUC) for a given false-positive rate can all be calculated.

Options for predict

at(varname) records the variable to be used as input for the above predictions.

auc predicts the total area under the ROC curve defined by the covariate values in the data. This is the default statistic.
roc predicts the ROC values for false-positive rates stored in varname specified in at().

invroc predicts the false-positive rates for given ROC values stored in varname specified in at().

pauc predicts the partial area under the ROC curve up to each false-positive rate stored in varname specified in at().

classvar(varname) performs the prediction for the specified classifier.

Options

intpts(#) specifies that # points be used in the pAUC calculation.

se(newvar) specifies that standard errors be produced and stored in newvar.

ci(stubname) requests that confidence intervals be produced and the lower and upper bounds be stored in stubname_l and stubname_u, respectively.

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.

bfile(filename, ...) uses bootstrap replicates of parameters from rocreg stored in filename to estimate standard errors and confidence intervals of predictions.

btype(n | p | bc) specifies whether to produce normal-based (n), percentile (p), or bias-corrected (bc) confidence intervals. The default is btype(n).
estat

Description for estat

`estat nproc` allows calculation of all the ROC curve summary statistics for covariate-specific ROC curves, as well as for a nonparametric ROC estimation. Under nonparametric estimation, a single ROC curve is estimated by `rocreg`. Covariates can affect this estimation, but there are no separate covariate-specific ROC curves. Thus, the input arguments for `estat nproc` are taken in the command line rather than from the data as variable values.

<td>estimate partial area under the ROC curve up to each false-positive rate</td>
</tr>
</tbody>
</table>

At least one option must be specified.

Options for estat nproc

- `auc` estimates the total area under the ROC curve.
- `roc(numlist)` estimates the ROC for each of the false-positive rates in `numlist`. The values in `numlist` must be in the range (0,1).
- `invroc(numlist)` estimates the false-positive rate for each of the ROC values in `numlist`. The values in `numlist` must be in the range (0,1).
- `pauc(numlist)` estimates the partial area under the ROC curve up to each false-positive rate in `numlist`. The values in `numlist` must be in the range (0,1).

Remarks and examples

Remarks are presented under the following headings:

- Using `predict after rocreg`
- Using `estat nproc`
Using predict after rocreg

`predict`, after parametric `rocreg`, predicts the AUC, the ROC value, the false-positive rate (invROC), or the pAUC value. The default is `auc`.

We begin by estimating the area under the ROC curve for each of the three age-specific ROC curves in example 1 of [R] `rocregplot`: 30, 40, and 50 months.

Example 1: Parametric ROC, AUC

In example 6 of [R] `rocreg`, a probit ROC model was fit to audiology test data from Norton et al. (2000). The estimating equations method of Alonzo and Pepe (2002) was used to fit the model. Gender and age were covariates that affected the control distribution of the classifier `y1` (DPOAE 65 at 2 kHz). Age was a ROC covariate for the model, so we fit separate ROC curves at each age.

Following Janes, Longton, and Pepe (2009), we drew the ROC curves for ages 30, 40, and 50 months in example 1 of [R] `rocregplot`. Now, we use `predict` to estimate the AUC for the ROC curve at each of those ages.

The bootstrap dataset saved by `rocreg` in example 6 of [R] `rocreg`, `nnhs2y1.dta`, is used in the `bfile()` option.

We will store the AUC prediction in the new variable `predAUC`. We specify the `se()` option with the new variable name `seAUC` to produce an estimate of the prediction’s standard error. By specifying the stubname `cin` in `ci()`, we tell `predict` to create normal-based confidence intervals (the default) as new variables `cin_l` and `cin_u`.

```

</tr>
</tbody>
</table>

As expected, we find the AUC to increase with age.

Essentially, we have a stored bootstrap sample of ROC covariate coefficient estimates in `nnhs2y1.dta`. We calculate the AUC using each set of coefficient estimates, resulting in a sample of AUC estimates. Then, the bootstrap standard error and confidence intervals are calculated based on this AUC sample. Further details of the computation of the standard error and percentile confidence intervals can be found in Methods and formulas and in [R] `bootstrap`.

We can also produce percentile or bias-corrected confidence intervals by specifying `btype(p)` or `btype(bc)`, which we now demonstrate.
predict can also estimate the ROC value and the false-positive rate (invROC).

Example 2: Parametric ROC, invROC, and ROC value

In example 7 of [R] rocreg, we fit the ROC curve for status variable hearing loss (d) and classifier negative signal-to-noise ratio nsnr with ROC covariates frequency (xf), intensity (xl), and hearing loss severity (xd). The data were obtained from Stover et al. (1996). The model fit was probit with bootstrap resampling. We saved 50 bootstrap replications in the dataset nsnrf.dta.

The covariate value combinations xf = 10.01, xl = 5.5, and xd = .5, and xf = 10.01, xl = 6.5, and xd = 4 are of interest. In example 3 of [R] rocregplot, we estimated the ROC values for false-positive rates 0.2 and 0.7 and the false-positive rate for a ROC value of 0.5 by using rocregplot. We will use predict to replicate the estimation.

We begin by appending observations with our desired covariate combinations to the data. We also create two new variables: rocinp, which contains the ROC values for which we wish to predict the corresponding invROC values, and invrocinp, which contains the invROC values corresponding to the ROC values we wish to predict.

Now, we list the confidence intervals for false-positive rate under the covariate values \(xf=10.01, \ xl=6.5,\) and \(xd=4\).

. list xf xl xd invrocinp invrocit cin* in 1852

<table>
<thead>
<tr>
<th></th>
<th>xf</th>
<th>xl</th>
<th>xd</th>
<th>invrocinp</th>
<th>invrocit</th>
<th>cin_l</th>
<th>cin_u</th>
</tr>
</thead>
<tbody>
<tr>
<td>1852.</td>
<td>10.01</td>
<td>6.5</td>
<td>4</td>
<td>.5</td>
<td>.0043298</td>
<td>-.0031867</td>
<td>.0118463</td>
</tr>
</tbody>
</table>

The \texttt{predict} command can also be used after a maximum-likelihood ROC model is fit.
Example 3: Maximum likelihood ROC, invROC, and ROC value

In the previous example, we revisited the estimating equations fit of a probit model with ROC covariates frequency (xf), intensity (xl), and hearing loss severity (xd) to the Stover et al. (1996) audiology study data. A maximum likelihood fit of the same model was performed in example 10 of [R] rocreg. In example 2 of [R] rocregplot, we used rocregplot to estimate ROC values and false-positive rates for this model under two covariate configurations. We will use predict to obtain the same estimates. We will also estimate the partial area under the ROC curve.

We append the data as in the previous example. This leads to the following four final observations in the data.

```
. use https://www.stata-press.com/data/r18/dp, clear
   (Stover - DPOAE test data)
. rocreg d nsnr, probit ctrlcov(xf xl) roccov(xf xl xd) ml cluster(id)
      (output omitted)
. append using newdata
. list xf xl xd invrocinp rocinp in 1849/1852
    xf   xl   xd  invrocinp  rocinp
  1849. 10.01  5.5   .5     .2     .2
  1850. 10.01  6.5   4     .2     .2
  1851. 10.01  5.5   .5     .5     .7
  1852. 10.01  6.5   4     .5     .7
```

Now, we predict the ROC value for false-positive rates of 0.2 and 0.7. Under maximum likelihood prediction, only Wald-type confidence intervals are produced. We specify a new variable name for the standard error in the `se()` option and a stubname for the confidence interval variables in the `ci()` option.

```
. predict rocit in 1849/1852, roc at(rocinp) se(seroc) ci(ci)
. list xf xl xd rocinp rocit seroc ci_l ci_u if !missing(rocit), noobs
    xf   xl   xd  rocinp  rocit    seroc  ci_l  ci_u
  10.01  5.5   .5     .2     .7608593 .0510501 .660803 .8609157
  10.01  6.5   4     .2     .9499408 .0179824 .914696 .9851856
  10.01  5.5   .5     .5     .978951  .0097382 .9598644 .9980376
  10.01  6.5   4     .5     .9985001 .0009657 .9966073 1.000393
```

These results match our estimates in example 2 of [R] rocregplot. We also match example 2 of [R] rocregplot when we estimate the false-positive rate for a ROC value of 0.5.

```
. drop ci*
. predict invrocit in 1851/1852, invroc at(invrocinp) se(serocinv) ci(ci)
. list xf xl xd invrocinp invrocit serocinv ci_l ci_u if !missing(invrocit), noobs
    xf   xl   xd  invrocinp  invrocit  serocinv  ci_l   ci_u
  10.01  5.5   .5      .5      .0578036 .0198626  .0188736 .0967336
  10.01  6.5   4      .5      .0055624 .0032645  -.0008359 .0119607
```
Example 4: Maximum likelihood ROC, pAUC, and ROC value

In example 13 of [R] rocreg, we fit a maximum-likelihood marginal probit model to each classifier of the fictitious dataset generated from Hanley and McNeil (1983). In example 5 of [R] rocregplot, rocregplot was used to draw the ROC for the mod1 and mod3 classifiers. Estimates of the ROC value and false-positive rate were also obtained with Wald-type confidence intervals.

We return to this example, this time using predict to estimate the ROC value and false-positive rate. We will also estimate the pAUC for the false-positive rates of 0.3 and 0.8.

First, we add the input variables to the data. The variable paucinp will hold the 0.3 and 0.8 false-positive rates that we will input to pAUC. The variable invrocinp holds the ROC value of 0.8 for which we will estimate the false-positive rate. Finally, the variable rocinp holds the false-positive rates of 0.15 and 0.75 for which we will estimate the ROC value.

```
. use https://www.stata-press.com/data/r18/ct2, clear
   (Reconstruction of CT images)
. rocreg status mod1 mod2 mod3, probit ml
   (output omitted)
. quietly generate paucinp = .3 in 111
. quietly replace paucinp = .8 in 112
. quietly generate invrocinp = .8 in 112
. quietly generate rocinp = .15 in 111
. quietly replace rocinp = .75 in 112

Then, we estimate the ROC value for false-positive rates 0.15 and 0.75 under classifier mod1. The point estimate is stored in roc1. Wald confidence intervals and standard errors are also estimated. We find that these results match those of example 5 of [R] rocregplot.

```
```
. predict roc1 in 111/112, classvar(mod1) roc at(rocinp) se(sr1) ci(cir1)
. list rocinp roc1 sr1 cir1* in 111/112
   +---------+---------+---------+---------+---------+
   | rocinp  |  roc1   |   sr1   |   cir1_l |   cir1_u |
   +---------+---------+---------+---------+---------+
   |  111.   | .15     | .793493 | .0801363 | .6364293 |
   |  112.   | .75     | .993165 | .0069689 | .9795067 |
   +---------+---------+---------+---------+---------+
```
```
Now, we perform the same estimation under the classifier mod3.

```
. predict roc3 in 111/112, classvar(mod3) roc at(rocinp) se(sr3) ci(cir3)
. list rocinp roc3 sr3 cir3* in 111/112
   +---------+---------+---------+---------+---------+
   | rocinp  |  roc3   |   sr3   |   cir3_l |   cir3_u |
   +---------+---------+---------+---------+---------+
   |  111.   | .15     | .888859 | .0520118 | .7869184 |
   |  112.   | .75     | .995394 | .0043435 | .9868811 |
   +---------+---------+---------+---------+---------+
```
```
Next, we estimate the false-positive rate for the ROC value of 0.8. These results also match example 5 of [R] rocregplot.

```
. predict invroc1 in 112, classvar(mod1) invroc at(invrocinp) se(sir1) ci(ciir1)
. list invrocinp invroc1 sir1 ciir1* in 112
   +---------+---------+---------+---------+---------+
   | invrocinp|  invroc1 |   sir1  |   ciir1_l |   ciir1_u |
   +---------+---------+---------+---------+---------+
   |  112.   | .8      | .155643 | .069699  | .0190361 |
   +---------+---------+---------+---------+---------+
```
Finally, we estimate the pAUC for false-positive rates of 0.3 and 0.8. The point estimate is calculated by numeric integration. Wald confidence intervals are obtained with the delta method. Further details are presented in Methods and formulas.

Using estat nproc

When you initially use rocreg to fit a nonparametric ROC curve, you can obtain bootstrap estimates of a ROC value, false-positive rate, area under the ROC curve, and partial area under the ROC curve. The estat nproc command allows the user to estimate these parameters after rocreg has originally been used.

The seed and resampling settings used by rocreg are used by estat nproc. So the results for these new statistics are identical to what they would be if they had been initially estimated in the rocreg command. These new statistics, together with those previously estimated in rocreg, are returned in r() .

We demonstrate with an example.

Example 5: Nonparametric ROC, invROC, and pAUC

In example 3 of [R] rocreg, we examined data from a pancreatic cancer study (Wieand et al. 1989). Two continuous classifiers, y1 (CA 19-9) and y2 (CA 125), were used for the true status variable d. In that example, we estimated various quantities including the false-positive rate for a ROC value of 0.6 and the pAUC for a false-positive rate of 0.5. Here we replicate that estimation with a call to rocreg to estimate the former and follow that with a call to estat nproc to estimate the latter. For simplicity, we restrict estimation to classifier y1 (CA 19-9).

We start by executing rocreg, estimating the false-positive rate for a ROC value of 0.6. This value is specified in invroc(). Case–control resampling is used by specifying the bootcc option.
. use https://research.fredhutch.org/content/dam/stripe/diagnostic-biomarkers-statistical-center/files/wiedat2b.dta, clear
(S. Wieand - Pancreatic cancer diagnostic marker data)
. rocreg d y1, invroc(.6) bseed(8378923) bootcc nodots

Bootstrap results

</code></pre>
The advantages of using `estat nproc` are twofold. First, you can estimate additional parameters of interest without having to respecify the bootstrap settings you did with `rocreg`; instead `estat nproc` uses the bootstrap settings that were stored by `rocreg`. Second, parameters estimated with `estat nproc` are added to those parameters estimated by `rocreg` and returned in the matrices `r(b)` (parameter estimates) and `r(V)` (variance–covariance matrix). Thus, you can also obtain correlations between any quantities you wish to estimate.

### Stored results

`estat nproc` stores the following in `r()`:

- **Matrices**
  - `r(b)`: coefficient vector
  - `r(V)`: variance–covariance matrix of the estimators
  - `r(ci_normal)`: normal-approximation confidence intervals
  - `r(ci_percentile)`: percentile confidence intervals
  - `r(ci_bc)`: bias-corrected confidence intervals

### Methods and formulas

Details on computation of the nonparametric ROC curve and the estimation of the parametric ROC curve model coefficients can be found in [R] `rocreg`. Here we describe how to estimate the ROC curve summary statistics for a parametric model. The cumulative distribution function, $g$, can be the standard normal cumulative distribution function, \( \Phi \).

Methods and formulas are presented under the following headings:

- **Parametric model: Summary parameter definition**
- **Maximum likelihood estimation**
- **Estimating equations estimation**
Parametric model: Summary parameter definition

Conditioning on covariates \( x \), we have the following ROC curve model:

\[
\text{ROC}(u) = g\{x'\beta + \alpha g^{-1}(u)\}
\]

\( x \) can be constant, and \( \beta = \beta_0 \), the constant intercept.

We can solve this equation to obtain the false-positive rate value \( u \) for a ROC value of \( r \):

\[
u = g\left\{g^{-1}(r) - x'\beta\right\}\alpha^{-1}
\]

The partial area under the ROC curve for the false-positive rate \( u \) is defined by

\[
p\text{AUC}(u) = \int_o^u g\{x'\beta + \alpha g^{-1}(t)\}dt
\]

The area under the ROC curve is defined by

\[
\text{AUC} = \int_o^1 g\{x'\beta + \alpha g^{-1}(t)\}dt
\]

When \( g \) is the standard normal cumulative distribution function \( \Phi \), we can express the AUC as

\[
\text{AUC} = \Phi\left(\frac{x'\beta}{\sqrt{1 + \alpha^2}}\right)
\]

Maximum likelihood estimation

We allow maximum likelihood estimation under probit parametric models, so \( g = \Phi \). The ROC value, false-positive rate, and AUC parameters all have closed-form expressions in terms of the covariate values \( x \), coefficient vector \( \beta \), and slope parameter \( \alpha \). So to estimate these three types of summary parameters, we use the delta method (Oehlert 1992; Phillips and Park 1988). Particularly, we use the \textit{nlcom} command (see [\textit{R} \text{nlcom}]) to implement the delta method.

To estimate the partial area under the ROC curve for false-positive rate \( u \), we use numeric integration. A trapezoidal approximation is used in calculating the integrals. A numeric integral of the \( \text{ROC}(t) \) function conditioned on the covariate values \( x \), coefficient vector \( \widehat{\beta} \), and slope parameter estimate \( \widehat{\alpha} \) is computed over the range \( t = [0, u] \). This gives us the point estimate of \( p\text{AUC}(u) \).

To calculate the standard error and confidence intervals for the point estimate of \( p\text{AUC}(u) \), we again use the delta method. Details on the delta method algorithm can be found in \textit{Methods and formulas} of [\textit{R} \text{nlcom}] and the earlier mentioned references.

Under maximum likelihood estimation, the coefficient estimates \( \widehat{\beta} \) and slope estimate \( \widehat{\alpha} \) are asymptotically normal with variance matrix \( V \). For convenience, we rename the parameter vector \( [\beta', \alpha] \) to the \( k \)-parameter vector \( \theta = [\theta_1, \ldots, \theta_k] \). We will also explicitly refer to the conditioning of the ROC curve by \( \theta \) in its mention as \( \text{ROC}(t, \theta) \).

Under the delta method, the continuous scalar function of the estimate \( \widehat{\theta} \), \( f(\widehat{\theta}) \) has asymptotic mean \( f(\theta) \) and asymptotic covariance \( \widehat{\text{Var}}\{f(\theta)\} = fVf' \).
where \( f \) is the \( 1 \times k \) matrix of derivatives for which

\[
f_{1j} = \frac{\partial f(\theta)}{\partial \theta_j} \quad j = 1, \ldots, k
\]

The asymptotic covariance of \( f(\hat{\theta}) \) is estimated and then used in conjunction with \( f(\hat{\theta}) \) for further inference, including Wald confidence intervals, standard errors, and hypothesis testing.

In the case of \( pAUC(u) \) estimation, our \( f(\hat{\theta}) \) is the aforementioned numeric integral of the ROC curve. It estimates \( f(\theta) \), the true integral of the ROC curve on the \([0, u]\) range. The \( V \) variance matrix is estimated using the likelihood information that \texttt{rocreg} calculated, and the estimation is performed by \texttt{rocreg} itself.

The partial derivatives of \( f(\theta) \) can be determined by using Leibnitz’s rule (Weisstein 2011):

\[
f_{1j} = \frac{\partial}{\partial \theta_j} \int_0^u \text{ROC}(t, \theta) dt = \int_0^u \frac{\partial}{\partial \theta_j} \text{ROC}(t, \theta) dt \quad j = 1, \ldots, k
\]

When \( \theta_j \) corresponds with the slope parameter \( \alpha \), we obtain the following partial derivative:

\[
\frac{\partial}{\partial \alpha} pAUC(u) = \int_0^u \phi \{ x' \beta + \alpha \Phi^{-1}(t) \} \Phi^{-1}(t) dt
\]

The partial derivative of \( f(\theta) \) [\( pAUC(u) \)] for \( \beta_0 \) is the following:

\[
\frac{\partial}{\partial \beta_0} pAUC(u) = \int_0^u \phi \{ x' \beta + \alpha \Phi^{-1}(t) \} dt
\]

For a nonintercept coefficient, we obtain the following:

\[
\frac{\partial}{\partial \beta_i} pAUC(u) = \int_0^u x_i \phi \{ x' \beta + \alpha \Phi^{-1}(t) \} dt
\]

We can estimate each of these integrals by numeric integration, plugging in the estimates \( \hat{\beta} \) and \( \hat{\alpha} \) for the parameters. This, together with the previously calculated estimate \( \hat{V} \), provides an estimate of the asymptotic covariance of \( f(\hat{\theta}) = pAUC(u) \), which allows us to perform further statistical inference on \( pAUC(u) \).

**Estimating equations estimation**

When we fit a model using the Alonzo and Pepe (2002) estimating equations method, we use the bootstrap to perform inference on the ROC curve summary parameters. Each bootstrap sample provides a sample of the coefficient estimates \( \beta \) and the slope estimates \( \alpha \). Using the formulas in \textit{Parametric model: Summary parameter definition} under \textit{Methods and formulas}, we can obtain an estimate of the ROC, false-positive rate, or AUC for each resample. Using numeric integration (with the trapezoidal approximation), we can also estimate the \( pAUC \) of the resample.
By making these calculations, we obtain a bootstrap sample of our summary parameter estimate. We then obtain bootstrap standard errors, normal approximation confidence intervals, percentile confidence intervals, and bias-corrected confidence intervals using this bootstrap sample. Further details can be found in [R] bootstrap.

**Title**

*rocregplot* — Plot marginal and covariate-specific ROC curves after *rocreg*

---

**Description**

Under parametric estimation, *rocregplot* plots the fitted ROC curves for specified covariate values and classifiers. If *rocreg*, *probit* or *rocreg, probit ml* were previously used, the false-positive rates (for specified ROC values) and ROC values (for specified false-positive rates) for each curve may also be plotted, along with confidence intervals.

Under nonparametric estimation, *rocregplot* will plot the fitted ROC curves using the `_fpr_*` and `_roc_*` variables produced by *rocreg*. Point estimates and confidence intervals for false-positive rates and ROC values that were computed in *rocreg* may be plotted as well.

**Quick start**

Plot ROC curve after any *rocreg* command

```
rocregplot
```

Name graph *mygraph* and save as *myfile.gph*

```
rocregplot, name(mygraph) saving(myfile)
```

Plot ROC curve only for *v2* after fitting a model with *v1* and *v2*

```
rocregplot, classvars(v2)
```

Add bias-corrected CI for the ROC value at a false-positive rate of 0.7 from estimation with bootstrap resampling that specified *roc(.7)*

```
rocregplot, btype(bc)
```

*Plots following parametric estimation only*

Plot curve evaluated at *x* = 30 and *x* = 50

```
rocregplot, at1(x=30) at2(x=50)
```

After bootstrap resampling with resampled observations saved in *myfile.dta*

```
rocregplot, at1(x=30) at2(x=50) bfile(myfile)
```

And draw CI for ROC values at false-positive rates 0.1, 0.2, and 0.3

```
rocregplot, at1(x=30) at2(x=50) roc(.1 .2 .3) bfile(myfile)
```

common_options

classvars(varlist) restricts plotting ROC curves to specified classification variables.
noreline suppresses plotting the reference line.

Scatter

plot#opts(scatter_options) affects the rendition of classifier #’s false-positive rate and ROC scatter points. This option applies only to non-ROC covariate estimation graphing. See [G-2] graph twoway scatter.

Reference line

rlopts(line_options) affects the rendition of the reference line. See [G-3] cline_options.

Y axis, X axis, Titles, Legend, Overall

twoway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and options for saving the graph to disk (see [G-3] saving_option).

boot_options

bfile(filename) uses bootstrap replicates of parameters from rocreg stored in filename to estimate standard errors and confidence intervals of predictions. bfile() must be specified with either roc() or invroc() if parametric estimation with bootstrapping was used.

btype(n | p | bc) indicates the desired type of confidence interval rendering. n draws normal-based, p draws percentile, and bc draws bias-corrected confidence intervals for specified false-positive rates and ROC values in roc() and invroc(). The default is btype(n).

Remarks and examples

Remarks are presented under the following headings:

Plotting covariate-specific ROC curves
Plotting marginal ROC curves

Plotting covariate-specific ROC curves

The rocregplot command is also demonstrated in [R] rocreg. We will further demonstrate its use with several examples. Particularly, we will show how rocregplot can draw the ROC curves of covariate models that have been fit using rocreg.
Example 1: Parametric ROC

In example 6 of Stata documentation on rocreg, we fit a probit ROC model to audiology test data from Norton et al. (2000). The estimating equation method of Alonzo and Pepe (2002) was used to fit the model. Gender and age were covariates that affected the control distribution of the classifier $y_1$ (DPOAE 65 at 2 kHz). Age was a ROC covariate for the model, so we fit separate ROC curves at each age.

Following Janes, Longton, and Pepe (2009), we draw the ROC curves for ages 30, 40, and 50 months. The `at1()`, `at2()`, and `at3()` options are used to specify the age covariates.

```
use https://www.stata-press.com/data/r18/nnhs
(Norton - neonatal audiology data)
rocreg d y1, probit ctrlcov(currage male) ctrlmodel(linear) roccov(currage)
> cluster(id) bseed(56930) bsave(nnhs2y1, replace)
(output omitted)
rocregplot, at1(currage=30) at2(currage=40) at3(currage=50)
```

Here we use the default entries of the legend, which indicate the “at #” within the specified `at*` options and the classifier to which the curve corresponds. ROC curve one corresponds with `currage=30`, two with `currage=40`, and three with `currage=50`. The positive effect of age on the ROC curve is evident. At an age of 30 months (`currage=30`), the ROC curve of $y_1$ (DPOAE 65 at 2 kHz) is nearly equivalent to that of a noninformative test that gives equal probability to hearing loss. At age 50 months (`currage=50`), corresponding to some of the oldest children in the study, the ROC curve shows that test $y_1$ (DPOAE 65 at 2 kHz) is considerably more powerful than the noninformative test.

You may create your own legend by specifying the `legend()` option. The default legend is designed for the possibility of multiple covariates. Here we could change the legend entries to `currage` values and gain some extra clarity. However, this may not be feasible when there are many covariates present.

We can also use rocregplot after maximum likelihood estimation.

Example 2: Maximum likelihood ROC

We return to the audiology study with frequency (`xf`), intensity (`xl`), and hearing loss severity (`xd`) covariates from Stover et al. (1996) that we examined in example 10 of Stata documentation on rocreg. Negative
signal-to-noise ratio is again used as a classifier. Using maximum likelihood, we fit a probit model to these data with the indicated ROC covariates.

After fitting the model, we wish to compare the ROC curves of two covariate combinations. The first has an intensity value of 5.5 (the lowest intensity, corresponding to 55 decibels) and a frequency of 10.01 (the lowest frequency, corresponding to 1001 hertz). We give the first combination a hearing loss severity value of 0.5 (the lowest). The second covariate combination has the same frequency, but the highest intensity value of 6.5 (65 decibels). We give this second covariate set a higher severity value of 4. We will visually compare the two ROC curves resulting from these two covariate value combinations.

We specify false-positive rates of 0.7 first followed by 0.2 in the \texttt{roc()} option to visually compare the size of the ROC curve at large and small false-positive rates. Because maximum likelihood estimation was used to fit the model, a Wald confidence interval is produced for the estimated ROC value and false-positive rate parameters. Further details are found in \textit{Methods and formulas}.

\begin{verbatim}
. use https://www.stata-press.com/data/r18/dp
(Stover - DPOAE test data)
. rocreg d nsnr, probit ctrlcov(xf xl) roccov(xf xl xd) ml cluster(id)
(output omitted)
\end{verbatim}
At the higher false-positive rate value of 0.7, we see little difference in the ROC values and note that the confidence intervals nearly overlap. Now, we view the same curves with the lower false-positive rate compared.
The lower false-positive rate of 0.2 shows clearly distinguishable ROC values. Now, we specify option `invroc(.5)` to view how the false-positive rates vary at a ROC value of 0.5.
. rocregplot, at1(xf=10.01, xl=5.5, xd=.5) at2(xf=10.01, xl=6.5, xd=4) invroc(.5)

</tr>
</tbody>
</table>

At a ROC value of 0.5, the false-positive rates for both curves are small and close to one another.

Technical note

We can use the testnl command to support our visual observations with statistical inference. We use it to perform a Wald test of the null hypothesis that the two ROC curves just rendered are equal at a false-positive rate of 0.7.
. testnl normal(_b[i_cons]+10.01*_b[xf]+5.5*_b[xl] +.5*_b[xd]+_b[s_cons]*invnormal(.7)) =
   normal(_b[i_cons]+10.01*_b[xf]+6.5*_b[xl] + 4*_b[xd]+_b[s_cons]*invnormal(.7))

(1) normal(_b[i_cons]+10.01*_b[xf]+5.5*_b[xl] +.5*_b[xd]+_b[s_cons]*invnormal(.7)) =
   normal(_b[i_cons]+10.01*_b[xf]+6.5*_b[xl] + 4*_b[xd]+_b[s_cons]*invnormal(.7))

chi2(1) = 4.53
Prob > chi2 = 0.0332

The test is significant at the 0.05 level, and thus we find that the two curves are significantly different. Now, we will use testnl again to test equality of the false-positive rates for each curve with a ROC value of 0.5. The inverse ROC formula used is derived in Methods and formulas.

. testnl normal((invnormal(.5)-(_b[i_cons]+10.01*_b[xf]+5.5*_b[xl]+.5*_b[xd])) /_b[s_cons]) =
   normal((invnormal(.5)-(_b[i_cons]+10.01*_b[xf]+6.5*_b[xl]+4*_b[xd])) /_b[s_cons])

(1) normal((invnormal(.5)-(_b[i_cons]+10.01*_b[xf]+5.5*_b[xl]+.5*_b[xd])) /_b[s_cons]) =
   normal((invnormal(.5)-(_b[i_cons]+10.01*_b[xf]+6.5*_b[xl]+4*_b[xd])) /_b[s_cons])

chi2(1) = 8.01
Prob > chi2 = 0.0046

We again reject the null hypothesis that the two curves are equal at the 0.05 level.

The model of our last example was also fit using the estimating equations method in example 7 of [R] rocreg. We will demonstrate rocregplot after that model fit as well.

Example 3: Parametric ROC, invROC, and ROC value

In example 2, we used rocregplot after a maximum likelihood model fit of the ROC curve for classifier nsnr and covariates frequency (xf), intensity (xl), and hearing loss severity (xd). The data were obtained from the audiology study described in Stover et al. (1996). In example 7 of [R] rocreg, we fit the model using the estimating equations method of Alonzo and Pepe (2002). Under this method, bootstrap resampling is used to make inferences. We saved 50 bootstrap replications in nsnr.dta, which we re-create below.

We use rocregplot to draw the ROC curves for nsnr under the covariate values xf = 10.01, xl = 5.5, and xd = .5, and xf = 10.01, xl = 6.5, and xd = 4. The at#() options are used to specify the covariate values. The previous bootstrap results are made available to rocregplot with the bfile() option. As before, we will specify 0.2 and 0.7 as false-positive rates in the roc() option and 0.5 as a ROC value in the invroc() option. We do not specify btype() and thus our graph will contain normal-based bootstrap confidence bands, the default.

As shown in the graph, we find that the ROC values at a false-positive rate of 0.7 are close together, as they were in the maximum likelihood estimation in example 2. We now repeat this process for the lower false-positive rate of 0.2 by using the roc(.2) option.

```
. rocregplot, at1(xf=10.01, xl=5.5, xd=.5) at2(xf=10.01, xl=6.5, xd=4) > roc(.2) bfile(nsnrf)
```

The point estimates of the ROC value and false-positive rate are both computed directly using the point estimates of the ROC coefficients. Calculation of the standard errors and confidence intervals is slightly more complicated. Essentially, we have stored a sample of our ROC covariate coefficient estimates in `nsnrf.dta`. We then calculate the ROC value or false-positive rate estimates using each set of coefficient estimates, resulting in a sample of point estimates. Then, the bootstrap standard error and confidence intervals are calculated based on these bootstrap samples. Details of the computation of the standard error and percentile confidence intervals can be found in *Methods and formulas* and in [*R*] bootstrap.

As mentioned in [*R* `rocreg`], 50 resamples is a reasonable lower bound for obtaining bootstrap standard errors (Mooney and Duval 1993). However, it may be too low for obtaining percentile and bias-corrected confidence intervals. Normal-based confidence intervals are valid when the bootstrap distribution exhibits normality. See [*R* bootstrap postestimation] for more details.

We can assess the normality of the bootstrap distribution by using a normal probability plot. Stata provides this in the `pnorm` command (see [*R* Diagnostic plots]). We will use `nsnrf.dta` to draw a normal probability plot for the ROC estimate corresponding to a false-positive rate of 0.2. We use the covariate values `xf = 10.01`, `xl = 6.5`, and `xd = 4`.

```stata
use nsnrf
(bootstrap: rocregstat)
generate double rocp2 = nsnr_b_i_cons + 10.01*nsnr_b_xf + 6.5*nsnr_b_xl + 4*nsnr_b_xd+nsnr_b_s_cons*invnormal(.2)
replace rocp2 = normal(rocp2)
(50 real changes made)
```
The closeness of the points to the horizontal line on the normal probability plot shows us that the bootstrap distribution is approximately normal. So it is reasonable to use the normal-based confidence intervals for ROC at a false-positive rate of 0.2 under covariate values $x_f = 10.01$, $x_l = 6.5$, and $x_d = 4$.

### Plotting marginal ROC curves

The `rocregplot` command can also be used after fitting models with no covariates. We will demonstrate this with an empirical ROC model fit in `[R] rocreg`.

#### Example 4: Nonparametric ROC

We run `rocregplot` after fitting the single-classifier, empirical ROC model shown in example 1 of `[R] rocreg`. There we empirically predicted the ROC curve of the classifier `rating` for the true status variable `disease` from the Hanley and McNeil (1982) data. The `rocreg` command saves variables `_roc_rating` and `_fpr_rating`, which give the ROC values and false-positive rates, respectively, for every value of `rating`. These variables are used by `rocregplot` to render the ROC curve.

```stata
. use https://www.stata-press.com/data/r18/hanley, clear
(Tomographic images)
. rocreg disease rating, noboot
Nonparametric ROC estimation
Control standardization: empirical
ROC method : empirical

Number of obs = 109

Area under the ROC curve
 Status : disease
 Classifier: rating

<table>
<thead>
<tr>
<th>Bootstrap</th>
<th>95% confidence interval</th>
</tr>
</thead>
<tbody>
<tr>
<td>coefficient</td>
<td>Bias</td>
</tr>
<tr>
<td>.8407708</td>
<td>.</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>.</td>
<td>(BC)</td>
</tr>
</tbody>
</table>
```
We end our discussion of `rocregplot` by showing its use after a marginal probit model.

Example 5: Maximum likelihood ROC, invROC, and ROC value

In example 13 of [R] `rocreg`, we fit a maximum-likelihood probit model to each classifier of the fictitious dataset generated from Hanley and McNeil (1983).

We use `rocregplot` after the original `rocreg` command to draw the ROC curves for classifiers `mod1` and `mod3`. This is accomplished by specifying the two variables in the `classvars()` option. We will use the `roc()` option to obtain confidence intervals for ROC values at false-positive rates of 0.15 and 0.75. We will specify the `invroc()` option to obtain false-positive rate confidence intervals for a ROC value of 0.8. As mentioned previously, these are Wald confidence intervals.

First, we will view results for a false-positive rate of 0.75.

```
. use https://www.stata-press.com/data/r18/ct2, clear
   (Reconstruction of CT images)
. rocreg status mod1 mod2 mod3, probit ml
   (output omitted)
. rocregplot, classvars(mod1 mod3) roc(.75)
```

```
 ROC curve
   Status : status
   Classifier: mod1

          ROC |   Coefficient |    Std. err. |          [95% conf. interval]
        --- |--------------|-------------|---------------------------------|
        .75 |     .9931655 |    .0069689 |        .9795067   1.006824

   Status : status
   Classifier: mod3

          ROC |   Coefficient |    Std. err. |          [95% conf. interval]
        --- |--------------|-------------|---------------------------------|
        .75 |    .9953942  |    .0043435 |        .9868811   1.003907
```
We see that the estimates for each of the two ROC curves are close. Because this is a marginal model, the actual false-positive rate and the true-positive rate for each observation are plotted in the graph. The added point estimates of the ROC value at false-positive rate 0.75 are shown as diamond (mod3) and circle (mod1) symbols in the upper-right-hand corner of the graph at FPR = 0.75. Confidence bands are also plotted at FPR = 0.75 but are so narrow that they are barely noticeable. Under both classifiers, the ROC value at 0.75 is very high. Now, we will compare these results to those with a lower false-positive rate of 0.15.

```
. rocregplot, classvars(mod1 mod3) roc(.15)
```

<table>
<thead>
<tr>
<th>ROC</th>
<th>Coefficient</th>
<th>Std. err.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>.15</td>
<td>.7934935</td>
<td>.0801363</td>
<td>.6364292 .9505578</td>

</thead>
<tbody>
<tr>
<td>.15</td>
<td>.8888596</td>
<td>.0520118</td>
<td>.7869184 .9908008</td>
</tr>
</tbody>
</table>
The ROC value for the false-positive rate of 0.15 is more separated in the two classifiers. Here we see that mod3 has a larger ROC value than mod1 for this false-positive rate, but the confidence intervals of the estimates overlap.

By specifying `invroc(.8)`, we obtain invROC confidence intervals corresponding to a ROC value of 0.8.

```
. rocregplot, classvars(mod1 mod3) invroc(.8)
False-positive rate
Status : status
Classifier: mod1

<table>
<thead>
<tr>
<th>invROC</th>
<th>Coefficient</th>
<th>Std. err.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>.8</td>
<td>.1556435</td>
<td>.069699</td>
<td>.019036 .2922509</td>
</tr>
</tbody>
</table>

Status : status
Classifier: mod3

<table>
<thead>

<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>.8</td>
<td>.0661719</td>
<td>.045316</td>
<td>-.0226458 .1549896</td>
</tr>
</tbody>
</table>
```

The graph shows the ROC curves for Modality 1 and Modality 3, with fits for the respective classifiers.
For estimation of the false-positive rate at a ROC value of 0.8, the confidence intervals overlap. Both classifiers require only a small false-positive rate to achieve a ROC value of 0.8.

Methods and formulas

Details on computation of the nonparametric ROC curve and the estimation of the parametric ROC curve model coefficients can be found in [R] rocreg. Here we describe how to estimate the ROC values and false-positive rates of a parametric model. The cumulative distribution function $g$ can be the standard normal cumulative distribution function.

Methods and formulas are presented under the following headings:

- Parametric model: Summary parameter definition
- Maximum likelihood estimation
- Estimating equations estimation

### Parametric model: Summary parameter definition

Conditioning on covariates $\mathbf{x}$, we have the following ROC curve model:

$$\text{ROC} (u) = g \{ \mathbf{x}' \beta + \alpha g^{-1} (u) \}$$

$\mathbf{x}$ can be constant, and $\beta = \beta_0$, the constant intercept.

With simple algebra, we can solve this equation to obtain the false-positive rate value $u$ for a ROC value of $r$:

$$u = g \left[ \{g^{-1} (r) - \mathbf{x}' \beta \} \alpha^{-1} \right]$$
Maximum likelihood estimation

We allow maximum likelihood estimation under probit parametric models, so \( g = \Phi \). The ROC value and false-positive rate parameters all have closed-form expressions in terms of the covariate values \( x \), coefficient vector \( \beta \), and slope parameter \( \alpha \). Thus to estimate these two types of summary parameters, we use the delta method (Oehlert 1992; Phillips and Park 1988). Particularly, we use the \texttt{nlcom} command (see \texttt{[R] nlcom}) to implement the delta method.

Under maximum likelihood estimation, the coefficient estimates \( \hat{\beta} \) and slope estimate \( \hat{\alpha} \) are asymptotically normal with variance matrix \( V \). For convenience, we rename the parameter vector \( [\beta', \alpha] \) to the \( k \)-parameter vector \( \theta = [\theta_1, \ldots, \theta_k] \). We will also explicitly refer to the conditioning of the ROC curve by \( \theta \) in its mention as \( \text{ROC}(t, \theta) \).

Under the delta method, the continuous scalar function of the estimate \( \hat{\theta} \), \( f(\hat{\theta}) \) has asymptotic mean \( f(\theta) \) and asymptotic covariance

\[
\hat{\text{Var}} \left\{ f(\hat{\theta}) \right\} = fVf'
\]

where \( f \) is the \( 1 \times k \) matrix of derivatives for which

\[
f_{1j} = \frac{\partial f(\theta)}{\partial \theta_j} \quad j = 1, \ldots, k
\]

The asymptotic covariance of \( f(\hat{\theta}) \) is estimated and then used in conjunction with \( f(\hat{\theta}) \) for further inference, including Wald confidence intervals, standard errors, and hypothesis testing.

Estimating equations estimation

When we fit a model using the Alonzo and Pepe (2002) estimating equations method, we use the bootstrap to perform inference on the ROC curve summary parameters. Each bootstrap sample provides a sample of the coefficient estimates \( \beta \) and the slope estimates \( \alpha \). Using the formulas above, we can obtain an estimate of the ROC value or false-positive rate for each resample.

By making these calculations, we obtain a bootstrap sample of our summary parameter estimate. We then obtain bootstrap standard errors, normal approximation confidence intervals, percentile confidence intervals, and bias-corrected confidence intervals using this bootstrap sample. Further details can be found in \texttt{[R] bootstrap}.

[U] 20 Estimation and postestimation commands
Description

The above command is used to perform receiver operating characteristic (ROC) analyses with rating and discrete classification data.

The two variables `refvar` and `classvar` must be numeric. The reference variable indicates the true state of the observation, such as diseased and nondiseased or normal and abnormal, and must be coded as 0 and 1. The rating or outcome of the diagnostic test or test modality is recorded in `classvar`, which must be at least ordinal, with higher values indicating higher risk.

`roctab` performs nonparametric ROC analyses. By default, `roctab` calculates the area under the ROC curve. Optionally, `roctab` can plot the ROC curve, display the data in tabular form, and produce Lorenz-like plots.

See [R] `rocfit` for a command that fits maximum-likelihood ROC models.

Quick start

AUC, standard error, and CI for ROC curve of binary true state, `true`, as a function of classification variable `v`

```
roctab true v
```

Also plot the ROC curve

```
roctab true v, graph summary
```

Same as above, but plot sensitivity versus specificity instead of the ROC curve

```
roctab true v, specificity summary
```

Exact binomial CI instead of asymptotic normal CI for AUC estimate

```
roctab true v, binomial
```

Gini and Pietra indices

```
roctab true v, lorenz
```

Options

**Main**

- `lorenz`: specifies that the Gini and Pietra indices be reported. Optionally, `graph` will plot the Lorenz-like curve.
- `binomial`: specifies that exact binomial confidence intervals be calculated.
- `nolabel`: specifies that numeric codes be displayed rather than value labels.
detail outputs a table displaying the sensitivity, specificity, the percentage of subjects correctly classified, and two likelihood ratios for each possible cutpoint of classvar.

table outputs a $2 \times k$ contingency table displaying the raw data.

bamber specifies that the standard error for the area under the ROC curve be calculated using the method suggested by Bamber (1975). Otherwise, standard errors are obtained as suggested by DeLong, DeLong, and Clarke-Pearson (1988).

hanley specifies that the standard error for the area under the ROC curve be calculated using the method suggested by Hanley and McNeil (1982). Otherwise, standard errors are obtained as suggested by DeLong, DeLong, and Clarke-Pearson (1988).

graph produces graphical output of the ROC curve. If lorenz is specified, graphical output of a Lorenz-like curve will be produced.

norefline suppresses plotting the 45-degree reference line from the graphical output of the ROC curve.

summary reports the area under the ROC curve, its standard error, and its confidence interval. If lorenz is specified, Lorenz indices are reported. This option is needed only when also specifying graph.

specificity produces a graph of sensitivity versus specificity instead of sensitivity versus $(1 - \text{specificity})$. specificity implies graph.

level(#) specifies the confidence level, as a percentage, for the confidence intervals. The default is level(95) or as set by set level; see [R] level.

plotplotopts(plot_options) affects the rendition of the plotted ROC curve—the curve’s plotted points connected by lines. The plot_options can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] marker_options, [G-3] marker_label_options, and [G-3] cline_options.

rlopts(cline_options) affects the rendition of the reference line; see [G-3] cline_options.

addplot(plot) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

twoway_options are any of the options documented in [G-3] twoway_options, excluding by(). These include options for titling the graph (see [G-3] title_options) and for saving the graph to disk (see [G-3] saving_option).

Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Nonparametric ROC curves
- Lorenz-like curves
Introduction

The `roctab` command provides nonparametric estimation of the ROC for a given classifier and true-status reference variable. The Lorenz curve functionality of `roctab`, which provides an alternative to standard ROC analysis, is discussed in *Lorenz-like curves*.

Nonparametric ROC curves

The points on the nonparametric ROC curve are generated using each possible outcome of the diagnostic test as a classification cutpoint and computing the corresponding sensitivity and 1—specificity. These points are then connected by straight lines, and the area under the resulting ROC curve is computed using the trapezoidal rule.

Example 1

Hanley and McNeil (1982) presented data from a study in which a reviewer was asked to classify, using a five-point scale, a random sample of 109 tomographic images from patients with neurological problems. The rating scale was as follows: 1 = definitely normal, 2 = probably normal, 3 = questionable, 4 = probably abnormal, and 5 = definitely abnormal. The true disease status was normal for 58 of the patients and abnormal for the remaining 51 patients.

Here we list 9 of the 109 observations:

```stata
use https://www.stata-press.com/data/r18/hanley
list disease rating in 1/9
```

<table>

<td>0 1</td>
</tr>
</tbody>
</table>

For each observation, `disease` identifies the true disease status of the subject (0 = normal, 1 = abnormal), and `rating` contains the classification value assigned by the reviewer.

We can use `roctab` to calculate and plot the nonparametric ROC curve by specifying both the `summary` and `graph` options. By also specifying the `table` option, we obtain a contingency table summarizing our dataset.
. roctab disease rating, table graph summary

By default, `roctab` reports the area under the curve, its standard error, and its confidence interval. The `graph` option can be used to plot the ROC curve.

The ROC curve is plotted by computing the sensitivity and specificity using each value of the rating variable as a possible cutpoint. A point is plotted on the graph for each of the cutpoints. These plotted points are joined by straight lines to form the ROC curve, and the area under the ROC curve is computed using the trapezoidal rule.
We can tabulate the computed sensitivities and specificities for each of the possible cutpoints by specifying `detail`.

```
. roctab disease rating, detail
Detailed report of sensitivity and specificity

</tbody>
</table>
```

Each cutpoint in the table indicates the ratings used to classify tomographs as being from an abnormal subject. For example, the first cutpoint (>= 1) indicates that all tomographs rated as 1 or greater are classified as coming from abnormal subjects. Because all tomographs have a rating of 1 or greater, all are considered abnormal. Consequently, all abnormal cases are correctly classified (sensitivity = 100%), but none of the normal patients is classified correctly (specificity = 0%). For the second cutpoint (>=2), tomographs with ratings of 1 are classified as normal, and those with ratings of 2 or greater are classified as abnormal. The resulting sensitivity and specificity are 94.12% and 56.90%, respectively. Using this cutpoint, we correctly classified 74.31% of the 109 tomographs. Similar interpretations can be used on the remaining cutpoints. As mentioned, each cutpoint corresponds to a point on the nonparametric ROC curve. The first cutpoint (>=1) corresponds to the point at (1,1), and the last cutpoint (> 5) corresponds to the point at (0,0).

`detail` also reports two likelihood ratios suggested by Choi (1998): the likelihood ratio for a positive test result (LR+) and the likelihood ratio for a negative test result (LR–). The LR+ is the ratio of the probability of a positive test among the truly positive subjects to the probability of a positive test among the truly negative subjects. The LR– is the ratio of the probability of a negative test among the truly positive subjects to the probability of a negative test among the truly negative subjects. Choi points out that LR+ corresponds to the slope of the line from the origin to the point on the ROC curve determined by the cutpoint. Similarly, LR– corresponds to the slope from the point (1,1) to the point on the ROC curve determined by the cutpoint.

By default, `roctab` calculates the standard error for the area under the curve by using an algorithm suggested by DeLong, DeLong, and Clarke-Pearson (1988) and asymptotic normal confidence intervals. Optionally, standard errors based on methods suggested by Bamber (1975) or Hanley and McNeil (1982) can be computed by specifying `bamber` or `hanley`, respectively, and an exact binomial confidence interval can be obtained by specifying `binomial`.
Lorenz-like curves

For applications where it is known that the risk status increases or decreases monotonically with increasing values of the diagnostic test, the ROC curve and associated indices are useful in assessing the overall performance of a diagnostic test. When the risk status does not vary monotonically with increasing values of the diagnostic test, however, the resulting ROC curve can be nonconvex and its indices can be unreliable. For these situations, Lee (1999) proposed an alternative to the ROC analysis based on Lorenz-like curves and the associated Pietra and Gini indices.

Lee (1999) mentions at least three specific situations where results from Lorenz curves are superior to those obtained from ROC curves: 1) a diagnostic test with similar means but very different standard deviations in the abnormal and normal populations, 2) a diagnostic test with bimodal distributions in either the normal or abnormal population, and 3) a diagnostic test distributed symmetrically in the normal population and skewed in the abnormal.

When the risk status increases or decreases monotonically with increasing values of the diagnostic test, the ROC and Lorenz curves yield interchangeable results.

Example 2

To illustrate the use of the `lorenz` option, we constructed a fictitious dataset that yields results similar to those presented in Table III of Lee (1999). The data assume that a 12-point rating scale was used to classify 442 diseased and 442 healthy subjects. We list a few of the observations.

```
. list in 1/7, noobs sep(0)
+-----------------+--------+-------+
<table>
<thead>
<tr>
<th>disease</th>
<th>class</th>
<th>pop</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>5</td>
<td>66</td>

<td>11</td>
<td>17</td>
</tr>
<tr>
<td>0</td>
<td>6</td>
<td>85</td>
</tr>
<tr>
<td>0</td>
<td>3</td>
<td>19</td>
</tr>
<tr>
<td>0</td>
<td>10</td>
<td>19</td>
</tr>
<tr>
<td>0</td>
<td>2</td>
<td>7</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>16</td>
</tr>
</tbody>
</table>
+-----------------+--------+-------+
```

The data consist of 24 observations: 12 observations from diseased individuals and 12 from nondiseased individuals. Each observation corresponds to one of the 12 classification values of the rating-scale variable, `class`. The number of subjects represented by each observation is given by the `pop` variable, making this a frequency-weighted dataset. The data were generated assuming a binormal distribution of the latent variable with similar means for the normal and abnormal populations but with the standard deviation for the abnormal population five times greater than that of the normal population.
The resulting ROC curve is nonconvex or, as termed by Lee, “wiggly”. Lee argues that for this and similar situations, the Lorenz curve and indices are preferred.

Like ROC curves, a more bowed Lorenz curve suggests a better diagnostic test. This bowedness is quantified by the Pietra index, which is geometrically equivalent to twice the largest triangle that can be inscribed in the area between the curve and the diagonal line, and the Gini index, which is equivalent to twice the area between the Lorenz curve and the diagonal. Lee (1999) provides several additional interpretations for the Pietra and Gini indices.
Stored results

`roctab` stores the following in `r()`:

Scalars
- `r(N)` number of observations
- `r(se)` standard error for the area under the ROC curve
- `r(lb)` lower bound of CI for the area under the ROC curve
- `r(ub)` upper bound of CI for the area under the ROC curve
- `r(level)` confidence level
- `r(area)` area under the ROC curve
- `r(pietra)` Pietra index
- `r(gini)` Gini index

Macros
- `r(cutpoints)` description of cutpoints (detail only)

Matrices
- `r(detail)` matrix with details on sensitivity and specificity for each cutpoint (detail only)

Methods and formulas

Assume that we applied a diagnostic test to each of $N_n$ normal and $N_a$ abnormal subjects. Further assume that the higher the outcome value of the diagnostic test, the higher the risk of the subject being abnormal. Let $\hat{\theta}$ be the estimated area under the curve, and let $X_i, i = 1, 2, \ldots, N_a$ and $Y_j, j = 1, 2, \ldots, N_n$ be the values of the diagnostic test for the abnormal and normal subjects, respectively.

The points on the nonparametric ROC curve are generated using each possible outcome of the diagnostic test as a classification cutpoint and computing the corresponding sensitivity and $1 - \text{specificity}$. These points are then connected by straight lines, and the area under the resulting ROC curve is computed using the trapezoidal rule.

The default standard error for the area under the ROC curve is computed using the algorithm described by DeLong, DeLong, and Clarke-Pearson (1988). For each abnormal subject, $i$, define

$$V_{10}(X_i) = \frac{1}{N_n} \sum_{j=1}^{N_n} \psi(X_i, Y_j)$$

and for each normal subject, $j$, define

$$V_{01}(Y_j) = \frac{1}{N_a} \sum_{i=1}^{N_a} \psi(X_i, Y_j)$$

where

$$\psi(X, Y) = \begin{cases} 
1 & Y < X \\
\frac{1}{2} & Y = X \\
0 & Y > X 
\end{cases}$$
Define

\[ S_{10} = \frac{1}{N_a - 1} \sum_{i=1}^{N_a} \{V_{10}(X_i) - \hat{\theta}\}^2 \]

and

\[ S_{01} = \frac{1}{N_n - 1} \sum_{j=1}^{N_n} \{V_{01}(Y_j) - \hat{\theta}\}^2 \]

The variance of the estimated area under the ROC curve is given by

\[ \text{var}(\hat{\theta}) = \frac{1}{N_a} S_{10} + \frac{1}{N_n} S_{01} \]

The Hanley standard error for the area under the ROC curve is computed using the algorithm described by Hanley and McNeil (1982). It requires the calculation of two quantities: \( Q_1 \) is \( \text{Pr} \) (two randomly selected abnormal subjects will both have a higher score than a randomly selected normal subject), and \( Q_2 \) is \( \text{Pr} \) (one randomly selected abnormal subject will have a higher score than any two randomly selected normal subjects). The Hanley and McNeil variance of the estimated area under the ROC curve is

\[ \text{var}(\hat{\theta}) = \hat{\theta}(1 - \hat{\theta}) + (N_a - 1)(Q_1 - \hat{\theta}^2) + (N_n - 1)(Q_2 - \hat{\theta}^2) \]

The Bamber standard error for the area under the ROC curve is computed using the algorithm described by Bamber (1975). For any two \( Y \) values, \( Y_j \) and \( Y_k \), and any \( X_i \) value, define

\[ b_{yyx} = p(Y_j, Y_k < X_i) + p(X_i < Y_j, Y_k) - 2p(Y_j < X_i < Y_k) \]

and similarly, for any two \( X \) values, \( X_i \) and \( X_l \), and any \( Y_j \) value, define

\[ b_{xxy} = p(X_i, X_l < Y_j) + p(Y_j < X_i, X_l) - 2p(X_i < Y_j < X_l) \]

Bamber’s unbiased estimate of the variance for the area under the ROC curve is

\[ \text{var}(\hat{\theta}) = \frac{1}{4} (N_a - 1)(N_n - 1) \{p(X \neq Y) + (N_a - 1)b_{xxy} + (N_n - 1)b_{yyx} - 4(N_a + N_n - 1)(\hat{\theta} - 0.5)^2\} \]

Asymptotic confidence intervals are constructed and reported by default, assuming a normal distribution for the area under the ROC curve.

Exact binomial confidence intervals are calculated as described in [R] ci, with \( p \) equal to the area under the ROC curve.

Description

`rreg` performs one version of robust regression of `depvar` on `indepvars`.

Also see *Robust standard errors* in [R] `regress` for standard regression with robust variance estimates and [R] `qreg` for quantile (including median) regression.

Quick start

Robust regression of `y` on `x`

```
rreg y x
```

Add a categorical covariate `a` using factor-variable syntax

```
rreg y x i.a
```

Same as above, but set the tuning parameter to 8

```
rreg y x i.a, tune(8)
```

Generate a new variable `wvar` containing the final weight for each observation

```
rreg y x i.a, genwt(wvar)
```

Set confidence level to 99%

```
rreg y x i.a, level(99)
```

Menu

Statistics > Linear models and related > Other > Robust regression
Syntax

```
rreg depvar [ indepvars ] [ if ] [ in ] [ , options ]
```

<td>graph graph weights during convergence</td>
</tr>
<tr>
<td></td>
<td>coeflegend display legend instead of statistics</td>
</tr>
</tbody>
</table>

**Options**

```
rreg depvar [ indepvars ] [ if ] [ in ] [ , options ]
```

**Model**

tune(#) is the biweight tuning constant. The default is tune(7), meaning seven times the median absolute deviation from the median residual; see *Methods and formulas*. Lower tuning constants downweight outliers rapidly but may lead to unstable estimates (less than 6 is not recommended). Higher tuning constants produce milder downweighting.

**Reporting**

level(#) set confidence level; default is level(95)

genwt(newvar) creates the new variable newvar containing the weights assigned to each observation.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabels, fvwrap(#), fwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

**Optimization**

optimization_options: iterate(#), tolerance(#), [no]log iterate() specifies the maximum number of iterations; iterations stop when the maximum change in weights drops below tolerance(); and log/nolog specifies whether to show the iteration log (see set iterlog in [R] set iter). These options are seldom used.

```
by, collect, mfp, mi estimate, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.
```

coefflegend does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
graph allows you to graphically watch the convergence of the iterative technique. The weights obtained from the most recent round of estimation are graphed against the weights obtained from the previous round.

The following option is available with `rreg` but is not shown in the dialog box: ` coeflegend`; see [R] Estimation options.

### Remarks and examples

`rreg` first performs an initial screening based on Cook’s distance > 1 to eliminate gross outliers before calculating starting values and then performs Huber iterations followed by biweight iterations, as suggested by Li (1985).

#### Example 1

We wish to examine the relationship between mileage rating, weight, and location of manufacture for the 74 cars in the `auto.dta`. As a point of comparison, we begin by fitting an ordinary regression:

```stata
    use https://www.stata-press.com/data/r18/auto
    (1978 automobile data)
    . regress mpg weight foreign
    Source             SS     df       MS          Number of obs =      74
                      F(2, 71) = 69.75
    Model             1619.2877     2  809.643849      Prob > F =    0.0000
    Residual          824.171761    71  11.6080531     R-squared =    0.6627
    Total             2443.45946    73  33.4720474     Adj R-squared =    0.6532
    
    Coefficient  Std. err.     t     P>|t|    [95% conf. interval]
    weight      -.0065879  .0006371  -10.34  0.000  -.0078583  -.0053175
    foreign    -1.650029   1.075994  -1.53  0.130  -3.7955  .4954422
    _cons       41.6797   2.165547   19.25  0.000  37.36172  45.99768
```

We now compare this with the results from `rreg`:

```stata
    . rreg mpg weight foreign
    Huber iteration 1: Maximum difference in weights = .80280176
    Huber iteration 2: Maximum difference in weights = .2915438
    Huber iteration 3: Maximum difference in weights = .08911171
    Huber iteration 4: Maximum difference in weights = .02697328
    Biweight iteration 5: Maximum difference in weights = .29186818
    Biweight iteration 6: Maximum difference in weights = .11988101
    Biweight iteration 7: Maximum difference in weights = .03315872
    Biweight iteration 8: Maximum difference in weights = .00721325
    Robust regression     Number of obs =      74
                          F( 2, 71) = 168.32

```

Note the large change in the `foreign` coefficient.
Technical note

It would have been better if we had fit the previous robust regression by typing \texttt{rreg mpg weight foreign, genwt(w)}. The new variable, \textit{w}, would then contain the estimated weights. Let’s pretend that we did this:

```
. rreg mpg weight foreign, genwt(w)  
(output omitted)  
. summarize w, detail
```

<table>
<thead>

</tbody>
</table>

Being familiar with the automobile data, we immediately spotted two things: the \textit{VW} is the only diesel car in our data, and the weight recorded for the Plymouth Arrow is incorrect.
Example 2

If we specify no explanatory variables, `rreg` produces a robust estimate of the mean:

```
. rreg mpg
Huber iteration 1: Maximum difference in weights = .64471879
Huber iteration 2: Maximum difference in weights = .05098336
Huber iteration 3: Maximum difference in weights = .0099887
Biweight iteration 4: Maximum difference in weights = .25197391
Biweight iteration 5: Maximum difference in weights = .00358606
Robust regression Number of obs = 74
F( 0, 73) = 0.00
Prob > F = .

mpg Coefficient Std. err. t P>|t| [95% conf. interval]
_cons 20.68825 .641813 32.23 0.000 19.40912 21.96738
```

The estimate is given by the coefficient on `_cons`. The mean is 20.69 with an estimated standard error of 0.6418. The 95% confidence interval is [19.4, 22.0]. By comparison, `ci means` (see [R] ci) gives us the standard calculation:

```
. ci means mpg
Variable Obs Mean Std. err. [95% conf. interval]
mpg 74 21.2973 .6725511 19.9569 22.63769
```

Stata has an active user community working in the area of robust statistics. You may also be interested in robust estimators and outlier detection tools from Verardi and McCathie (2012), Verardi and Dehon (2010), Jann (2010), and Verardi and Croux (2009), to name a few. See [R] ssc for how to install community-contributed packages.
Stored results

`rreg` stores the following in `e()`:

Scalars
- `e(N)` number of observations
- `e(mss)` model sum of squares
- `e(df_m)` model degrees of freedom
- `e(rss)` residual sum of squares
- `e(df_r)` residual degrees of freedom
- `e(r2)` $R^2$
- `e(r2_a)` adjusted $R^2$
- `e(F)` $F$ statistic
- `e(rmse)` root mean squared error
- `e(rank)` rank of `e(V)`

Macros
- `e(cmd)` `rreg`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(genwt)` variable containing the weights
- `e(title)` title in estimation output
- `e(model)` `ols`
- `e(properties)` `b V`
- `e(predict)` program used to implement `predict`
- `e(marginsok)` predictions allowed by `margins`
- `e(asbalanced)` factor variables `fvset` as `asbalanced`
- `e(asobserved)` factor variables `fvset` as `asobserved`

Matrices
- `e(b)` coefficient vector
- `e(V)` variance–covariance matrix of the estimators

Functions
- `e(sample)` marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices
- `r(table)` matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any `r`-class command is run after the estimation command.

Methods and formulas

`rreg` begins by fitting the regression (see [R] `regress`), calculating Cook’s $D$ (see [R] `predict` and [R] `regress postestimation`), and excluding any observation for which $D > 1$.

Thereafter, `rreg` works iteratively: it performs a regression, calculates case weights from absolute residuals, and regresses again using those weights. Iterations stop when the maximum change in weights drops below `tolerance()`. Weights derive from one of two weight functions, Huber weights and biweights. Huber weights (Huber 1964) are used until convergence, and then, from that result, biweights are used until convergence. The biweight was proposed by Beaton and Tukey (1974, 151–152) after the Princeton robustness study (Andrews et al. 1972) had compared various estimators. Both weighting functions are used because Huber weights have problems dealing with severe outliers, whereas biweights sometimes fail to converge or have multiple solutions. The initial Huber weighting should improve the behavior of the biweight estimator.
In Huber weighting, cases with small residuals receive weights of 1; cases with larger residuals receive gradually smaller weights. Let $e_i = y_i - X_i \hat{b}$ represent the $i$th-case residual. The $i$th scaled residual $u_i = e_i / s$ is calculated, where $s = M / 0.6745$ is the residual scale estimate and $M = \text{med}(|e_i - \text{med}(e_i)|)$ is the median absolute deviation from the median residual. Huber estimation obtains case weights:

$$w_i = \begin{cases} 1 & \text{if } |u_i| \leq c_h \\ c_h / |u_i| & \text{otherwise} \end{cases}$$

rreg defines $c_h = 1.345$, so downweighting begins with cases whose absolute residual exceeds $(1.345 / 0.6745)M \approx 2M$.

With biweights, all cases with nonzero residuals receive some downweighting, according to the smoothly decreasing biweight function

$$w_i = \begin{cases} \{1 - (u_i / c_b)^2\}^2 & \text{if } |u_i| \leq c_b \\ 0 & \text{otherwise} \end{cases}$$

where $c_b = 4.685 \times \text{tune()} / 7$. Thus when $\text{tune()} = 7$, cases with absolute residuals of $(4.685 / 0.6745)M \approx 7M$ or more are assigned 0 weight and thus are effectively dropped. Goodall (1983, 377) suggests using a value between 6 and 9, inclusive, for $\text{tune()}$ in the biweight case and states that performance is good between 6 and 12, inclusive.

The tuning constants $c_h = 1.345$ and $c_b = 4.685$ (assuming $\text{tune()}$ is set at the default 7) give rreg about 95% of the efficiency of OLS when applied to data with normally distributed errors (Hamilton 1991b). Lower tuning constants downweight outliers more drastically (but give up Gaussian efficiency); higher tuning constants make the estimator more like OLS.

Standard errors are calculated using the pseudovalues approach described in Street, Carroll, and Ruppert (1988).

Acknowledgment

The current version of rreg is due to the work of Lawrence Hamilton of the Department of Sociology at the University of New Hampshire.

predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, residuals, and diagonal elements of the hat matrix.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xb</td>
<td>linear prediction; the default</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>

<tr>
<td>residuals</td>
<td>residuals</td>
</tr>
<tr>
<td>hat</td>
<td>diagonal elements of the hat matrix</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type `predict ... if e(sample) ... if wanted only for the estimation sample.`

Options for predict

- `xb`, the default, calculates the linear prediction.
- `stdee` calculates the standard error of the linear prediction.
- `residuals` calculates the residuals.
- `hat` calculates the diagonal elements of the hat matrix. You must have run the `rreg` command with the `genwt()` option.
margins

Description for margins

margins estimates margins of response for linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [options]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>

**runtest — Test for random order**

### Description

`runtest` tests whether the observations of `varname` are serially independent—that is, whether they occur in a random order—by counting how many runs there are above and below a threshold. By default, the median is used as the threshold. A small number of runs indicates positive serial correlation; a large number indicates negative serial correlation.

### Quick start

Run test for the serial independence of the observations of `v1`

```plaintext
runtest v1
```

Use the mean of `v1`, rather than the median, as the threshold for counting runs

```plaintext
runtest v1, mean
```

Use 10 as the threshold for counting runs

```plaintext
runtest v1, threshold(10)
```

Same as above, but ignore any values of `v1` equal to the threshold when counting runs

```plaintext
runtest v1, threshold(10) drop
```

### Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Test for random order
Syntax

```
runtest varname [in] [, options]
```

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>continuity</td>
<td>continuity correction</td>
</tr>
<tr>
<td>drop</td>
<td>ignore values equal to the threshold</td>
</tr>
<tr>
<td>split</td>
<td>randomly split values equal to the threshold as above or below the threshold; default is to count as below</td>
</tr>
<tr>
<td>mean</td>
<td>use mean as threshold; default is median</td>
</tr>
<tr>
<td>threshold(#)</td>
<td>assign arbitrary threshold; default is median</td>
</tr>
</tbody>
</table>

Options

- **continuity** specifies a continuity correction that may be helpful in small samples. If there are fewer than 10 observations either above or below the threshold, however, the tables in Swed and Eisenhart (1943) provide more reliable critical values. By default, no continuity correction is used.

- **drop** directs `runtest` to ignore any values of `varname` that are equal to the threshold value when counting runs and tabulating observations. By default, `runtest` counts a value as being above the threshold when it is strictly above the threshold and as being below the threshold when it is less than or equal to the threshold.

- **split** directs `runtest` to randomly split values of `varname` that are equal to the threshold. In other words, when `varname` is equal to threshold, a “coin” is flipped. If it comes up heads, the value is counted as above the threshold. If it comes up tails, the value is counted as below the threshold.

- **mean** directs `runtest` to tabulate runs above and below the mean rather than the median.

- **threshold(#)** specifies an arbitrary threshold to use in counting runs. For example, if `varname` has already been coded as a 0/1 variable, the median generally will not be a meaningful separating value.

Remarks and examples

`runtest` performs a nonparametric test of the hypothesis that the observations of `varname` occur in a random order by counting how many runs there are above and below a threshold. If `varname` is positively serially correlated, it will tend to remain above or below its median for several observations in a row; that is, there will be relatively few runs. If, on the other hand, `varname` is negatively serially correlated, observations above the median will tend to be followed by observations below the median and vice versa; that is, there will be relatively many runs.

By default, `runtest` uses the median for the threshold, and this is not necessarily the best choice. If `mean` is specified, the mean is used instead of the median. If `threshold(#)` is specified, # is used. Because `runtest` divides the data into two states—above and below the threshold—it is appropriate for data that are already binary; for example, win or lose, live or die, rich or poor, etc. Such variables are often coded as 0 for one state and 1 for the other. Here you should specify `threshold(0)` because, by default, `runtest` separates the observations into those that are greater than the threshold and those that are less than or equal to the threshold.
As with most nonparametric procedures, the treatment of ties complicates the test. Observations equal to the threshold value are ties and can be treated in one of three ways. By default, they are treated as if they were below the threshold. If `drop` is specified, they are omitted from the calculation and the total number of observations is adjusted. If `split` is specified, each is randomly assigned to the above- and below-threshold groups. The random assignment is different each time the procedure is run unless you specify the random-number seed; see [R] `set seed`.

### Example 1

We can use `runtest` to check regression residuals for serial correlation.

```
. use https://www.stata-press.com/data/r18/run1
. scatter resid year, connect(l) yline(0) title(Regression residuals)
```

The graph gives the impression that these residuals are positively correlated. Excursions above or below zero—the natural threshold for regression residuals—tend to last for several observations. `runtest` can evaluate the statistical significance of this impression.

```
. runtest resid, thresh(0)
N(resid <= 0) = 8
N(resid > 0) = 8
obs = 16
N(runs) = 5
z = -2.07
Prob>|z| = .04
```

There are five runs in these 16 observations. Using the normal approximation to the true distribution of the number of runs, the five runs in this series are fewer than would be expected if the residuals were serially independent. The \( p \)-value is 0.04, indicating a two-sided significant result at the 5% level. If the alternative hypothesis is positive serial correlation, rather than any deviation from randomness, then the one-sided \( p \)-value is \( 0.04/2 = 0.015 \). With so few observations, however, the normal approximation may be inaccurate. (Tables compiled by Swed and Eisenhart list five runs as the 5% critical value for a one-sided test.)

`runtest` is a nonparametric test. It ignores the magnitudes of the observations and notes only whether the values are above or below the threshold. We can demonstrate this feature by reducing the information about the regression residuals in this example to a 0/1 variable that indicates only whether a residual is positive or negative.
As expected, `runtest` produces the same answer as before.

---

**Technical note**

The run test can also be used to test the null hypothesis that two samples are drawn from the same underlying distribution. The run test is sensitive to differences in the shapes, as well as the locations, of the empirical distributions.

Suppose, for example, that two different additives are added to the oil in 10 different cars during an oil change. The cars are run until a viscosity test determines that another oil change is needed, and the number of miles traveled between oil changes is recorded. The data are

```stata
. use https://www.stata-press.com/data/r18/additive, clear
. list
+---+-----+------+
|   |    |      |
|---+-----+------|
| 1.| 1   | 4024 |
| 2.| 1   | 4756 |
| 3.| 1   | 7993 |
| 4.| 1   | 5025 |
| 5.| 1   | 4188 |
| 6.| 2   | 3007 |
| 7.| 2   | 1988 |
| 8.| 2   | 1051 |
| 9.| 2   | 4478 |
|10.| 2   | 4232 |
+---+-----+------+
```

To test whether the additives generate different distributions of miles between oil changes, we sort the data by `miles` and then use `runtest` to see whether the marker for each additive occurs in random order:

```stata
. sort miles
. runtest additive, thresh(1)
N(additive <= 1) = 5
N(additive > 1) = 5
    obs = 10
    N(runs) = 4
        z  = -1.34
    Prob>|z| = .18
```

Here the additives do not produce statistically different results.
A test that is related to the run test is the runs up-and-down test. In the latter test, the data are classified not by whether they lie above or below a threshold but by whether they are steadily increasing or decreasing. Thus an unbroken string of increases in the variable of interest is counted as one run, as is an unbroken string of decreases. According to Madansky (1988), the run test is superior to the runs up-and-down test for detecting trends in the data, but the runs up-and-down test is superior for detecting autocorrelation.

runtest can be used to perform a runs up-and-down test. Using the regression residuals from the example above, we can perform a runtest on their first differences:

```
use https://www.stata-press.com/data/r18/run1
generate resid_D = resid - resid[_n-1]
runtest resid_D, thresh(0)
```

```
N(resid_D <= 0) = 7
N(resid_D > 0) = 8
obs = 15
N(runs) = 6
z = -1.33
Prob>|z| = .18
```

Edgington (1961) has compiled a table of the small-sample distribution of the runs up-and-down statistic, and this table is reprinted in Madansky (1988). For large samples, the $z$ statistic reported by runtest is incorrect for the runs up-and-down test. Let $N$ be the number of observations (15 here), and let $r$ be the number of runs (6). The expected number of runs in the runs up-and-down test is

$$\mu_r = \frac{2N - 1}{3}$$

the variance is

$$\sigma_r^2 = \frac{16N - 29}{90}$$

and the correct $z$ statistic is

$$\hat{z} = \frac{r - \mu_r}{\sigma_r}$$

runtest will tolerate missing values at the beginning or end of a series, as occurred in the technical note above (generating first differences resulted in a missing value for the first observation). runtest, however, will issue an error message if there are any missing observations in the interior of the series (in the portion covered by the `in range` qualifier). To perform the test anyway, simply drop the missing observations before using runtest.
**Stored results**

`runtest` stores the following in `r()`:

Scalars
- `r(N)` number of observations
- `r(p)` p-value of z
- `r(N_below)` number below the threshold
- `r(z)` z statistic
- `r(N_above)` number above the threshold
- `r(n_runs)` number of runs
- `r(mean)` expected number of runs
- `r(Var)` variance of the number of runs

**Methods and formulas**

`runtest` begins by calculating the number of observations below the threshold, \( n_0 \); the number of observations above the threshold, \( n_1 \); the total number of observations, \( N = n_0 + n_1 \); and the number of runs, \( r \). These statistics are always reported, so the exact tables of critical values in Swed and Eisenhart (1943) may be consulted if necessary.

The expected number of runs under the null is
\[
\mu_r = \frac{2n_0n_1}{N} + 1
\]

the variance is
\[
\sigma^2_r = \frac{2n_0n_1(2n_0n_1 - N)}{N^2(N - 1)}
\]

and the normal approximation test statistic is
\[
\hat{z} = \frac{r - \mu_r}{\sigma_r}
\]

**Acknowledgment**

`runtest` was written by Sean Becketti, author of the Stata Press book *Introduction to Time Series Using Stata, Revised Edition*.

scobit depvar [ indepvars ] [ if ] [ in ] [ weight ] [ , options ]
```

### options Description

**Model**

- `noconstant` suppress constant term
- `offset(varname)` include `varname` in model with coefficient constrained to 1
- `asis` retain perfect predictor variables
- `constraints(constraints)` apply specified linear constraints

**SE/Robust**

- `vce(vcetype)` `vcetype` may be `oim`, `robust`, `cluster clustvar`, `opg`, `bootstrap`, or `jackknife`

**Reporting**

- `level(#)` set confidence level; default is `level(95)`
- `nocnsreport` do not display constraints
- `display_options` control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

**Maximization**

- `maximize_options` control the maximization process
- `collinear` keep collinear variables
- `coeflegend` display legend instead of statistics

`indepvars` may contain factor variables; see [U 11.4.3 Factor variables].

`bootstrap`, `by`, `collect`, `fp`, `jackknife`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [U 11.1.10 Prefix commands].

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] svy.

`fweights`, `iweights`, and `pweights` are allowed; see [U 11.1.6 weight].

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 18 Estimation and postestimation commands for more capabilities of estimation commands.

### Options

- `noconstant`, `offset(varname)`, `constraints(constraints)`; see [R] Estimation options.

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] probit.
**SE/Robust**

\texttt{vce(vcetype)} specifies the type of standard error reported, which includes types that are derived from asymptotic theory (\texttt{oim}, \texttt{opg}), that are robust to some kinds of misspecification (\texttt{robust}), that allow for intragroup correlation (\texttt{cluster clustvar}), and that use bootstrap or jackknife methods (\texttt{bootstrap}, \texttt{jackknife}); see \cite{R vce option}.

**Reporting**

\texttt{level(#)}; see \cite{R Estimation options}.

\texttt{nocnsreport}; see \cite{R Estimation options}.

\texttt{display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(\texttt{fmt}), pformat(\texttt{fmt}), sformat(\texttt{fmt}), and nolstretch}; see \cite{R Estimation options}.

**Maximization**

\texttt{maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), \texttt{ltolerance(#)}, \texttt{nrtolerance(#)}, \texttt{nonrtolerance}, and from(init_specs)}; see \cite{R Maximize}. These options are seldom used.

Setting the optimization type to \texttt{technique(bhhh)} resets the default \texttt{vcetype} to \texttt{vce(opg)}.

The following options are available with \texttt{scobit} but are not shown in the dialog box:

\texttt{collinear, coeflegend}; see \cite{R Estimation options}.

### Remarks and examples

Remarks are presented under the following headings:

- Skewed logistic model
- Robust standard errors

#### Skewed logistic model

\texttt{scobit} fits maximum likelihood models with dichotomous dependent variables coded as 0/1 (or, more precisely, coded as 0 and not 0).

#### Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a model explaining whether a car is foreign based on its mileage. Here is an overview of our data:
The variable `foreign` takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$ \Pr(\text{foreign} = 1) = F(\beta_0 + \beta_1 \text{mpg}) $$

where $$ F(z) = 1 - 1/\{1 + \exp(z)\}^\alpha. $$

To fit this model, we type

```
. scobit foreign mpg
```

Fitting logistic model:

```
Iteration 0: Log likelihood = -45.03321
Iteration 1: Log likelihood = -39.380959
Iteration 2: Log likelihood = -39.288802
Iteration 3: Log likelihood = -39.28864
Iteration 4: Log likelihood = -39.28864
```

Fitting full model:

```
Iteration 0: Log likelihood = -39.28864
Iteration 1: Log likelihood = -39.286393
Iteration 2: Log likelihood = -39.284415
Iteration 3: Log likelihood = -39.284234
Iteration 4: Log likelihood = -39.284197
Iteration 5: Log likelihood = -39.284196
```
We find that cars yielding better gas mileage are less likely to be foreign. The likelihood-ratio test at the bottom of the output indicates that the model is not significantly different from a logit model. Therefore, we should use the more parsimonious model.

Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if the dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If the dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

Formally, when we type scobit y x, Stata fits the model

$$Pr(y_j \neq 0 \mid x_j) = 1 - 1 / \left\{1 + \exp(x_j \beta)\right\}^\alpha$$

Robust standard errors

If you specify the vce(robust) option, scobit reports robust standard errors as described in [U] 20.22 Obtaining robust variance estimates. For the model of foreign on mpg, the robust calculation increases the standard error of the coefficient on mpg by around 25%:
Without \texttt{vce(robust)}, the standard error for the coefficient on \textit{mpg} was reported to be 0.241, with a resulting confidence interval of \([-0.29, 0.65]\).

Specifying the \texttt{vce(cluster \textit{clusvar})} option relaxes the independence assumption required by the skewed logit estimator to being just independence between clusters. To demonstrate this, we will switch to a different dataset.

\section*{Example 2}

We are studying the unionization of women in the United States and have a dataset with 26,200 observations on 4,434 women between 1970 and 1988. For our purposes, we will use the variables \textit{age} (the women were 14–26 in 1968 and the data thus span the age range of 16–46), \textit{grade} (years of schooling completed, ranging from 0 to 18), \textit{not_smsa} (28\% of the person-time was spent living outside an SMSA—standard metropolitan statistical area), \textit{south} (41\% of the person-time was in the South), and \textit{year}. Each of these variables is included in the regression as a covariate along with the interaction between \textit{south} and \textit{year}. This interaction, along with the \textit{south} and \textit{year} variables, is specified in the \texttt{scobit} command using factor-variables notation, \texttt{south##c.year}. We also have variable \textit{union}. Overall, 22\% of the person-time is marked as time under union membership and 44\% of these women have belonged to a union.

We fit the following model, ignoring that women are observed an average of 5.9 times each in these data:

\begin{verbatim}
. use https://www.stata-press.com/data/r18/union, clear
(NLS Women 14-24 in 1968)
. scobit union age grade not_smsa south##c.year, nrtol(1e-3)
(output omitted)
Skewed logistic regression Number of obs = 26,200
Zero outcomes = 20,389
Log likelihood = -13540.61 Nonzero outcomes = 5,811

|                | Coefficient | Std. err. | z     | P>|z|   | [95% conf. interval] |
|----------------|-------------|-----------|-------|-------|----------------------|
| union age      | .0185363    | .0043615  | 4.25  | 0.00  | .0099879 .0270848    |
| grade          | .0452801    | .0057124  | 7.93  | 0.00  | .034084 .0564761     |
| not_smsa       | -.1886826   | .0317801  | -5.94 | 0.00  | -.2509705 -.1263947  |
| 1.south        | -.1422372   | .3949301  | -3.60 | 0.00  | -.2.19642 -.6483233  |
| year           | -.0133016   | .0049575  | -2.68 | 0.007 | -.0230181 -.0035851  |
| south##c.year  | .0105663    | .0049233  | 2.15  | 0.032 | .0009167 .0202158    |
| _cons          | -.10.3557   | 68.97573  | -0.15 | 0.881 | -145.5456 124.8342   |

/Lnalpha        | 9.136018   | 68.97398  | 0.13  | 0.895 | -126.0505 144.3225   |

alpha           | 9283.72     | 640335.1  | 1.81e-55 | 4.77e+62 |

LR test of alpha=1: chi2(1) = 3.76 Prob > chi2 = 0.0524

Note: Likelihood-ratio tests are recommended for inference with \texttt{scobit} models.
\end{verbatim}

The reported standard errors in this model are probably meaningless. Women are observed repeatedly, so the observations are not independent. Looking at the coefficients, we find a large southern effect against unionization and a different time trend for the south. The \texttt{vce(cluster \textit{clusvar})} option provides a way to fit this model and obtains correct standard errors:
. scobit union age grade not_smsa south##c.year, vce(cluster id) nrtol(1e-3)
(output omitted)

Skewed logistic regression
Number of obs = 26,200
Zero outcomes = 20,389
Log pseudolikelihood = -13540.61
Nonzero outcomes = 5,811

(Std. err. adjusted for 4,434 clusters in idcode)

|    | Coefficient | std. err. | z    | P>|z| | [95% conf. interval] |

scobit, vce(cluster clustvar) is robust to assumptions about within-cluster correlation. That is, it inefficiently sums within cluster for the standard error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation (as do the xtgee population-averaged models; see [XT] xtgee).

Technical note

The scobit model can be difficult to fit because of the functional form. Often, it requires many iterations, or the optimizer prints out warning and informative messages during the optimization. For example, without the nrtol(1e-3) option, the model using the union dataset will not converge. See [R] Maximize for details about the optimizer.

Technical note

The main reason for using scobit rather than logit is that the effects of the regressors on the probability of success are not constrained to be the largest when the probability is 0.5. Rather, the independent variables might show their largest impact when the probability of success is 0.3 or 0.6. This added flexibility results because the scobit function, unlike the logit function, can be skewed and is not constrained to be mirror symmetric about the 0.5 probability of success.

As Nagler (1994) pointed out, the point of maximum impact is constrained under the scobit model to fall within the interval \((0, 1 - e^{-1})\) or approximately \((0, 0.63)\). Achen (2002) notes that if we believe the maximum impact to be outside that range, we can instead fit the “power logit” model by simply reversing the 0s and 1s of our outcome variable and fitting a scobit model on failure, rather than success. We would need to reverse the signs of the coefficients if we wanted to interpret them in terms of impact on success, or we could leave them as they are and interpret them in terms of impact on failure. The important thing to remember is that the scobit model, unlike the logit model, is not invariant to the choice of which result is assigned to success.
scobit stores the following in e():

Scalars
- e(N) number of observations
- e(k) number of parameters
- e(k_eq) number of equations in e(b)
- e(k_aux) number of auxiliary parameters
- e(k_dv) number of dependent variables
- e(ll) log likelihood
- e(ll_c) log likelihood, comparison model
- e(N_f) number of failures (zero outcomes)
- e(N_s) number of successes (nonzero outcomes)
- e(alpha) alpha
- e(N_clust) number of clusters
- e(chi2_c) \( \chi^2 \) for comparison test
- e(rank) rank of e(V)
- e(ic) number of iterations
- e(rc) return code
- e(converged) 1 if converged, 0 otherwise

Macros
- e(cmd) scobit
- e(cmdline) command as typed
- e(depvar) name of dependent variable
- e(wtype) weight type
- e(wexp) weight expression
- e(title) title in estimation output
- e(clustvar) name of cluster variable
- e(offset) linear offset variable
- e(chi2_ct) Wald or LR; type of model \( \chi^2 \) test corresponding to e(chi2_c)
- e(vce) vcetype specified in vce()
- e(vcetype) title used to label Std. err.
- e(opt) type of optimization
- e(which) max or min; whether optimizer is to perform maximization or minimization
- e(ml_method) type of ml method
- e(user) name of likelihood-evaluator program
- e(technique) maximization technique
- e(properties) b V
- e(predict) program used to implement predict
- e(footnote) program used to implement the footnote display
- e(asbalanced) factor variables fvset as asbalanced
- e(asobserved) factor variables fvset as asobserved

Matrices
- e(b) coefficient vector
- e(Cns) constraints matrix
- e(ilog) iteration log (up to 20 iterations)
- e(gradient) gradient vector
- e(V) variance–covariance matrix of the estimators
- e(V_modelbased) model-based variance

Functions
- e(sample) marks estimation sample

In addition to the above, the following is stored in r():

Matrices
- r(table) matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in \( r() \) are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.
Methods and formulas

Skewed logit analysis is an alternative to logit that relaxes the assumption that individuals with initial probability of 0.5 are most sensitive to changes in independent variables.

The log-likelihood function for skewed logit is

$$\ln L = \sum_{j \in S} w_j \ln F(x_j b) + \sum_{j \notin S} w_j \ln \left\{1 - F(x_j b)\right\}$$

where $S$ is the set of all observations $j$ such that $y_j \neq 0$, $F(z) = 1 - 1/\{1 + \exp(z)\}^\alpha$, and $w_j$ denotes the optional weights. $\ln L$ is maximized as described in [R] Maximize.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce(robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.

scobit also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

Menu for predict

Statistics  >  Postestimation

Syntax for predict

predict [type] newvar [if] [in] [ , statistic nooffset]

predict [type] stub* [if] [in], scores

statistic  Description

Main
pr  probability of a positive outcome; the default
xb  x_j b, linear prediction
stdp  standard error of the linear prediction

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

pr, the default, calculates the probability of a positive outcome.
xb calculates the linear prediction.
stdp calculates the standard error of the linear prediction.
nooffset is relevant only if you specified offset(varname) for scobit. It modifies the calculations made by predict so that they ignore the offset variable; the linear prediction is treated as x_j b rather than as x_j b + offset_j.
scores calculates equation-level score variables.

The first new variable will contain ∂ln L/∂(x_j β).
The second new variable will contain ∂ln L/∂ln α.
margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [ marginlist ] [ , options ]
margins [ marginlist ] , predict(statistic ...) [ predict(statistic ...) ... ] [ options ]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>probability of a positive outcome; the default</td>
</tr>
<tr>
<td>xb</td>
<td>$x_j b$, linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] margins.

Remarks and examples

Once you have fit a model, you can obtain the predicted probabilities by using the predict command for both the estimation sample and other samples; see [U] 20 Estimation and postestimation commands and [R] predict. Here we will make only a few additional comments.

predict without arguments calculates the predicted probability of a positive outcome. With the xb option, it calculates the linear combination $x_j b$, where $x_j$ are the independent variables in the $j$th observation and $b$ is the estimated parameter vector.

With the stdp option, predict calculates the standard error of the prediction, which is not adjusted for replicated covariate patterns in the data.
Example 1

In example 1 of [R] scobit, we fit the model scobit foreign mpg. To obtain predicted probabilities, we type

```
. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. keep make mpg weight foreign
. scobit foreign mpg
   (output omitted)
. predict p
   (option pr assumed; Pr(foreign))
. summarize foreign p
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>

[R] scobit — Skewed logistic regression

[U] 20 Estimation and postestimation commands
sdtest — Variance-comparison tests

Description
sdtest performs tests on the equality of standard deviations (variances). In the first form, sdtest tests that the standard deviation of varname is #. In the second form, sdtest performs the same test, using the standard deviations of the two groups defined by groupvar. In the third form, sdtest tests that varname1 and varname2 have the same standard deviation.

sdtesti is the immediate form of sdtest; see \[U\] 19 Immediate commands.

Both the traditional F test for the homogeneity of variances and Bartlett’s generalization of this test to K samples are sensitive to the assumption that the data are drawn from an underlying Gaussian distribution. See, for example, the cautionary results discussed by Markowski and Markowski (1990). Levene (1960) proposed a test statistic for equality of variance that was found to be robust under nonnormality. Then Brown and Forsythe (1974) proposed alternative formulations of Levene’s test statistic that use more robust estimators of central tendency in place of the mean. These reformulations were demonstrated to be more robust than Levene’s test when dealing with skewed populations.

robvar reports Levene’s robust test statistic (W_0) for the equality of variances between the groups defined by groupvar and the two statistics proposed by Brown and Forsythe that replace the mean in Levene’s formula with alternative location estimators. The first alternative (W_{50}) replaces the mean with the median. The second alternative replaces the mean with the 10% trimmed mean (W_{10}).

Quick start
Test that the standard deviation of v1 is equal to 2
sdtest v1=2

Equality of standard deviations (variances) test for v1 comparing the two groups defined by catvar1
sdtest v1, by(catvar1)

Robust equality of variances test for v1 comparing the groups defined by catvar1
robvar v1, by(catvar1)

Compare the variances of v2 and v3
sdtest v2 == v3

Same as above, but with separate tests for each group defined by catvar2
by catvar2, sort: sdtest v2 == v3

Test sd1 = sd2 for sd1 = 34, sd2 = 45, N1 = 143, and N2 = 184
sdtesti 143 . 34 184 . 45
Menu

sdtest
Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Variance-comparison test

sdtesti
Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Variance-comparison test calculator

robvar
Statistics > Summaries, tables, and tests > Classical tests of hypotheses > Robust equal-variance test

Syntax

One-sample variance-comparison test

\[ \text{sdtest} \ varname == \# [ \text{if} ] [ \text{in} ] , \text{level(\#)} ] \]

Two-sample variance-comparison test using groups

\[ \text{sdtest} \ varname [ \text{if} ] [ \text{in} ] , \text{by(groupvar)} [ \text{level(\#)} ] \]

Two-sample variance-comparison test using variables

\[ \text{sdtest} \ varname_1 == \ varname_2 [ \text{if} ] [ \text{in} ] , \text{level(\#)} ] \]

Immediate form of one-sample variance-comparison test

\[ \text{sdtesti} \ \# \text{obs} \{ \text{#mean} | . \} \ #sd \ #\text{val} , \text{level(\#)} ] \]

Immediate form of two-sample variance-comparison test

\[ \text{sdtesti} \ \#\text{obs}_1 \{ \text{#mean}_1 | . \} \ #sd_1 \ #\text{obs}_2 \{ \text{#mean}_2 | . \} \ #sd_2 , \text{level(\#)} ] \]

Robust tests for equality of variances

\[ \text{robvar} \ varname [ \text{if} ] [ \text{in} ] , \text{by(groupvar)} \]

by and collect are allowed with sdtest and robvar, and collect is allowed with sdtesti; see [U] 11.1.10 Prefix commands.

Options

\text{level(\#)} \text{ specifies the confidence level, as a percentage, for confidence intervals of the means. The default is level(95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.}

\text{by(groupvar)} \text{ specifies the groupvar that defines the groups to be compared. For sdtest, there should be two groups, but for robvar there may be more than two groups. Do not confuse the by() option with the by prefix; both may be specified.}
Remarks and examples

Remarks are presented under the following headings:

- Basic form
- Immediate form
- Robust test

Basic form

sdtest performs two different statistical tests: one testing equality of variances and the other testing that the standard deviation is equal to a known constant. Which test it performs is determined by whether you type a variable name or a number to the right of the equal sign.

Example 1: One-sample test of variance

We have a sample of 74 automobiles. For each automobile, we know the mileage rating. We wish to test whether the overall standard deviation is 5 mpg:

```
. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. sdtest mpg == 5
One-sample test of variance
```

```
<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>.6725511</td>
<td>5.785503</td>
<td>19.9569 22.63769</td>
</tr>
</tbody>
</table>

sd = sd(mpg)  c = chi2 = 97.7384
H0: sd = 5  Degrees of freedom = 73
Ha: sd < 5    Ha: sd != 5    Ha: sd > 5
Pr(C < c) = 0.9717  2*Pr(C > c) = 0.0565  Pr(C > c) = 0.0283
```

Example 2: Variance ratio test

We are testing the effectiveness of a new fuel additive. We run an experiment on 12 cars, running each without and with the additive. The data can be found in [R] ttest. The results for each car are stored in the variables mpg1 and mpg2:

```
. use https://www.stata-press.com/data/r18/fuel
. sdtest mpg1==mpg2
```

```
<table>
<thead>
<tr>

<td>20.57909 23.17091</td>
</tr>
</tbody>
</table>

ratio = sd(mpg1) / sd(mpg2)  f = 0.7054
H0: ratio = 1  Degrees of freedom = 11, 11
Ha: ratio < 1  Ha: ratio != 1  Ha: ratio > 1
Pr(F < f) = 0.2862  2*Pr(F < f) = 0.5725  Pr(F > f) = 0.7138
```

We cannot reject the hypothesis that the standard deviations are the same.
In [R] `ttest`, we draw an important distinction between paired and unpaired data, which, in this example, means whether there are 12 cars in a before-and-after experiment or 24 different cars. For `sdtest`, on the other hand, there is no distinction. If the data had been unpaired and stored as described in [R] `ttest`, we could have typed `sdtest mpg, by(treated)`, and the results would have been the same.

### Immediate form

**Example 3: sdtesti**

Immediate commands are used not with data, but with reported summary statistics. For instance, to test whether a variable on which we have 75 observations and a reported standard deviation of 6.5 comes from a population with underlying standard deviation 6, we would type

```
. sdtesti 75 . 6.5 6
```

One-sample test of variance

<table>
<thead>
<tr>
<th></th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>75</td>
<td>.7505553</td>
<td>6.5</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

sd = sd(x)  
H0: sd = 6  
Degrees of freedom = 74  
Ha: sd < 6  
Ha: sd != 6  
Ha: sd > 6  
Pr(C < c) = 0.8542  
2*Pr(C > c) = 0.2916  
Pr(C > c) = 0.1458

The mean plays no role in the calculation, so it may be omitted.

To test whether the variable comes from a population with the same standard deviation as another for which we have a calculated standard deviation of 7.5 over 65 observations, we would type

```
. sdtesti 75 . 6.5 65 . 7.5
```

Variance ratio test

<table>
<thead>
<tr>
<th></th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>75</td>
<td>.7505553</td>
<td>6.5</td>
<td>.</td>
<td>.</td>

<tr>
<td>y</td>
<td>65</td>
<td>.9302605</td>
<td>7.5</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>Combined</td>
<td>140</td>
<td>.</td>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

ratio = sd(x) / sd(y)  
f = 0.7511  
H0: ratio = 1  
Degrees of freedom = 74, 64  
Ha: ratio < 1  
Ha: ratio != 1  
Ha: ratio > 1  
Pr(F < f) = 0.1172  
2*Pr(F < f) = 0.2344  
Pr(F > f) = 0.8828
Robust test

Example 4: robvar

We wish to test whether the standard deviation of the length of stay for patients hospitalized for a given medical procedure differs by gender. Our data consist of observations on the length of hospital stay for 1778 patients: 884 males and 894 females. Length of stay, `lengthstay`, is highly skewed (skewness coefficient = 4.912591) and thus violates Bartlett’s normality assumption. Therefore, we use `robvar` to compare the variances.

```
. use https://www.stata-press.com/data/r18/stay
. robvar lengthstay, by(sex)
```

<table>
<thead>
<tr>
<th>Gender</th>
<th>Summary of Length of stay in days</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Mean</td>
<td>Std. dev.</td>
<td>Freq.</td>
</tr>
<tr>
<td>Male</td>
<td>9.0874434</td>
<td>9.7884747</td>
<td>884</td>
</tr>
<tr>
<td>Female</td>
<td>8.800671</td>
<td>9.1081478</td>
<td>894</td>
</tr>
<tr>
<td>Total</td>
<td>8.9432508</td>
<td>9.4509466</td>
<td>1,778</td>
</tr>
</tbody>
</table>

W0 = 0.55505315 df(1, 1776) Pr > F = 0.45635888
W50 = 0.42714734 df(1, 1776) Pr > F = 0.51347664
W10 = 0.44577674 df(1, 1776) Pr > F = 0.50443411

For these data, we cannot reject the null hypothesis that the variances are equal. However, Bartlett’s test yields a significance probability of 0.0319 because of the pronounced skewness of the data.

Technical note

`robvar` implements both the conventional Levene’s test centered at the mean and a median-centered test. In a simulation study, Conover, Johnson, and Johnson (1981) compare the properties of the two tests and recommend using the median test for asymmetric data, although for small sample sizes the test is somewhat conservative. See Carroll and Schneider (1985) for an explanation of why both mean- and median-centered tests have approximately the same level for symmetric distributions, but for asymmetric distributions the median test is closer to the correct level.

Stored results

`sdtest` and `sdtesti` store the following in `r()`:

Scalars

- `r(N)` number of observations
- `r(p_l)` lower one-sided p-value
- `r(p_u)` upper one-sided p-value
- `r(p)` two-sided p-value
- `r(F)` F statistic
- `r(sd)` standard deviation
- `r(sd_1)` standard deviation for first variable
- `r(sd_2)` standard deviation for second variable
- `r(df)` degrees of freedom
- `r(df_1)` numerator degrees of freedom
- `r(df_2)` denominator degrees of freedom
- `r(chi2)` $\chi^2$
robvar stores the following in r():

Scalars

\[ r(N) \quad \text{number of observations} \]
\[ r(w50) \quad \text{Brown and Forsythe’s } F \text{ statistic (median)} \]
\[ r(p_{w50}) \quad \text{Brown and Forsythe’s } p \text{-value} \]
\[ r(w0) \quad \text{Levene’s } F \text{ statistic} \]
\[ r(p_{w0}) \quad \text{Levene’s } p \text{-value} \]
\[ r(w10) \quad \text{Brown and Forsythe’s } F \text{ statistic (trimmed mean)} \]
\[ r(p_{w10}) \quad \text{Brown and Forsythe’s } p \text{-value (trimmed mean)} \]
\[ r(df_1) \quad \text{numerator degrees of freedom} \]
\[ r(df_2) \quad \text{denominator degrees of freedom} \]

Methods and formulas

See Armitage et al. (2002, 149–153) or Bland (2015, 144–145) for an introduction and explanation of the calculation of these tests.

The test for \( \sigma = \sigma_0 \) is given by

\[
\chi^2 = \frac{(n - 1)s^2}{\sigma_0^2}
\]

which is distributed as \( \chi^2 \) with \( n - 1 \) degrees of freedom.

The test for \( \sigma_x^2 = \sigma_y^2 \) is given by

\[
F = \frac{s_x^2}{s_y^2}
\]

which is distributed as \( F \) with \( n_x - 1 \) and \( n_y - 1 \) degrees of freedom.

Let \( X_{ij} \) be the \( j \)th observation of \( X \) for the \( i \)th group. Let \( Z_{ij} = |X_{ij} - \bar{X}_i| \), where \( \bar{X}_i \) is the mean of \( X \) in the \( i \)th group. Levene’s test statistic is

\[
W_0 = \frac{\sum_i n_i (Z_i - \bar{Z})^2 / (g - 1)}{\sum_i \sum_j (Z_{ij} - \bar{Z}_i)^2 / \sum_i (n_i - 1)}
\]

where \( n_i \) is the number of observations in group \( i \) and \( g \) is the number of groups. \( W_{50} \) is obtained by replacing \( \bar{X}_i \) with the \( i \)th group median of \( X_{ij} \), whereas \( W_{10} \) is obtained by replacing \( \bar{X}_i \) with the 10% trimmed mean for group \( i \).

</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Options for search</td>
<td>Option for set searchdefault</td>
</tr>
<tr>
<td>Remarks and examples</td>
<td>Acknowledgment</td>
<td>Also see</td>
</tr>
</tbody>
</table>

**Description**

`search` searches a keyword database and the Internet for Stata materials related to your query. Capitalization of the words following `search` is irrelevant, as is the inclusion or exclusion of special characters such as commas and hyphens.

`set searchdefault` affects the default behavior of the `search` command. `all` is the default.

`search, all` is the best way to search for information on a topic across all sources, including the system help, the FAQs at the Stata website, the *Stata Journal*, and all Stata-related Internet sources including community-contributed additions. From the results, you can click to go to a source or to install additions.

**Quick start**

Search local keyword database and materials available via Stata’s `net` command for all words (`word1, word2, and word3`)

```
search word1 word2 word3
```

Same as above, but match any word (`word1, word2, or word3`)

```
search word1 word2 word3, or
```

Search for *Stata Journal* articles about new commands like `regress`

```
search regress, sj
```

Search the manuals for entries about `tabulate` and related commands

```
search tabulate, manual
```
Syntax

```
search word [word ...] [, search_options]
```

```
set searchdefault {all|local|net} [, permanently]
```

<table>
<thead>
<tr>
<th>search_options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all</td>
<td>search across both the local keyword database and the net material; the default</td>
</tr>
<tr>

</tr>
<tr>
<td>manual</td>
<td>search the entries in the Stata Documentation</td>
</tr>
<tr>
<td>sj</td>
<td>search the entries in the Stata Journal</td>
</tr>
</tbody>
</table>

Options for search

all, the default (unless changed by set searchdefault), specifies that the search be performed across both the local keyword database and the net materials. The results of a search performed with all and no other options will be displayed in the Viewer window.

local specifies that the search be performed using only Stata’s keyword database. The results of a search performed with local and no other options will be displayed in the Viewer window.

net specifies that the search be performed across the materials available via Stata’s net command. Using `search word [word ...]`, net is equivalent to typing `net search word [word ...]` (without options); see [R] net search. The results of a search performed with net and no other options will be displayed in the Viewer window.

author specifies that the search be performed on the basis of the author’s name rather than keywords. A search with the author option is performed on the local keyword database only, and the results are displayed in the Results window.

entry specifies that the search be performed on the basis of entry IDs rather than keywords. A search with the entry option is performed on the local keyword database only, and the results are displayed in the Results window.

exact prevents matching on abbreviations. A search with the exact option is performed across both the local keyword database and the net materials, and the results are displayed in the Results window.

faq limits the search to the FAQs on the Stata and other select websites. A search with the faq option is performed on the local keyword database only, and the results are displayed in the Results window.
historical adds to the search entries that are of historical interest only. By default, such entries are not listed. Past entries are classified as historical if they discuss a feature that later became an official part of Stata. Updates to historical entries will always be found, even if historical is not specified. A search with the historical option is performed on the local keyword database only, and the results are displayed in the Results window.

or specifies that an entry be listed if any of the words typed after search are associated with the entry. The default is to list the entry only if all the words specified are associated with the entry. A search with the or option is performed on the local keyword database only, and the results are displayed in the Results window.

manual limits the search to entries in the Stata Documentation; that is, the search is limited to the User’s Guide and all the reference manuals. A search with the manual option is performed on the local keyword database only, and the results are displayed in the Results window.

sj limits the search to entries in the Stata Journal; see [R] sj. A search with the sj option is performed on the local keyword database only, and the results are displayed in the Results window.

Option for set searchdefault

permanently specifies that, in addition to making the change right now, the searchdefault setting be remembered and become the default setting when you invoke Stata.

Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Internet searches
- Author searches
- Entry ID searches
- Return codes

Introduction

See [U] 4 Stata’s help and search facilities for a tutorial introduction to search. search is one of Stata’s most useful commands. To understand the advanced features of search, you need to know how it works.

search has a database—files—containing the titles, etc., of every entry in the Stata Documentation, undocumented help files, NetCourses, Stata Press books, FAQs posted on the Stata website, videos posted on the Stata YouTube channel, selected articles on StataCorp’s official blog, selected community-contributed FAQs and examples, and the articles in the Stata Journal. In these files is a list of words, called keywords, associated with each entry.

When you type search xyz, search reads the database and compares the list of keywords with xyz. If it finds xyz in the list or a keyword that allows an abbreviation of xyz, it displays the entry.

When you type search xyz abc, search does the same thing but displays an entry only if it contains both keywords. The order does not matter, so you can search linear regression or search regression linear.
Obviously, how many entries `search` finds depends on how the search database was constructed. We have included a plethora of keywords under the theory that, for a given request, it is better to list too much rather than risk listing nothing at all. Still, you are in the position of guessing the keywords. Do you look up normality test, normality tests, or tests of normality? Well, normality test would be best, but all would work. In general, use the singular, and strike the unnecessary words. For guidelines for specifying keywords, see [U] 4.6 More on search.

`set searchdefault` allows you to specify where `search` searches. `set searchdefault all`, the default, indicates that both the keyword database and the Internet are to be searched. `set searchdefault local` restricts `search` to using only Stata’s keyword database. `set searchdefault net` restricts `search` to searching only the Internet.

### Internet searches

`search` with the `net` option searches the Internet for community-contributed additions to Stata, including, but not limited to, community-contributed additions published in the *Stata Journal* (*SJ*). `search keywords, net` performs the same search as the command `net search` (with no options); see [R] `net search`.

```plaintext
.. search random effect, net

Search of web resources from Stata and other users
(contacting https://www.stata.com)
# packages found (Stata Journal listed first)
------------------------------------------------------
(output omitted)
st0468_1 from http://www.stata-journal.com/software/sj18-4
  SJ18-4 st0468_1. Update: Estimate hybrid and... / Update: Estimate hybrid and correlated random- / effects and Mundlak mixed-effects models for / linear and nonlinear outcomes / by Reinhard Schunck, GESIS -- Leibniz-Institute / for the Social Sciences, Cologne, Germany / Francisco

st0543 from http://www.stata-journal.com/software/sj18-4
  SJ18-4 st0543. Fit dynamic random-effects probit... / Fit dynamic random-effects probit models with / unobserved heterogeneity / by Raffaele Grotti, / Department of Political and Social Sciences / European University Institute / San Domenico di Fiesole, Italy / Giorgio Cutuli,

(output omitted)
@end of search
```

### Author searches

`search` ordinarily compares the words following `search` with the keywords for the entry. If you specify the `author` option, however, it compares the words with the author’s name. In the search database, we have filled in author names for all *SJ* inserts.

For instance, in the *Acknowledgments* of [R] `kdensity`, you will discover the name Isaías H. Salgado-Ugarte. You want to know if he has written any articles in the *SJ*. To find out, you type

```plaintext
.. search Salgado-Ugarte, author
(output omitted)
```

Names like Salgado-Ugarte are confusing to many people. `search` does not require you to specify the entire name; what you type is compared with each “word” of the name and, if any part matches, the entry is listed. The hyphen is a special character, and you can omit it. Thus, you can obtain the same list by looking up Salgado, Ugarte, or Salgado Ugarte without the hyphen.
Entry ID searches

If you specify the `entry` option, `search` compares what you have typed with the entry ID. The entry ID is not the title—it is the reference listed to the left of the title that tells you where to look. For instance, in

```
[R]  regress ............................................. Linear regression
      (help regress)
```

`[R] regress` is the entry ID. This is a reference, of course, to this manual. In

```
FAQ ............................. Analysis of multiple failure-time survival data
      ............................. M. Cleves and I. Canette
      07/09 How do I analyze multiple failure-time data using Stata?
```

“FAQ” is the entry ID. In

```
SJ-7-1  st0118  .  A survey on survey stat.: What is and can be done in Stata
      ............................. F. Kreuter and R. Valliant
      Q1/07  SJ7(1):1--21  (no commands)
      discusses survey issues in analyzing complex survey data and describes some of Stata’s capabilities for such analyses
```

“SJ-7-1” is the entry ID.

`search` with the `entry` option searches these entry IDs.

Thus you could generate a table of contents for the `User’s Guide` by typing

```
. search [U], entry
   (output omitted)
```

You could generate a table of contents for `Stata Journal, Volume 1, Issue 1`, by typing

```
. search sj-1-1, entry
   (output omitted)
```
Return codes

In addition to indexing the entries in the User’s Guide and all the Reference manuals, search also can be used to search return codes.

To see information on return code 131, type

```
.search rc 131
```

```
[P] error ........................................ Return code 131
not possible with test;
You requested a test of a hypothesis that is nonlinear in the
variables. test tests only linear hypotheses. Use testnl.
(output omitted)
```

If you want a list of all Stata return codes, type

```
.search error, entry
```

(output omitted)

Acknowledgment

We thank Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the Stata Journal and author of Speaking Stata Graphics for his contributions to the search command.

[U] 4 Stata’s help and search facilities
**serrbar — Graph standard error bar chart**

**Description**

`serrbar` is typically used with a dataset containing means, standard deviations or standard errors, and an `xvar`. `serrbar` uses these data to create a standard error bar chart. The means are plotted against `xvar`, and error bars around the means have a width determined by the standard deviation or standard error. While it is most common to use `serrbar` with this type of data, `serrbar` may also be used to create a scatterplot with error bars for other types of data.

**Quick start**

Plot of $y$ versus $x$ with error bars representing $y \pm s$

```
serrbar y s x
```

Same as above, but with error bars for $y \pm 2 \times s$

```
serrbar y s x, scale(2)
```

**Menu**

Statistics > Other > Quality control > Standard error bar chart
Syntax

\texttt{serrbar mvar svar xvar [if] [in] [, options]}

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{scale(#)}</td>
<td>scale length of graph bars; default is \texttt{scale(1)}</td>
</tr>
<tr>
<td>\texttt{rcap_options}</td>
<td>affect rendition of capped spikes</td>
</tr>
<tr>
<td>\texttt{mvopts(scatter_options)}</td>
<td>affect rendition of plotted points</td>
</tr>
<tr>
<td>\texttt{addplot(plot)}</td>
<td>add other plots to generated graph</td>
</tr>
<tr>
<td>\texttt{twoway_options}</td>
<td>any options other than by() documented in [G-3] \texttt{twoway_options}</td>
</tr>
</tbody>
</table>

Options

- \texttt{scale(#)} controls the length of the bars. The upper and lower limits of the bars will be \texttt{mvar + scale() \times svar} and \texttt{mvar - scale() \times svar}. The default is \texttt{scale(1)}.

- \texttt{rcap_options} affect the rendition of the plotted error bars (the capped spikes). See [G-2] \texttt{graph twoway rcap}.

- \texttt{mvopts(scatter_options)} affects the rendition of the plotted points (\texttt{mvar} versus \texttt{xvar}). See [G-2] \texttt{graph twoway scatter}.

- \texttt{addplot(plot)} provides a way to add other plots to the generated graph; see [G-3] \texttt{addplot_option}.

- \texttt{twoway_options} are any of the options documented in [G-3] \texttt{twoway_options}, excluding by(). These include options for titling the graph (see [G-3] \texttt{title_options}) and for saving the graph to disk (see [G-3] \texttt{saving_option}).
Remarks and examples

Example 1

In quality-control applications, the three most commonly used variables with this command are the process mean, process standard deviation, and time. For instance, we have data on the average weights and standard deviations from an assembly line in San Francisco for the period January 8 to January 16. Our data are

```
. use https://www.stata-press.com/data/r18/assembly
. list, sep(0) divider
```

<table>
<thead>
<tr>
<th>date</th>
<th>mean</th>
<th>std</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>108</td>
<td>192.22</td>
</tr>
<tr>
<td>2</td>
<td>109</td>
<td>192.64</td>
</tr>
<tr>
<td>3</td>
<td>110</td>
<td>192.37</td>
</tr>
<tr>
<td>4</td>
<td>113</td>
<td>194.76</td>
</tr>
<tr>
<td>5</td>
<td>114</td>
<td>192.69</td>
</tr>
<tr>
<td>6</td>
<td>115</td>
<td>195.02</td>
</tr>
<tr>
<td>7</td>
<td>116</td>
<td>193.40</td>
</tr>
</tbody>
</table>

We type `serrbar mean std date, scale(2)` but, after seeing the result, decide to make it fancier:

```
. serrbar mean std date, scale(2) title("Observed weight variation")
> sub("San Francisco plant, 1/8 to 1/16") yline(195) yaxis(1 2)
> ylab(195, axis(2)) ytitle("", axis(2))
```

Acknowledgment

`serrbar` was written by Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the *Stata Journal* and author of *Speaking Stata Graphics*.

Title

**set — Overview of system parameters**

**Description**

This entry provides a reference to Stata’s **set** commands. For many entries, more thorough information is provided elsewhere; see the Reference field in each entry below for the location of this information.

To reset system parameters to factory defaults, see [R] **set_defaults**.

**Syntax**

```
set [ setcommand ...]
```

*set* typed without arguments is equivalent to *query* typed without arguments.

**Remarks and examples**

**set adosize**

```
Syntax:       set adosize # [, permanently]
Default:     1,000
Description: sets the maximum amount of memory that automatically loaded do-files may consume. 10 ≤ # ≤ 10000.
Reference:   [P] **sysdir**
```

**set autotabgraphs** (Windows only)

```
Syntax:        set autotabgraphs {on|off} [, permanently]
Default:      off
Description:  determines whether graphs are created as tabs within one window or as separate windows.
Reference:    help autotabgraphs
```

**set cformat**

```
Syntax:       set cformat [fmt] [, permanently]
Description:  specifies the output format of coefficients, standard errors, and confidence limits in coefficient tables. **fmt** is a numerical format; see [D] **format**.
Reference:    [R] **set cformat**
```

**set clevel**

```
Syntax:       set clevel # [, permanently]
Default:     95
Description: sets the default credible level for credible intervals for all commands that report credible intervals. 10.00 ≤ # ≤ 99.99, and # can have at most two digits after the decimal point.
Reference:   [BAYES] **set clevel**
```
set coeftabresults
Syntax: 
set coeftabresults {on|off}
Default: on
Description: determines whether coefficient table results are stored in r().
There is no permanently option because permanently is implied.
Reference: help coeftabresults

set collect_double
Syntax: 
set collect_double {on|off} [, permanently]
Default: on
Description: controls the storage type for numeric values that are saved in collections when using collect save.
Reference: [TABLES] set collect_double

set collect_label
Syntax: 
set collect_label {default|label} [, permanently]
Default: default
Description: controls the default labels used in tables created by collect.
Reference: [TABLES] set collect_label

set collect_style
Syntax: 
set collect_style {default|style} [, permanently]
Default: default
Description: controls the default styles used in tables created by collect.
Reference: [TABLES] set collect_style

set collect_warn
Syntax: 
set collect_warn {on|off} [, permanently]
Default: on
Description: controls whether collect shows notes warning about unrecognized tags.
Reference: [TABLES] set collect_warn
set conren (Unix console only)
Syntax 1: set conren
Syntax 2: set conren clear
Syntax 3: set conren \[sf | bf | it\]
\{result | [txt | text] | input | error | link | hilite\}
[\text{char} [\text{char} ...]]
Syntax 4: set conren \{ulon | uloff\} [char [char ...]]
Syntax 5: set conren reset [char [char ...]]
Description: can possibly make the output on your screen appear prettier.
set conren displays a list of the currently defined display codes.
set conren clear clears all codes.
set conren followed by a font type (bf, sf, or it) and display context (result,
error, link, or hilite) and then followed by a series of space-separated
characters sets the code for the specified font type and display context. If the font
type is omitted, the code is set to the same specified code for all three font types.
set conren ulon and set conren uloff set the codes for turning on and off
underlining.
set conren reset sets the code that will turn off all display and underlining codes.
Reference: [GSU] conren

set copycolor (Mac and Windows only)
Syntax: set copycolor \{automatic | asis | gs1 | gs2 | gs3\} [, permanently]
Default: automatic
Description: determines how colors are handled when graphs are copied to the Clipboard.
Reference: [G-2] set printcolor

set dockable (Windows only)
Syntax: set dockable \{on | off\} [, permanently]
Default: on
Description: determines whether to enable the use of dockable window characteristics,
including the ability to dock or tab a window into another window.
Reference: help dockable

set docx_hardbreak
Syntax: set docx_hardbreak \{on | off\}
Default: off
Description: determines whether spaces are added after hard line breaks within text blocks.
Reference: [RPT] set docx

set docx_paramode
Syntax: set docx_paramode \{on | off\}
Default: off
Description: determines whether empty lines in a text block signal the beginning of a
new paragraph.
Reference: [RPT] set docx
set doeditbackup
Syntax: set doeditbackup {on|off}
Default: on
Description: determines whether to enable automatic backups of documents in the Do-file Editor.
Reference: help doeditbackup

set dots
Syntax: set dots {on|off} [, permanently]
Default: on
Description: enables or disables commands that support the dots() option from reporting a dot each time statistics are computed from a sample or resample of the dataset.
Reference: help dots

set doublebuffer (Windows only)
Syntax: set doublebuffer {on|off} [, permanently]
Default: on
Description: enables or disables double buffering of the Results, Viewer, and Data Editor windows. Double buffering prevents the windows from flickering when redrawn or resized. Users who encounter performance problems such as the Results window outputting very slowly should disable double buffering.
Reference: help doublebuffer

set dp
Syntax: set dp {comma|period} [, permanently]
Default: period
Description: determines whether a period or a comma is to be used as the decimal point.
Reference: [D] format

set dtable_style
Syntax: set dtable_style {dtable|style} [, permanently]
Default: dtable
Description: controls the default styles used in tables created by dtable.
Reference: [TABLES] set dtable_style

set dtascomplevel
Syntax: set dtascomplevel #
Default: 1
Description: sets the compression level for frames save, where # can be any integer between 0 and 9.
Reference: help dtascomplevel

set emptycells
Syntax: set emptycells {keep|drop} [, permanently]
Default: keep
Description: sets what to do with empty cells in interactions.
Reference: [R] set emptycells
set etable_style
Syntax: set etable_style {etable | style} [, permanently]
Default: etable
Description: controls the default styles used in tables created by etable.
Reference: [TABLES] set etable_style

set fastscroll (Unix and Windows only)
Syntax: set fastscroll {on | off} [, permanently]
Default: on
Description: sets the scrolling method for new output in the Results window. Setting fastscroll to on is faster but can be jumpy. Setting fastscroll to off is slower but smoother.
Reference: help fastscroll

set floatwindows (Windows only)
Syntax: set floatwindows {on | off}
Default: off
Description: determines whether to enable floating window behavior for dialog boxes and dockable window. The term “float” in this context means that a window will always float over the main Stata window; these windows cannot be placed behind the main Stata window. There is no permanently option because permanently is implied.
Reference: help floatwindows

set fredkey
Syntax: set fredkey key [, permanently]
Description: sets the API key for importing data from the Federal Reserve Economic Data.
Reference: [D] import fred

set fvbase
Syntax: set fvbase {on | off}
Description: specifies whether to automatically determine the default base level for factor variables.
Reference: help fvbase

set fvlabel
Syntax: set fvlabel {on | off} [, permanently]
Description: specifies whether to display factor-variable value labels in coefficient tables.
Reference: [R] set showbaselevels

set fvtrack
Syntax: set fvtrack {term | factor} [, permanently]
Description: allows you to control how Stata keeps track of factor levels when you use factor-variables notation.
Reference: help fvtrack

set fvwrap
Syntax: set fvwrap # [, permanently]
Description: specifies that long value labels wrap # lines in coefficient tables.
Reference: [R] set showbaselevels
set fvwrapon
Syntax: \texttt{set fvwrapon \{word|width\} [, permanently\]}
Description: specifies whether value labels that wrap will break at word boundaries or break based on available space.
Reference: [R] set showbaselevels

set graphics
Syntax: \texttt{set graphics \{on|off\}}
Default: on; default is off for console Stata
Description: determines whether graphs are displayed on your monitor.
Reference: [G-2] set graphics

set haverdir
Syntax: \texttt{set haverdir "path" [, permanently\]}
Description: specifies the directory where the Haver databases are stored.
Reference: [D] import haver

set httpproxy
Syntax: \texttt{set httpproxy \{on|off\} [, init\]}
Default: off
Description: turns on/off the use of a proxy server. There is no \texttt{permanently} option because \texttt{permanently} is implied.
Reference: [R] netio

set httpproxyauth
Syntax: \texttt{set httpproxyauth \{on|off\}}
Default: off
Description: determines whether authorization is required for the proxy server. There is no \texttt{permanently} option because \texttt{permanently} is implied.
Reference: [R] netio

set httpproxyhost
Syntax: \texttt{set httpproxyhost \"name\"}
Description: sets the name of a host to be used as a proxy server. There is no \texttt{permanently} option because \texttt{permanently} is implied.
Reference: [R] netio

set httpproxyport
Syntax: \texttt{set httpproxyport \#}
Default: 8080 if Stata cannot autodetect the proper setting for your computer.
Description: sets the port number for a proxy server. There is no \texttt{permanently} option because \texttt{permanently} is implied.
Reference: [R] netio
set httpproxypw
Syntax: set httpproxypw ["password"]
Description: sets the appropriate password. There is no permanently option because permanently is implied.
Reference: [R] netio

set httpproxyuser
Syntax: set httpproxyuser ["name"]
Description: sets the appropriate user ID. There is no permanently option because permanently is implied.
Reference: [R] netio

set include_bitmap (Mac only)
Syntax: set include_bitmap {on|off} [, permanently]
Default: on
Description: sets the output behavior when copying an image to the Clipboard.
Reference: help include_bitmap

set iterlog
Syntax: set iterlog {on|off} [, permanently]
Description: specifies whether to display an iteration log.
Reference: [R] set iter

set java_heapmax
Syntax: set java_heapmax {default|#[m|g]}
Description: sets the maximum amount of heap memory allocated for the Java Virtual Machine.
Reference: set java_heapmax is a synonym for java set heapmax; see [P] Java utilities

set java_home
Syntax: set java_home {default|"path_to_java_home_dir"}
Description: sets the path to the Java Runtime Environment.
Reference: set java_home is a synonym for java set home; see [P] Java utilities

set kmp_blocktime
Syntax: set kmp_blocktime # [, permanently]
Default: -1
Description: controls the behavior of the OpenMP run time library regarding the suspension of threads in Stata when they are idle. This can be changed only in Stata/MP.
Reference: help kmp_blocktime

set lapack_mkl
Syntax: set lapack_mkl {on|off} [, permanently]
Default: on
Description: specifies whether to use Intel MKL LAPACK routines.
Reference: [M-1] LAPACK
set lapack_mkl_cnr
Syntax: set lapack_mkl_cnr \{default|auto|compatible|off\}
Default: on
Description: sets the conditional numerical reproducibility mode for Intel MKL LAPACK routines.
Reference: [M-1] LAPACK

set level
Syntax: set level \# [, permanently]
Default: 95
Description: sets the default confidence level for confidence intervals for all commands that report confidence intervals. $10.00 \leq \# \leq 99.99$, and \# can have at most two digits after the decimal point.
Reference: [R] level

set linegap
Syntax: set linegap \#
Default: 1
Description: sets the space between lines, in pixels, in the Results window. There is no permanently option because permanently is implied.
Reference: help linegap

set linesize
Syntax: set linesize \#
Default: 1 less than the full width of the screen
Description: sets the line width, in characters, for both the screen and the log file.
Reference: [R] log

set locale_functions
Syntax: set locale_functions locale
Default: en_US
Description: sets the locale to be used by functions that take locale as an optional argument.
Reference: [P] set locale_functions

set locale_ui
Syntax: set locale_ui locale
Default: en_US
Description: sets the locale that Stata uses for the user interface.
Reference: [P] set locale_ui

set locksplitters (Windows only)
Syntax: set locksplitters \{on|off\} [, permanently]
Default: off
Description: determines whether splitters should be locked so that docked windows cannot be resized.
Reference: help locksplitters
set logmsg
  Syntax:    set logmsg {on | off}
  Default:  on
  Description: specifies whether the default message is displayed at the top and bottom of log files.
  Reference: [R] log

set logtype
  Syntax:    set logtype {text | smcl} [, permanently]
  Default:  smcl
  Description: sets the default log filetype.
  Reference: [R] log

set lstretch
  Syntax:    set lstretch [on | off] [, permanently]
  Default:  on
  Description: specifies whether to automatically widen the coefficient table up to the width of the Results window to accommodate longer variable names.
  Reference: help lstretch

set matacache, set matafavor, set matalibs, set matalnum, set matamofirst, set mataoptimize, set matasolveto, and set matastrict; see [M-3] mata set.

set maxbezierpath (Mac only)
  Syntax:    set maxbezierpath # [, permanently]
  Default:  0
  Description: sets the maximum number of lines that can be added to a Bézier path when rendering a Stata graph to the screen.
  Reference: help maxbezierpath

set maxdb
  Syntax:    set maxdb # [, permanently]
  Default:  50
  Description: sets the maximum number of dialog boxes whose contents are remembered from one invocation to the next during a session. $5 \leq \# \leq 1000$
  Reference: [R] db

set maxiter
  Syntax:    set maxiter # [, permanently]
  Default:  300
  Description: sets the default maximum number of iterations for estimation commands. $0 \leq \# \leq 16000$
  Reference: [R] set iter
set max_memory
Syntax: set max_memory [#b|k|m|g] [, permanently]
Default: . (all the memory the operating system will supply)
Description: specifies the maximum amount of memory Stata can use to store your data.
\[2 \times \text{segment size} \leq \# \leq \text{max.} \]
Reference: [D] memory

set max_preservemem
Syntax: set max_preservemem [#b|k|m|g] [, permanently]
Default: 1g (1 gigabyte)
Description: controls the maximum amount of memory preserve will use to store
preserved datasets in memory.
Reference: [P] preserve

set maxvar
Syntax: set maxvar # [, permanently]
Default: 5000 for Stata/MP and Stata/SE and 2048 for Stata/BE
Description: sets the maximum number of variables. This can be changed only in Stata/MP and
Stata/SE. 2048 \leq # \leq 32767
Reference: [D] memory

set min_memory
Syntax: set min_memory [#b|k|m|g] [, permanently]
Default: 0
Description: specifies an amount of memory Stata will not fall below. This setting affects
efficiency, not the size of datasets you can analyze. 0 \leq # \leq \text{max. memory}
Reference: [D] memory

set more
Syntax: set more {on|off} [, permanently]
Default: off
Description: pauses when --more-- is displayed, continuing only when the user presses a key.
Reference: [R] more

set niceness
Syntax: set niceness # [, permanently]
Default: 5
Description: affects how soon Stata gives back unused segments to the operating system.
0 \leq # \leq 10
Reference: [D] memory

set notifyuser (Mac only)
Syntax: set notifyuser {on|off} [, permanently]
Default: on
Description: sets the default Notification Manager behavior in Stata.
Reference: help notifyuser
**set obs**

**Syntax:**
```bash
set obs #
```

**Default:** current number of observations

**Description:** changes the number of observations in the current dataset. # must be at least as large as the current number of observations. If there are variables in memory, the values of all new observations are set to *missing*.

**Reference:** [D] obs

**set odbcdriver**

**Syntax:**
```bash
set odbcdriver {unicode|ansi} [, permanently]
```

**Default:** unicode

**Description:** determines whether Unicode or ANSI is your ODBC driver.

**Reference:** [D] odbc

**set odbcmgr (Mac and Unix only)**

**Syntax:**
```bash
set odbcmgr {iodbc|unixodbc} [, permanently]
```

**Default:** iodbc

**Description:** determines whether iODBC or unixODBC is your ODBC driver manager.

**Reference:** [D] odbc

**set output**

**Syntax:**
```bash
set output {proc|inform|error}
```

**Default:** proc

**Description:** specifies the output to be displayed. proc means display all output; inform suppresses procedure output but displays informative messages and error messages; error suppresses all output except error messages. *set output* is seldom used.

**Reference:** [P] quietly

**set pagesize**

**Syntax:**
```bash
set pagesize #
```

**Default:** 2 less than the physical number of lines on the screen

**Description:** sets the number of lines between —more— messages.

**Reference:** [R] more

**set pformat**

**Syntax:**
```bash
set pformat [fmt] [, permanently]
```

**Description:** specifies the output format of p-values in coefficient tables. fmt is a numerical format; see [D] format.

**Reference:** [R] set cformat

**set pinnable (Windows only)**

**Syntax:**
```bash
set pinnable {on|off} [, permanently]
```

**Default:** on

**Description:** determines whether to enable the use of pinnable window characteristics for certain windows in Stata.

**Reference:** help pinnable
set playsnd (Mac only)
Syntax: set playsnd \{on | off\} [ , permanently ]
Default: on
Description: sets the sound behavior for the Notification Manager behavior in Stata.
Reference: help playsnd

set printcolor
Syntax: set printcolor \{automatic | asis | gs1 | gs2 | gs3\} [ , permanently ]
Default: automatic
Description: determines how colors are handled when graphs are printed.
Reference: [G-2] set printcolor

set processors
Syntax: set processors #
Description: sets the number of processors or cores that Stata/MP will use. The default is the number of processors available on the computer, or the number of processors allowed by Stata/MP’s license, whichever is less.
Reference: help processors

set python_exec
Syntax: set python_exec pyexecutable [, permanently ]
Description: sets which version of Python to use.
Reference: set pythonExec is a synonym for python set exec;
see [P] PyStata integration

set python_userpath
Syntax: set python_userpath path [ path ... ] [, permanently prepend ]
Description: sets the user’s own module search paths in addition to the system search paths.
Reference: set python_userpath is a synonym for python set userpath;
see [P] PyStata integration

set reshape_favor
Syntax: set reshape_favor \{default | memory | speed\} [, permanently ]
Description: sets the default method for reshaping data.
Reference: [D] reshape

set reventries
Syntax: set reventries # [, permanently ]
Default: 5000
Description: sets the number of scrollback lines available in the History window. $5 \leq \# \leq 32000$.
Reference: help reventries
set revkeyboard (Mac only)
Syntax: \texttt{set revkeyboard \{on|off\} [, permanently\}}
Default: on
Description: sets the keyboard navigation behavior for the History window. on indicates that you can use the keyboard to navigate and enter items from the History window into the Command window. off indicates that all keyboard input be directed at the Command window; items can be entered from the History window only by using the mouse.
Reference: help revkeyboard

set rmsg
Syntax: \texttt{set rmsg \{on|off\} [, permanently\}}
Default: off
Description: indicates whether a return message telling the execution time is to be displayed at the completion of each command.
Reference: [P] rmsg

set rng
Syntax: \texttt{set rng \{default|mt64|mt64s|kiss32\}}
Default: default
Description: determines which random-number generator Stata’s random-number functions and commands will use.
Reference: [R] set rng

set rngstate
Syntax: \texttt{set rngstate \textit{statecode}}
Description: resets the state of the random-number generator to the value specified.
Reference: [R] set seed

set rngstream
Syntax: \texttt{set rngstream \#}
Description: specifies the stream from which Stata’s stream random-number generator should draw random numbers.
Reference: [R] set rngstream

set scheme
Syntax: \texttt{set scheme \textit{schemename} [, permanently\}}
Default: s2color
Description: determines the overall look for graphs.
Reference: [G-2] set scheme

set scrollbufsize
Syntax: \texttt{set scrollbufsize \#}
Default: 200000
Description: sets the scrollback buffer size, in bytes, for the Results window; may be set between 10,000 and 2,000,000.
Reference: help scrollbufsize
set searchdefault
Syntax: set searchdefault {local|net|all} [, permanently]
Default: local
Description: sets the default behavior of the search command. set searchdefault local restricts search to use only Stata’s keyword database. set searchdefault net restricts search to searching only the Internet. set searchdefault all indicates that both the keyword database and the Internet are to be searched.
Reference: [R] search

set seed
Syntax: set seed #
Default: 123456789
Description: specifies initial value of the random-number seed used by the random-number functions, such as runiform() and rnormal().
Reference: [R] set seed

set segmentsize
Syntax: set segmentsize #[b|k|m|g] [, permanently]
Default: 32m for 64-bit machines
Description: Stata allocates memory for data in units of segmentsize. This setting changes the amount of memory in a single segment.
1m ≤ # ≤ 32g for 64-bit machines
Reference: [D] memory

set sformat
Syntax: set sformat [fmt] [, permanently]
Description: specifies the output format of test statistics in coefficient tables. fmt is a numerical format; see [D] format.
Reference: [R] set cformat

set showbaselevels
Syntax: set showbaselevels {on|off|all} [, permanently]
Description: specifies whether to display base levels of factor variables and their interactions in coefficient tables.
Reference: [R] set showbaselevels

set showemptycells
Syntax: set showemptycells {on|off} [, permanently]
Description: specifies whether to display empty cells in coefficient tables.
Reference: [R] set showbaselevels

set showomitted
Syntax: set showomitted {on|off} [, permanently]
Description: specifies whether to display omitted coefficients in coefficient tables.
Reference: [R] set showbaselevels
set smoothfonts (Mac only)
Syntax: set smoothfonts {on | off}
Default: on
Description: determines whether to use font smoothing (antialiased text) in the Results, Viewer, and Data Editor windows.
Reference: help smoothfonts

set sortmethod
Syntax: set sortmethod {default | fsort | qsort}
Default: default
Description: determines which sorting method will be used by sort, gsort, and any other commands that use sorting as part of their computation.
Reference: [P] set sortmethod

set sortrngstate
Syntax: set sortrngstate #
Default: 1001XZA112210f4b16c1cb10507a1f38cb440c40003c9a835666fa1201b69...
Description: specifies the initial value of the state used for the random-number generator that randomizes data before they are sorted. This value is used by sort, gsort, and any other commands that use sorting as part of their computation.
Reference: [P] set sortrngstate

set table_style
Syntax: set table_style {table | style} [, permanently]
Default: table
Description: controls the default styles used in tables created by table.
Reference: [TABLES] set table_style

set taskbargroups (Windows only)
Syntax: set taskbargroups {on | off}
Default: on
Description: determines whether to enable taskbar grouping of windows in Stata.
Reference: help taskbargroups

set trace
Syntax: set trace {on | off}
Default: off
Description: determines whether to trace the execution of programs for debugging.
Reference: [P] trace

set tracedepth
Syntax: set tracedepth #
Default: 32000 (equivalent to ∞)
Description: if trace is set on, traces execution of programs and nested programs up to tracedepth. For example, if tracedepth is 2, the current program and any subroutine called would be traced, but subroutines of subroutines would not be traced.
Reference: [P] trace
set traceexpand
Syntax: \texttt{set traceexpand \{on|off\} \[, permanently\]}  
Default: on  
Description: if \texttt{trace} is set on, shows lines both before and after macro expansion. If \texttt{traceexpand} is set off, only the line before macro expansion is shown.  
Reference: \texttt{[P]} \texttt{trace}

set tracehilite
Syntax: \texttt{set tracehilite "pattern" \[, word\]}  
Default: ""  
Description: highlights \texttt{pattern} in the trace output.  
Reference: \texttt{[P]} \texttt{trace}

set traceindent
Syntax: \texttt{set traceindent \{on|off\} \[, permanently\]}  
Default: on  
Description: if \texttt{trace} is set on, indents displayed lines according to their nesting level. The lines of the main program are not indented. Two spaces of indentation are used for each level of nested subroutine.  
Reference: \texttt{[P]} \texttt{trace}

set tracenumber
Syntax: \texttt{set tracenumber \{on|off\} \[, permanently\]}  
Default: off  
Description: if \texttt{trace} is set on, shows the nesting level numerically in front of the line. Lines of the main program are preceded by 01, lines of subroutines called by the main program are preceded by 02, etc.  
Reference: \texttt{[P]} \texttt{trace}

set tracesep
Syntax: \texttt{set tracesep \{on|off\} \[, permanently\]}  
Default: on  
Description: if \texttt{trace} is set on, displays a horizontal separator line that displays the name of the subroutine whenever a subroutine is called or exits.  
Reference: \texttt{[P]} \texttt{trace}

set type
Syntax: \texttt{set type \{float|double\} \[, permanently\]}  
Default: float  
Description: specifies the default storage type assigned to new variables.  
Reference: \texttt{[D]} \texttt{generate}

set update_interval (Mac and Windows only)
Syntax: \texttt{set update_interval \#}  
Default: 7  
Description: sets the number of days to elapse before performing the next automatic update query.  
Reference: \texttt{[R]} \texttt{update}
set update_prompt (Mac and Windows only)
Syntax: set update_prompt \{on|off\}
Default: on
Description: determines whether a dialog is to be displayed before performing an automatic update query. There is no permanently option because permanently is implied.
Reference: [R] update

set update_query (Mac and Windows only)
Syntax: set update_query \{on|off\}
Default: on
Description: determines whether update query is to be automatically performed when Stata is launched. There is no permanently option because permanently is implied.
Reference: [R] update

set varabbrev
Syntax: set varabbrev \{on|off\} [, permanently]
Default: on
Description: indicates whether Stata should allow variable abbreviations.
Reference: [P] varabbrev

set varkeyboard (Mac only)
Syntax: set varkeyboard \{on|off\} [, permanently]
Default: on
Description: sets the keyboard navigation behavior for the Variables window. on indicates that you can use the keyboard to navigate and enter items from the Variables window into the Command window. off indicates that all keyboard input be directed at the Command window; items can be entered from the Variables window only by using the mouse.
Reference: help varkeyboard

Also see
[R] query — Display system parameters
[R] set Defaults — Reset system parameters to original Stata defaults
[M-3] mata set — Set and display Mata system parameters
[P] creturn — Return c-class values
**set cformat — Format settings for coefficient tables**

**Description**

set cformat specifies the output format of coefficients, standard errors, and confidence limits in coefficient tables.

set pformat specifies the output format of *p*-values in coefficient tables.

set sformat specifies the output format of test statistics in coefficient tables.

**Syntax**

set cformat `[fmt] [, permanently]`

set pformat `[fmt] [, permanently]`

set sformat `[fmt] [, permanently]`

where *fmt* is a numerical format.

**Option**

permanently specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

**Remarks and examples**

The formatting of the numbers in the coefficient table can be controlled by using the set cformat, set pformat, and set sformat commands or by using the cformat(`*fmt*`), pformat(`*fmt*`), and sformat(`*fmt*`) options at the time of estimation or on replay of the estimation command. See [R] Estimation options.

The maximum format widths for set cformat, set pformat, and set sformat in coefficient tables are 9, 5, and 8, respectively.
Example 1

We use auto.dta to illustrate.

```
. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. regress mpg weight displacement
```

```

[U] 20.9 Formatting the coefficient table
**set defaults — Reset system parameters to original Stata defaults**

**Description**

`set defaults` resets settings made by `set` to the original default settings that were shipped with Stata.

`set defaults` may not be used with `java`, `lapack`, `putdocx`, `python`, `rng`, or `sort` system-parameter categories.

**Syntax**

```
set defaults {category | all} [ , permanently ]
```

where `category` is one of `memory | output | interface | graphics | network | update | trace | mata | unicode | other`

**Option**

`permanently` specifies that, in addition to making the change right now, the settings be remembered and become the default settings when you invoke Stata.

**Remarks and examples**

**Example 1**

To assist us in debugging a new command, we modified some of the `trace` settings. To return them to their original values, we type

```
. set defaults trace
-> set trace off
-> set tracedepth 32000
-> set traceexpand on
-> set tracesep on
-> set traceindent on
-> set tracenumber off
-> set tracehilite ""
(preferences reset)
```

**Also see**

[R] query — Display system parameters
[R] set — Overview of system parameters
[M-3] mata set — Set and display Mata system parameters
set emptycells — Set what to do with empty cells in interactions

Description

set emptycells allows you to control how Stata handles interaction terms with empty cells. Stata can keep empty cells or drop them. The default is to keep empty cells.

Syntax

```
set emptycells {keep | drop} [, permanently]
```

Option

permanently specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

Remarks and examples

By default, Stata keeps empty cells so they can be reported in the coefficient table. For example, type

```
use https://www.stata-press.com/data/r18/auto
generate rep78#foreign, baselevels
```

and you will see a regression of mpg on 10 indicator variables because rep78 takes on 5 values and foreign takes on 2 values in the auto dataset. Two of those cells will be reported as empty because the data contain no observations of foreign cars with a rep78 value of 1 or 2.

Many real datasets contain a large number of empty cells, and this could cause the “unable to allocate matrix” error message, r(915). In that case, type

```
set emptycells drop
```

to get Stata to drop empty cells from the list of coefficients. If you commonly fit models with empty cells, you can permanently set Stata to drop empty cells by typing the following:

```
set emptycells drop, permanently
```

[R] set — Overview of system parameters
**Description**

`set iterlog` and `set maxiter` control the display of the iteration log and the maximum number of iterations, respectively, for estimation commands that iterate and for the Mata optimization functions `moptimize()`, `optimize()`, and `solvenl()`.

`set iterlog` specifies whether to display the iteration log. The default setting is on, which displays the log. You can specify `set iterlog off` to suppress it. To change whether the iteration log is displayed for a particular estimation command, you need not reset `iterlog`; you can specify the log or nolog option with that command. If you do not specify log or nolog, the `iterlog` setting is used. To view the current setting of `iterlog`, type `display c(iterlog)`.

`set maxiter` specifies the default maximum number of iterations. To change the maximum number of iterations performed by a particular estimation command, you need not reset `maxiter`; you can specify the `iterate(#)` option with that command. If you do not specify `iterate(#), the `maxiter` value is used. To view the current setting of `maxiter`, type `display c(maxiter)`.

**Syntax**

*Set whether to display the iteration log*

```
set iterlog {on|off} [, permanently]
```

*Set default maximum iterations*

```
set maxiter # [, permanently]
```

# is any number between 0 and 16,000; the initial value is set to 300.

**Option**

`permanently` specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

**Remarks and examples**

The `iterlog` setting is particularly useful in combination with the `nolog` and `log` options; see example 1 below. Also see [R] `Maximize` for details about the options. The `iterlog` setting has no effect on commands that suppress the iteration log by default, for example, commands prefixed with `svy`. To display the log with those commands, you need to use the `log` option.

You will rarely need to modify the `maxiter` setting to change the maximum number of iterations used by Stata’s iterative commands. Instead, you may want to specify the `iterate()` option with these commands. For example, specifying `iterate(0)` is useful for viewing results evaluated at the initial value of the coefficient vector.
The `iterlog` and `maxiter` settings also control the default output displayed by the Mata optimization functions `moptimize()`, `optimize()`, and `solvenl()`.

### Example 1: Display and suppress the iteration log

Stata estimation commands that iterate usually display the iteration log by default:

```stata
.logit foreign mpg
```

```
Iteration 0:  Log likelihood =  -45.03321
Iteration 1:  Log likelihood =  -39.380959
Iteration 2:  Log likelihood =  -39.288802
Iteration 3:  Log likelihood =  -39.28864
Iteration 4:  Log likelihood =  -39.28864

Logistic regression  Number of obs =    74  LR chi2(1) =  11.49
                     log likelihood = -39.28864  Prob > chi2 = 0.0007
                     Pseudo R2 =  0.1276

|         | Coefficient | Std. err. | z    | P>|z|  | [95% conf. interval] |
|---------|-------------|-----------|------|------|---------------------|
| foreign |             |           |      |      |                     |
| mpg     | 0.1597621   | 0.0525876 | 3.04 | 0.002| 0.0566922            | 0.262832 |
| _cons   | -4.378866   | 1.211295  | -3.62| 0.000| -6.752961            | -2.004771|
```

You can suppress the log by specifying the `nolog` option:

```stata
.logit foreign mpg, nolog
```

```
Logistic regression  Number of obs =    74  LR chi2(1) =  11.49
                     log likelihood = -39.28864  Prob > chi2 = 0.0007
                     Pseudo R2 =  0.1276

|         | Coefficient | Std. err. | z    | P>|z|  | [95% conf. interval] |
|---------|-------------|-----------|------|------|---------------------|
| foreign |             |           |      |      |                     |
| mpg     | 0.1597621   | 0.0525876 | 3.04 | 0.002| 0.0566922            | 0.262832 |
| _cons   | -4.378866   | 1.211295  | -3.62| 0.000| -6.752961            | -2.004771|
```

If you want to suppress the iteration log from all estimation commands every time they are run within the current Stata session, type

```stata
.set iterlog off
```

We can run `logit` again but now without the `nolog` option, and the iteration log will not be displayed:

```stata
.logit foreign mpg
```

```
Logistic regression  Number of obs =    74  LR chi2(1) =  11.49
                     log likelihood = -39.28864  Prob > chi2 = 0.0007
                     Pseudo R2 =  0.1276

|         | Coefficient | Std. err. | z    | P>|z|  | [95% conf. interval] |
|---------|-------------|-----------|------|------|---------------------|
| foreign |             |           |      |      |                     |
| mpg     | 0.1597621   | 0.0525876 | 3.04 | 0.002| 0.0566922            | 0.262832 |
| _cons   | -4.378866   | 1.211295  | -3.62| 0.000| -6.752961            | -2.004771|
```
Or we can run a different command, for example, `mlogit`, and the log will still be suppressed:

```
. mlogit rep78 mpg
```

Multinomial logistic regression

|                 | Coefficient | Std. err. | z    | P>|z| | [95% conf. interval] |
|-----------------|-------------|-----------|------|-----|----------------------|
|                 | rep78       |           |      |     |                      |
| 1               | mpg         | .0708122  | .1471461 | 0.48 | 0.630 | -0.2175888 | .3592132 |
|                 | _cons       | -4.137144 | 3.15707 | -1.31 | 0.190 | -10.32489 | 2.0506  |
| 2               | mpg         | -.0164251 | .0926724 | -0.18 | 0.859 | -.1980597 | .1652096 |
|                 | _cons       | -1.005118 | 1.822129 | -0.55 | 0.581 | -4.576426 | 2.56619 |
| 3               |             | (base outcome) |       |       |     |                      |
| 4               | mpg         | .0958626  | .0633329 | 1.51 | 0.130 | -.0282676 | .2199927 |
|                 | _cons       | -2.474187 | 1.341131 | -1.84 | 0.065 | -5.102756 | 1.543813 |
| 5               | mpg         | .2477469  | .0764076 | 3.24 | 0.001 | .0979908 | .397503  |
|                 | _cons       | -6.653164 | 1.841794 | -3.61 | 0.000 | -10.26301 | -3.043314 |
With the `iterlog` setting off, we can display the iteration log for specific commands by specifying the `log` option:

```
.mlogit rep78 mpg, log
Iteration 0: Log likelihood = -93.692061
Iteration 1: Log likelihood = -86.581485
Iteration 2: Log likelihood = -85.767758
Iteration 3: Log likelihood = -85.752385
Iteration 4: Log likelihood = -85.752375
Iteration 5: Log likelihood = -85.752375
Multinomial logistic regression
Number of obs = 69
LR chi2(4) = 15.88
Prob > chi2 = 0.0032
Log likelihood = -85.752375
Pseudo R2 = 0.0847
rep78          Coefficient  Std. err.   z    P>|z|    [95% conf. interval]
1             mpg         .0708122   .1471461    0.48  0.630    -.2175888   .3592132
            _cons       -4.137144   3.157077   -1.31  0.190   -10.32489   2.0506
2             mpg         -.0164251   .0926724   -0.18  0.859   -.1980597   .1652096
            _cons       -1.005118  1.822129   -0.55  0.581   -4.576426   2.56619
3             (base outcome)
4             mpg          .0958626   .0633329    1.51  0.130   -.0282676   .2199927
            _cons       -2.474187   1.341131   -1.84  0.065   -5.102756   .1543813
5             mpg          .2477469   .0764076    3.24  0.001     .0979908   .397503
            _cons       -6.653164   1.841794   -3.61  0.000   -10.26301  -3.043314
```

You can switch back to displaying iteration logs by typing

```
.set iterlog on
```

The default setting will be restored automatically the next time you invoke Stata. If you want the setting to be remembered for future Stata sessions, specify the `permanently` option with `set iterlog`.

**set rng** — Set which random-number generator (RNG) to use

**Description**

`set rng` determines which random-number generator (RNG) Stata’s random-number functions and commands will use.

**Syntax**

```
set rng {default | mt64 | mt64s | kiss32}
```

**Remarks and examples**

Remarks are presented under the following headings:

- Introduction
- Random-number generators in Stata

**Introduction**

By default, Stata uses the 64-bit Mersenne Twister (`mt64`) RNG. `mt64s` is a stream RNG based on the 64-bit Mersenne Twister. Earlier versions of Stata used the 32-bit KISS (keep it simple stupid) (`kiss32`) RNG.

With `set rng default` (the default), code running under version control will automatically use the appropriate RNG—`mt64` in Stata 14 and later and `kiss32` for earlier code.

The scope of `set rng` is the Stata session, do-file, or program in which `rng` is set.

Unless you want to simultaneously draw random numbers in separate instances of Stata, we recommend that you do not change Stata’s default behavior for its RNGs. See [R] set rngstream for an introduction to simultaneously drawing random numbers in separate instances of Stata.

See [FN] Random-number functions, [R] set seed, and [R] set rngstream for more information.

**Random-number generators in Stata**

The default RNG in Stata is the 64-bit Mersenne Twister. See Matsumoto and Nishimura (1998) for more details. The default RNG in Stata 13 and earlier versions was George Marsaglia’s 32-bit KISS generator (G. Marsaglia, 1994, pers. comm.). The KISS generator is still available under version control or via `set rng`. Multiple independent random-number streams (based on the 64-bit Mersenne Twister) are also supported for use in multiple simultaneous instances of Stata; see [R] set rngstream for more information on this. The abbreviations `mt64`, `kiss32`, and `mt64s` are used, respectively, to specify these three generators in Stata commands and functions.
So far, we have discussed two ways you can specify the RNG: with \texttt{set rng} and through version control. Another way to specify the RNG is with functions and system parameters explicitly named after the generators. In fact, all random-number functions have variants that are explicitly named after each generator, using the generator abbreviation as the suffix. For example, \texttt{runiform\_mt64()}, \texttt{runiform\_kiss32()}, and \texttt{runiform\_mt64s()} are variants of \texttt{runiform()} for each generator. Similarly, we have \texttt{rnormal\_mt64()}, \texttt{rnormal\_kiss32()}, \texttt{rnormal\_mt64s()}, etc.

The system parameters \texttt{seed} and \texttt{rngstate} also have variants explicitly named after each generator: \texttt{seed\_mt64}, \texttt{seed\_kiss32}, \texttt{seed\_mt64s}, \texttt{rngstate\_mt64}, \texttt{rngstate\_kiss32}, and \texttt{rngstate\_mt64s}.

For example, here is how you can use functions and parameters specific to \texttt{mt64} to set the seed, generate random numbers, preserve a state, generate more numbers, and restore the previously preserved state:

\begin{verbatim}
. set seed\_mt64 482637
. generate u = runiform\_mt64()
. local state = c(rngstate\_mt64)
. generate l = rlogistic\_mt64()
. set rngstate\_mt64 'state'
\end{verbatim}

Note that calling functions and setting parameters specific to, say, \texttt{kiss32}, will not change the current RNG, the seed of the current RNG, or the state of the current RNG—unless the current RNG is \texttt{kiss32}.

[R] \texttt{set seed} — Specify random-number seed and state
[FN] Random-number functions
[P] \texttt{version} — Version control
set rngstream — Specify the stream for the stream random-number generator

Description

set rngstream specifies the subsequence, known as a stream, from which Stata’s stream random-number generator should draw random numbers. When performing a bootstrap estimation or a Monte Carlo simulation in parallel on multiple machines, you should set the same seed on all machines but set a different stream on each machine. This will ensure that random numbers drawn on different machines are independent. We strongly recommend that you set the seed and the stream only once in each Stata session.

Syntax

    set rngstream #

# is any integer between 1 and 32,767.

Remarks and examples

Stata’s stream random-number generator, the stream 64-bit Mersenne Twister (mt64s), allows separate instances of Stata to simultaneously draw independent random numbers. This feature enables you to use bootstrap and to run Monte Carlo simulations in parallel on multiple machines.

What we call random numbers are elements in a sequence of deterministic numbers that appear to be random. A seed specifies a starting value in this sequence. In figure 1, each tick is an element in a random sequence and setting the seed to 12345 means that the tick identified by the arrow below is the first number drawn.

![Figure 1. Seed specifies first number in random sequence](image)

A stream random-number generator partitions a sequence of random numbers into nonoverlapping subsequences known as streams. The random numbers in each stream are independent of those in other streams because they come from distinct nonoverlapping subsets of the original sequence.
Figure 2 depicts a stream version of the generator depicted in figure 1. The stream version also starts at the place implied by seed 12345, but it additionally partitions the random numbers into 4 streams and a set of unused numbers.

![Figure 2. A stream version of figure 1 generator](image1)

In contrast to nonstream random-number generators, setting the seed for a random-number generator controls not just where the sequence starts but also how the sequence is partitioned. Compare figure 2 with figure 3 for an illustration.

![Figure 3. Changing the seed changes the streams](image2)

Seed 123456 specifies the first random number, and the streams of random numbers in figure 3 differ from those in figure 2.

The mt64s generator is a stream version of Stata’s default generator, the 64-bit Mersenne Twister implemented in mt64; see Matsumoto and Nishimura (1998) and Random-number generators in Stata in [R] set rng for more details. Our implementation of the method discussed in Haramoto et al. (2008) partitions the mt64 sequence into 32,767 streams, each containing $2^{128}$ random numbers. The remaining numbers are unused. The mt64s seed determines the starting point of every stream in the Mersenne Twister sequence.

Stream 1 of mt64s has the same starting point as the mt64 generator. That is, given the same seed, mt64s with rngstream set to 1 will generate the same random numbers as mt64.

The mt64s generator is designed to simultaneously draw independent random numbers on different machines. To draw from different streams that guarantee independence, use the same seed and change the stream. For example, to draw some uniform(0,1) random numbers from stream 10 of the mt64s generator under seed 123, type

```
. set rng mt64s
. set rngstream 10
. set seed 123
. generate u = runiform()
```

If we wanted to simultaneously draw some uniform(0,1) random numbers on another machine from stream 11 of the mt64s generator, we would type

```
. set rng mt64s
. set rngstream 11
. set seed 123
. generate u = runiform()
```

Again, each seed creates a different partition of the mt64 sequence into nonoverlapping subsets.

We strongly recommend that you set the stream and the seed once in each Stata session and draw numbers only from this stream.
c(rngstream) returns the current stream number. c(rngseed_mt64s) returns the last seed that was set for mt64s. See [P] creturn for more details. See [R] set seed for details about storing and restoring the current position in the random sequence.

As with the single-stream generators, use local state = c(rngstate) to store the current position in the current random stream; see [R] set seed for details. The mt64s state encodes the seed used in addition to the stream number, because the seed determines the position of every random number in every stream. Unlike the case of single-stream generators, restoring the state also restores the seed. For example, suppose you save an mt64s state with local state = c(rngstate) change the seed and the stream, and later restore that state with set rngstate ‘state’. The current mt64s seed is changed to the one encoded in state. In addition to changing the current stream to the one encoded in state, the current mt64s seed is changed to the one encoded in state. This behavior ensures any subsequent stream changes draw from nonoverlapping subsets.

set rngstream also sets the random-number generator to mt64s.

Example 1: Using stream random numbers to parallelize a bootstrap

We illustrate how to simultaneously perform 100 bootstrap replications on machine 1 and 100 bootstrap replications on machine 2. We focus on the mechanics of distributing the draws over machines using stream random numbers; see [R] bootstrap for an introduction to the bootstrap.

On machine 1, we type

. clear all
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. set rng mt64s
. set rngstream 1
. set seed 12345
. bootstrap, reps(100) saving(machine1, replace): regress mpg weight gear foreign

We used `regress` in this example, but the divide-and-conquer strategy reduces computation time for any command that works with `bootstrap`. In fact, problems that take longer produce more noticeable speed improvements. For computationally intensive problems, the two-machine time will be about one-half the one-machine time. Using distinct streams on many different machines can dramatically reduce the time required for computationally intensive problems.
Example 2: Using stream random numbers to parallelize a Monte Carlo simulation

We want to simultaneously perform 100 Monte Carlo replications on machine 3 and 100 Monte Carlo replications on machine 4. Again, we focus entirely on the mechanics of distributing the draws over machines. See Drukker (2015) for an introduction to Monte Carlo simulations using Stata.

As discussed in [R] simulate, the simulate command uses an ado-file that draws from the population of interest; it then computes and returns the estimates. Our program chi2sim draws from a $\chi^2$ distribution with one degree of freedom.

```stata
program define chi2sim, rclass
version 18.0
drop _all
set obs 200
tempvar z
generate `z' = rchi2(1)
summarize `z'
return scalar mean = r(mean)
return scalar Var = r(Var)
end
```

On machine 3, we type

```
. set rng mt64s
. set rngstream 3
. set seed 12345
. simulate mean=r(mean) var=r(Var), reps(500) saving(machine3, replace): chi2sim
   Command: chi2sim
   mean: r(mean)
   var: r(Var)
```

(file machine3.dta not found)
Simulations (500): ..........10.........20.........30.........40.........50......
> ....60.........70.........80.........90.........100.........110.........120....
> ....130.........140.........150.........160.........170.........180.........1
> 90.........200.........210.........220.........230.........240.........250....
> ....260.........270.........280.........290.........300.........310.........3
> 20.........330.........340.........350.........360.........370.........380....
> ....390.........400.........410.........420.........430.........440.........4
> 50.........460.........470.........480.........490.........500 done
On machine 4, we run a do-file that performs

```
set rng mt64s
set rngstream 4
set seed 12345
.simulate mean=r(mean) var=r(Var), reps(500) saving(machine4, replace): chi2sim
```

Command: chi2sim
mean: r(mean)
var: r(Var)

(file machine4.dta not found)

Simulations (500): ........10........20........30........40........50......
> ...60........70........80........90.........100........110........120....
> ....130.........140.........150.........160.........170........180........1
> 90........200.........210.........220.........230.........240.........250....
> ....260.........270.........280.........290.........300.........310.........3
> 20.........330.........340.........350.........360.........370.........380....
> ....390.........400.........410.........420.........430.........440.........4
> 50.........460.........470.........480.........490.........500 done

After copying machine4.dta from machine 4 to the working directory on machine 3, we combine the results by typing

```
.clear all
.use machine3
(simulate: chi2sim)
.append using machine4
.summarize mean var
```

<table>
<thead>

</table>

As in example 1, more machines enable further parallelization.

Technical note

While mt64s has been made robust to switching between streams within a Stata session, convoluted combinations of `set rngstream #` and `set seed #` can lead to drawing the same random numbers, just as it can in the case of single-stream generators. We strongly recommend that you do not switch between streams within a session.

Example 3: Position within a stream is stored

This example illustrates that the sequence picks up where it left off when the stream is switched, and it illustrates that `clear rngstream` resets all streams to their beginning positions. These features facilitate advanced programming techniques, and we recommend against using this feature in standard use.
set rngstream — Specify the stream for the stream random-number generator  2723

After setting the `rngstream` to 5 and setting the seed, we put the first 5 draws from stream 5 into observations 1–5 of x, switch to `rngstream` 6, put the first 10 random draws from stream 6 into y, return to `rngstream` 5, and put the next 5 draws from stream 5 into observations 6–10 of x. Then we use `clear rngstream` to initialize each `rngstream` at its initial position for seed 12345 and put the first 10 draws from stream 5 into z.

That the random numbers in x match those in z illustrates that the sequence picks up where it left off when the stream is switched and the seed has not been changed.

[FN] Random-number functions
set seed — Specify random-number seed and state

Description

set seed # specifies the initial value of the random-number seed used by the random-number functions, such as runiform() and rnormal().

set rngstate statecode resets the state of the random-number generator to the value specified, which is a state previously obtained from creturn value c(rngstate).

set seed # and set rngstate statecode apply to the current random-number generator. Every random-number generator in Stata has its own seed and state encoding.

Syntax

```
set seed #
set rngstate statecode
```

# is any number between 0 and $2^{31} - 1$ (or 2,147,483,647).

statecode is a random-number state previously obtained from creturn value c(rngstate).

Remarks and examples

Remarks are presented under the following headings:

Examples

Setting the seed

How to choose a seed

Do not set the seed too often

Preserving and restoring the random-number generator state

Examples

1. Specify initial value of random-number seed
   ```
   . set seed 339487731
   ```

2. Create variable u containing uniformly distributed pseudorandom numbers on the interval (0, 1)
   ```
   . generate u = runiform()
   ```

3. Create variable z containing normally distributed random numbers with mean 0 and standard deviation 1
   ```
   . generate z = rnormal()
   ```
4. Obtain state of pseudorandom-number generator and store it in a local macro named `state`
   ```stata
   . local state = c(rngstate)
   ```

5. Restore pseudorandom-number generator state to that previously stored in local macro named `state`
   ```stata
   . set rngstate `state`
   ```

### Setting the seed

Stata’s random-number generation functions, such as `runiform()` and `rnormal()`, do not really produce random numbers. These functions are deterministic algorithms that produce numbers that can pass for random. `runiform()` produces numbers that can pass for independent draws from a rectangular distribution over \((0, 1)\); `rnormal()` produces numbers that can pass for independent draws from \(N(0, 1)\). Stata’s random-number functions are formally called pseudorandom-number functions. The default pseudorandom-number generator introduced in Stata 14 is the 64-bit Mersenne Twister. See Matsumoto and Nishimura (1998) and Random-number generators in Stata in [R] set rng for more details.

The sequences the random-number functions produce are determined by the seed, which is just a number and which is set to 123456789 every time Stata is launched. This means that `runiform()` produces the same sequence each time you start Stata. The first time you use `runiform()` after Stata is launched, `runiform()` returns 0.348871704556195. The second time you use it, `runiform()` returns 0.266885709753138. The third time you use it, ...

To obtain different sequences, you must specify different seeds using the `set seed` command. You might specify the seed 472195:

```stata
. set seed 472195
```

If you were now to use `runiform()`, the first call would return 0.713028143573182, the second call would return 0.92052469911484, and so on. Whenever you `set seed 472195`, `runiform()` will return those numbers the first two times you use it.

Thus, you set the seed to obtain different pseudorandom sequences from the pseudorandom-number functions.

If you record the seed you set, pseudorandom results such as results from a simulation or imputed values from `mi impute` can be reproduced later. Whatever you do after setting the seed, if you set the seed to the same value and repeat what you did, you will obtain the same results.

### How to choose a seed

Your best choice for the seed is an element chosen randomly from the set \(\{0, 1, \ldots, 2^{31} - 1\}\) (where \(2^{31} - 1 = 2,147,483,647\)). We recommend that, but that is difficult to achieve because finding easy-to-access, truly random sources is difficult.

One person we know uses digits from the serial numbers from dollar bills he finds in his wallet. Of course, the numbers he obtains are not really random, but they are good enough, and they are probably a good deal more random than the seeds most people choose. Some people use dates and times, although we recommend against that because, over the day, it just gets later and later, and that is a pattern. Others try to make up a random number, figuring if they include enough digits, the result just has to be random. This is a variation on the five-second rule for dropped food, and we admit to using both of these rules.
It does not really matter how you set the seed, as long as there is no obvious pattern in the seeds that you set and as long as you do not set the seed too often during a session.

Nonetheless, here are two methods that we have seen used but you should not use:

1. The first time you set the seed, you set the number 1. The next time, you set 2, and then 3, and so on. Variations on this included setting 1001, 1002, 1003, . . . , or setting 1001, 2001, 3001, and so on.

   Do not follow any of these procedures. The seeds you set must not exhibit a pattern.

2. To set the seed, you obtain a pseudorandom number from `runiform()` and then use the digits from that to form the seed.

   This is a bad idea because the pseudorandom-number generator can converge to a cycle. If you obtained the pseudorandom-number generator unrelated to those in Stata, this would work well, but then you would have to find a rule to set the first generator's seed.

Choosing seeds that do not exhibit a pattern is of great importance. That the seeds satisfy the other properties of randomness is minor by comparison.

**Do not set the seed too often**

We cannot emphasize this enough: Do not set the seed too often.

To see why this is such a bad idea, consider the limiting case: You set the seed, draw one pseudorandom number, reset the seed, draw again, and so continue. The pseudorandom numbers you obtain will be nothing more than the seeds you run through a mathematical function. The results you obtain will not pass for random unless the seeds you choose pass for random. If you already had such numbers, why are you even bothering to use the pseudorandom-number generator?

The definition of too often is more than once per problem.

If you are running a simulation of 10,000 replications, set the seed at the start of the simulation and do not reset it until the 10,000th replication is finished. The pseudorandom-number generators provided by Stata have long periods. The longer you go between setting the seed, the more random-like are the numbers produced.

It is sometimes useful later to be able to reproduce in isolation any one of the replications, and so you might be tempted to set the seed to a known value for each of the replications. We negatively mentioned setting the seed to 1, 2, . . . , and it is in exactly such situations that we have seen this done. The advantage, however, is that you could reproduce the fifth replication merely by setting the seed to 5 and then repeating whatever it is that is to be replicated. If this is your goal, you do not need to reset the seed. You can record the state of the random-number generator, save the state with your replication results, and then use the recorded states later to reproduce whichever of the replications that you wish. This will be discussed in *Preserving and restoring the random-number generator state*.

There is another reason you might be tempted to set the seed more than once per problem. It sometimes happens that you run a simulation, let's say for 5,000 replications, and then you decide you should have run it for 10,000 replications. Instead of running all 10,000 replications afresh, you decide to save time by running another 5,000 replications and then combining those results with your previous 5,000 results. That is okay. We at StataCorp do this kind of thing. If you do this, it is important that you set the seed especially well, particularly if you repeat this process to add yet another 5,000 replications. It is also important that in each run there be a large enough number of replications, which is say thousands of them.

Even so, do not do this: You want 500,000 replications. To obtain them, you run in batches of 1,000, setting the seed 500 times. Unless you have a truly random source for the seeds, it is unlikely
you can produce a patternless sequence of 500 seeds. The fact that you ran 1,000 replications in between choosing the seeds does not mitigate the requirement that there be no pattern to the seeds you set.

In all cases, the best solution is to set the seed only once and then use the method we suggest in the next section.

**Preserving and restoring the random-number generator state**

In the previous section, we discussed the case in which you might be tempted to set the seed more frequently than otherwise necessary, either to save time or to be able to rerun any one of the replications. In such cases, there is an alternative to setting a new seed: recording the state of the pseudorandom-number generator and then restoring the state later should the need arise.

The state of the default random-number generator in Stata, the 64-bit Mersenne Twister, is a string of about 5,000 characters. The state can be displayed by typing `display c(rngstate)`. It is more practical to save the state, say, in a local macro named `state`:

```
local state = c(rngstate)
```

The state can later be restored by typing

```
set rngstate `state`
```

The state string specifies an entry point into the sequence produced by the pseudorandom-number generator. Let us explain.

The best way to use a pseudorandom-number generator would be to choose a seed once, draw random numbers until you use up the generator, and then get a new generator and choose a new key. Pseudorandom-number generators have a period, after which they repeat the original sequence. That is what we mean by using up a generator. The period of the 64-bit Mersenne Twister, the default pseudorandom-number generator in Stata, is $2^{19937} - 1$. This is roughly $10^{6000}$. It is difficult to imagine that you could ever use up this generator.

The string reported by `c(rngstate)` is an encoded form of the information necessary for Stata to reestablish exactly where it is located in the pseudorandom-number generator’s sequence.

We are not seriously suggesting you choose only one seed over your entire lifetime, but let’s look at how you might do that. Sometime after birth, when you needed your first random number, you would set your seed,

```
set seed 1073741823
```

On that day, you would draw, say, 10,000 pseudorandom numbers, perhaps to impute some missing values. Being done for the day, you can save the state, and then later restore it.

When you type `set rngstate` followed by a saved state string, Stata reestablishes the previous state. Thus, the next time you draw a pseudorandom number, Stata will produce the 10,001st result after setting seed 1073741823. Let’s assume that you draw 100,000 numbers this day. Done for the day, you save the state string.

On the third day, after setting the state to the saved state string above, you will be in a position to draw the 110,001st pseudorandom number.

In this way, you would eat your way through the $2^{19937} - 1$ random numbers, but you would be unlikely ever to make it to the end.

We do not expect you to set the seed just once in your life, but using the state string makes it easy to set the seed just once for a problem.
When we do simulations at StataCorp, we record `c(rngstate)` for each replication. Just like everybody else, we record results from replications as observations in datasets; we just happen to have an extra variable in the dataset, namely, a string variable named `state`. That string is filled in observation by observation from the then-current values of `c(rngstate)`, which is a function and so can be used in any context that a function can be used in Stata.

Anytime we want to reproduce a particular replication, we thus have the information we need to reset the pseudorandom-number generator, and having it in the dataset is convenient because we had to go there anyway to determine which replication we wanted to reproduce. If we want to add more replications later, we have a state string that we can use to continue from where we left off.

[R] set — Overview of system parameters
[R] set rng — Set which random-number generator (RNG) to use
[R] set rngstream — Specify the stream for the stream random-number generator
[FN] Random-number functions
[P] version — Version control
**set showbaselevels** specifies whether to display base levels of factor variables and their interactions in coefficient tables. **set showbaselevels on** specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables. **set showbaselevels all** specifies that all base levels of factor variables and interactions be reported.

**set showemptycells** specifies whether to display empty cells in coefficient tables.

**set showomitted** specifies whether to display omitted coefficients in coefficient tables.

**set fvlabel** specifies whether to display factor-variable value labels in coefficient tables. **set fvlabel on**, the default, specifies that the labels be displayed. **set fvlabel off** specifies that the levels of factor variables rather than the labels be displayed.

**set fvwrap #** specifies that long value labels wrap # lines in the coefficient table. The default is **set fvwrap 1**, which means that long value labels will be abbreviated to fit on one line.

**set fvwrapon** specifies whether value labels that wrap will break at word boundaries or break based on available space. **set fvwrapon word**, the default, specifies that value labels break at word boundaries. **set fvwrapon width** specifies that value labels break based on available space.

---

**Option**

**permanently** specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.
Remarks and examples

> Example 1

We illustrate the first three set commands using cholesterol2.dta.

. use https://www.stata-press.com/data/r18/cholesterol2
(Artificial cholesterol data, empty cells)
. generate x = race
. regress chol race##agegrp x

Note: 2.race#2.agegrp identifies no observations in the sample.
Note: x omitted because of collinearity.

Example 2

We illustrate the last three `set` commands using `jaw.dta`.

```stata
use https://www.stata-press.com/data/r18/jaw, clear
(Table 4.6. Two-way unbalanced data for fractures of the jaw, Rencher (1998))

.mvreg y1 y2 y3 = i.fracture
```

Description

signrank tests the equality of matched pairs of observations by using the Wilcoxon matched-pairs signed-rank test (Wilcoxon 1945). The null hypothesis is that both distributions are the same.

signtest also tests the equality of matched pairs of observations (Arbuthnott [1710], but better explained by Snedecor and Cochran [1989]) by calculating the differences between `varname` and the expression. The null hypothesis is that the median of the differences is zero; no further assumptions are made about the distributions. This, in turn, is equivalent to the hypothesis that the true proportion of positive (negative) signs is one-half.

For equality tests on unmatched data, see [R] ranksum.

Quick start

Wilcoxon matched-pairs signed-rank test for v1 and v2

```
signrank v1 = v2
```

Compute an exact p-value for the signed-rank test

```
signrank v1 = v2, exact
```

Conduct signed-rank test separately for groups defined by levels of catvar

```
by catvar: signrank v1 = v2
```

Test that the median of differences between matched pairs v1 and v2 is 0

```
signtest v1 = v2
```

Menu

signrank

Statistics > Nonparametric analysis > Tests of hypotheses > Wilcoxon matched-pairs signed-rank test

signtest

Statistics > Nonparametric analysis > Tests of hypotheses > Test equality of matched pairs
Syntax

Wilcoxon matched-pairs signed-rank test

\texttt{signrank \ varname = exp [if] [in] [, exact]}

Sign test of matched pairs

\texttt{signtest \ varname = exp [if] [in]}

by and collect are allowed with \texttt{signrank} and \texttt{signtest}; see \cite{U11.1.10} Prefix commands.

Option for \texttt{signrank}

\texttt{exact} specifies that the exact \( p \)-value be computed in addition to the approximate \( p \)-value. The exact \( p \)-value is based on the actual randomization distribution of the test statistic. The approximate \( p \)-value is based on a normal approximation to the randomization distribution. By default, the exact \( p \)-value is computed for sample sizes \( n \leq 200 \) because the normal approximation may not be precise in small samples. The exact computation can be suppressed by specifying \texttt{noexact}. For sample sizes larger than 200, you must specify \texttt{exact} to compute the exact \( p \)-value. The exact computation is available for sample sizes \( n \leq 2000 \).

Remarks and examples

\begin{itemize}
\item \textbf{Example 1: signrank}
\end{itemize}

We are testing the effectiveness of a new fuel additive. We run an experiment with 12 cars. We first run each car without the fuel treatment and measure the mileage. We then add the fuel treatment and repeat the experiment. The results of the experiment are

\begin{table}
\begin{tabular}{cccc}
\hline
Without treatment & With treatment & Without treatment & With treatment \\
\hline
20 & 24 & 18 & 17 \\
23 & 25 & 24 & 28 \\
21 & 21 & 20 & 24 \\
25 & 22 & 24 & 27 \\
18 & 23 & 23 & 21 \\
17 & 18 & 19 & 23 \\
\hline
\end{tabular}
\end{table}
We create two variables called mpg1 and mpg2, representing mileage without and with the treatment, respectively. We can test the null hypothesis that the treatment had no effect by typing

```
. use https://www.stata-press.com/data/r18/fuel
. signrank mpg1 = mpg2
```

Wilcoxon signed-rank test

<table>
<thead>
<tr>

<td>13.5</td>
<td>38.5</td>
</tr>
<tr>
<td>Negative</td>
<td>8</td>
<td>63.5</td>
<td>38.5</td>
</tr>
<tr>
<td>Zero</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

All | 12 | 78 | 78 |

Unadjusted variance 162.50
Adjustment for ties -1.62
Adjustment for zeros -0.25

Adjusted variance 160.62
H0: mpg1 = mpg2
    z = -1.973
    Prob > |z| = 0.0485
    Exact prob = 0.0479

Despite the small sample size, the p-value computed using a normal approximation, 0.0485, is similar to the exact p-value, 0.0479. These results indicate that we can reject the null hypothesis at a significance level of 0.05.

---

Example 2: signtest

```
. signtest mpg1 = mpg2
```

Sign test

<table>
<thead>
<tr>
<th>Sign</th>
<th>Observed</th>
<th>Expected</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive</td>
<td>3</td>
<td>5.5</td>
</tr>
<tr>

<tr>
<td>Zero</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

All | 12 | 12 |

One-sided tests:

- H0: median of mpg1 - mpg2 = 0 vs. 
  Ha: median of mpg1 - mpg2 > 0
  Pr(#positive >= 3) = Binomial(n = 11, x >= 3, p = 0.5) = 0.9673

- H0: median of mpg1 - mpg2 = 0 vs. 
  Ha: median of mpg1 - mpg2 < 0
  Pr(#negative >= 8) = Binomial(n = 11, x >= 8, p = 0.5) = 0.1133

Two-sided test:

- H0: median of mpg1 - mpg2 = 0 vs. 
  Ha: median of mpg1 - mpg2 != 0
  Pr(#positive >= 8 or #negative >= 8) = min(1, 2*Binomial(n = 11, x >= 8, p = 0.5)) = 0.2266

The summary table indicates that there were three comparisons for which mpg1 exceeded mpg2, eight comparisons for which mpg2 exceeded mpg1, and one comparison for which they were the same.
The \( p \)-values displayed below the summary table are based on a binomial(\( n, p = 1/2 \)) distribution for the test statistic, which is the number of positive or negative signs. Zeros are ignored. The \( n \) for the test is the number of nonzero differences. Because no approximation is used, the \( p \)-values are “exact” \( p \)-values. The \( p \)-value for the one-sided test, where the alternative hypothesis is that the median of \( mpg1 - mpg2 \) is smaller than zero, is 0.1133. The \( p \)-value for the two-sided test, where the alternative hypothesis is simply that the median of the differences is different from zero, is 0.2266 = \( 2 \times 0.1133 \).

**Stored results**

`signrank` stores the following in \( r() \):

Scalars
- \( r(N) \): sample size
- \( r(N\_pos) \): number of positive comparisons
- \( r(N\_neg) \): number of negative comparisons
- \( r(N\_tie) \): number of tied comparisons
- \( r(z) \): \( z \) statistic
- \( r(Var\_a) \): adjusted variance
- \( r(sum\_pos) \): sum of the positive ranks
- \( r(sum\_neg) \): sum of the negative ranks
- \( r(p) \): two-sided \( p \)-value from normal approximation
- \( r(p\_l) \): lower one-sided \( p \)-value from normal approximation
- \( r(p\_u) \): upper one-sided \( p \)-value from normal approximation
- \( r(p\_exact) \): two-sided exact \( p \)-value
- \( r(p\_l\_exact) \): lower one-sided exact \( p \)-value
- \( r(p\_u\_exact) \): upper one-sided exact \( p \)-value

`signtest` stores the following in \( r() \):

Scalars
- \( r(N) \): sample size
- \( r(N\_pos) \): number of positive comparisons
- \( r(N\_neg) \): number of negative comparisons
- \( r(N\_tie) \): number of tied comparisons
- \( r(p) \): two-sided \( p \)-value
- \( r(p\_l) \): lower one-sided \( p \)-value
- \( r(p\_u) \): upper one-sided \( p \)-value

**Methods and formulas**

For a practical introduction to these techniques with an emphasis on examples rather than theory, see Bland (2015) or Sprent and Smeeton (2007). For a summary of these tests, see Snedecor and Cochran (1989).

Methods and formulas are presented under the following headings:

- `signrank`
- `signtest`
Both the sign test and Wilcoxon signed-rank tests test the null hypothesis that the distribution of a random variable \( D = \text{varname} - \text{exp} \) has median zero. The sign test makes no additional assumptions, but the Wilcoxon signed-rank test makes the additional assumption that the distribution of \( D \) is symmetric. If \( D = X_1 - X_2 \), where \( X_1 \) and \( X_2 \) have the same distribution, then it follows that the distribution of \( D \) is symmetric about zero. Thus, the Wilcoxon signed-rank test is often described as a test of the hypothesis that two distributions are the same, that is, \( X_1 \sim X_2 \).

Let \( d_j \) denote the difference for any matched pair of observations,

\[
d_j = x_{1j} - x_{2j} = \text{varname} - \text{exp}
\]

for \( j = 1, 2, \ldots, n \).

Rank the absolute values of the differences, \( |d_j| \), and assign any tied values the average rank. Consider the signs of \( d_j \), and let

\[
r_j = \text{sign}(d_j) \text{ rank}(|d_j|)
\]

be the signed ranks. The test statistic is

\[
T_{\text{obs}} = \sum_{j=1}^{n} r_j = (\text{sum of ranks for + signs}) - (\text{sum of ranks for - signs})
\]

The distribution of the test statistic is based on Fisher’s principle of randomization (Fisher 1935). Fisher’s idea (stated in a modern way) was to look at a family of transformations of the observed data such that the a priori likelihood (under the null hypothesis) of the transformed data is the same as the likelihood of the observed data. The distribution of the test statistic is then produced by calculating its value for each of the transformed “randomization” datasets, assuming that each dataset is equally likely.

The null hypothesis is that the distribution of \( d_j \) is symmetric about 0. Hence, the likelihood is unchanged if we flip signs on the \( d_j \). The randomization distribution of our test statistic, \( T \), is all of its values resulting from the \( 2^n \) possible sign changes for the \( d_j \). Namely, the distribution is all the \( 2^n \) possible values of

\[
T = \sum_{j=1}^{n} S_j r_j
\]

where \( r_j \) are the observed signed ranks (considered fixed) and \( S_j \) is either +1 or −1. When the exact option is specified (or implied for \( n \leq 200 \)), this distribution is computed using a recursive algorithm whose computational time is proportional to \( n^3 \). (See Fisher [1935] for the principle of randomization; Wilcoxon, Katti, and Wilcox [1970] for the computation with untied ranks; and Baker and Tilbury [1993] for the general recursive algorithm.)

\( p \)-values can also be computed using a normal approximation to the randomization distribution. For the randomization distribution, the mean and variance are given by

\[
E(T) = 0 \quad \text{and} \quad \text{Var}_{\text{adj}}(T) = \sum_{j=1}^{n} r_j^2
\]

The test statistic for the Wilcoxon signed-rank test is often expressed (equivalently) as the sum of the positive signed ranks, \( T_+ \), where
\[ E(T_+) = \frac{n(n+1)}{4} \quad \text{and} \quad \text{Var}_{\text{adj}}(T_+) = \frac{1}{4} \sum_{j=1}^{n} r_j^2 \]

Zeros and ties do not affect the theory above, and the exact variance is still given by the above formula for \( \text{Var}_{\text{adj}}(T_+) \). When \( d_j = 0 \) is observed, \( r_j \) will always be zero in each of the randomization datasets, using \( \text{sign}(0) = 0 \). (This method of handling zeros is based on the theoretical arguments made by Pratt [1959].) When there are ties, averaged ranks are assigned for each group of ties and then treated the same as other ranks.

The “unadjusted variance” reported by \( \text{signrank} \) is the variance that the randomization distribution would have had if there had been no ties or zeros:

\[ \text{Var}_{\text{unadj}}(T_+) = \frac{1}{4} \sum_{j=1}^{n} j^2 = \frac{n(n+1)(2n+1)}{24} \]

The adjustment for zeros is the change in the variance when the ranks for the zeros are signed to make \( r_j = 0 \),

\[ \Delta \text{Var}_{\text{zero adj}}(T_+) = -\frac{1}{4} \sum_{j=1}^{n_0} j^2 = -\frac{n_0(n_0+1)(2n_0+1)}{24} \]

where \( n_0 \) is the number of zeros. The adjustment for ties is the change in the variance when the ranks (for nonzero observations) are replaced by averaged ranks:

\[ \Delta \text{Var}_{\text{ties adj}}(T_+) = \text{Var}_{\text{adj}}(T_+) - \text{Var}_{\text{unadj}}(T_+) - \Delta \text{Var}_{\text{zero adj}}(T_+) \]

A normal approximation is used to calculate

\[ z = \frac{T_+ - E(T_+)}{\sqrt{\text{Var}_{\text{adj}}(T_+)}} \]

\text{signtest}

The test statistic for the sign test is the number \( n_+ \) of differences

\[ d_j = x_{1j} - x_{2j} = \text{varname} - \text{exp} \]

greater than zero.

Again, the distribution of the test statistic is based on Fisher’s principle of randomization, which we described above for \( \text{signrank} \). For the sign test, the “data” are simply the set of signs of the differences. Under the null hypothesis of the sign test, the probability that \( d_j \) is less than zero is equal to the probability that \( d_j \) is greater than zero. Thus, you can transform the observed signs by flipping any number of them, and the set of signs will have the same likelihood. The \( 2^n \) possible sign changes form the family of randomization datasets. If you have no zeros, this procedure leads to \( n_+ \sim \text{binomial}(n, p = 1/2) \).

But what if some differences are zero? If you do have zeros, changing their signs leaves them as zeros. So, if you observe \( n_0 \) zeros, each of the \( 2^n \) sign-change datasets will also have \( n_0 \) zeros. Hence, the values of \( n_+ \) calculated over the sign-change datasets range from 0 to \( n - n_0 \), and the “randomization” distribution of \( n_+ \) is \( \text{binomial}(n - n_0, p = 1/2) \).
The work of Arbuthnott (1710) and later eighteenth-century contributions is discussed by Hald (2003, chap. 17).

Frank Wilcoxon (1892–1965) was born in Ireland to American parents. After working in various occupations (including merchant seaman, oil-well pump attendant, and tree surgeon), he settled in chemistry, gaining degrees from Rutgers and Cornell and employment from various companies. Working mainly on the development of fungicides and insecticides, Wilcoxon became interested in statistics in 1925 and made several key contributions to nonparametric methods. After retiring from industry, he taught statistics at Florida State until his death.

simulate eases the programming task of performing Monte Carlo–type simulations. Typing

```
. simulate exp_list, reps(#): command
```

runs `command` for # replications and collects the results in `exp_list`.

`command` defines the command that performs one simulation. Most Stata commands and user-written programs can be used with `simulate`, as long as they follow standard Stata syntax; see [U] 11 Language syntax. The by prefix may not be part of `command`.

`exp_list` specifies the expression to be calculated from the execution of `command`. If no expressions are given, `exp_list` assumes a default, depending upon whether `command` changes results in `e()` or `r()`. If `command` changes results in `e()`, the default is `_b`. If `command` changes results in `r()` (but not `e()`), the default is all the scalars posted to `r()`. It is an error not to specify an expression in `exp_list` otherwise.

Quick start

**Simple program for use with simulate**

Define program `myreg` to generate data and fit a linear regression

```
program myreg, eclass
    drop _all
    set obs 25
    generate x = rnormal()
    generate y = 3*x + 1 + rnormal()
    regress y x
end
```

Perform simulation

Record coefficients and SEs from 1,000 simulated replications of program `myreg`

```
simulate _b _se, reps(1000): myreg
```

Same as above, and set random-number seed to 5,762 for reproducible results

```
simulate _b _se, reps(1000) seed(5762): myreg
```
Syntax

 simulate [exp_list], reps(#) [options] : command

    _se[]

eqno is
    ##
    name

exp is a standard Stata expression; see [U] 13 Functions and expressions.
Distinguish between [], which are to be typed, and [], which indicate optional arguments.

Options

reps(#) is required—it specifies the number of replications to be performed.

nodots and dots(#) specify whether to display replication dots. By default, one dot character is displayed for each successful replication. An “x” is displayed if command returns an error or if any value in exp_list is missing. You can also control whether dots are displayed using set dots; see [R] set.

nodots suppresses display of the replication dots.

dots(#) displays dots every # replications. dots(0) is a synonym for nodots.

noisily requests that any output from command be displayed. This option implies the nodots option.
trace causes a trace of the execution of \texttt{command} to be displayed. This option implies the \texttt{noisily} option.

\texttt{saving(filename[, suboptions])} creates a Stata data file (.dta file) consisting of (for each statistic in \texttt{exp_list}) a variable containing the replicates.

\texttt{double} specifies that the results for each replication be saved as doubles, meaning 8-byte reals. By default, they are saved as floats, meaning 4-byte reals.

\texttt{every(#)} specifies that results be written to disk every \texttt{#}th replication. \texttt{every()} should be specified only in conjunction with \texttt{saving()} when \texttt{command} takes a long time for each replication. This will allow recovery of partial results should some other software crash your computer. See \texttt{[P] postfile}.

\texttt{replace} specifies that \texttt{filename} be overwritten if it exists.

\texttt{nolegend} suppresses display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

\texttt{verbose} requests that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

\texttt{seed(#)} sets the random-number seed. Specifying this option is equivalent to typing the following command before calling \texttt{simulate}:

\> \texttt{. set seed #}

\section*{Remarks and examples}

For an introduction to Monte Carlo methods, see Cameron and Trivedi (2022, chap. 5). White (2010) provides a command for analyzing results of simulation studies.

\section*{Example 1: Simulating basic summary statistics}

We have a dataset containing means and variances of 100-observation samples from a lognormal distribution (as a first step in evaluating, say, the coverage of a 95\%, \textit{t}-based confidence interval). Then we perform the experiment 1,000 times.

The following command definition will generate 100 independent observations from a lognormal distribution and compute the summary statistics for this sample.

\begin{verbatim}
program lnsim, rclass
version 18.0
    drop _all
    set obs 100
    generate z = exp(rnormal())
    summarize z
    return scalar mean = r(mean)
    return scalar Var = r(Var)
end
\end{verbatim}

We can save 1,000 simulated means and variances from \texttt{lnsim} by typing

\begin{verbatim}
    . set seed 1234
    . simulate mean=r(mean) var=r(Var), reps(1000) nodots: lnsim
\end{verbatim}

\> \texttt{Command: lnsim}

\> \texttt{mean: r(mean)}

\> \texttt{var: r(Var)}
. describe *
Variable name  Storage type  Display format  Value label  Variable label
mean  float  %9.0g  r(mean)
var  float  %9.0g  r(Var)

. summarize
Variable  Obs  Mean  Std. dev.  Min  Max
mean  1,000  1.630648  .2173062  1.106372  2.612052
var  1,000  4.60798  4.502166  .966087  7.05597

Technical note
Before executing our lnsim simulator, we can verify that it works by executing it interactively.

. set seed 1234
.lnsim
Number of observations (_N) was 0, now 100.
Variable  Obs  Mean  Std. dev.  Min  Max
z  100  1.534256  1.584568  .0400387  9.818309

. return list
scalars:
   r(Var) = 2.510857086217961
   r(mean) = 1.53425569280982

Example 2: Simulating a regression model

Consider a more complicated problem. Let’s experiment with fitting $y_j = a + bx_j + u_j$ when the true model has $a = 1$, $b = 2$, $u_j = z_j + cx_j$, and when $z_j$ is $N(0, 1)$. We will save the parameter estimates and standard errors and experiment with varying $c$. $x_j$ will be fixed across experiments but will originally be generated as $N(0, 1)$. We begin by interactively making the true data:

. drop _all
. set obs 100
Number of observations (_N) was 0, now 100.
. set seed 54321
. generate x = rnormal()
. generate true_y = 1+2*x
. save truth
file truth.dta saved

Our program is

program hetero1
version 18.0
args c
use truth, clear
generate y = true_y + (rnormal() + 'c'*x)
regress y x
end
Note the use of ‘c’ in our statement for generating y. c is a local macro generated from args c and thus refers to the first argument supplied to hetero1. If we want c = 3 for our experiment, we type

```
. simulate _b _se, reps(10000): hetero1 3
(output omitted)
```

Our program hetero1 could, however, be more efficient because it rereads the file truth once every replication. It would be better if we could read the data just once. In fact, if we read in the data right before running simulate, we really should not have to reread for each subsequent replication. A faster version reads

```
program hetero2
version 18.0
args c
capture drop y
generate y = true_y + (rnormal() + ‘c’*x)
regress y x
end
```

Requiring that the current dataset has the variables true_y and x may become inconvenient. Another improvement would be to require that the user supply variable names, such as in

```
program hetero3
version 18.0
args truey x c
capture drop y
generate y = ‘truey’ + (rnormal() + ‘c’*‘x’) regress y x
end
```

Thus, we can type

```
. simulate _b _se, reps(10000): hetero3 true_y x 3
(output omitted)
```

Example 3: Simulating a ratio of statistics

Now, let’s consider the problem of simulating the ratio of two medians. Suppose that each sample of size $n_i$ comes from a normal population with a mean $\mu_i$ and standard deviation $\sigma_i$, where $i = 1, 2$. We write the program below and save it as a text file called myratio.ado (see [U] 17 Ado-files). Our program is an rclass command that requires six arguments as input, identified by the local macros n1, mu1, sigma1, n2, mu2, and sigma2, which correspond to $n_1$, $\mu_1$, $\sigma_1$, $n_2$, $\mu_2$, and $\sigma_2$, respectively. With these arguments, myratio will generate the data for the two samples, use summarize to compute the two medians and store the ratio of the medians in r(ratio).

```
program myratio, rclass
version 18.0
args n1 mu1 sigma1 n2 mu2 sigma2
// generate the data
drop _all
local N = ‘n1’+‘n2’
set obs ‘N’
tempvar y
generate ‘y’ = rnormal()
replace ‘y’ = cond(_n<‘n1’,‘mu1’+‘y’*‘sigma1’,‘mu2’+‘y’*‘sigma2’)
// calculate the medians
tempname m1
summarize ‘y’ if _n<‘n1’, detail
```
scalar ‘m1’ = r(p50)
summarize ‘y’ if _n>‘n1’, detail // store the results
return scalar ratio = ‘m1’ / r(p50)
end

The result of running our simulation is

. set seed 19192
. simulate ratio=r(ratio), reps(1000) nodots: myratio 5 3 1 10 3 2
Command: myratio 5 3 1 10 3 2	ratio: r(ratio)

. summarize

<table>

</tr>
</tbody>
</table>

Technical note

Stata lets us do simulations of simulations and simulations of bootstraps. Stata’s bootstrap command (see [R] bootstrap) works much like simulate, except that it feeds the user-written program a bootstrap sample. Say that we want to evaluate the bootstrap estimator of the standard error of the median when applied to lognormally distributed data. We want to perform a simulation, resulting in a dataset of medians and bootstrap estimated standard errors.

As background, summarize (see [R] summarize) calculates summary statistics, leaving the mean in r(mean) and the standard deviation in r(sd). summarize with the detail option also calculates summary statistics, but more of them, and leaves the median in r(p50).

Thus, our plan is to perform simulations by randomly drawing a dataset: we calculate the median of our random sample, we use bootstrap to obtain a dataset of medians calculated from bootstrap samples of our random sample, the standard deviation of those medians is our estimate of the standard error, and the summary statistics are stored in the results of summarize.

Our simulator is

program define bsse, rclass
version 18.0
drop _all
set obs 100
generate x = rnormal()
tempfile bsfile
bootstrap midp=r(p50), rep(100) saving('bsfile'):
summarize x, detail
use 'bsfile', clear
summarize midp
return scalar mean = r(mean)
return scalar sd = r(sd)
end
We can obtain final results, running our simulation 1,000 times, by typing

```
.set seed 48901
.simulate med=r(mean) bs_se=r(sd), reps(1000): bsse
```

```
Command: bsse
  med: r(mean)
  bs_se: r(sd)
Simulations (1,000): ..........10.........20.........30.........40.........50....

The Stata Journal (SJ) is a quarterly journal containing articles about statistics, data analysis, teaching methods, and effective use of Stata’s language. The SJ publishes reviewed articles with shorter notes and comments, regular columns, tips, book reviews, and other material of interest to researchers applying statistics in a variety of disciplines. The SJ began publication in the fourth quarter of 2001 with SJ Volume 1 Number 1. You can read all about the SJ at https://www.stata-journal.com.

The SJ is a printed and electronic journal with corresponding software. You must subscribe to the SJ; see https://www.stata-journal.com/subscription/ to purchase a subscription or an individual article. Electronic copies of SJ articles that are older than three years are available at no charge from https://www.stata-journal.com/archives.html.

The software is available at no charge; see below for installation instructions.

Remarks and examples

Remarks are presented under the following headings:

- Installing the Stata Journal software
  - Obtaining from the Internet by pointing and clicking
  - Obtaining from the Internet via command mode

Installing the Stata Journal software

Each issue of the Stata Journal is labeled Volume #, Number #. Volume 1 refers to the first year of publication, Volume 2 to the second, and so on. Issues are numbered 1, 2, 3, and 4 within each year. The first issue of the Journal was published in the fourth quarter of 2001, and that issue is numbered Volume 1, Number 1. For installation purposes, we refer to this issue as sj1-1.

The articles, columns, notes, and comments that make up the Stata Journal are assigned a letter-and-number code, called an insert tag, such as st0001, an0034, or ds0011. The letters represent a category: st is the statistics category, an is the announcements category, etc. The numbers are assigned sequentially, so st0001 is the first article in the statistics category.

Sometimes inserts are subsequently updated, either to fix bugs or to add new features. A number such as st0001_1 indicates that this article, column, note, or comment is an update to the original st0001 article. Updates are complete; that is, installing st0001_1 provides all the features of the original article and more.

The Stata Journal software may be obtained by pointing and clicking or by using command mode.

The sections below detail how to install an insert. In all cases, pretend that you wish to install insert st0274 from sj12-4.
Obtaining from the Internet by pointing and clicking

1. Select Help > SJ and community-contributed features.
2. Click on Stata Journal.
3. Click on sj12-4.
4. Click on st0274.
5. Click on (click here to install).

Obtaining from the Internet via command mode

Type the following:

```
.net from https://www.stata-journal.com/software
.net cd sj12-4
.net describe st0274
.net install st0274
```

The above could be shortened to

```
.net from https://www.stata-journal.com/software/sj12-4
.net describe st0274
.net install st0274
```

Alternatively, you could type

```
.net sj 12-4
.net describe st0274
.net install st0274
```

but going about it the long way is more entertaining, at least the first time.

For each variable in `varlist`, `sktest` presents a test for normality based on skewness and another based on kurtosis and then combines the two tests into an overall test statistic. `sktest` requires a minimum of eight observations to make its calculations. See [MV] `mvtest normality` for multivariate tests of normality.

**Quick start**

Test for normality of `v1` based on skewness and kurtosis

```
sktest v1
```

Separate tests for `v1` and `v2`

```
sktest v1 v2
```

With frequency weights in `wvar`

```
sktest v1 v2 [fweight=wvar]
```

Suppress adjustment to the overall $\chi^2$ test

```
sktest v1 v2, noadjust
```

**Menu**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Skewness and kurtosis normality tests
Syntax

```
sktest varlist [if] [in] [weight] [, options]
```

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main</td>
<td></td>
</tr>
<tr>
<td>noadjust</td>
<td>do not adjust the overall $\chi^2$ test statistic and its $p$-value</td>
</tr>
<tr>
<td>nolstretch</td>
<td>do not automatically widen table for long variable names</td>
</tr>
</tbody>
</table>

Collect is allowed; see [U] 11.1.10 Prefix commands.

Aweights and fweights are allowed; see [U] 11.1.6 weight.

nolstretch does not appear in the dialog box.

Option

```
noadjust, which suppresses the empirical adjustment made by Royston (1991c) to the overall $\chi^2$ test statistic and its $p$-value and presents the unaltered test as described by D’Agostino, Belanger, and D’Agostino (1990).
```

The following option is available with sktest but is not shown in the dialog box:

```
nolstretch; see [R] Estimation options.
```

Remarks and examples

Also see [R] swilk for the Shapiro–Wilk and Shapiro–Francia tests for normality. Those tests are, in general, preferred for nonaggregated data (Gould and Rogers 1991; Gould 1992; Royston 1991c). Moreover, a normal quantile plot should be used with any test for normality; see [R] Diagnostic plots for more information.

Example 1

Using our automobile dataset, we will test whether the variables mpg and trunk are normally distributed:

```
. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. sktest mpg trunk
```

```
Skewness and kurtosis tests for normality

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Pr(skewness)</th>
<th>Pr(kurtosis)</th>
<th>Adj chi2(2)</th>
<th>Prob&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>74</td>
<td>0.0015</td>
<td>0.0804</td>
<td>10.95</td>
<td>0.0042</td>
</tr>
<tr>
<td>trunk</td>
<td>74</td>
<td>0.9115</td>
<td>0.0445</td>
<td>4.19</td>
<td>0.1228</td>
</tr>
</tbody>
</table>
```

We can reject the hypothesis that mpg is normally distributed, but we cannot reject the hypothesis that trunk is normally distributed, at least at the 12% level. The kurtosis for trunk is 2.19, as can be verified by issuing the command

```
. summarize trunk, detail
(output omitted)
```
and the $p$-value of 0.0445 shown in the table above indicates that it is significantly different from the kurtosis of a normal distribution at the 5% significance level. However, on the basis of skewness alone, we cannot reject the hypothesis that \texttt{trunk} is normally distributed.

### Technical note

\texttt{sktest} implements the test as described by D’Agostino, Belanger, and D’Agostino (1990) but with the adjustment made by Royston (1991c). In the above example, if we had specified the \texttt{noadjust} option, the $\chi^2$ values would have been 13.13 for \texttt{mpg} and 4.05 for \texttt{trunk}. With the adjustment, the $\chi^2$ value might show as ‘.’. This result should be interpreted as an absurdly large number; the data are most certainly not normal.

### Stored results

\texttt{sktest} stores the following in \texttt{r()}:  

**Scalars**  
- $r(N)$: number of observations  
- $r(chi2)$: overall $\chi^2$  
- $r(p\_skew)$: $p$-value for test based on skewness  
- $r(p\_kurt)$: $p$-value for test based on kurtosis  
- $r(p\_chi2)$: $p$-value for overall $\chi^2$ test  

**Matrices**  
- $r(table)$: matrix of displayed results, one row per variable

### Methods and formulas

\texttt{sktest} implements the test described by D’Agostino, Belanger, and D’Agostino (1990) with the empirical correction developed by Royston (1991c).

Let $g_1$ denote the coefficient of skewness and $b_2$ denote the coefficient of kurtosis as calculated by \texttt{summarize}, and let $n$ denote the sample size. If weights are specified, then $g_1$, $b_2$, and $n$ denote the weighted coefficients of skewness and kurtosis and weighted sample size, respectively. See [R] \texttt{summarize} for the formulas for skewness and kurtosis.

To perform the test of skewness, we compute

$$Y = g_1 \left\{ \frac{(n+1)(n+3)}{6(n-2)} \right\}^{1/2}$$

$$\beta_2(g_1) = \frac{3(n^2 + 27n - 70)(n + 1)(n + 3)}{(n - 2)(n + 5)(n + 7)(n + 9)}$$

$$W^2 = -1 + \left\{ 2 \beta_2(g_1) - 1 \right\}^{1/2}$$

and

$$\alpha = \left\{ \frac{2}{W^2 - 1} \right\}^{1/2}$$

Then, the distribution of the test statistic

$$Z_1 = \frac{1}{\sqrt{\ln W}} \ln \left[ \frac{Y}{\alpha} + \left\{ \frac{(Y/\alpha)^2 + 1}{2} \right\}^{1/2} \right]$$

is approximately standard normal under the null hypothesis that the data are distributed normally.
To perform the test of kurtosis, we compute
\[
E(b_2) = \frac{3(n-1)}{n+1}
\]
\[
\text{var}(b_2) = \frac{24n(n-2)(n-3)}{(n+1)^2(n+3)(n+5)}
\]
\[
X = \left\{ b_2 - E(b_2) \right\} / \sqrt{\text{var}(b_2)}
\]
\[
\sqrt{\beta_1(b_2)} = \frac{6(n^2 - 5n + 2)}{(n + 7)(n + 9)} \left\{ \frac{6(n + 3)(n + 5)}{n(n - 2)(n - 3)} \right\}^{1/2}
\]
and
\[
A = 6 + \frac{8}{\sqrt{\beta_1(b_2)}} \left[ \frac{2}{\sqrt{\beta_1(b_2)}} + \left\{ 1 + \frac{4}{\beta_1(b_2)} \right\}^{1/2} \right]
\]

Then, the distribution of the test statistic
\[
Z_2 = \frac{1}{\sqrt{2/(9A)}} \left[ \left( 1 - \frac{2}{9A} \right) - \left\{ \frac{1 - 2/A}{1 + X \sqrt{2/(A - 4)}} \right\}^{1/3} \right]
\]
is approximately standard normal under the null hypothesis that the data are distributed normally.

D’Agostino, Balanger, and D’Agostino Jr.’s omnibus test of normality uses the statistic
\[
K^2 = Z_1^2 + Z_2^2
\]
which has approximately a \(\chi^2\) distribution with 2 degrees of freedom under the null of normality.

Royston (1991c) proposed the following adjustment to the test of normality, which \texttt{sktest} uses by default. Let \(\Phi(x)\) denote the cumulative standard normal distribution function for \(x\), and let \(\Phi^{-1}(p)\) denote the inverse cumulative standard normal function [that is, \(x = \Phi^{-1}\{\Phi(x)\}\)]. Define the following terms:
\[
Z_c = -\Phi^{-1} \left\{ \exp \left( -\frac{1}{2} K^2 \right) \right\}
\]
\[
Z_t = 0.55n^{0.2} - 0.21
\]
\[
a_1 = (-5 + 3.46 \ln n) \exp(-1.37 \ln n)
\]
\[
b_1 = 1 + (0.854 - 0.148 \ln n) \exp(-0.55 \ln n)
\]
\[
a_2 = a_1 - \left\{ 2.13/(1 - 2.37 \ln n) \right\} Z_t
\]
and
\[
b_2 = 2.13/(1 - 2.37 \ln n) + b_1
\]

If \(Z_c < -1\) set \(Z = Z_c\); else if \(Z_c < Z_t\) set \(Z = a_1 + b_1 Z_c\); else set \(Z = a_2 + b_2 Z_c\). Define \(P = 1 - \Phi(Z)\). Then, \(K^2 = -2 \ln P\) is approximately distributed \(\chi^2\) with 2 degrees of freedom.

The relative merits of the skewness and kurtosis test versus the Shapiro–Wilk and Shapiro–Francia tests have been a subject of debate. Our recommendation is to use the Shapiro–Francia test whenever possible, that is, whenever dealing with nonaggregated or ungrouped data (Gould and Rogers 1991; Gould 1992); see [R] \texttt{swilk}. If normality is rejected, use \texttt{sktest} to determine the source of the problem.
As both D’Agostino, Belanger, and D’Agostino (1990) and Royston (1991d) mention, researchers should also examine the normal quantile plot to determine normality rather than blindly relying on a few test statistics. See the \texttt{qnorm} command documented in \texttt{R} \texttt{Diagnostic plots} for more information on normal quantile plots.

\texttt{sktest} is similar in spirit to the Jarque–Bera (1987) test of normality. The Jarque–Bera test statistic is also calculated from the sample skewness and kurtosis, though it is based on asymptotic standard errors with no corrections for sample size. In effect, \texttt{sktest} offers two adjustments for sample size, that of Royston (1991c) and that of D’Agostino, Belanger, and D’Agostino (1990).

**Acknowledgments**

\texttt{sktest} has benefited greatly by the comments and work of Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book \textit{Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model}. At this point, the program should be viewed as due as much to Royston as to us, except, of course, for any errors. We are also indebted to Nicholas J. Cox of the Department of Geography at Durham University, UK, and coeditor of the \textit{Stata Journal} and author of \textit{Speaking Stata Graphics} for his helpful comments.

[MV] mvtest normality — Multivariate normality tests
slogit — Stereotype logistic regression

Description

slogit fits Anderson’s (1984) maximum-likelihood stereotype logistic regression model for categorical dependent variables. Stereotype logistic models can be used when the relevance of the ordering is unclear. These models do not impose the proportional-odds assumption.

Quick start

One-dimensional model of y as a function of x1 and x2
slogit y x1 x2

Add indicators for categorical variable a and set y = 1 as the base category
slogit y x1 x2 i.a, baseoutcome(1)

Multidimensional model reparameterizing a multinomial logit when y has 4 categories
slogit y x1 x2 i.a, dimensions(3) baseoutcome(1)

Menu

Statistics > Categorical outcomes > Stereotype logistic regression
### Syntax

`slogit depvar [indepvars] [if] [in] [weight] [, options]`

#### options

**Model**
- `dimension(#)`
  - dimension of the model; default is `dimension(1)`
- `baseoutcome(# | lbl)`
  - set the base outcome to `#` or `lbl`; default is the last outcome
- `constraints(numlist)`
  - apply specified linear constraints
- `nocorner`
  - do not generate the corner constraints

**SE/Robust**
- `vce(vcetype)`
  - `vcetype` may be `oim`, `robust`, `cluster clustvar`, `opg`, `bootstrap`, or `jackknife`

**Reporting**
- `level(#)`
  - set confidence level; default is `level(95)`
- `nocnsreport`
  - do not display constraints
- `display_options`
  - control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

**Maximization**
- `maximize_options`
  - control the maximization process; seldom used
- `initialize(initype)`
  - method of initializing scale parameters; `initype` can be `constant`, `random`, or `svd`; see `Options` for details
- `nonormalize`
  - do not normalize the numeric variables
- `collinear`
  - keep collinear variables
- `coeflegend`
  - display legend instead of statistics

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.

bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] svy.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

collinear and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

### Options

#### Model

- `dimension(#)`
  - specifies the dimension of the model, which is the number of equations required to describe the relationship between the dependent variable and the independent variables. The maximum dimension is `min(m − 1, p)`, where `m` is the number of categories of the dependent variable and `p` is the number of independent variables in the model. The stereotype model with maximum dimension is a reparameterization of the multinomial logistic model.

- `baseoutcome(# | lbl)`
  - specifies the outcome level whose scale parameters and intercept are constrained to be zero. The base outcome may be specified as a number or a label. By default, `slogit` assumes
that the outcome levels are ordered and uses the largest level of the dependent variable as the base outcome.

**constraints**(*numlist*); see [R] Estimation options.

By default, the linear equality constraints suggested by Anderson (1984), termed the corner constraints, are generated for you. You can add constraints to these as needed, or you can turn off the corner constraints by specifying **nocorner**. These constraints are in addition to the constraints placed on the $\phi$ parameters corresponding to **baseoutcome(#)**.

**nocorner** specifies that **slogit** not generate the corner constraints. If you specify **nocorner**, you must specify at least dimension() $\times$ dimension() constraints for the model to be identified.

---

**SE/Robust**

**vce(vcetype)** specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] **vce option**.

If specifying **vce(bootstrap)** or **vce(jackknife)**, you must also specify **baseoutcome()**.

---

**Reporting**

**level(#)**, **nocnsreport**; see [R] Estimation options.

**display_options**: **noci**, **nopvalues**, **noomitted**, **vsquish**, **noemptycells**, **baselevels**, **allbaselevels**, **nofvlabel**, **fwrap(#)**, **fwwrapon(style)**, **cformat(\%fmt)**, **pformat(\%fmt)**, **sformat(\%fmt)**, and **nolstretch**; see [R] Estimation options.

---

**Maximization**

**maximize_options**: **difficult**, **technique(algorithm_spec)**, **iterate(#)**, [no]log, **trace**, **gradient**, **showstep**, **hessian**, **showtolerance**, **tolerance(#)**, **ltolerance(#)**, **nrtolerance(#)**, **nonrtolerance**, and **from(init_specs)**; see [R] Maximize. These options are seldom used.

Setting the optimization type to **technique(bhhh)** resets the default **vcetype** to **vce(opg)**.

**initialize(constant|random|svd)** specifies how initial estimates are computed. The default, **initialize(constant)**, is to set the scale parameters to the constant min($1/2$, $1/d$), where $d$ is the dimension specified in dimension().

**initialize(random)** requests that uniformly distributed random numbers between 0 and 1 be used as initial values for the scale parameters. If you specify this option, you should also use **set seed** to ensure that you can replicate your results; see [R] set seed.

**initialize(svd)** requests that a singular value decomposition (SVD) be performed on the matrix of regression estimates from **mlogit** to reduce its rank to the dimension specified in dimension(). **slogit** uses the reduced-rank components of the SVD as initial estimates for the scale and regression coefficients. For details, see Methods and formulas.

**nonormalize** specifies that the numeric variables not be normalized. Normalization of the numeric variables improves numerical stability but consumes more memory in generating temporary double-precision variables. Variables that are of type **byte** are not normalized, and if initial estimates are specified using the from() option, normalization of variables is not performed. See Methods and formulas for more information.
The following options are available with `slogit` but are not shown in the dialog box: `collinear`, `coeflegend`; see [R] Estimation options.

Remarks and examples

Remarks are presented under the following headings:

- Introduction
- One-dimensional model
- Higher-dimension models

Introduction

Like multinomial logistic and ordered logistic models, stereotype logistic models are used with categorical dependent variables. They are often used when subjects are requested to assess or judge something. In a multinomial logistic model, the categories cannot be ranked. By contrast, in an ordered logistic model, the categories follow a natural ranking scheme and are subject to the proportional-odds assumption. Stereotype logistic regression can be viewed as a compromise between these two models and is primarily used when you are unsure of the relevance of the ordering of the outcome.

A common case is when subjects are asked to assess or judge something. For example, consider a survey in which consumers are asked to rate the quality of a product on a scale from 1 to 5, with 1 indicating poor quality and 5 indicating excellent quality. If the categories are monotonically related to one underlying latent variable, the ordered logistic model is appropriate. However, suppose that consumers weigh two or three latent factors when assessing quality. The stereotype logistic model is preferred to the ordered logistic model in this case because it allows you to specify multiple equations to capture the effects of the latent variables. Unlike multinomial logit models, the number of equations you specify could be fewer than \(m - 1\), where \(m\) is the number of categories of the dependent variable. Stereotype logistic models are also used when categories may be indistinguishable. Suppose that a consumer must choose among A, B, C, or D. Multinomial logistic modeling assumes that the four choices are distinct in the sense that a consumer choosing one of the goods can distinguish its characteristics from the others. If goods A and B are in fact similar, consumers may be randomly picking between the two. One alternative is to combine the two categories and fit a three-category multinomial logistic model. A more flexible alternative is to use a stereotype logistic model.

In the multinomial logistic model, you estimate \(m - 1\) parameter vectors \(\tilde{\beta}_k\), \(k = 1, \ldots, m - 1\), where \(m\) is the number of categories of the dependent variable. The stereotype logistic model is a restriction on the multinomial model in the sense that there are \(d\) parameter vectors, where \(d\) is between one and \(\min(m - 1, p)\), and \(p\) is the number of regressors. The relationship between the stereotype model’s coefficients \(\beta_j\), \(j = 1, \ldots, d\), and the multinomial model’s coefficients is \(\tilde{\beta}_k = -\sum_{j=1}^{d} \phi_{jk} \beta_j\). The \(\phi\)s are scale parameters to be estimated along with the \(\beta_j\)s.

Given a row vector of covariates \(x\), let \(\eta_k = \theta_k - \sum_{j=1}^{d} \phi_{jk} x \beta_j\). The probability of observing outcome \(k\) is

\[
\Pr(Y_i = k) = \begin{cases} 
\frac{\exp(\eta_k)}{1 + \sum_{l=1}^{m-1} \exp(\eta_l)} & k < m \\
1 + \sum_{l=1}^{m-1} \exp(\eta_l) & k = m 
\end{cases}
\]
This model includes a set of $\theta$ parameters so that each equation has an unrestricted constant term. If $d = m - 1$, the stereotype model is just a reparameterization of the multinomial logistic model. To identify the $\phi$s and the $\beta$s, you must place at least $d^2$ restrictions on the parameters. By default, `slogit` uses the “corner constraints” $\phi_{jj} = 1$ and $\phi_{jk} = 0$ for $j \neq k$, $k \leq d$, and $j \leq d$.

For a discussion of the stereotype logistic model, see Lunt (2005).

### One-dimensional model

> **Example 1**

We have 2 years of repair rating data on the make, price, mileage rating, and gear ratio of 104 foreign and 44 domestic automobiles (with 13 missing values on repair rating). We wish to fit a stereotype logistic model to discriminate between the levels of repair rating using mileage, price, gear ratio, and origin of the manufacturer. Here is an overview of our data:

```
. use https://www.stata-press.com/data/r18/auto2yr
(Automobile models)
. tabulate repair

<table>
<thead>
<tr>
<th>Repair rating</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Poor</td>
<td>5</td>
<td>3.70</td>
<td>3.70</td>
</tr>
<tr>
<td>Fair</td>
<td>19</td>
<td>14.07</td>
<td>17.78</td>
</tr>
<tr>
<td>Average</td>
<td>57</td>
<td>42.22</td>
<td>60.00</td>
</tr>
<tr>
<td>Good</td>
<td>38</td>
<td>28.15</td>
<td>88.15</td>
</tr>
<tr>
<td>Excellent</td>
<td>16</td>
<td>11.85</td>
<td>100.00</td>
</tr>
<tr>
<td>Total</td>
<td>135</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>
```

The variable `repair` can take five values, 1, $\ldots$, 5, which represent the subjective rating of the car model’s repair record as Poor, Fair, Average, Good, and Excellent.

We wish to fit the one-dimensional stereotype logistic model

$$
\eta_k = \theta_k - \phi_k (\beta_1 \text{foreign} + \beta_2 \text{mpg} + \beta_3 \text{price} + \beta_4 \text{gratio})
$$

for $k < 5$ and $\eta_5 = 0$. To fit this model, we type
The coefficient associated with the first scale parameter, $\phi_{11}$, is 1, and its standard error and other statistics are missing. This is the corner constraint applied to the one-dimensional model; in the header, this constraint is listed as $[\phi_{11}]_{cons} = 1$. Also, the $\phi$ and $\theta$ parameters that are associated with the base outcome are identified. Keep in mind, though, that there are no coefficient estimates for $[\phi_{15}]_{cons}$ or $[\theta_{5}]_{cons}$ in the ereturn matrix $e(b)$. The Wald statistic is for a test of the joint significance of the regression coefficients on foreign, mpg, price, and gratio.

The one-dimensional stereotype model restricts the multinomial logistic regression coefficients $\tilde{\beta}_k$, $k = 1, \ldots, m - 1$ to be parallel; that is, $\tilde{\beta}_k = -\phi_k \beta$. As Lunt (2001) discusses, in the one-dimensional stereotype model, one linear combination $x_i \beta$ best discriminates the outcomes of the dependent variable, and the scale parameters $\phi_k$ measure the distance between the outcome levels and the linear predictor. If $\phi_1 \geq \phi_2 \geq \cdots \phi_{m-1} \geq \phi_m \equiv 0$, the model suggests that the subjective assessment of the dependent variable is indeed ordered. Here the maximum likelihood estimates of the $\phi$’s are not monotonic, as would be assumed in an ordered logit model.
We test that $\phi_1 = \phi_2$ by typing

```
.test [phi1_2]_cons = [phi1_1]_cons
( 1) - [phi1_1]_cons + [phi1_2]_cons = 0
  chi2( 1) = 0.55
  Prob > chi2 = 0.4576
```

Because the two parameters are not statistically different, we decide to add a constraint to force $\phi_1 = \phi_2$:

```
.constraint define 1 [phi1_2]_cons = [phi1_1]_cons
.slogit repair foreign mpg price gratio, constraint(1) nolog
```

Stereotype logistic regression

| Coefficient | Std. err. | z     | P>|z|   | [95% conf. interval] |
|-------------|-----------|-------|-------|---------------------|
| foreign     | 7.166515  | 1.690177 | 4.24  | 0.000               | 3.853829 10.4792 |
| mpg         | 0.2340043 | 0.0807042 | 2.90  | 0.004               | 0.0758271 0.3921816 |
| price       | -0.000041 | 0.0001618 | -0.25 | 0.800               | -0.0003581 0.000276 |
| gratio      | -5.218107 | 1.798717  | -2.90 | 0.004               | -8.743528 -1.692686 |

(1) $\phi_1$_cons = 1
(2) - $\phi_1$_cons + $\phi_1$_2_cons = 0

''repair

The $\phi$ estimates are now monotonically decreasing and the standard errors of the $\phi$'s are small relative to the size of the estimates, so we conclude that, with the exception of outcomes Poor and Fair, the groups are distinguishable for the one-dimensional model and that the quality assessment can be ordered.

Higher-dimension models

The stereotype logistic model is not limited to ordered categorical dependent variables; you can use it on nominal data to reduce the dimension of the regressions. Recall that a multinomial model fit to a categorical dependent variable with $m$ levels will have $m-1$ sets of regression coefficients. However, a model with fewer dimensions may fit the data equally well, suggesting that some of the categories are indistinguishable.
Example 2

As discussed in [R] mlogit, we have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). Patients may have either an indemnity (fee-for-service) plan or a prepaid plan, such as an HMO, or may be uninsured. Demographic variables include age, gender, race, and site.

First, we fit the saturated, two-dimensional model that is equivalent to a multinomial logistic model. We choose the base outcome to be 1 (indemnity insurance) because that is the default for mlogit.

```

| Uninsure                 |             |           |       |     |                     |
| age                      | -.0077961   | .0114418  | -0.68 | 0.496 | -.0302217 .0146294 |
| male                     | .4518496    | .3674867  | 1.23  | 0.219 | -.268411 1.172111  |
| nonwhite                 | .2170589    | .4256361  | 0.51  | 0.610 | -.6171725 1.05129  |
| site                     |             |           |       |     |                     |
| 2                        | -1.211563   | .4705127  | -2.57 | 0.010 | -.2.133751 -.2893747 |
| 3                        | -.2078123   | .3662926  | -0.57 | 0.570 | -.9257327 .510108  |
| _cons                    | -1.286943   | .5923219  | -2.17 | 0.030 | -.2.447872 -.1260134 |

Apart from having opposite signs, the coefficients from the stereotype logistic model are identical to those from the multinomial logit model. Recall the definition of $\eta_k$ given in the Remarks and examples, particularly the minus sign in front of the summation. One other difference in the output is that the constant estimates labeled `/theta` in the `slogit` output are the constants labeled `_cons` in the `mlogit` output.
Next, we examine the one-dimensional model.

+-------------------------------------------------------------+
(insure=Indemnity is the base outcome)
```

We have reduced a two-dimensional multinomial model to one dimension, reducing the number of estimated parameters by four and decreasing the model likelihood by \( \approx 5.4 \).

`slogit` does not report a model likelihood-ratio test. The test of \( d = 1 \) (a one-dimensional model) versus \( d = 0 \) (the null model) does not have an asymptotic \( \chi^2 \) distribution because the unconstrained \( \phi \) parameters (/phi1_3 in this example) cannot be identified if \( \beta = 0 \). More generally, this problem precludes testing any hierarchical model of dimension \( d \) versus \( d - 1 \). Of course, the likelihood-ratio test of a full-dimension model versus \( d = 0 \) is valid because the full model is just multinomial logistic, and all the \( \phi \) parameters are fixed at 0 or 1.

⚠️ Technical note

The stereotype model is a special case of the reduced-rank vector generalized linear model discussed by Yee and Hastie (2003). If we define \( \eta_{ik} = \theta_k - \sum_{j=1}^{d} \phi_{jk} x_i \beta_j \), for \( k = 1, \ldots, m - 1 \), we can write the expression in matrix notation as

\[
\eta_i = \theta + \Phi (x_i B)'
\]

where \( \Phi \) is a \((m - 1) \times d\) matrix containing the \( \phi_{jk} \) parameters and \( B \) is a \( p \times d\) matrix with columns containing the \( \beta_j \) parameters, \( j = 1, \ldots, d \). The factorization \( \Phi B' \) is not unique because \( \Phi B' = \Phi M M^{-1} B' \) for any nonsingular \( d \times d\) matrix \( M \). To avoid this identifiability problem, we choose \( M = \Phi_1^{-1} \), where

\[
\Phi = \begin{pmatrix} \Phi_1 \\ \Phi_2 \end{pmatrix}
\]

and \( \Phi_1 \) is \( d \times d\) of rank \( d \) so that

\[
\Phi M = \begin{pmatrix} I_d \\ \Phi_2 \Phi_1^{-1} \end{pmatrix}
\]
and $I_d$ is a $d \times d$ identity matrix. Thus, the corner constraints used by \texttt{slogit} are $\phi_{jj} \equiv 1$ and $\phi_{jk} \equiv 0$ for $j \neq k$ and $k, j \leq d$.

### Stored results

\texttt{slogit} stores the following in \texttt{e()}: 

**Scalars**

- \texttt{e(N)}: number of observations
- \texttt{e(k)}: number of parameters
- \texttt{e(k\_indvars)}: number of independent variables
- \texttt{e(k\_out)}: number of outcomes
- \texttt{e(k\_eq)}: number of equations in \texttt{e(b)}
- \texttt{e(k\_eq\_model)}: number of equations in overall model test
- \texttt{e(df\_m)}: Wald test degrees of freedom
- \texttt{e(df\_0)}: null model degrees of freedom
- \texttt{e(k\_dim)}: model dimension
- \texttt{e(i\_base)}: base outcome index
- \texttt{e(ll)}: log likelihood
- \texttt{e(ll\_0)}: null model log likelihood
- \texttt{e(N\_clust)}: number of clusters
- \texttt{e(chi2)}: $\chi^2$
- \texttt{e(p)}: $p$-value for model test
- \texttt{e(ic)}: number of iterations
- \texttt{e(rank)}: rank of \texttt{e(V)}
- \texttt{e(rc)}: return code
- \texttt{e(converged)}: 1 if converged, 0 otherwise

**Macros**

- \texttt{e(cmd)}: \texttt{slogit}
- \texttt{e(cmdline)}: command as typed
- \texttt{e(depvar)}: name of dependent variable
- \texttt{e(indvars)}: independent variables
- \texttt{e(wtype)}: weight type
- \texttt{e(wexp)}: weight expression
- \texttt{e(title)}: title in estimation output
- \texttt{e(clustvar)}: name of cluster variable
- \texttt{e(out\#)}: outcome labels, $\# = 1,..., e(k\_out)$
- \texttt{e(chi2type)}: $\chi^2$ test
- \texttt{e(vce)}: \texttt{vcetype} specified in \texttt{vce()} 
- \texttt{e(vcetype)}: title used to label Std. err.
- \texttt{e(opt)}: type of optimization
- \texttt{e(which)}: \texttt{max} or \texttt{min}; whether optimizer is to perform maximization or minimization
- \texttt{e(ml\_method)}: type of \texttt{ml} method
- \texttt{e(user)}: name of likelihood-evaluator program
- \texttt{e(technique)}: maximization technique
- \texttt{e(properties)}: $b$ $V$
- \texttt{e(predict)}: program used to implement \texttt{predict}
- \texttt{e(marginsnotok)}: predictions disallowed by \texttt{margins}
- \texttt{e(marginsdefault)}: default \texttt{predict()} specification for \texttt{margins}
- \texttt{e(footnote)}: program used to implement the footnote display
- \texttt{e(asbalanced)}: factor variables \texttt{fvset} as \texttt{asbalanced}
- \texttt{e(asobserved)}: factor variables \texttt{fvset} as \texttt{asobserved}

**Matrices**

- \texttt{e(b)}: coefficient vector
- \texttt{e(outcomes)}: outcome values
- \texttt{e(Cns)}: constraints matrix
- \texttt{e(ilog)}: iteration log (up to 20 iterations)
- \texttt{e(gradient)}: gradient vector
- \texttt{e(V)}: variance–covariance matrix of the estimators
- \texttt{e(V\_modelbased)}: model-based variance
In addition to the above, the following is stored in `r()`:

Matrices
- `r(table)`
  matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

**Methods and formulas**

`slogit` obtains the maximum likelihood estimates for the stereotype logistic model by using `ml`; see [R] `ml`. Each set of regression estimates, one set of \( \beta_j \)'s for each dimension, constitutes one `ml` model equation. The \( d \times (m - 1) \phi \)'s and the \( (m - 1) \theta \)'s are `ml` ancillary parameters.

Without loss of generality, let the base outcome level be the \( m \)th level of the dependent variable. Define the row vector \( \phi_k = (\phi_{1k}, \ldots, \phi_{dk}) \) for \( k = 1, \ldots, m - 1 \), and define the \( p \times d \) matrix \( B = (\beta_1, \ldots, \beta_d) \). For observation \( i \), the log odds of outcome level \( k \) relative to level \( m \), \( k = 1, \ldots, m - 1 \) is the index

\[
\ln \left\{ \frac{\Pr(Y_i = k)}{\Pr(Y_i = m)} \right\} = \eta_{ik} = \theta_k - \phi_k (x_i B)' = \theta_k - \phi_k \nu_i'
\]

The row vector \( \nu_i \) can be interpreted as a latent variable reducing the \( p \)-dimensional vector of covariates to a more interpretable \( d < p \) dimension.

The probability of the \( i \)th observation having outcome level \( k \) is then

\[
\Pr(Y_i = k) = p_{ik} = \begin{cases} 
\frac{e^{\eta_{ik}}}{1 + \sum_{j=1}^{m-1} e^{\eta_{ij}}}, & \text{if } k < m \\
1, & \text{if } k = m 
\end{cases}
\]

from which the log-likelihood function is computed as

\[
L = \sum_{i=1}^{n} w_i \sum_{k=1}^{m} I_k(y_i) \ln(p_{ik})
\]

Here \( w_i \) is the weight for observation \( i \) and

\[
I_k(y_i) = \begin{cases} 
1, & \text{if observation } y_i \text{ has outcome } k \\
0, & \text{otherwise}
\end{cases}
\]

Numeric variables are normalized for numerical stability during optimization where a new double-precision variable \( \tilde{x}_j \) is created from variable \( x_j, j = 1, \ldots, p \), such that \( \tilde{x}_j = (x_j - \bar{x}_j)/s_j \). This feature is turned off if you specify `nonormalize`, or if you use the `from()` option for initial estimates. Normalization is not performed on byte variables, including the indicator variables generated by [R] `xi`. The linear equality constraints for regression parameters, if specified, must be scaled also. Assume that a constraint is applied to the regression parameter associated with variable \( j \) and dimension \( i \), \( \beta_{ji} \), and the corresponding element of the constraint matrix (see [P] `makecns`) is divided by \( s_j \).
After convergence, the parameter estimates for variable $j$ and dimension $i$—$\tilde{\beta}_{ji}$, say—are transformed back to their original scale, $\beta_{ji} = \tilde{\beta}_{ji}/s_j$. For the intercepts, you compute

$$\theta_k = \tilde{\theta}_k + \sum_{i=1}^{d} \phi_{ik} \frac{\sum_{j=1}^{p} \tilde{\beta}_{ji} x_j}{s_j}$$

Initial values are computed using estimates obtained using mlogit to fit a multinomial logistic model. Let the $p \times (m-1)$ matrix $\tilde{B}$ contain the multinomial logistic regression parameters less the $m-1$ intercepts. Each $\phi$ is initialized with constant values $\min(1/2, 1/d)$, the initialize(constant) option (the default), or, with uniform random numbers, the initialize(random) option. Constraints are then applied to the starting values so that the structure of the $(m-1) \times d$ matrix $\Phi$ is

$$\Phi = \begin{pmatrix} \phi_1 \\ \phi_2 \\ \vdots \\ \phi_{m-1} \end{pmatrix} = \begin{pmatrix} I_d \\ \tilde{\Phi} \end{pmatrix}$$

where $I_d$ is a $d \times d$ identity matrix. Assume that only the corner constraints are used, but any constraints you place on the scale parameters are also applied to the initial scale estimates, so the structure of $\Phi$ will change accordingly. The $\phi$ parameters are invariant to the scale of the covariates, so initial estimates in $[0, 1]$ are reasonable. The constraints guarantee that the rank of $\Phi$ is at least $d$, so the initial estimates for the stereotype regression parameters are obtained from $B = \tilde{B} \Phi (\Phi')^{-1}$.

One other approach for initial estimates is provided: initialize(svd). It starts with the mlogit estimates and computes $\tilde{B}' = UDV'$, where $U_{m-1 \times p}$ and $V_{p \times p}$ are orthonormal matrices and $D_{p \times p}$ is a diagonal matrix containing the singular values of $\tilde{B}$. The estimates for $\Phi$ and $B$ are the first $d$ columns of $U$ and $VD$, respectively (Yee and Hastie 2003).

The score for regression coefficients is

$$u_i(\beta_j) = \frac{\partial L_{ik}}{\partial \beta_j} = x_i \left( \sum_{l=1}^{m-1} \phi_{jl} p_{il} - \phi_{jk} \right)$$

the score for the scale parameters is

$$u_i(\phi_{jl}) = \frac{\partial L_{ik}}{\partial \phi_{jl}} = \begin{cases} x_i \beta_j (p_{ik} - 1), & \text{if } l = k \\ x_i \beta_j p_{il}, & \text{if } l \neq k \end{cases}$$

for $l = 1, \ldots, m-1$; and the score for the intercepts is

$$u_i(\theta_l) = \frac{\partial L_{ik}}{\partial \theta_l} = \begin{cases} 1 - p_{ik}, & \text{if } l = k \\ -p_{il}, & \text{if } l \neq k \end{cases}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce(robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.
slogit also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

predict

Description for predict

predict creates a new variable containing predictions such as probabilities, indexes for the kth outcome, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [ type ] { stub* | newvar | newvarlist } [ if ] [ in ] [, statistic outcome(outcome) ]
```

```
predict [ type ] stub* [ if ] [ in ], scores
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>probability of one of or all the dependent variable outcomes; the default</td>
</tr>
<tr>
<td>xb</td>
<td>index for the kth outcome</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the index for the kth outcome</td>
</tr>
</tbody>
</table>

You specify one or k new variables with pr, where k is the number of outcomes. If you specify one new variable and you do not specify outcome(), then outcome(#1) is assumed.

You specify one new variable with xb and stdp. If you do not specify outcome(), then outcome(#1) is assumed.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

pr, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify k new variables, where k is the number of categories of the dependent variable. Alternatively, you can specify stub*; in which case, pr will store predicted probabilities in variables stub1, stub2, ..., stubk. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option outcome(); if you omit outcome(), the first outcome value, outcome(#1), is assumed.

Say that you fit a model by typing estimation_cmd y x1 x2, and y takes on four values. Then, you could type predict p1 p2 p3 p4 to obtain all four predicted probabilities; alternatively, you could type predict p* to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type predict p1, outcome(#1) (or simply predict p1), predict p2, outcome(#2), and so on. See option outcome() for other ways to refer to outcome values.

xb calculates the index, \( \theta_k - \sum_{j=1}^{d} \phi_{jk}x_i\beta_j \), for outcome level \( k \neq e(i_{\text{base}}) \) and dimension \( d = e(k_{\text{dim}}) \). It returns a vector of zeros if \( k = e(i_{\text{base}}) \). A synonym for xb is index. If outcome() is not specified, outcome(#1) is assumed.

stdp calculates the standard error of the index. A synonym for stdp is seindex. If outcome() is not specified, outcome(#1) is assumed.
outcome(outcome) specifies for which outcome the predicted probabilities are to be calculated. outcome() should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. outcome() is not allowed with scores.

scores calculates the equation-level score variables. For models with d dimensions and m levels, \(d + (d + 1)(m - 1)\) new variables are created. Assume \(j = 1, \ldots, d\) and \(k = 1, \ldots, m\) in the following.

The first \(d\) new variables will contain \(\partial \ln L / \partial (x\beta_j)\).

The next \(d(m - 1)\) new variables will contain \(\partial \ln L / \partial \phi_{jk}\).

The last \(m - 1\) new variables will contain \(\partial \ln L / \partial \theta_k\).

margins

description for margins

margins estimates margins of response for probabilities and indexes for the \(k\)th outcome.

menu for margins

Statistics > Postestimation

syntax for margins

margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>probabilities for each outcome</td>
</tr>
<tr>
<td>pr</td>
<td>probability of one of or all the dependent variable outcomes</td>
</tr>
<tr>
<td>xb</td>
<td>index for the (k)th outcome</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

pr and xb default to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than \(e(b)\).

For the full syntax, see [R] margins.

Remarks and examples

Once you have fit a stereotype logistic model, you can obtain the predicted probabilities by using the predict command for both the estimation sample and other samples; see [U] 20 Estimation and postestimation commands and [R] predict.
predict without arguments (or with the pr option) calculates the predicted probability of each outcome of the dependent variable. You must therefore give a new variable name for each of the outcomes. To compute the estimated probability of one outcome, you use the outcome(outcome) option where outcome is the level encoding the outcome. If the dependent variable’s levels are labeled, the outcomes can also be identified by the label values (see [D] label).

The xb option in conjunction with outcome(outcome) specifies that the index be computed for the outcome encoded by level outcome. Its approximate standard error is computed if the stdp option is specified. Only one of the pr, xb, or stdp options can be specified with a call to predict.

Example 1

In example 2 of [R] slogit, we fit the one-dimensional stereotype model, where the depvar is insure with levels $k = 1$ for outcome Indemnity, $k = 2$ for Prepaid, and $k = 3$ for Uninsure. The base outcome for the model is Indemnity, so for $k \neq 1$ the vector of indices for the $k$th level is

$$\eta_k = \theta_k - \phi_k (\beta_1 \text{age} + \beta_2 \text{male} + \beta_3 \text{nonwhite} + \beta_4 2.\text{site} + \beta_5 3.\text{site})$$

We estimate the group probabilities by calling predict after slogit.

```
. use https://www.stata-press.com/data/r18/sysdsn1
  (Health insurance data)
. slogit insure age male nonwhite i.site, dim(1) base(1) nolog
  (output omitted)
. predict pIndemnity pPrepaid pUninsure, p
. list pIndemnity pPrepaid pUninsure insure in 1/10

  pIndemnity pPrepaid pUninsure  insure
  ------------- ------------- ------------- -----
     1.      .5419344     .3754875    .0825782  Indemnity
     2.      .4359638     .496328     .0677081  Prepaid
     3.      .5111583     .4105107    .0783309  Indemnity
     4.      .3941132     .5442234    .0616633  Prepaid
     5.      .4655651     .4625064    .0719285     .
     6.      .4401779     .4915102    .0683118  Prepaid
     7.      .4632122     .4651931    .0715948  Prepaid
     8.      .3772302     .5635696    .0592002     .
     9.      .4867758     .4383018    .0749225  Uninsure
    10.      .5823668     .3295802    .0880531  Prepaid
```

Observations 5 and 8 are not used to fit the model because insure is missing at these points, but predict estimates the probabilities for these observations because none of the independent variables is missing. You can use if e(sample) in the call to predict to use only those observations that are used to fit the model.

Methods and formulas

predict

Let level $b$ be the base outcome that is used to fit the stereotype logistic regression model of dimension $d$. The index for observation $i$ and level $k \neq b$ is $\eta_{ik} = \theta_k - \sum_{j=1}^{d} \phi_{jk} x_i \beta_j$. This is the log odds of outcome encoded as level $k$ relative to that of $b$ so that we define $\eta_{ib} \equiv 0$. The outcome probabilities for this model are defined as $\Pr(Y_i = k) = e^{\eta_{ik}} / \sum_{j=1}^{m} e^{\eta_{ij}}$. Unlike in mlogit, ologit, and oprobit, the index is no longer a linear function of the parameters. The standard error of index $\eta_{ik}$ is thus computed using the delta method (see also [R] predictnl).
The equation-level score for regression coefficients is

$$\frac{\partial \ln L_{ik}}{\partial x_i \beta_j} = \left( \sum_{l=1}^{m-1} \phi_{jl} p_{il} - \phi_{jk} \right)$$

the equation-level score for the scale parameters is

$$\frac{\partial \ln L_{ik}}{\partial \phi_{jl}} = \begin{cases} x_i \beta_j (p_{ik} - 1), & \text{if } l = k \\ x_i \beta_j p_{il}, & \text{if } l \neq k \end{cases}$$

for $l = 1, \ldots, m - 1$; and the equation-level score for the intercepts is

$$\frac{\partial \ln L_{ik}}{\partial \theta_l} = \begin{cases} 1 - p_{ik}, & \text{if } l = k \\ -p_{il}, & \text{if } l \neq k \end{cases}$$

[R] slogit — Stereotype logistic regression

[U] 20 Estimation and postestimation commands
smooth applies the specified resistant, nonlinear smoother to \textit{varname} and stores the smoothed series in \textit{newvar}.

Quick start

Running median smoother of span 3 for \textit{v}, placing smoothed values in the new variable \textit{newv}.

\begin{verbatim}
smooth 3 v, generate(newv)
\end{verbatim}

Same as above, but with a compound smoother of running medians, first of span 3, then span 5.

\begin{verbatim}
smooth 35 v, generate(newv)
\end{verbatim}

Same as above, but repeating the span-5 running median until convergence.

\begin{verbatim}
smooth 35R v, generate(newv)
\end{verbatim}

Same as above, splitting any repeated values after the span-3 running median.

\begin{verbatim}
smooth 3S5R v, generate(newv)
\end{verbatim}

Same as above, but apply the compound smoother to the resulting rough.

\begin{verbatim}
smooth 3S5R,twice v, generate(newv)
\end{verbatim}

Menu

Statistics $\rightarrow$ Nonparametric analysis $\rightarrow$ Robust nonlinear smoother
Syntax

\[
\text{smooth} \; \text{smoother}[, \text{twice}] \; \text{varname} \; [\text{if}] \; [\text{in}], \; \text{generate(newvar)}
\]

where \text{smoother} is specified as \text{Sm}[ \text{Sm}[\ldots] \] and \text{Sm} is one of

\[
\{1|2|3|4|5|6|7|8|9\}[\text{R}] \\
3[\text{R}]3[\text{S}]3[\text{S}|\text{R}]3[\text{S}|\text{R}]\ldots \\
\text{E} \\
\text{H}
\]

Letters may be specified in lowercase if preferred. Examples of \text{smoother}[,\text{twice}] include

\[
3\text{RSSH} \quad 3\text{RSSH},\text{twice} \quad 4253\text{H} \quad 4253\text{H},\text{twice} \quad 43\text{RSR2H},\text{twice} \\
3\text{rssh} \quad 3\text{rssh},\text{twice} \quad 4253\text{h} \quad 4253\text{h},\text{twice} \quad 43\text{rsr2h},\text{twice}
\]

Option

\[
\text{generate(newvar)}
\]

is required; it specifies the name of the new variable that will contain the smoothed values.

Remarks and examples

Smoothing is an exploratory data-analysis technique for making the general shape of a series apparent. In this approach (Tukey 1977), the observed data series is assumed to be the sum of an underlying process that evolves smoothly (the smooth) and of an unsystematic noise component (the rough); that is,

\[
data = \text{smooth} + \text{rough}
\]

Smoothed values \(z_t\) are obtained by taking medians (or some other location estimate) of each point in the original data \(y_t\) and a few of the points around it. The number of points used is called the span of the smoother. Thus, a span-3 smoother produces \(z_t\) by taking the median of \(y_{t-1}, y_t, \text{ and } y_{t+1}\). \text{smooth} provides running median smoothers of spans 1 to 9—indicated by the digit that specifies their span. Median smoothers are resistant to isolated outliers, so they provide robustness to spikes in the data. Because the median is also a nonlinear operator, such smoothers are known as robust (or resistant) nonlinear smoothers.

\text{smooth} also provides the Hanning linear, nonrobust smoother, indicated by the letter \text{H}. Hanning is a span-3 smoother with binomial weights. Repeated applications of \text{H}—\text{HH}, \text{HHH}, etc.—provide binomial smoothers of span 5, 7, etc. See Cox (1997, 2004) for a graphical application of this fact.

Because one smoother usually cannot adequately separate the smooth from the rough, compound smoothers—multiple smoothers applied in sequence—are used. The smoother 35H, for instance, then smooths the data with a span-3 median smoother, smooths the result with a span-5 median smoother, and finally smooths that result with the Hanning smoother. \text{smooth} allows you to specify any number of smoothers in any sequence.

Three refinements can be combined with the running median and Hanning smoothers. First, the endpoints of a smooth can be given special treatment. This is specified by the \text{E} operator. Second, smoothing by 3, the span-3 running median, tends to produce flat-topped hills and valleys. The splitting operator, \text{S}, “splits” these repeated values, applies the endpoint operator to them, and then “rejoins” the series. Finally, it is sometimes useful to repeat an odd-span median smoother or the splitting operator until the smooth no longer changes. Following a digit or an \text{S} with an \text{R} specifies this type of repetition.
Even the best smoother may fail to separate the smooth from the rough adequately. To guard against losing any systematic components of the data series, after smoothing, the smoother can be reapplied to the resulting rough, and any recovered signal can be added back to the original smooth. The `twice` operator specifies this procedure. More generally, an arbitrary smoother can be applied to the rough (using a second `smooth` command), and the recovered signal can be added back to the smooth. This more general procedure is called reroughing (Tukey 1977).

The details of each of the smoothers and operators are explained in *Methods and formulas* below.

### Example 1

`smooth` is designed to recover the general features of a series that has been contaminated with noise. To demonstrate this, we construct a series, add noise to it, and then `smooth` the noisy version to recover an estimate of the original data. First, we construct and display the data:

```stata
. drop _all
. set obs 10
. set seed 123456789
. generate time = _n
. label variable time "Time"
. generate x = _n^3 - 10*_n^2 + 5*_n
. label variable x "Signal"
. generate z = x + 50*rnormal()
. label variable z "Observed series"
. scatter x z time, c(l .) m(i o) ytitle(""
```

![Graph showing the signal and observed series](image)
Now we smooth the noisy series, \( z \), assumed to be the only data we would observe:

```
. smooth 4253eh,twice z, gen(sz)
. label variable sz "Smoothed series"
. scatter x z time, c(l . l) m(i o i) ytitle(""") || scatter sz time,
> c(l . l) m(i o i) ytitle(""") clpattern(dash_dot)
```

![Graph showing smoothing process](https://www.stata-press.com/data/r18/fishdata)

**Example 2**

Salgado-Ugarte and Curtis-García (1993) provide data on the frequencies of observed fish lengths. In this example, the series to be smoothed—the frequencies—is ordered by fish length rather than by time.

```
. use https://www.stata-press.com/data/r18/fishdata, clear

```

![Graph showing smoothed frequencies](https://www.stata-press.com/data/r18/fishdata)
Technical note

*smooth* allows missing values at the beginning and end of the series, but missing values in the middle are not allowed. Leading and trailing missing values are ignored. If you wish to ignore missing values in the middle of the series, you must drop the missing observations before using *smooth*. Doing so, of course, would violate *smooth*’s assumption that observations are equally spaced—each observation represents a year, a quarter, or a month (or a 1-year birth-rate category). In practice, *smooth* produces good results as long as the spaces between adjacent observations do not vary too much.

Smoothing is usually applied to time series, but any variable with a natural order can be smoothed. For example, a smoother might be applied to the birth rate recorded by the age of the mothers (birthrate for 17-year-olds, birthrate for 18-year-olds, and so on).

Methods and formulas

Methods and formulas are presented under the following headings:

- Running median smoothers of odd span
- Running median smoothers of even span
- Repeat operator
- Endpoint rule
- Splitting operator
- Hanning smoother
- Twicing

Running median smoothers of odd span

The smoother 3 defines

\[ z_t = \text{median}(y_{t-1}, y_t, y_{t+1}) \]

The smoother 5 defines

\[ z_t = \text{median}(y_{t-2}, y_{t-1}, y_t, y_{t+1}, y_{t+2}) \]

and so on. The smoother 1 defines \( z_t = \text{median}(y_t) \), so it does nothing.

Endpoints are handled by using smoothers of shorter, odd span. Thus, for 3,

\[
\begin{align*}
z_1 &= y_1 \\
z_2 &= \text{median}(y_1, y_2, y_3) \\
&
\vdots \\
z_{N-1} &= \text{median}(y_{N-2}, y_{N-1}, y_N) \\
Z_N &= y_N
\end{align*}
\]
For 5,

\[
\begin{align*}
  z_1 &= y_1 \\
  z_2 &= \text{median}(y_1, y_2, y_3) \\
  z_3 &= \text{median}(y_1, y_2, y_3, y_4, y_5) \\
  z_4 &= \text{median}(y_2, y_3, y_4, y_5) \\
    &\vdots \\
  z_{N-2} &= \text{median}(y_{N-4}, y_{N-3}, y_{N-2}, y_{N-1}, y_N) \\
  z_{N-1} &= \text{median}(y_{N-2}, y_{N-1}, y_N) \\
  Z_N &= y_N
\end{align*}
\]

and so on.

**Running median smoothers of even span**

Define the \text{median()} function as returning the linearly interpolated value when given an even number of arguments. Thus, the smoother 2 defines

\[
z_{t+0.5} = (y_t + y_{t+1})/2
\]

The smoother 4 defines \(z_{t+0.5}\) as the linearly interpolated median of \((y_{t-1}, y_t, y_{t+1}, y_{t+2})\), and so on. Endpoints are always handled using smoothers of shorter, even span. Thus, for 4,

\[
\begin{align*}
  z_{0.5} &= y_1 \\
  z_{1.5} &= \text{median}(y_1, y_2) = (y_1 + y_2)/2 \\
  z_{2.5} &= \text{median}(y_1, y_2, y_3, y_4) \\
    &\vdots \\
  z_{N-2.5} &= \text{median}(y_{N-4}, y_{N-3}, y_{N-2}, y_N) \\
  z_{N-1.5} &= \text{median}(y_{N-2}, y_{N-1}) \\
  z_{N-0.5} &= \text{median}(y_{N-1}, y_N) \\
  z_{N+0.5} &= y_N
\end{align*}
\]

As defined above, an even-span smoother increases the length of the series by 1 observation. However, the series can be recentered on the original observation numbers, and the “extra” observation can be eliminated by smoothing the series again with another even-span smoother. For instance, the smooth of 4 illustrated above could be followed by a smooth of 2 to obtain
\[
\begin{align*}
z_1^* &= (z_{0.5} + z_{1.5})/2 \\
z_2^* &= (z_{1.5} + z_{2.5})/2 \\
z_3^* &= (z_{2.5} + z_{3.5})/2 \\
&\vdots \\
z_{N-2}^* &= (z_{N-2.5} + z_{N-1.5})/2 \\
z_{N-1}^* &= (z_{N-1.5} + z_{N-0.5})/2 \\
z_N^* &= (z_{N-0.5} + z_{N+0.5})/2
\end{align*}
\]

smooth keeps track of the number of even smoothers applied to the data and expands and shrinks the length of the series accordingly. To ensure that the final smooth has the same number of observations as \texttt{varname}, smooth requires you to specify an even number of even-span smoothers. However, the pairs of even-span smoothers need not be contiguous; for instance, 4253 and 4523 are both allowed.

**Repeat operator**

\texttt{R} indicates that a smoother is to be repeated until convergence, that is, until repeated applications of the smoother produce the same series. Thus, \texttt{3} applies the smoother of running medians of span 3. \texttt{33} applies the smoother twice. \texttt{3R} produces the result of repeating \texttt{3} an infinite number of times. \texttt{R} should be used only with odd-span smoothers because even-span smoothers are not guaranteed to converge.

The smoother \texttt{453R2} applies a span-4 smoother, followed by a span-5 smoother, followed by repeated applications of a span-3 smoother, followed by a span-2 smoother.

**Endpoint rule**

The endpoint rule \texttt{E} modifies the values \(z_1\) and \(z_N\) according to the following formulas:

\[
\begin{align*}
z_1 &= \text{median}(3z_2 - 2z_3, z_1, z_2) \\
z_N &= \text{median}(3z_{N-2} - 2z_{N-1}, z_N, z_{N-1})
\end{align*}
\]

When the endpoint rule is not applied, endpoints are typically “copied in”; that is, \(z_1 = y_1\) and \(z_N = y_N\).

**Splitting operator**

The smoothers \texttt{3} and \texttt{3R} can produce flat-topped hills and valleys. The split operator attempts to eliminate such hills and valleys by splitting the sequence, applying the endpoint rule \texttt{E}, rejoining the series, and then resmoothing by \texttt{3R}.

The \texttt{S} operator may be applied only after \texttt{3}, \texttt{3R}, or \texttt{S}.

We recommend that the \texttt{S} operator be repeated once (\texttt{SS}) or until no further changes take place (\texttt{SR}).
Hanning smoother

H is the Hanning linear smoother:

\[ z_t = \frac{(y_{t-1} + 2y_t + y_{t+1})}{4} \]

Endpoints are copied in: \( z_1 = y_1 \) and \( z_N = y_N \). H should be applied only after all nonlinear smoothers.

Twicing

A smoother divides the data into a smooth and a rough:

\[ \text{data} = \text{smooth} + \text{rough} \]

If the smoothing is successful, the rough should exhibit no pattern. Twicing refers to applying the smoother to the observed, calculating the rough, and then applying the smoother to the rough. The resulting “smoothed rough” is then added back to the smooth from the first step.

Acknowledgments

\texttt{smooth} was originally written by William Gould (1992)—at which time it was named \texttt{nlsm}—and was inspired by Salgado-Ugarte and Curts-García (1992). Salgado-Ugarte and Curts-García (1993) subsequently reported anomalies in \texttt{nlsm}’s treatment of even-span median smoothers. \texttt{smooth} corrects these problems and incorporates other improvements but otherwise is essentially the same as originally published.

**Title**

**spearman —** Spearman’s and Kendall’s correlations

**Description**

`spearman` displays Spearman’s rank correlation coefficients for all pairs of variables in `varlist` or, if `varlist` is not specified, for all the variables in the dataset. When there are two variables, an exact \( p \)-value can be calculated optionally using permutations.

`ktau` displays Kendall’s rank correlation coefficients between the variables in `varlist` or, if `varlist` is not specified, for all the variables in the dataset. `ktau` is intended for use on small- and moderate-sized datasets; it requires considerable computation time for larger datasets.

**Quick start**

Spearmann’s rank correlation coefficient with approximate \( p \)-value for \( v1 \) and \( v2 \)

`spearman v1 v2`

As above, but report an exact \( p \)-value calculated using Monte Carlo permutations

`spearman v1 v2, exact`

As above, but perform 100,000 Monte Carlo permutations rather than the default of 10,000, and set the random-number seed for reproducibility

`spearman v1 v2, exact(montecarlo, reps(100000) rseed(1234))`

Display Spearmann’s rank correlation coefficients in a matrix for all pairs of \( v1, v2, \) and \( v3 \)

`spearman v1 v2 v3`

Display \( p \)-values as well as correlation coefficients

`spearman v1 v2 v3, stats(rho p)`

Same as above, but perform Bonferroni’s adjustment to \( p \)-values

`spearman v1 v2 v3, stats(rho p) bonferroni`

Kendall’s rank correlation coefficients, scores, and standard errors of the scores for pairs of \( v1, v2, \) and \( v3 \)

`ktau v1 v2 v3, stats(taua taub score se)`

Same as above, but use pairwise instead of casewise deletion

`ktau v1 v2 v3, stats(taua taub score se) pw`

by and collect are allowed with `spearman` and `ktau`; see [U] 11.1.10 Prefix commands.

where the elements of `spearman_list` may be

- `rho` correlation coefficient
- `obs` number of observations
- `p` `p`-value

and the elements of `ktau_list` may be

- `taua` correlation coefficient $\tau_a$
- `taub` correlation coefficient $\tau_b$
- `score` score
- `se` standard error of score
- `obs` number of observations
- `p` `p`-value
Options for spearman

```
stats(spearman_list) specifies the statistics to be displayed in the matrix of output. stats(rho) is the default. Up to three statistics may be specified; stats(rho obs p) would display the correlation coefficient, number of observations, and p-value. If varlist contains only two variables, all statistics are shown in tabular form, and stats(), print(), and star() have no effect unless the matrix option is specified.

print(#) specifies the p-value cutoff for correlation coefficients to be printed. Correlation coefficients with larger p-values are left blank in the matrix. Typing spearman, print(.10) would display only those correlation coefficients that have p-values less than or equal to 0.10.

star(#) specifies the p-value cutoff for correlation coefficients to be marked with a star. Typing spearman, star(.05) would star all correlation coefficients that have p-values less than or equal to 0.05.

bonferroni makes the Bonferroni adjustment to p-values. This adjustment affects displayed p-values and the print() and star() options. Thus, spearman, print(.05) bonferroni prints coefficients with Bonferroni-adjusted p-values of 0.05 or less.

sidak makes the Šidák adjustment to p-values. This adjustment affects displayed p-values and the print() and star() options. Thus, spearman, print(.05) sidak prints coefficients with Šidák-adjusted p-values of 0.05 or less.

pw specifies that correlations be calculated using pairwise deletion of observations with missing values. By default, spearman uses casewise deletion, where observations are ignored if any of the variables in varlist are missing.

matrix forces spearman to display the statistics as a matrix, even if varlist contains only two variables. matrix is implied if more than two variables are specified.

exact and exact(exact_specs) specify that an exact p-value be reported. This option is available only when varlist contains only two variables.

exact specifies that an exact p-value from a Monte Carlo permutation test be reported. exact is a synonym for exact(montecarlo).

exact(montecarlo[, options] | enumerate[, options]) specifies that an exact p-value be reported in addition to the approximate p-value. Specifying exact(montecarlo) does a Monte Carlo permutation test. Specifying exact(enumerate) does an enumeration of all possible permutations. Because the number of all possible permutations is typically extremely large, enumeration is feasible only for very small datasets. The number of permutations will be displayed, and you can click on Break to stop the computation. The exact p-value is computed by permute.

exact(montecarlo[, options]) allows options show, reps(#), rseed(#), saving(filename[, sav_options]), level(#), dots(#), nodots, and eps(#). The show option specifies that the table produced by permute also be displayed. By default, 10,000 Monte Carlo permutations are done. That is, the default is the same as specifying exact(montecarlo, reps(10000)). The default for dots() is dots(100) when reps() is ≥ 10,000; otherwise, it is dots(1). See Options in [R] permute.

exact(enumerate[, options]) allows options show, saving(filename[, sav_options]), dots(#), nodots, and eps(#). The show option specifies that the table produced by permute also be displayed. The default for dots() is dots(100). See Options in [R] permute.
```
Options for ktau

stats(ktau_list) specifies the statistics to be displayed in the matrix of output. stats(taua) is the default. Up to six statistics may be specified; stats(taua taub score se obs p) would display the correlation coefficients $\tau_a$ and $\tau_b$, score, standard error of score, number of observations, and $p$-value. If varlist contains only two variables, all statistics are shown in tabular form and stats(), print(), and star() have no effect unless the matrix option is specified.

print(#) specifies the $p$-value cutoff for correlation coefficients to be printed. Correlation coefficients with larger $p$-values are left blank in the matrix. Typing ktau, print(.10) would display only those correlation coefficients that have $p$-values less than or equal to 0.10.

star(#) specifies the $p$-value cutoff for correlation coefficients to be marked with a star. Typing ktau, star(.05) would star all correlation coefficients that have $p$-values less than or equal to 0.05.

bonferroni makes the Bonferroni adjustment to $p$-values. This adjustment affects displayed $p$-values and the print() and star() options. Thus, ktau, print(.05) bonferroni prints coefficients with Bonferroni-adjusted $p$-values of 0.05 or less.

sidak makes the Šidák adjustment to $p$-values. This adjustment affects displayed $p$-values and the print() and star() options. Thus, ktau, print(.05) sidak prints coefficients with Šidák-adjusted $p$-values of 0.05 or less.

pw specifies that correlations be calculated using pairwise deletion of observations with missing values. By default, ktau uses casewise deletion, where observations are ignored if any of the variables in varlist are missing.

matrix forces ktau to display the statistics as a matrix, even if varlist contains only two variables. matrix is implied if more than two variables are specified.

Remarks and examples

Example 1

We wish to calculate the correlation coefficients among marriage rate (mrgrate), divorce rate (divorce_rate), and median age (medage) in state data. We can calculate the standard Pearson correlation coefficients and $p$-values by typing

```
. use https://www.stata-press.com/data/r18/states2
(State data)
. pwcorr mrgrate divorce_rate medage, sig
```

<table>
<thead>
<tr>
<th></th>
<th>mrgrate</th>
<th>divorce_rate</th>
<th>medage</th>
</tr>
</thead>
<tbody>
<tr>
<td>mrgrate</td>
<td>1.0000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>divorce_rate</td>
<td>0.7895</td>
<td>1.0000</td>
<td>0.0000</td>
</tr>
<tr>
<td>medage</td>
<td>0.0011</td>
<td>-0.1526</td>
<td>1.0000</td>
</tr>
<tr>
<td></td>
<td>0.9941</td>
<td>0.2900</td>
<td></td>
</tr>
</tbody>
</table>
We can calculate Spearman’s rank correlation coefficients by typing

```
.spearman mrgrate divorce_rate medage, stats(rho p)
```

Number of observations = 50

<table>
<thead>
<tr>
<th>Key</th>
<th>mrgrate</th>
<th>divorce_rate</th>
<th>medage</th>
</tr>
</thead>
<tbody>
<tr>
<td>rho</td>
<td>1.0000</td>
<td>0.6933</td>
<td>-0.4869</td>
</tr>
<tr>
<td>p-value</td>
<td>.</td>
<td>0.0000</td>
<td>0.0004</td>
</tr>
</tbody>
</table>

The large difference in the results is caused by one observation. Nevada’s marriage rate is almost 10 times higher than the state with the next-highest marriage rate. An important feature of the Spearman rank correlation is its reduced sensitivity to extreme values compared with the Pearson correlation.

We can calculate Kendall’s rank correlations by typing

```
.ktau mrgrate divorce_rate medage, stats(taua taub p)
```

Number of observations = 50

<table>
<thead>
<tr>
<th>Key</th>
<th>mrgrate</th>
<th>divorce_rate</th>
<th>medage</th>
</tr>
</thead>
<tbody>
<tr>
<td>tau_a</td>
<td>0.9829</td>
<td>0.5110</td>
<td>-0.3486</td>
</tr>
<tr>
<td>tau_b</td>
<td>1.0000</td>
<td>0.9804</td>
<td>-0.1698</td>
</tr>
<tr>
<td>p-value</td>
<td>.</td>
<td>0.5206</td>
<td>0.9845</td>
</tr>
</tbody>
</table>

There are tied values for variables `mrgrate`, `divorce_rate`, and `medage`, so average ranks are used for the tied values. As a result, $\tau_a < 1$ on the diagonal (see Methods and formulas for the definition of $\tau_a$).

According to Conover (1999, 323), “Spearman’s $\rho$ tends to be larger than Kendall’s $\tau$ in absolute value. However, as a test of significance, there is no strong reason to prefer one over the other because both will produce nearly identical results in most cases.”
Newson (2000a, 2000b, 2000c, 2001, 2003, 2005, 2006) introduces confidence intervals for Kendall’s $\tau_a$. The community-contributed \texttt{somersd} command provides these confidence intervals along with additional rank statistics such as Somers’ $D$ and Harrell’s $C$ and their corresponding confidence intervals.

See Seed (2001) for confidence intervals for Spearman’s rank correlation.

Example 2

We illustrate \texttt{spearman} and \texttt{ktau} with the auto data, which contains some missing values.

```stata
use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
spearman mpg rep78
Number of observations = 69
Spearman’s rho = 0.3098
Test of H0: mpg and rep78 are independent
  Prob = 0.0098
```

Because we specified two variables, \texttt{spearman} displayed the sample size, correlation, and $p$-value in tabular form. To obtain just the correlation coefficient displayed in matrix form, we type

```stata
spearman mpg rep78, stats(rho) matrix
Number of observations = 69

<table>
<thead>
<tr>
<th></th>
<th>mpg</th>
<th>rep78</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>1.0000</td>
<td></td>
</tr>
<tr>
<td>rep78</td>
<td>0.3098</td>
<td>1.0000</td>
</tr>
</tbody>
</table>
```

We can specify the \texttt{pw} option with \texttt{spearman} and \texttt{ktau} so that all nonmissing observations between a pair of variables when calculating their correlation coefficient are used. In the output below, some correlations are based on 74 observations, whereas others are based on 69 because 5 observations contain a missing value for \texttt{rep78}.

```stata
spearman mpg price rep78, pw stats(rho obs p) star(0.01)
Number of observations:
  min = 69
  avg = 71
  max = 74

<table>
<thead>
<tr>
<th></th>
<th>mpg</th>
<th>price</th>
<th>rep78</th>
</tr>
</thead>
<tbody>
<tr>
<td>rho</td>
<td>1.0000</td>
<td>-0.5419*</td>
<td>1.0000</td>
</tr>
<tr>
<td>Number of obs</td>
<td>74</td>
<td>74</td>
<td>74</td>
</tr>
<tr>
<td>p-value</td>
<td>0.0000</td>
<td>0.0000</td>
<td>0.0098</td>
</tr>
</tbody>
</table>
```

The `Key` table shows the significance levels for the correlations.

```stata
Key
  rho
  Number of obs
  p-value

<table>
<thead>
<tr>
<th></th>
<th>mpg</th>
<th>price</th>
<th>rep78</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>1.0000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>price</td>
<td>-0.5419*</td>
<td>1.0000</td>
<td></td>
</tr>
<tr>
<td>rep78</td>
<td>0.3098*</td>
<td>0.1028</td>
<td>1.0000</td>
</tr>
<tr>
<td></td>
<td>69</td>
<td>69</td>
<td>69</td>
</tr>
<tr>
<td></td>
<td>0.0098</td>
<td>0.4000</td>
<td>0.0098</td>
</tr>
</tbody>
</table>
```
The bonferroni and sidak options provide adjusted $p$-values:

```
.ktau mpg price rep78, stats(taua taub score se p) bonferroni
```

Number of observations = 69

<table>
<thead>
<tr>
<th>tau_a</th>
<th>tau_b</th>
<th>score</th>
<th>se of score</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>0.9471</td>
<td>1.0000</td>
<td>2222.0000</td>
<td>191.8600</td>
</tr>
<tr>
<td>price</td>
<td>-0.3973</td>
<td>1.0000</td>
<td>-0.4082</td>
<td>1.0000</td>
</tr>
<tr>
<td>rep78</td>
<td>0.2076</td>
<td>0.0648</td>
<td>0.7136</td>
<td>0.0000</td>
</tr>
</tbody>
</table>

Example 3

We continue with the auto data and show an example of `spearman` with the `exact` option.

```
.set seed 1234
.spearman mpg gear_ratio if foreign == 1, exact
```

Permutations (10,000): ........1,000. ..........2,000. .........3,000. ........4,000.
> ........5,000. ........6,000. .........7,000. .........8,000. ........9,000. .........10,000 done

Number of observations = 22

Spearman’s rho = 0.4881

Test of H0: mpg and gear_ratio are independent

Prob = 0.0222

Exact prob = 0.0214 (10,000 Monte Carlo permutations)

By default, `exact` does a Monte Carlo permutation test with 10,000 permutations. Because it is a Monte Carlo test, we set the random-number generator seed before running `spearman` for reproducibility.

The exact $p$-value from the Monte Carlo permutation test is 0.0214, which is close to the approximate $p$-value of 0.0222. Note that the approximate $p$-value is not based on the normal distribution or the $t$ distribution. It is calculated using a beta distribution fit to the first four moments of the null distribution of Spearman’s rank correlation, and these four moments are calculated exactly for any value of $N$, the number of observations. See *Methods and formulas* below.
Let’s increase the number of Monte Carlo permutations to 1,000,000 to see how close the approximate \( p \)-value is to the exact \( p \)-value. We specify \texttt{dots(10000)} to see a dot every 10,000th permutation, rather than the default of every 1,000th permutation. This time we set the random-number generator seed using a suboption. The exact \( p \)-value is computed by \texttt{permute}, and we can see \texttt{permute}'s output by specifying the \texttt{show} suboption.

\[ . \texttt{spearman mpg gear\_ratio if foreign == 1,} \]
\[ >  \texttt{exact(montecarlo, reps(1000000) dots(10000) rseed(1234) show)} \]

```
Permutations (1,000,000): ................100,000...........200,000...........300,000......
> ...400,000...........500,000...........600,000...........700,000...........800,000....
> .....900,000...........1,000,000 done
```

<td>0.0230</td>
<td>0.0001</td>
<td>0.0227</td>
</tr>
</tbody>
</table>

Notes: For lower one-sided test, \( c = \#\{T <= T(obs)\} \) and \( p = p_{\text{lower}} = c/n \).
For upper one-sided test, \( c = \#\{T >= T(obs)\} \) and \( p = p_{\text{upper}} = c/n \).
For two-sided test, \( p = 2*\min(p_{\text{lower}}, p_{\text{upper}}) \); SE and CI approximate.

Number of observations = 22
Spearman’s rho = 0.4881

Test of H0: mpg and gear\_ratio are independent

\[ \text{Prob} = 0.0222 \]

Exact prob = 0.0230 (1,000,000 Monte Carlo permutations)

With this increase in the number of permutations, the exact \( p \)-value is now calculated as 0.0230. From the table produced by \texttt{permute}, we see that this \( p \)-value has a confidence interval of \([0.0227, 0.0233]\), accounting for the Monte Carlo error. The approximate \( p \)-value of 0.0222 falls outside this confidence interval, but it is still very close. Not bad for \( N = 22 \).

\section*{Example 4}

For very small sample sizes, an exact \( p \)-value can be computed by enumerating the full permutation distribution. Here is an example using the auto data with sample size \( N = 11 \).

\[ . \texttt{spearman mpg gear\_ratio if foreign == 1 & mpg <= 24,} \]
\[ >  \texttt{exact(enumerate, dots(10000))} \]

```
(enumerating all 831,600 possible permutations)
```

Permutations (831,600): ................100,000...........200,000...........300,000........
> ...400,000...........500,000...........600,000...........700,000...........800,000....
> one

Number of observations = 11
Spearman’s rho = 0.5636

Test of H0: mpg and gear\_ratio are independent

\[ \text{Prob} = 0.0722 \]

Exact prob = 0.0747 (enumerated all 831,600 permutations)

The exact \( p \)-value is 0.0747. The approximate \( p \)-value is 0.0722, which is quite close to the exact \( p \)-value in this case, even with only 11 observations.
For \( N = 11 \), the permutation distribution consists of \( 11! = 39,916,800 \) permutations. However, the output above says that there are only 831,600 permutations. This is because the values of mpg in this sample are not all unique.

```
. tabulate mpg if foreign == 1 & mpg <= 24

14          1       9.09    9.09
17          2      18.18   27.27
18          2      18.18   45.45
21          2      18.18   63.64
23          3      27.27   90.91
24          1       9.09  100.00
Total      11   100.00
```

The multiplicities in the values of mpg yield permutations that give identical results, and we need to enumerate only the permutations that are distinct. From the values of mpg, we see that each distinct permutation has a multiplicity of \( 2! \times 2! \times 3! = 48 \), and \( 39,916,800/48 = 831,600 \), which reduces considerably the number of permutations that need to be computed.

`permute`, which computes the permutations, permutes the first variable of the two in the `spearman varlist` command. So to best exploit this, the variable that produces the most multiplicities in the permutations should be placed first in `varlist` when doing an enumeration.

Charles Edward Spearman (1863–1945) was a British psychologist who made contributions to correlation, factor analysis, test reliability, and psychometrics. After several years’ military service, he obtained a PhD in experimental psychology at Leipzig and became a professor at University College London, where he sustained a long program of work on the interpretation of intelligence tests. Ironically, the rank correlation version bearing his name is not the formula he advocated.

Maurice George Kendall (1907–1983) was a British statistician who contributed to rank correlation, time series, multivariate analysis, among other topics, and wrote many statistical texts. Most notably, perhaps, his advanced survey of the theory of statistics went through several editions, later ones with Alan Stuart; the baton has since passed to others. Kendall was employed in turn as a government and business statistician, as a professor at the London School of Economics, as a consultant, and as director of the World Fertility Survey. He was knighted in 1974.
Stored results

spearman stores the following in r():

Scalars
- \( r(N) \): number of observations (last variable pair)
- \( r(\rho) \): \( \rho \) (last variable pair)
- \( r(p) \): two-sided \( p \)-value (last variable pair)
- \( r(p_l) \): lower one-sided \( p \)-value (last variable pair)
- \( r(p_u) \): upper one-sided \( p \)-value (last variable pair)
- \( r(p_{exact}) \): two-sided exact \( p \)-value
- \( r(p_{l_exact}) \): lower one-sided exact \( p \)-value
- \( r(p_{u_exact}) \): upper one-sided exact \( p \)-value
- \( r(n_{perm}) \): number of permutations performed

Macros
- \( r(exact) \): "montecarlo" or "enumerate"
- \( r(rngstate) \): random-number state used for Monte Carlo permutations

Matrices
- \( r(Nobs) \): number of observations
- \( r(Rho) \): \( \rho \)
- \( r(P) \): two-sided \( p \)-value

If `exact(...)`, `show` is specified, the stored results from `permute` are returned as well; see `Stored results in [R] permute`.

ktau stores the following in r():

Scalars
- \( r(N) \): number of observations (last variable pair)
- \( r(\tau_a) \): \( \tau_a \) (last variable pair)
- \( r(\tau_b) \): \( \tau_b \) (last variable pair)
- \( r(score) \): Kendall’s score (last variable pair)
- \( r(se_score) \): standard error of score (last variable pair)
- \( r(p) \): two-sided \( p \)-value (last variable pair)

Matrices
- \( r(Nobs) \): number of observations
- \( r(Tau_a) \): \( \tau_a \)
- \( r(Tau_b) \): \( \tau_b \)
- \( r(Score) \): Kendall’s score
- \( r(Se_Score) \): standard error of score
- \( r(P) \): two-sided \( p \)-value

Methods and formulas

Methods and formulas are presented under the following headings:

Spearman’s rank correlation
Exact \( p \)-values
Kendall’s tau

Spearman's rank correlation

Spearman’s (1904) rank correlation is calculated as Pearson’s correlation computed on the ranks (averaged for ties) (Conover 1999, 314–315). Ranks are as calculated by `egen`; see [D] egen.
If \( x_i \) and \( y_i \), where \( i = 1, 2, \ldots, n \), are the ranks of one variable pair, and \( n \) is the number of observations, then Spearman’s rank correlation is

\[
\rho = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum (x_i - \bar{x})^2} \sqrt{\sum (y_i - \bar{y})^2}}
\]

where \( \bar{x} = (\sum x_i)/n \) is the mean of \( x \) and \( \bar{y} \) is defined similarly.

Under the null hypothesis of independence (or, more generally, exchangeability), the distribution of \( \rho \) is given by all the possible permutations of \( x_i \) with \( y_i \) fixed. For the permutation distribution, an equivalent statistic to \( \rho \) is

\[
T = \sum x_i y_i
\]

The moments of \( T \) for the permutation distribution can be computed exactly. Its mean is

\[
E(T) = \frac{1}{n} \left\{ \sum_i x_i \right\} \left\{ \sum_i y_i \right\}
\]

Assume now that the ranks, \( x_i \) and \( y_i \), are adjusted so that their means are zero. With this assumption, we have (Stuart, Ord, and Arnold 1999, eqs. 27.42 and 27.43)

\[
E(T^2) = \frac{1}{n-1} \left\{ \sum_i x_i^2 \right\} \left\{ \sum_i y_i^2 \right\}
\]

\[
E(T^3) = \frac{1}{n} \left\{ \sum_i x_i^3 \right\} \left\{ \sum_i y_i^3 \right\} + \frac{3}{n(n-1)} \left\{ \sum_{i \neq j} x_i^2 x_j \right\} \left\{ \sum_{i \neq j} y_i^2 y_j \right\} + \frac{36}{n(n-1)(n-2)} \left\{ \sum_{i<j<k} x_i x_j x_k \right\} \left\{ \sum_{i<j<k} y_i y_j y_k \right\}
\]

\[
E(T^4) = \frac{1}{n} \left\{ \sum_i x_i^4 \right\} \left\{ \sum_i y_i^4 \right\} + \frac{4}{n(n-1)} \left\{ \sum_{i \neq j} x_i^3 x_j \right\} \left\{ \sum_{i \neq j} y_i^3 y_j \right\} + \frac{12}{n(n-1)} \left\{ \sum_{i<j} x_i^2 x_j^2 \right\} \left\{ \sum_{i<j} y_i^2 y_j^2 \right\} + \frac{24}{n(n-1)(n-2)} \left\{ \sum_{i<j<k} x_i^2 x_j x_k \right\} \left\{ \sum_{i<j<k} y_i^2 y_j y_k \right\} + \frac{576}{n(n-1)(n-2)(n-3)} \left\{ \sum_{i<j<k<l} x_i x_j x_k x_l \right\} \left\{ \sum_{i<j<k<l} y_i y_j y_k y_l \right\}
\]

Note that Stuart, Ord, and Arnold (1999, eq. 27.43) express \( E(T^3) \) and \( E(T^4) \) in terms of \( k \) statistics, but that formulation is exactly equivalent to the equations given above.
An approximate $p$-value for Spearman’s rank correlation is calculated by fitting a four-parameter beta distribution to the first four moments of $T$. (See Lord [1965] and Hanson [1991] for a description of the technique of fitting a four-parameter beta distribution to moments of another distribution.) The four-parameter beta distribution with domain $[l, u]$ is

$$f(x) = \frac{(-l + x)^{\alpha - 1} (u - x)^{\beta - 1}}{(u - l)^{\alpha + \beta - 1} B(\alpha, \beta)}$$

where $0 \leq l < u \leq 1$ and $B(\alpha, \beta)$ is the beta function with $\alpha > 0$ and $\beta > 0$.

The parameters for the beta distribution are calculated as follows. Let $m$ be the mean of $T$, $v$ its variance, $g_3$ its skewness, and $g_4$ its kurtosis (see Methods and formulas in [R] summarize). Define

$$r = \frac{6(g_4 - g_3^2 - 1)}{6 + 3g_3^2 - 2g_4}$$

and

$$d = 1 - \frac{24(r + 1)}{(r + 2)(r + 3)g_4 - 3(r - 6)(r + 1)}$$

Let

$$a = \frac{r(1 - \sqrt{d})}{2}$$

$$b = \frac{r(1 + \sqrt{d})}{2}$$

If $g_3 > 0$, then $\alpha = a$ and $\beta = b$; otherwise, $\alpha = b$ and $\beta = a$. The domain boundaries are given by

$$l = m - \alpha \sqrt{\frac{v(\alpha + \beta + 1)}{\alpha \beta}}$$

$$u = m + \beta \sqrt{\frac{v(\alpha + \beta + 1)}{\alpha \beta}}$$

To calculate the $p$-values, we first scale the observed value of $T$ to the domain of beta:

$$s = \frac{T_{obs} - l}{u - l}$$

Then the lower and upper one-sided $p$-values are given by

$$p_{lower} = \text{ibeta}(\alpha, \beta, s)$$

$$p_{upper} = \text{ibetatail}(\alpha, \beta, s)$$

where \text{ibeta} is Stata’s two-parameter cumulative beta distribution and \text{ibetatail} is the function for its upper tail; see [FN] Statistical functions. The two-sided $p$-value is given by

$$p = \min\{1, 2 \min(p_{lower}, p_{upper})\}$$
**Exact p-values**

Exact p-values for Spearman’s rank correlation are computed by `permute`. For details on the permutation computation, see [R] permute.

**Kendall’s tau**

Kendall’s $\tau$ is calculated in the following manner. For any two pairs of ranks $(x_i, y_i)$ and $(x_j, y_j)$, $1 \leq i, j \leq n$, define them as concordant if

$$(x_i - x_j)(y_i - y_j) > 0$$

and discordant if this product is less than zero.

Kendall’s (1938; also see Kendall and Gibbons [1990] or Bland [2015], 187–188) score $S$ is defined as $C - D$, where $C$ ($D$) is the number of concordant (discordant) pairs. Let $N = n(n-1)/2$ be the total number of pairs, so $\tau_a$ is given by

$$\tau_a = \frac{S}{N}$$

and $\tau_b$ is given by

$$\tau_b = \frac{S}{\sqrt{N - U \sqrt{N - V}}}$$

where

$$U = \sum_{i=1}^{N_1} u_i (u_i - 1)/2$$

$$V = \sum_{j=1}^{N_2} v_j (v_j - 1)/2$$

and where $N_1$ is the number of sets of tied $x$ values, $u_i$ is the number of tied $x$ values in the $i$th set, $N_2$ is the number of sets of tied $y$ values, and $v_j$ is the number of tied $y$ values in the $j$th set.

Under the null hypothesis of independence, the variance of $S$ is exactly (Kendall and Gibbons 1990, 66)

$$\text{Var}(S) = \frac{1}{18} \left\{ n(n-1)(2n+5) - \sum_{i=1}^{N_1} u_i (u_i - 1)(2u_i + 5) - \sum_{j=1}^{N_2} v_j (v_j - 1)(2v_j + 5) \right\}$$

$$+ \frac{1}{9n(n-1)(n-2)} \left\{ \sum_{i=1}^{N_1} u_i (u_i - 1)(u_i - 2) \right\} \left\{ \sum_{j=1}^{N_2} v_j (v_j - 1)(v_j - 2) \right\}$$

$$+ \frac{1}{2n(n-1)} \left\{ \sum_{i=1}^{N_1} u_i (u_i - 1) \right\} \left\{ \sum_{j=1}^{N_2} v_j (v_j - 1) \right\}$$

Using a normal approximation with a continuity correction,

$$z = \frac{|S| - 1}{\sqrt{\text{Var}(S)}}$$
For the hypothesis of independence, the statistics $S$, $\tau_a$, and $\tau_b$ produce equivalent tests and give the same $p$-value.

For Kendall’s $\tau$, the normal approximation is surprisingly accurate for sample sizes as small as 8, at least for calculating $p$-values under the null hypothesis for continuous variables. See Kendall and Gibbons [1990, chap. 4], who also present some tables for calculating exact $p$-values for $n < 10$.

Let $v$ be the number of variables specified so that $k = v(v - 1)/2$ correlation coefficients are to be estimated. If bonferroni is specified, the adjusted $p$-value is $p' = \min(1, kp)$. If sidak is specified, $p' = \min\{1, 1 - (1 - p)^n\}$. See Methods and formulas in [R] oneway for a more complete description of the logic behind these adjustments.

Early work on rank correlation is surveyed by Kruskal (1958).

Acknowledgment

The original version of ktau was written by Sean Becketti, author of the Stata Press book Introduction to Time Series Using Stata, Revised Edition.

spikeplot produces a frequency plot for a variable in which the frequencies are depicted as vertical lines from zero. The frequency may be a count, a fraction, or the square root of the count (Tukey’s rootogram, circa 1965). The vertical lines may also originate from a baseline other than zero at the user’s option.

Quick start

Spike plot of v1
spikeplot v1

Same as above, but apply frequency weights wvar
spikeplot v1 [fweight = wvar]

Plot proportions of the total number of observations instead of frequencies
spikeplot v1, fraction

Tukey’s rootogram of v2
spikeplot v2, root

**Add plots**

| `addplot(plot)`           | add other plots to generated graph                                          |

**Y axis, X axis, Titles, Legend, Overall, By**

| `twoway_options`          | any options documented in [G-3] `twoway_options`                           |

`fweights, aweights, and iweights` are allowed; see [U] 11.1.6 `weight`.

### Options

**Main**

- `round(#)` rounds the values of `varname` to the nearest multiple of # (bin width). This action effectively specifies the bin width.

- `fraction` specifies that the vertical scale be the proportion of total values (percentage) rather than the count.

- `root` specifies that the vertical scale show square roots. This option may not be specified if `fraction` is specified.

**Plot**

- `spike_options` affect the rendition of the plotted spikes; see [G-2] `graph twoway spike`.

**Add plots**

- `addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] `addplot_option`.

**Y axis, X axis, Titles, Legend, Overall, By**

- `twoway_options` are any of the options documented in [G-3] `twoway_options`. These include options for titling the graph (see [G-3] `title_options`), options for saving the graph to disk (see [G-3] `saving_option`), and the `by()` option (see [G-3] `by_option`).
Remarks and examples

Example 1

Cox and Brady (1997a) present an illustrative example using the age structure of the population of Ghana from the 1960 census (rounded to the nearest 1,000). The dataset has ages from 0 (less than 1 year) to 90. To view the distribution of ages, we would like to use each integer from 0 to 90 as the bins for the dataset.

```
. use https://www.stata-press.com/data/r18/ghanaage
(Age structure of population of Ghana)
. spikeplot age [fw=pop], ytitle("Population in 1,000s") xlab(0(10)90)
> xmtick(5(10)85)
```

The resulting graph shows a “heaping” of ages at the multiples of 5. Also, ages ending in even numbers are more frequent than ages ending in odd numbers (except for 5). This preference for reporting ages is well known in demography and other social sciences.

Note also that we used the `ytitle()` option to override the default title of “Frequency” and that we used the `xlab()` and `xmtick()` options with `numlist` to further customize the resulting graph. See [U] 11.1.8 `numlist` for details on specifying `numlists`.

Example 2

The rootogram is a plot of the square-root transformation of the frequency counts. The square root of a normal distribution is a multiple of another normal distribution.

```
. clear
. set seed 1234567
. set obs 5000
Number of observations (N) was 0, now 5,000.
. generate normal = rnormal()
. label variable normal "Gaussian(0,1) random numbers"
```
Interpreting a histogram in terms of normality is thus similar to interpreting the rootogram for normality.

This example also shows how the `round()` option is used to bin the values for a spike plot of a continuous variable.
Example 3

Spike plots can also be used to produce time-series plots. `varname` should be the time variable, and weights should be specified as the values for those times. To get a plot of daily rainfalls, we type

```
. spikeplot day [fw=rain] if rain, ytitle("Daily rainfall in mm")
```

The `base()` option of `graph twoway spike` may be used to set a different baseline, such as when we want to show variations relative to an average or to some other measure of level.

Acknowledgments

The original version of `spikeplot` was written by Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* and by Anthony R. Brady founder of Sealed Envelope, London (1997a, 1997b).

[R] `histogram` — Histograms for continuous and categorical variables
Description

`scc` works with packages (and files) from the Statistical Software Components (SSC) Archive, which is often called the Boston College Archive and is provided by http://repec.org.

The SSC has become the premier Stata download site for community-contributed software on the web. `scc` provides a convenient interface to the resources available there. For example, on Statalist (see https://www.statalist.org/), users will often write

The program can be found by typing `scc install newprogramname`.

Typing that would load everything associated with `newprogramname`, including the help files.

If you are searching for what is available, type `scc new` and `scc hot`, and see [R] `search`. `search` searches the SSC and other places, too. `search` provides a GUI interface from which programs can be installed, including the programs at the SSC Archive.

You can uninstall particular packages by using `scc uninstall`. For the packages that you keep, see [R] `ado update` for an automated way of keeping those packages up to date.

Command overview

`scc new` summarizes the packages made available or updated recently. Output is presented in the Stata Viewer, and from there you may click to find out more about individual packages or to install them.

`scc hot` lists the most popular packages—popular based on a moving average of the number of downloads in the past three months. By default, 10 packages are listed.

`scc describe pkgname` describes, but does not install, the specified package. Use `search` to find packages; see [R] `search`. If you know the package name but do not know the exact spelling, type `scc describe` followed by one letter, a–z or _ (underscore), to list all the packages starting with that letter.

`scc install pkgname` installs the specified package. You do not have to describe a package before installing it. (You may also install a package by using `net install`; see [R] `net`.)

`scc uninstall pkgname` removes the previously installed package from your computer. It does not matter how the package was installed. (`scc uninstall` is a synonym for `ado uninstall`, so either may be used to installed any package.)

`scc type filename` types a specific file stored at SSC. `scc cat` is a synonym for `scc type`, which may appeal to those familiar with Unix.

`scc copy filename` copies a specific file stored at SSC to your computer. By default, the file is copied to the current directory, but you can use options to change this. `scc copy` is a rarely used alternative to `scc install ...`, all. `scc cp` is a synonym for `scc copy`. 
Quick start

Describe mycommand at SSC

Options

Options are presented under the following headings:

Options for use with ssc new
Options for use with ssc hot
Option for use with ssc describe
Options for use with ssc install
Option for use with ssc type
Options for use with ssc copy

Options for use with ssc new

saving(filename[, replace]) specifies that the “what’s new” summary be saved in filename. If filename is specified without a suffix, filename.smcl is assumed. If saving() is not specified, saving(ssc_results.smcl) is assumed.

type specifies that the “what’s new” results be displayed in the Results window rather than in the Viewer.

Options for use with ssc hot

n(#) specifies the number of packages to list; n(10) is the default. Specify n(.) to list all packages in order of popularity.

author(name) lists the 10 most popular packages by the specified author. If n(#) is also specified, the top # packages are listed.

Option for use with ssc describe

saving(filename[, replace]) specifies that, in addition to the description’s being displayed on your screen, it be saved in the specified file.

If filename is specified without an extension, .smcl will be assumed, and the file will be saved as a SMCL file.

If filename is specified with an extension, no default extension is added. If the extension is .log, the file will be stored as a text file.

If replace is specified, filename is replaced if it already exists.

Options for use with ssc install

all specifies that any ancillary files associated with the package be downloaded to your current directory, in addition to the program and help files being installed. Ancillary files are files that do not end in .ado or .sthlp and typically contain datasets or examples of the use of the new command.

You can find out which files are associated with the package by typing ssc describe pkgname before or after installing. If you install without using the all option and then want the ancillary files, you can ssc install again.

replace specifies that any files being downloaded that already exist on your computer be replaced by the downloaded files. If replace is not specified and any files already exist, none of the files from the package is downloaded or installed.
It is better not to specify the `replace` option and wait to see if there is a problem. If there is a problem, it is usually better to uninstall the old package by using `ssc uninstall` or `ado uninstall` (which are, in fact, the same command).

**Option for use with `ssc type`**

`asis` affects how files with the suffixes `.smcl` and `.sthlp` are displayed. The default is to interpret SMCL directives the file might contain. `asis` specifies that the file be displayed in raw, uninterpreted form.

**Options for use with `ssc copy`**

`plus` specifies that the file be copied to the PLUS directory, the directory where community-contributed additions are installed. Typing `sysdir` will display the identity of the PLUS directory on your computer; see `[P] sysdir`.

`personal` specifies that the file be copied to your PERSONAL directory as reported by `sysdir`; see `[P] sysdir`.

If neither `plus` nor `personal` is specified, the default is to copy the file to the current directory.

`replace` specifies that, if the file already exists on your computer, the new file replace it.

`public` specifies that the new file be made readable by everyone; otherwise, the file will be created according to the default permission you have set with your operating system.

`binary` specifies that the file being copied is a binary file and that it is to be copied as is. The default is to assume that the file is a text file and change the end-of-line characters to those appropriate for your computer/operating system.

**Remarks and examples**

Users can add new features to Stata, and some users choose to make new features that they have written available to others via the web. The files that comprise a new feature are called a package, and a package usually consists of one or more ado-files and help files. The `net` command (see `[R] net`) makes it reasonably easy to install and uninstall packages regardless of where they are on the web. One site, the SSC, has become particularly popular as a repository for additions to Stata. Command `ssc` is an easier to use version of `net` designed especially for the SSC.

Many packages are available at the SSC. Packages have names, such as `oaxaca`, `estout`, or `egenmore`. At SSC, capitalization is not significant, so `Oaxaca`, `ESTOUT`, and `EGENmore` are ways of writing the same package names.

When you type

```
.ssc install oaxaca
```

the files associated with the package are downloaded and installed on your computer. Package names usually correspond to the names of the command being added to Stata, so one would expect that installing the package `oaxaca` will add command `oaxaca` to Stata on your computer, and expect that typing `help oaxaca` will provide the documentation. That is the situation here, but that is not always so. Before or after installing a package, type `ssc describe pkgname` to obtain the details.
Example 1

ssc new summarizes the packages most recently made available or updated. Output is presented in the Viewer, from which you may click on a package name to find out more or install it. Try it for yourself! Type ssc new in the Command window.

ssc hot provides a list of the most popular packages at SSC.

```
.ssc hot
```

(output omitted)

(Click on package name for description)

**ssc describe pkgname** describes, but does not install, the specified package. You must already know the name of the package. See [R] search for assistance in searching for packages. Sometimes you know the package name, but you do not know the exact spelling. Then, you can type **ssc describe** followed by one letter, a–z or _, to list all the packages starting with that letter; even so, using search is better.

```
.ssc describe i
```

http://fmwww.bc.edu/repec/bocode/i/ (no title)

**PACKAGES you could -net describe-:**

(output omitted)

```
ivreg2     module for extended instrumental variables/2SLS and GMM estimation
ivreg210   module for extended instrumental variables/2SLS and GMM estimation (v10)
ivreg28    module for extended instrumental variables/2SLS and GMM estimation (v8)
ivreg29    module for extended instrumental variables/2SLS and GMM estimation (v9)
ivreg2h    module to perform instrumental variables estimation using heteroskedasticity-based instruments
ivreg2hdfe module to estimate an Instrumental Variable Linear Regression Model with two High Dimensional Fixed Effects
ivreg2m    module to identify treatment-effects estimates with potentially misreported and endogenous program participation
ivreg_ss   module to compute confidence intervals, standard errors, and p-values in an IV regression in which the excluded instrumental variable has a shift-share structure
ivreghdfe  module for extended instrumental variable regressions with multiple levels of fixed effects
ivregress2 module to export first and second-stage results similar to ivregress
```

(output omitted)

(type **ssc describe pkgname** for more information on pkgname)
The default setting for the `saving()` option is for the output to be saved with the `.smcl` extension. You could also save the file with a `log` extension, and in this case, the file would be stored as a text file. For example, we could type

```
    . ssc describe i, saving(i.index)
```
or the following:

```
    . ssc describe ivreg2, saving(ivreg2.log)
```

**ssc install** `pkgname` installs the specified package. You do not have to describe a package before installing it. There are ways of installing packages other than **ssc install**, such as **net**; see [R] **net**. It does not matter how a package is installed. For instance, a package can be installed using **net** and still be uninstalled using **ssc**.

```
    . ssc install ivreg2
    checking ivreg2 consistency and verifying not already installed...
    installing into C:\ado\plus\...
    installation complete.
```

**ssc uninstall** `pkgname` removes the specified, previously installed package from your computer. You can uninstall immediately after installation or at any time in the future. (Technical note: **ssc uninstall** is a synonym for **ado uninstall**, so it can uninstall any installed package, not just packages obtained from the **ssc**.)

```
    . ssc uninstall ivreg2
    package ivreg2 from http://fmwww.bc.edu/repec/bocode/i
    'IVREG2': module for extended instrumental variables/2SLS and GMM
    estimation
    (package uninstalled)
```

**ssc type** `filename` types a specific file stored at the **ssc**. Although not shown in the syntax diagram, **ssc cat** is a synonym for **ssc type**, which may appeal to those familiar with Unix. To view only the `ivreg2` help file from the `ivreg2` package, you would type

```
    . ssc type ivreg2.sthlp
```

```
help for ivreg2

Extended instrumental variables/2SLS, GMM and AC/HAC, LIML and k-class regression

Full syntax
(output omitted)
```

**ssc copy** `filename` copies a specific file stored at the **ssc** to your computer. By default, the file is copied to the current directory, but you can use options to change this. **ssc copy** is a rarely used alternative to **ssc install**..., all. **ssc cp** is a synonym for **ssc copy**.

```
    . ssc copy ivreg2.ado
    (file ivreg2.ado copied to current directory)
```

For more details on the **ssc** Archive and for information on how to submit your own programs to the **ssc**, see [http://repec.org/bocode/s/sscs股本mit.html](http://repec.org/bocode/s/sscs股本mit.html).
Acknowledgments

ssc is based on archutil by Nicholas J. Cox of the Department of Geography at Durham University, UK, who is coeditor of the Stata Journal and author of Speaking Stata Graphics and by Christopher F. Baum of the Department of Economics at Boston College and author of the Stata Press books An Introduction to Modern Econometrics Using Stata and An Introduction to Stata Programming and coauthor of the Stata Press book Environmental Econometrics Using Stata. The reworking of the original was done with their blessing and their participation.

Baum maintains the Stata-related files stored at the SSC Archive. We thank him for this contribution to the Stata community.

stem displays stem-and-leaf plots.

Quick start

Stem-and-leaf plot for v1
stem v1

Same as above, with 2 lines per interval of 10
stem v1, lines(2)

Specify that each stem has a width of 5 (equivalent to above)
stem v1, width(5)

Stem-and-leaf plot for v2 with an interval of 100
stem v2, digits(2)

Same as above, with 4 lines per interval of 100
stem v2, digits(2) lines(4)

Display v2 rounded to the nearest hundred
stem v2, round(100)

Do not display empty stems
stem v2, prune

</tr>
</tbody>
</table>

by and collect are allowed; see [U] 11.1.10 Prefix commands.

Options

prune prevents printing any stems that have no leaves.

round(#) rounds the data to this value and displays the plot in these units. If round() is not specified, noninteger data will be rounded automatically.

truncate(#) truncates the data to this value and displays the plot in these units.

digits(#) sets the number of digits per leaf. The default is 1.

lines(#) sets the number of stems per every data interval of 10$^{\text{digits}}$. The value of lines() must divide 10$^{\text{digits}}$; that is, if digits(1) is specified, then lines() must divide 10. If digits(2) is specified, then lines() must divide 100, etc. Only one of lines() or width() may be specified. If neither is specified, an appropriate value will be set automatically.

width(#) sets the width of a stem. lines() is equal to 10$^{\text{digits}}$/width, and this option is merely an alternative way of setting lines(). The value of width() must divide 10$^{\text{digits}}$. Only one of width() or lines() may be specified. If neither is specified, an appropriate value will be set automatically.

Note: If lines() or width() is not specified, digits() may be decreased in some circumstances to make a better-looking plot. If lines() or width() is set, the user-specified value of digits() will not be altered.

Remarks and examples

Example 1

Stem-and-leaf displays are a compact way to present considerable information about a batch of data. For instance, using our automobile data (described in [U] 1.2.2 Example datasets):
The stem-and-leaf display provides a way to list our data. The expression to the left of the vertical bar is called the stem; the digits to the right are called the leaves. All the stems that begin with the same digit and the corresponding leaves, written beside each other, reconstruct an observation of the data. Thus, if we look at the four stems that begin with the digit 1 and their corresponding leaves, we see that we have two cars rated at 12 mpg, 6 cars at 14, 2 at 15, and so on. The car with the highest mileage rating in our data is rated at 41 mpg.

The above plot is a five-line plot with `lines()` equal to 5 (five lines per interval of 10) and `width()` equal to 2 (two leaves per stem).

Instead, we could specify `lines(2)`:  

```
. stem mpg, lines(2)
```

```
Stem-and-leaf plot for mpg (Mileage (mpg))
1*  22
1f  4444455
1s  66667777
1.  88888888899999999
2*  00011111
2t  22222333
2f  444455555
2s  666
2.  8889
3*  001
3t
3f  455
3s
3.
4*  1
```

`stem mpg, width(5)` would produce the same plot as above.
The stem-and-leaf display provides a crude histogram of our data, one not so pretty as that produced by *histogram* (see [R] *histogram*), but one that is nonetheless informative.

**Example 2**

The miles per gallon rating fits easily into a stem-and-leaf display because, in our data, it has two digits. However, *stem* does not require two digits.

```
. stem price, lines(1) digits(3)

Stem-and-leaf plot for price (Price)

3*** 291,299,667,748,798,799,829,895,955,984,995
4*** 010,060,082,099,172,181,187,195,296,389,424,425,453,482,499, ... (26)
5*** 079,104,172,189,222,379,397,705,719,788,798,799,886,899
6*** 165,229,295,303,342,486,850
7*** 140,827
8*** 129,814
9*** 690,735
10*** 371,372
11*** 385,497,995
12*** 990
13*** 466,594
14*** 500
15*** 906
```

The (26) at the right of the second stem shows that there were 26 leaves on this stem—too many to display on one line.

We can make a more compact stem-and-leaf plot by rounding. To display *stem* in units of 100, we could type

```
. stem price, round(100)

Stem-and-leaf plot for price (Price)

price rounded to nearest multiple of 100
plot in units of 100

3* 3377889
4* 000011122223444555555667777899
5* 112224477888899
6* 2233359
7* 18
8* 18
9* 77
10* 44
11* 45
12* 0
13* 056
14* 5
15* 9
```

*price*, in our data, has four or five digits. *stem* presented the display in terms of units of 100, so a car that cost $3,291 was treated for display purposes as $3,300.
Technical note

Stem-and-leaf diagrams have been used in Japanese railway timetables, as shown in Tufte (1990, 46–47).

Stored results

stem stores the following in r():

Scalars

\[ r(width) \] \quad \text{width of a stem}

\[ r(digits) \] \quad \text{number of digits per leaf; default is 1}

Macros

\[ r(round) \] \quad \text{number specified in round()}

\[ r(truncate) \] \quad \text{number specified in truncate()}

Description

stepwise performs stepwise estimation. Typing

   . stepwise, pr(#) : command

performs backward-selection estimation for command. The stepwise selection method is determined by the following option combinations:

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr(#)</td>
<td>backward selection</td>
</tr>
<tr>
<td>pr(#) hierarchical</td>
<td>backward hierarchical selection</td>
</tr>
<tr>
<td>pr(#) pe(#)</td>
<td>backward stepwise</td>
</tr>
<tr>
<td>pe(#)</td>
<td>forward selection</td>
</tr>
<tr>
<td>pe(#) hierarchical</td>
<td>forward hierarchical selection</td>
</tr>
<tr>
<td>pr(#) pe(#) forward</td>
<td>forward stepwise</td>
</tr>
</tbody>
</table>

command defines the estimation command to be executed. The following Stata commands are supported by stepwise:

   betareg, clogit, cloglog, glm, intreg, logistic, logit, nbreg, 
   ologit, oprobit, poisson, probit, qreg, regress, scobit, stcox, 
   stcrreg, stintreg, streg, tobit

stepwise expects command to have the following form:

   command_name [ depvar ] term [ term ... ] [ if ] [ in ] [ weight ] [ , command_options ]

where term is either varname or (varlist) (a varlist in parentheses indicates that this group of variables is to be included or excluded together). depvar is not present when command_name is stcox, stcrreg, stintreg, or streg; otherwise, depvar is assumed to be present. For intreg, depvar is actually two dependent variable names (depvar1 and depvar2).

sw is a synonym for stepwise.

For model selection and estimation using lasso, see the Stata Lasso Reference Manual.
Quick start

Backward selection, removing terms with $p \geq 0.2$

```
stepwise, pr(.2): regress y x1 x2 x3 x4
```

Same as above, and select from the indicators for categorical variable a

```
stepwise, pr(.2): regress y x1 x2 x3 x4 i.a
```

Same as above, but force x1 to be included in model

```
stepwise, pr(.2) lockterm1: regress y x1 x2 x3 x4 i.a
```

Consider the indicators for a as a group for inclusion in model

```
stepwise, pr(.2): regress y x1 x2 x3 x4 (i.a)
```

Add d1, d2, and d3, and force them to be included in model

```
stepwise, pr(.2) lockterm1: regress y (d1 d2 d3) x1 x2 x3 x4 (i.a)
```

Forward selection, adding terms with $p < 0.1$

```
stepwise, pe(.1): regress y x1 x2 x3 x4
```

Backward stepwise selection, removing terms with $p \geq 0.2$ and adding those with $p < 0.1$

```
stepwise, pr(.2) pe(.1): regress y x1 x2 x3 x4
```

Forward stepwise selection, adding terms with $p < 0.1$ and removing those with $p \geq 0.2$

```
stepwise, pr(.2) pe(.1) forward: regress y x1 x2 x3 x4
```

Backward hierarchical selection

```
stepwise, pr(.2) hierarchical: regress y x1 x2 x3 x4
```

Forward hierarchical selection

```
stepwise, pe(.1) hierarchical: regress y x1 x2 x3 x4
```

Note: In the above examples, `regress` could be replaced with any estimation command allowing the `stepwise` prefix.

Menu

</tr>
<tr>
<td><code>forward</code></td>
</tr>
<tr>
<td><code>hierarchical</code></td>
</tr>
<tr>
<td><code>lockterm1</code></td>
</tr>
<tr>
<td><code>lr</code></td>
</tr>
<tr>
<td>Reporting</td>
</tr>
<tr>
<td><code>display_options</code></td>
</tr>
</tbody>
</table>

*At least one of `pr(#)` or `pe(#)` must be specified.*

by is allowed; see [U] 11.1.10 Prefix commands.

Weights are allowed if `command` allows them; see [U] 11.1.6 weight.

All postestimation commands behave as they would after `command` without the `stepwise` prefix; see the postestimation manual entry for `command`.

Options

**Model**

- `pr(#)` specifies the significance level for removal from the model; terms with $p \geq pr()$ are eligible for removal.
- `pe(#)` specifies the significance level for addition to the model; terms with $p < pe()$ are eligible for addition.

**Model 2**

- `forward` specifies the forward-stepwise method and may be specified only when both `pr()` and `pe()` are also specified. Specifying both `pr()` and `pe()` without `forward` results in backward-stepwise selection. Specifying only `pr()` results in backward selection, and specifying only `pe()` results in forward selection.
- `hierarchical` specifies hierarchical selection.
- `lockterm1` specifies that the first term be included in the model and not be subjected to the selection criteria.
- `lr` specifies that the test of term significance be the likelihood-ratio test. The default is the less computationally expensive Wald test; that is, the test is based on the estimated variance–covariance matrix of the estimators.

**Reporting**

- `display_options`: `noci`, `nopvalues`, `cformat(\%fmt)`, `pformat(\%fmt)`, `sformat(\%fmt)`, and `nolstretch`; see [R] Estimation options.

Programming for stepwise

Introduction

Typing

`. stepwise, pr(.10): regress y1 x1 x2 d1 d2 d3 x4 x5`

performs a backward-selection search for the regression model $y_1$ on $x_1$, $x_2$, $d_1$, $d_2$, $d_3$, $x_4$, and $x_5$. In this search, each explanatory variable is said to be a term. Typing

`. stepwise, pr(.10): regress y1 x1 x2 (d1 d2 d3) (x4 x5)`

operforms a similar backward-selection search, but the variables $d_1$, $d_2$, and $d_3$ are treated as one term, as are $x_4$ and $x_5$. That is, $d_1$, $d_2$, and $d_3$ may or may not appear in the final model, but they appear or do not appear together.

Example 1

Using the automobile dataset, we fit a backward-selection model of mpg:

`. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)`

`. stepwise, pr(.2): regress mpg c.weight##c.weight displ gear turn headroom > i.foreign price
note: 0b.foreign omitted because of estimability.
Wald test, begin with full model:
p = 0.7116 >= 0.2000, removing headroom
p = 0.6138 >= 0.2000, removing displacement
p = 0.3278 >= 0.2000, removing price

| weight | -.0158002   | .0039169  | -4.03 | 0.000 | -.0236162 -.0079842 |
| c.weight##c.weight | 1.77e-06 | 6.20e-07 | 2.86 | 0.006 | 5.37e-07 3.01e-06 |
| foreign | -3.615107 | 1.260844 | -2.87 | 0.006 | -6.131082 -1.099131 |
| gear_ratio | 2.011674 | 1.468831 | 1.37 | 0.175 | -.9193321 4.94268 |
| turn | -.3087038 | .1763099 | -1.75 | 0.084 | -.6605248 .0431172 |
| _cons | 59.02133 | 9.3903 | 6.29 | 0.000 | 40.28327 77.75938 |
This estimation treated each variable as its own term and thus considered each one separately. The engine displacement and gear ratio should really be considered together:

```
.stepwise, pr(.2): regress mpg c.weight##c.weight (displ gear) turn headroom
   > i.foreign price
note: 0b.foreign omitted because of estimability.
```

Wald test, begin with full model:
p = 0.7116 >= 0.2000, removing headroom
p = 0.3944 >= 0.2000, removing displacement gear_ratio
p = 0.2798 >= 0.2000, removing price

**Search logic for a step**

Before discussing the complete search logic, consider the logic for a step—the first step—in detail. The other steps follow the same logic. If you type

```
.stepwise, pr(.20): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the logic is

1. Fit the model y on x1 x2 d1 d2 d3 x4 x5.
2. Consider dropping x1.
3. Consider dropping x2.
4. Consider dropping d1 d2 d3.
5. Consider dropping x4 x5.
6. Find the term above that is least significant. If its significance level is \( \geq 0.20 \), remove that term.

If you type

```
.stepwise, pr(.20) hierarchical: regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the logic would be different because the hierarchical option states that the terms are ordered. The initial logic would become

1. Fit the model y on x1 x2 d1 d2 d3 x4 x5.
2. Consider dropping x4 x5—the last term.
3. If the significance of this last term is \( \geq 0.20 \), remove the term.
The process would then stop or continue. It would stop if \( x_4 \) \( x_5 \) were not omitted, and otherwise, \texttt{stepwise} would continue to consider the significance of the next-to-last term, \( d_1 \) \( d_2 \) \( d_3 \).

Specifying \texttt{pe()} rather than \texttt{pr()} switches to forward estimation. If you type

\begin{verbatim}
   . stepwise, pe(.20): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
\end{verbatim}

\texttt{stepwise} performs forward-selection search. The logic for the first step is

1. Fit a model of \( y \) on nothing (meaning a constant).
2. Consider adding \( x_1 \).
3. Consider adding \( x_2 \).
4. Consider adding \( d_1 \) \( d_2 \) \( d_3 \).
5. Consider adding \( x_4 \) \( x_5 \).
6. Find the term above that is most significant. If its significance level is \( < 0.20 \), add that term.

As with backward estimation, if you specify \texttt{hierarchical},

\begin{verbatim}
   . stepwise, pe(.20) hierarchical: regress y1 x1 x2 (d1 d2 d3) (x4 x5)
\end{verbatim}

the search for the most significant term is restricted to the next term:

1. Fit a model of \( y \) on nothing (meaning a constant).
2. Consider adding \( x_1 \)—the first term.
3. If the significance is \( < 0.20 \), add the term.

If \( x_1 \) were added, \texttt{stepwise} would next consider \( x_2 \); otherwise, the search process would stop.

\texttt{stepwise} can also use a stepwise selection logic that alternates between adding and removing terms. The full logic for all the possibilities is given below.
## Full search logic

<table>
<thead>
<tr>
<th>Option</th>
<th>Logic</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr() (backward selection)</td>
<td>Fit the full model on all explanatory variables. While the least-significant term is “insignificant”, remove it and reestimate.</td>
</tr>
<tr>
<td>pr() hierarchical (backward hierarchical selection)</td>
<td>Fit full model on all explanatory variables. While the last term is “insignificant”, remove it and reestimate.</td>
</tr>
<tr>
<td>pr() pe() (backward stepwise)</td>
<td>Fit full model on all explanatory variables. If the least-significant term is “insignificant”, remove it and reestimate; otherwise, stop. Do that again: if the least-significant term is “insignificant”, remove it and reestimate; otherwise, stop. Repeatedly, if the most-significant excluded term is “significant”, add it and reestimate; if the least-significant included term is “insignificant”, remove it and reestimate; until neither is possible.</td>
</tr>
<tr>
<td>pe() (forward selection)</td>
<td>Fit “empty” model. While the most-significant excluded term is “significant”, add it and reestimate.</td>
</tr>
<tr>
<td>pe() hierarchical (forward hierarchical selection)</td>
<td>Fit “empty” model. While the next term is “significant”, add it and reestimate.</td>
</tr>
<tr>
<td>pr() pe() forward (forward stepwise)</td>
<td>Fit “empty” model. If the most-significant excluded term is “significant”, add it and reestimate; otherwise, stop. Do that again: if the most-significant excluded term is “significant”, add it and reestimate; otherwise, stop. Repeatedly, if the least-significant included term is “insignificant”, remove it and reestimate; if the most-significant excluded term is “significant”, add it and reestimate; until neither is possible.</td>
</tr>
</tbody>
</table>
Examples

The following two statements are equivalent; both include solely single-variable terms:

```
    . stepwise, pr(.2): regress price mpg weight displ
    . stepwise, pr(.2): regress price (mpg) (weight) (displ)
```

The following two statements are equivalent; the last term in each is r1, ..., r4:

```
    . stepwise, pr(.2) hierarchical: regress price mpg weight displ (r1-r4)
    . stepwise, pr(.2) hierarchical: regress price (mpg) (weight) (displ) (r1-r4)
```

To group variables weight and displ into one term, type

```
    . stepwise, pr(.2) hierarchical: regress price mpg (weight displ) (r1-r4)
```

*stepwise* can be used with commands other than *regress*; for instance,

```
    . stepwise, pr(.2): logit outcome (sex weight) treated1 treated2
    . stepwise, pr(.2): logistic outcome (sex weight) treated1 treated2
```

Either statement would fit the same model because *logistic* and *logit* both perform logistic regression; they differ only in how they report results; see [R] *logit* and [R] *logistic*.

We use the *lockterm1* option to force the first term to be included in the model. To keep treated1 and treated2 in the model no matter what, we type

```
    . stepwise, pr(.2) lockterm1: logistic outcome (treated1 treated2) ...
```

After *stepwise* estimation, we can type *stepwise* without arguments to redisplay results,

```
    . stepwise
    (output from logistic appears)
```

or type the underlying estimation command:

```
    . logistic
    (output from logistic appears)
```

At estimation time, we can specify options unique to the command being stepped:

```
    . stepwise, pr(.2): logit outcome (sex weight) treated1 treated2, or
```

or is *logit*’s option to report odds ratios rather than coefficients; see [R] *logit*.

Estimation sample considerations

Whether you use backward or forward estimation, *stepwise* forms an estimation sample by taking observations with nonmissing values of all the variables specified (except for *depvar1* and *depvar2* for *intreg*). The estimation sample is held constant throughout the stepping. Thus, if you type

```
    . stepwise, pr(.2) hierarchical: regress amount sk edul sval
```

and variable sval is missing in half the data, that half of the data will not be used in the reported model, even if sval is not included in the final model.

The function *e(sample)* identifies the sample that was used. *e(sample)* contains 1 for observations used and 0 otherwise. For instance, if you type

```
    . stepwise, pr(.2) pe(.10): logistic outcome x1 x2 (x3 x4) (x5 x6 x7)
```
and the final model is outcome on x1, x5, x6, and x7, you could re-create the final regression by typing

```
.logistic outcome x1 x5 x6 x7 if e(sample)
```

You could obtain summary statistics within the estimation sample of the independent variables by typing

```
.summarize x1 x5 x6 x7 if e(sample)
```

If you fit another model, e(sample) will automatically be redefined. Typing

```
.stepwise, lock pr(.2): logistic outcome (x1 x2) (x3 x4) (x5 x6 x7)
```

would automatically drop e(sample) and re-create it.

### Messages

**note: ______ omitted because of estimability.**

This indicates that a variable was omitted because its coefficient could not be estimated. This message is most commonly issued because the variable is collinear with other variables in the model. For instance, say that you type

```
.stepwise, pr(.2): regress y x1 x2 x3 x4
```

and x2 is collinear with x3, one of these variables will automatically be omitted. If you type

```
.stepwise, pr(.2): regress y x1 x2 i.a
```

and include indicators for factor variable a in your model, the set of indicators for a are perfectly collinear, and one will be omitted with the note indicating that it was omitted because of estimability.

**note: ______ omitted because of estimability.**

You probably received this message in fitting a logistic or probit model. Regardless of estimation strategy, stepwise checks that the full model can be fit. The indicated variable had a 0 or infinite standard error.

For logistic, logit, and probit, this message is typically caused by one-way causation. Assume that you type

```
.stepwise, pr(.2): logistic outcome (x1 x2 x3) d1
```

and assume that variable d1 is an indicator (dummy) variable. Further assume that whenever d1 = 1, outcome = 1 in the data. Then the coefficient on d1 is infinite. One (conservative) solution to this problem is to drop the d1 variable and the d1==1 observations. The underlying estimation commands probit, logit, and logistic report the details of the difficulty and solution; stepwise simply accumulates such problems and reports the above summary messages. Thus, if you see this message, you could type

```
.logistic outcome x1 x2 x3 d1
```

to see the details. Although you should think carefully about such situations, Stata’s solution of dropping the offending variables and observations is, in general, appropriate.
Programming for stepwise

`stepwise` requires that `command_name` follow standard Stata syntax and allow the `if` qualifier; see [U] 11 Language syntax. Furthermore, `command_name` must have `sw` or `swml` as a program property; see [P] program properties. If `command_name` has `swml` as a property, `command_name` must store the log-likelihood value in `e(ll)` and model degrees of freedom in `e(df_m)`.

Stored results

`stepwise` stores whatever is stored by the underlying estimation command.

Also, `stepwise` stores `stepwise` in `e(stepwise)`.

Methods and formulas

Some statisticians do not recommend stepwise procedures; see Sribney (1998) for a summary.

[R] nestreg — Nested model statistics

[LASSO] Lasso intro — Introduction to lasso
Description

Results of calculations are stored by many Stata commands so that they can be easily accessed and substituted into later commands.

`return list` lists results stored in `r()`.

`ereturn list` lists results stored in `e()`.

`sreturn list` lists results stored in `s()`.

This entry discusses using stored results. Programmers wishing to store results should see [P] return and [P] ereturn.

Syntax

[List results from general commands, stored in r()]

`return list [ , all]`

[List results from estimation commands, stored in e()]

`ereturn list [ , all]`

[List results from parsing commands, stored in s()]

`sreturn list`

Option

`all` is for use with `return list` and `ereturn list`. `all` specifies that hidden and historical stored results be listed along with the usual stored results. This option is seldom used. See Using hidden and historical stored results and Programming hidden and historical stored results under Remarks and examples of [P] return for more information. These sections are written in terms of `return list`, but everything said there applies equally to `ereturn list`.

`all` is not allowed with `sreturn list` because `s()` does not allow hidden or historical results.

Remarks and examples

Stata commands are classified as being

- **r-class**: general commands that store results in `r()`
- **e-class**: estimation commands that store results in `e()`
- **s-class**: parsing commands that store results in `s()`
- **n-class**: commands that do not store in `r()`, `e()`, or `s()`
There is also a c-class, c(), containing the values of system parameters and settings, along with certain constants, such as the value of pi; see [P] creturn. A program, however, cannot be c-class.

You can look at the Stored results section of the manual entry of a command to determine whether it is r-, e-, s-, or n-class, but it is easy enough to guess.

Commands producing statistical results are either r-class or e-class. They are e-class if they present estimation results and r-class otherwise. s-class is a class used by programmers and is primarily used in subprograms performing parsing. n-class commands explicitly state where the result is to go. For instance, generate and replace are n-class because their syntax is generate varname = ... and replace varname = ....

After executing a command, you can type return list, ereturn list, or sreturn list to see what has been stored.

Example 1

. use https://www.stata-press.com/data/r18/auto4
(1978 automobile data)
. describe
Contains data from https://www.stata-press.com/data/r18/auto4.dta
Observations: 74 1978 automobile data
Variables: 6 6 Apr 2022 00:20

<table>

Sorted by: . return list

scalars:
   r(changed) = 0
   r(width) = 25
   r(k) = 6
   r(N) = 74

macros:
   r(datalabel) : "1978 automobile data"

To view all stored results, including those that are historical or hidden, specify the all option.

. return list, all

scalars:
   r(changed) = 0
   r(width) = 25
   r(k) = 6
   r(N) = 74

macros:
   r(datalabel) : "1978 automobile data"

Historical; used before Stata 12, may exist only under version control

scalars:
   r(widthmax) = 1048576
   r(k_max) = 5000
   r(N_max) = 2147483619
r(widthmax), r(k_max), and r(N_max) are historical stored results. They are no longer relevant because Stata dynamically adjusts memory beginning with Stata 12.

Technical note

In the above example, we stated that r(widthmax) and r(N_max) are no longer relevant. In fact, they are not useful. Stata no longer has a fixed memory size, so the methods used to calculate r(widthmax) and r(N_max) are no longer appropriate.

Example 2

You can use stored results in expressions.

```stata
. summarize mpg
Variable | Obs  Mean Std. dev.    Min   Max
---------|------|-------|-----------|------|------|
    mpg   |  74  21.30  5.785503  12.00  41.00

. return list
scalars:
    r(N) = 74
    r(sum_w) = 74
    r(mean) = 21.2973038101513
    r(Var) = 33.4720473898556
    r(sd) =  5.785503209735141
    r(min) =  12
    r(max) =  41
    r(sum) = 1576

. generate double mpgstd = (mpg-r(mean))/r(sd)
. summarize mpgstd
Variable | Obs  Mean Std. dev.  Min  Max
---------|------|-------|--------|------|------|
    mpgstd|  74  -1.64e-16  1.000000 -1.606999  3.40553
```

Be careful to use results stored in r() soon because they will be replaced the next time you execute another r-class command. For instance, although r(mean) was 21.3 (approximately) after `summarize mpg`, it is -1.64e–16 now because you just ran `summarize` with `mpgstd`. 
Example 3

e-class is really no different from r-class, except for where results are stored and that, when an estimation command stores results, it tends to store a lot of them:

```
. regress mpg weight length
(output omitted)
. ereturn list

scalars:
  e(N) = 74
  e(df_m) = 2
  e(df_r) = 71
  e(F) = 69.34050004300227
  e(r2) = .6613903979336323
  e(rmse) = 3.413681741382589
  e(mss) = 1616.08062422659
  e(rss) = 827.3788352328695
  e(r2_a) = .6518520992838754
  e(ll) = -194.3267619410807
  e(ll_0) = -234.3943376482347
  e(rank) = 3

macros:
  e(cmdline) : "regress mpg weight length"
  e(title) : "Linear regression"
  e(marginsok) : "XB default"
  e(vce) : "ols"
  e(depvar) : "mpg"
  e(cmd) : "regress"
  e(properties) : "b V"
  e(predict) : "regres_p"
  e(model) : "ols"
  e(estat_cmd) : "regress_estat"

matrices:
  e(b) : 1 x 3
  e(V) : 3 x 3
  e(beta) : 1 x 2

functions:
  e(sample)
```

These e-class results will stick around until you run another estimation command. Typing `return list` and `ereturn list` is the easy way to find out what a command stores.

Both r- and e-class results come in four types: scalars, macros, matrices, and functions. (s-class results come in only one type—macros—and as earlier noted, s-class is used solely by programmers, so ignore it.)

Scalars are just that—numbers by any other name. You can subsequently refer to `r(mean)` or `e(rmse)` in numeric expressions and obtain the result to full precision.

Macros are strings. For instance, `e(depvar)` contains “mpg”. You can refer to it, too, in subsequent expressions, but really that would be of most use to programmers, who will refer to it using constructs like "'e(depvar)'". In any case, macros are macros, and you obtain their contents just as you would a local macro, by enclosing their name in single quotes. The name here is the full name, so ‘e(depvar)’ is mpg.

Matrices are matrices, and all estimation commands store `e(b)` and `e(V)` containing the coefficient vector and variance–covariance matrix of the estimates (VCE).
Functions are stored by e-class commands only, and the only function existing is `e(sample)`. `e(sample)` evaluates to 1 (meaning true) if the observation was used in the previous estimation and to 0 (meaning false) otherwise.

**Technical note**

Say that some command set `r(scalar)` and `r(macro)`, the first being stored as a scalar and the second as a macro. In theory, in subsequent use you are supposed to refer to `r(scalar)` and `'r(macro)'`. In fact, however, you can refer to either one with or without quotes, so you could refer to `'r(scalar)'` and `r(macro)`. Programmers sometimes do this.

When you refer to `r(scalar)`, you are referring to the full double-precision stored result. Think of `r(scalar)` without quotes as a function returning the value of the stored result `scalar`. When you refer to `r(scalar)` in quotes, Stata understands `'r(scalar)'` to mean “substitute the printed result of evaluating `r(scalar)`”. Pretend that `r(scalar)` equals the number 23. Then, `'r(scalar)'` is 23, the character 2 followed by 3.

Referring to `r(scalar)` in quotes is sometimes useful. Say that you want to use the immediate command `cii` with `r(scalar)`. The immediate command `cii` requires its arguments to be numbers—numeric literals in programmer’s jargon—and it will not take an expression. Thus, you could not type `cii r(scalar) ...`. You could, however, type `cii 'r(scalar)' ...` because `'r(scalar)'` is just a numeric literal.

For `r(macro)`, you are supposed to refer to it in quotes: `'r(macro)'`. If, however, you omit the quotes in an expression context, Stata evaluates the macro and then pretends that it is the result of function-returning-string. There are side effects of this, the most important being that the result is trimmed to 80 characters.

Referring to `r(macro)` without quotes is never a good idea; the feature was included merely for completeness.

You can even refer to `r(matrix)` in quotes (assume that `r(matrix)` is a matrix). `'r(matrix)'` does not result in the matrix being substituted; it returns the word `matrix`. Programmers sometimes find that useful.

[P] ereturn — Post the estimation results

[P] return — Return stored results

[U] 18.8 Accessing results calculated by other programs

[U] 18.9 Accessing results calculated by estimation commands
suest — Seemingly unrelated estimation

Description

suest is a postestimation command; see [U] 20 Estimation and postestimation commands.

suest combines the estimation results—parameter estimates and associated (co)variance matrices—stored under namelist into one parameter vector and simultaneous (co)variance matrix of the sandwich/robust type. This (co)variance matrix is appropriate even if the estimates were obtained on the same or on overlapping data.

Typical applications of suest are tests for intramodel and cross-model hypotheses using test or testnl, for example, a generalized Hausman specification test. lincom and nlcom may be used after suest to estimate linear combinations and nonlinear functions of coefficients. suest may also be used to adjust a standard VCE for clustering or survey design effects.

Different estimators are allowed, for example, a regress model and a probit model; the only requirement is that predict produce equation-level scores with the score option after an estimation command. The models may be estimated on different samples, due either to explicit if or in selection or to missing values. If weights are applied, the same weights (type and values) should be applied to all models in namelist. The estimators should be estimated without vce(robust) or vce(cluster clustvar) options. suest returns the robust VCE, allows the vce(cluster clustvar) option, and automatically works with results from the svy prefix command (only for vce(linearized)). See example 8 in [SVY] svy postestimation for an example using suest with svy: ologit.

Because suest posts its results like a proper estimation command, its results can be stored via estimates store. Moreover, like other estimation commands, suest typed without arguments replays the results.

Quick start

Combined results for stored estimates m1 and m2

suest m1 m2

Same as above, but report exponentiated coefficients and label them “Odds ratio”

suest m1 m2, eform(Odds ratio)

With cluster–robust standard errors adjusting for clustering by levels of cvar

suest m1 m2, vce(cluster cvar)

Use svyset data after specifying command prefix svy: to estimate m1 and m2

suest m1 m2
Syntax

```
suest namelist [, options]
```

where `namelist` is a list of one or more names under which estimation results were stored via `estimates store`; see `[R] estimates store`. Wildcards may be used. * and _all refer to all stored results. A period (.) may be used to refer to the last estimation results, even if they have not (yet) been stored.

`collect` is allowed; see `[U] 11.1.10 Prefix commands.`

`coeflegend` does not appear in the dialog box.

### Options

#### SE/Robust

- `svy` specifies that estimation results should be modified to reflect the survey design effects according to the `svyset` specifications, see `[SVY] svyset.`

  The `svy` option is implied when `suest` encounters survey estimation results from the `svy` prefix; see `[SVY] svy`. Poststratification is allowed only with survey estimation results from the `svy` prefix.

- `vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`) and that allow for intragroup correlation (`cluster clustvar`); see `[R] vce_option`.

  The `vce()` option may not be combined with the `svy` option or estimation results from the `svy` prefix.

#### Reporting

- `level(#)` specifies the confidence level, as a percentage, for confidence intervals of the coefficients; see `[R] level.`

- `collect` is allowed; see `[U] 11.1.10 Prefix commands.`

  `collect` is implied when `suest` encounters survey estimation results from the `svy` prefix; see `[SVY] svy`. Poststratification is allowed only with survey estimation results from the `svy` prefix.
dir displays a table describing the models in namelist just like estimates dir namelist.

eform(string) displays the coefficient table in exponentiated form: for each coefficient, \( \exp(b) \) rather than \( b \) is displayed, and standard errors and confidence intervals are transformed. string is the table header that will be displayed above the transformed coefficients and must be 11 characters or fewer, for example, eform("Odds ratio").

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

The following option is available with suest but is not shown in the dialog box: coeflegend; see [R] Estimation options.

Remarks and examples

Remarks are presented under the following headings:

Using suest
Remarks on regress
Testing the assumption of the independence of irrelevant alternatives
Testing proportionality
Testing cross-model hypotheses

Using suest

If you plan to use suest, you must take precautions when fitting the original models. These restrictions are relaxed when using svy commands; see [SVY] svy postestimation.

1. suest works with estimation commands that allow predict to generate equation-level score variables when supplied with the score (or scores) option. For example, equation-level score variables are generated after running mlogit by typing

   . predict sc*, scores

   To ensure that suest generates the appropriate scores and therefore an appropriate VCE, you should not modify the values of the variables used in the models in between fitting the models and using suest.

2. Estimation should take place without the vce(robust) or vce(cluster clustvar) option. suest always computes the robust estimator of the (co)variance, and suest has a vce(cluster clustvar) option.

   The within-model covariance matrices computed by suest are identical to those obtained by specifying a vce(robust) or vce(cluster clustvar) option during estimation. suest, however, also estimates the between-model covariances of parameter estimates.

3. Finally, the estimation results to be combined should be stored by estimates store; see [R] estimates store.

   After estimating and storing a series of estimation results, you are ready to combine the estimation results with suest,

   . suest name1 [ name2 ... ] [, vce(cluster clustvar)]
and you can subsequently use postestimation commands, such as \texttt{test}, to test hypotheses. Here an important issue is how \texttt{suest} assigns names to the equations. If you specify one model \textit{name}, the original equation names are left unchanged; otherwise, \texttt{suest} constructs new equation names. The coefficients of a single-equation model (such as \texttt{logit} and \texttt{poisson}) that was \texttt{est}imated \texttt{store}d under name \texttt{X} are collected under equation \texttt{X}. With a multiequation model stored under name \texttt{X}, \texttt{suest} prefixes \texttt{X} to an original equation name \textit{eq}, forming equation name, \texttt{X}eq.

\begin{itemize}
  \item \textbf{Technical note}

  Earlier we said that standard errors from \texttt{suest} are identical to those obtained by specifying the \texttt{vce(robust)} option with each command individually. Thus if you fit a logistic model using \texttt{logit} with the \texttt{vce(robust)} option, you will get the same standard errors when you type

  \begin{verbatim}
  . suest .
  \end{verbatim}

  directly after \texttt{logit} using the same data without the \texttt{vce(robust)} option.

  This is not true for multiple estimation results when the estimation samples are not all the same. The standard errors from \texttt{suest} will be slightly smaller than those from individual model fits using the \texttt{vce(robust)} option because \texttt{suest} uses a larger number of observations to estimate the simultaneous (co)variance matrix.

  \item \textbf{Technical note}

  In rare circumstances, \texttt{suest} may have to truncate equation names to 32 characters. When equation names are not unique because of truncation, \texttt{suest} numbers the equations within models, using equations named \texttt{X}\#.  

\end{itemize}

\section*{Remarks on \texttt{regress}}

\texttt{regress} (see \cite[R]{regress}) does not include its ancillary parameter, the residual variance, in its coefficient vector and (co)variance matrix. Moreover, while the \texttt{score} option is allowed with \texttt{predict} after \texttt{regress}, a score variable is generated for the mean but not for the variance parameter. \texttt{suest} contains special code that assigns the equation name \texttt{mean} to the coefficients for the mean, adds the equation \texttt{lnvar} for the log variance, and computes the appropriate two score variables itself.

\section*{Testing the assumption of the independence of irrelevant alternatives}

The multinomial logit model and the closely related conditional logit model satisfy a probabilistic version of the assumption of the independence of irrelevant alternatives (IIA), implying that the ratio of the probabilities for two alternatives does not depend on what other alternatives are available. \citet{Hausman:1984} proposed a test for this assumption that is implemented in the \texttt{hausman} command. The standard Hausman test has several limitations. First, the test statistic may be undefined because the estimated \texttt{VCE} does not satisfy the required asymptotic properties of the test. Second, the classic Hausman test applies only to the test of the equality of two estimators. Third, the test requires access to a fully efficient estimator; such an estimator may not be available, for example, if you are analyzing complex survey data. Using \texttt{suest} can overcome these three limitations.
Example 1

In our first example, we follow the analysis of the type of health insurance reported in [R] `mlogit` and demonstrate the `hausman` command with the `suest/test` combination. We fit the full multinomial logit model for all three alternatives and two restricted multinomial models in which one alternative is excluded. After fitting each of these models, we give them a title with the `estimates title` command and then store them with the `estimates store` command.

Legend: * p<0.05; ** p<0.01; *** p<0.001

Comparing the coefficients between models does not suggest substantial differences. We can formally test that coefficients are the same for the full model m1 and the restricted models m2 and m3 by using the **hausman** command. **hausman** expects the models to be specified in the order “always consistent” first and “efficient under \( H_0 \)” second.

\]

Warning: chi2 < 0 ==&gt; model fitted on these data fails to meet the asymptotic assumptions of the Hausman test; see **suest** for a generalized test.
According to the test of \( m_1 \) against \( m_2 \), we cannot reject the hypothesis that the coefficients of \( m_1 \) and \( m_2 \) are the same. The second Hausman test is not well defined—something that happens fairly often. The problem is due to the estimator of the variance \( V(b-B) \) as \( V(b) - V(B) \), which is a feasible estimator only asymptotically. Here it simply is not a proper variance matrix, and the Hausman test becomes undefined.

`suest m1 m2` estimates the simultaneous (co)variance of the coefficients of models \( m_1 \) and \( m_2 \). Although `suest` is technically a postestimation command, it acts like an estimation command in that it stores the simultaneous coefficients in `e(b)` and the full (co)variance matrix in `e(V)`. We could have used the `estat vce` command to display the full (co)variance matrix to show that the cross-model covariances were indeed estimated. Typically, we would not have a direct interest in `e(V)`.

```

`suest` created equation names by combining the name under which we stored the results using `estimates store` with the original equation names. Thus, in the simultaneous estimation result, equation `Prepaid` originating in model `m1` is named `m1_Prepaid`. According to the McFadden–Hausman specification of a test for IIA, the coefficients of the equations `m1_Prepaid` and `m2_Prepaid` should be equal. This equality can be tested easily with the `test` command. The `cons` option specifies that the intercept `_cons` be included in the test.

```
. test [m1_Prepaid] = [m2_Prepaid], cons
( 1)  [m1_Prepaid]age = [m2_Prepaid]age = 0
( 2)  [m1_Prepaid]male = [m2_Prepaid]male = 0
( 3)  [m1_Prepaid]_cons = [m2_Prepaid]_cons = 0
    chi2(  3) =  0.89
    Prob > chi2 =  0.8266
```

The Hausman test via `suest` is comparable with that computed by `hausman`, but they use different estimators of the variance of the difference of the estimates. The `hausman` command estimates \( V(b-B) \) by \( V(b) - V(B) \), whereas `suest` estimates \( V(b-B) \) by \( V(b) - \text{cov}(b,B) - \text{cov}(B,b) + V(B) \). One advantage of the second estimator is that it is always admissible, so the resulting test is always well defined. This quality is illustrated in the Hausman-type test of IIA comparing models `m1` and `m3`.

  ( 1) [m1_Uninsure]age - [m3_Uninsure]age = 0
  ( 2) [m1_Uninsure]male - [m3_Uninsure]male = 0
  ( 3) [m1_Uninsure]_cons - [m3_Uninsure]_cons = 0
    chi2(  3) = 1.49
    Prob > chi2 = 0.6845

Although the classic Hausman test computed by hausman is not defined here, the suest-based test is just fine. We cannot reject the equality of the common coefficients across m1 and m3.

A second advantage of the suest approach is that we can estimate the (co)variance matrix of the multivariate normal distribution of the estimators of the three models m1, m2, and m3 and test that the common coefficients are equal.

```

Again, we do not find evidence against the correct specification of the multinomial logit for type of insurance. The classic Hausman test assumes that one of the estimators (named B in hausman) is efficient, that is, it has minimal (asymptotic) variance. This assumption ensures that \(V(b) - V(B)\) is an admissible, viable estimator for \(V(b - B)\). The assumption that we have an efficient estimator is a restrictive one. It is violated, for instance, if our data are clustered. We want to adjust for clustering via a vce(cluster clustvar) option by requesting the cluster-adjusted sandwich estimator of variance. Consequently, in such a case, hausman cannot be used. This problem does not exist with the suest version of the Hausman test. To illustrate this feature, we suppose that the data are clustered by city—we constructed an imaginary variable cityid for this illustration. If we plan to apply suest, we would not specify the vce(cluster clustvar) option at the time of estimation. suest has a vce(cluster clustvar) option. Thus, we do not need to refit the models; we can call suest and test right away.
suest provides some descriptive information about the clustering on cityid. Like any other estimation command, `suest` informs us that the standard errors are adjusted for clustering. The Hausman-type test obtained from the `test` command uses a simultaneous (co)variance of `m1` and `m2` appropriately adjusted for clustering. In this example, we still do not have reason to conclude that the multinomial logit model in this application is misspecified, that is, that IIA is violated.

The multinomial logit model is a special case of the conditional logistic regression model; see `clogit`. Like the multinomial logistic regression model, the conditional logistic regression model also makes the IIA assumption. Consider an example, introduced in [CM] `cmclogit`, in which the demand for American, Japanese, and European cars is modeled in terms of the number of local dealers of the respective brands and of some individual attributes incorporated in interaction with the nationality of cars. We want to perform a Hausman-type test for IIA comparing the decision between all nationalities with the decision between non-American cars. The following code fragment demonstrates how to conduct a Hausman test for IIA via `suest` in this case.
Testing proportionality

The applications of `suest` that we have discussed so far concern Hausman-type tests for mis-specification. To test such a hypothesis, we compared two estimators that have the same probability limit if the hypothesis holds true, but otherwise have different limits. We may also want to compare the coefficients of models (estimators) for other substantive reasons. Although we most often want to test whether coefficients differ between models or estimators, we may occasionally want to test other constraints (see Hausman and Ruud [1987]).

Example 2

In this example, using simulated labor market data for siblings, we consider two dependent variables, income (`inc`) and whether a person was promoted in the last year (`promo`). We apply familiar economic arguments regarding human capital, according to which employees have a higher income and a higher probability of being promoted, by having more human capital. Human capital is acquired through formal education (`edu`) and on-the-job training experience (`exp`). We study whether income and promotion are “two sides of the same coin”, that is, whether they reflect a common latent variable, “human capital”. Accordingly, we want to compare the effects of different aspects of human capital on different outcome variables.

We estimate fairly simple labor market equations. The income model is estimated with `regress`, and the estimation results are stored under the name `Inc`.

```
. use https://www.stata-press.com/data/r18/income
. regress inc edu exp male

Source | SS       df    MS           Number of obs = 277
-------+--------------------------------------
Model  | 2058.44672  3  686.148908    F(3, 273) = 42.34
        |          Prob > F = 0.0000
Residual | 4424.05183 273 16.2053181     R-squared = 0.3175
        |          Adj R-squared = 0.3100
Total  | 6482.49855 276 23.4873136    Root MSE = 4.0256

          | inc       Coefficient  Std. err.      t    P>|t|     [95% conf. interval]
-------+--------------------------------------------------
edu    |    2.213707   .243247     9.10    0.000   1.734828   2.692585
exp    |    1.47293   .231044     6.38    0.000   1.018076   1.927785
male   |   .5381153   .4949466     1.09   0.278    -.436282   1.512513
_cons  |    1.255497   .3115808     4.03    0.000    .642091   1.868904
```

Being sibling data, the observations are clustered on family of origin, `famid`. In the estimation of the regression parameters, we did not specify a `vce(cluster famid)` option to adjust standard errors for clustering on family (`famid`). Thus, the standard errors reported by `regress` are potentially flawed. This problem will, however, be corrected by specifying a `vce(cluster clustvar)` option with `suest`.

Next, we estimate the promotion equation with `probit` and again store the results under an appropriate name.
The coefficients in the income and promotion equations definitely seem to be different. However, because the scales of the two variables are different, we would not expect the coefficients to be equal. The correct hypothesis here is that the proportionality of the coefficients of the two models, apart from the constant, are equal. This formulation would still reflect that the relative effects of the different aspects of human capital do not differ between the dependent variables. We can obtain a nonlinear Wald test for the hypothesis of proportionality by using the `testnl` command on the combined estimation results of the two estimators. Thus, we first have to form the combined estimation results. At this point, we specify the `vce(cluster famid)` option to adjust for the clustering of observations on `famid`.
The standard errors reported by `suest` are identical to those reported by the respective estimation commands when invoked with the `vce(cluster famid)` option. We are now ready to test for proportionality:

\[ H_0: \frac{\beta_{\text{edu}}^{\text{Income}}}{\beta_{\text{edu}}^{\text{Promotion}}} = \frac{\beta_{\text{exp}}^{\text{Income}}}{\beta_{\text{exp}}^{\text{Promotion}}} = \frac{\beta_{\text{male}}^{\text{Income}}}{\beta_{\text{male}}^{\text{Promotion}}} \]

It is straightforward to translate this into syntax suitable for `testnl`, recalling that the coefficient of variable \( v \) in equation \( eq \) is denoted by \( [eq]v \).

```plaintext
. testnl [Inc_mean]edu/[Promo_promo]edu = [Inc_mean]exp/[Promo_promo]exp
   > [Inc_mean]male/[Promo_promo]male
(1) [Inc_mean]edu/[Promo_promo]edu = [Inc_mean]exp/[Promo_promo]exp
(2) [Inc_mean]edu/[Promo_promo]edu = [Inc_mean]male/[Promo_promo]male
    chi2(2) = 0.61
    Prob > chi2 = 0.7385
```

From the evidence, we fail to reject the hypotheses that the coefficients of the income and promotion equations are proportional. Thus, it is not unreasonable to assume that income and promotion can be explained by the same latent variable, “labor market success”.

A disadvantage of the nonlinear Wald test is that it is not invariant with respect to representation: a Wald test for a mathematically equivalent formulation of the nonlinear constraint usually leads to a different test result. An equivalent formulation of the proportionality hypothesis is

\[ H_0: \begin{align*}
\beta_{\text{edu}}^{\text{Income}} \beta_{\text{exp}}^{\text{Promotion}} &= \beta_{\text{edu}}^{\text{Promotion}} \beta_{\text{exp}}^{\text{Income}} \\
\beta_{\text{edu}}^{\text{Income}} \beta_{\text{male}}^{\text{Promotion}} &= \beta_{\text{edu}}^{\text{Promotion}} \beta_{\text{male}}^{\text{Income}}
\end{align*} \]

This formulation is “more linear” in the coefficients. The asymptotic \( \chi^2 \) distribution of the nonlinear Wald statistic can be expected to be more accurate for this representation.

```plaintext
. testnl ([Inc_mean]edu*[Promo_promo]exp = [Inc_mean]exp*[Promo_promo]edu)
   > ([Inc_mean]edu*[Promo_promo]male = [Inc_mean]male*[Promo_promo]edu)
(1) [Inc_mean]edu*[Promo_promo]exp = [Inc_mean]exp*[Promo_promo]edu
(2) [Inc_mean]edu*[Promo_promo]male = [Inc_mean]male*[Promo_promo]edu
    chi2(2) = 0.46
    Prob > chi2 = 0.7936
```

Here the two representations lead to similar test statistics and \( p \)-values. As before, we fail to reject the hypothesis of proportionality of the coefficients of the two models.

---

**Testing cross-model hypotheses**

**Example 3**

In this example, we demonstrate how some cross-model hypotheses can be tested using the facilities already available in most estimation commands. This demonstration will explain the intricate relationship between the cluster adjustment of the robust estimator of variance and the `suest` command. It will also be made clear that a new facility is required to perform more general cross-model testing.
We want to test whether the effect of \( x_1 \) on the binary variable \( y_1 \) is the same as the effect of \( x_2 \) on the binary \( y_2 \); see Clogg, Petkova, and Haritou (1995). In this setting, \( x_1 \) may equal \( x_2 \), and \( y_1 \) may equal \( y_2 \). We assume that logistic regression models can be used to model the responses, and for simplicity, we ignore further predictor variables in these models. If the two logit models are fit on independent samples so that the estimators are (stochastically) independent, a Wald test for \( \hat{b}(x_1) = \hat{b}(x_2) \) rejects the null hypothesis if

\[
\frac{\hat{b}(x_1) - \hat{b}(x_2)}{\left[ \hat{\sigma}^2\{\hat{b}(x_1)\} + \hat{\sigma}^2\{\hat{b}(x_2)\} \right]^{1/2}}
\]

is larger than the appropriate \( \chi^2_1 \) threshold. If the models are fit on the same sample (or on dependent samples), so that the estimators are stochastically dependent, the above test that ignores the covariance between the estimators is not appropriate.

It is instructive to see how this problem can be tackled by “stacking” data. In the stacked format, we doubled the number of observations. The dependent variable is \( y_1 \) in the first half of the data and is \( y_2 \) in the second half of the data. The predictor variable \( z_1 \) is set to \( x_1 \) in the first half of the expanded data and to 0 in the rest. Similarly, \( z_2 \) is 0 in the first half and \( x_2 \) in the second half. The following diagram illustrates the transformation, in the terminology of the \texttt{reshape} command, from wide to long format.

\[
\begin{pmatrix}
\text{id} & y_1 & y_2 & x_1 & x_2 \\
1 & y_{11} & y_{21} & x_{11} & x_{21} \\
2 & y_{12} & y_{22} & x_{12} & x_{22} \\
3 & y_{13} & y_{23} & x_{13} & x_{23} \\
\end{pmatrix}
\quad \implies \quad
\begin{pmatrix}
\text{id} & y & z_1 & z_2 & \text{model} \\
1 & y_{11} & 0 & 1 \\
2 & y_{12} & 0 & 1 \\
3 & y_{13} & 0 & 1 \\
1 & y_{21} & x_{21} & 2 \\
2 & y_{22} & x_{22} & 2 \\
3 & y_{23} & x_{23} & 2 \\
\end{pmatrix}
\]

The observations in the long-format data organization are \textit{clustered} on the original subjects and are identified with the identifier \texttt{id}. The clustering on \texttt{id} has to be accounted for when fitting a simultaneous model. The simplest way to deal with clustering is to use the cluster adjustment of the robust or sandwich estimator; see \texttt{[P] robust}. The data manipulation can be accomplished easily with the \texttt{stack} command; see \texttt{[D] stack}. Subsequently, we fit a simultaneous logit model and perform a Wald test for the hypothesis that the coefficients of \( z_1 \) and \( z_2 \) are the same. A full setup to obtain the cross-model Wald test could then be as follows:

```
. generate zero = 0 // a variable that is always 0
. generate one = 1 // a variable that is always 1
. generate two = 2 // a variable that is always 2
. stack id y1 x1 zero one id y2 zero x2 two, into(id y z1 z2 model)
. generate model2 = (model==2)
. logit y model2 z1 z2, vce(cluster id)
. test _b[z1] = _b[z2]
```

The coefficient of \( z_1 \) represents the effect of \( x_1 \) on \( y_1 \), and similarly, \( z_2 \) for the effect of \( x_2 \) on \( y_2 \). The variable \texttt{model2} is a dummy for the “second model”, which is included to allow the intercept in the second model to differ from that in the first model. The estimates of the coefficient of \( z_1 \) and its standard error in the combined model are the same as the estimates of the coefficient of \( z_1 \) and its standard error if we fit the model on the unstacked data.

```
. logit y1 x1, vce(robust)
```
The `vce(cluster clustvar)` option specified with the `logit` command for the stacked data ensures that the covariances of \_\_\_b\[z1\] and \_\_\_b\[z2\] are indeed estimated. This estimation ensures that the Wald test for the equality of the coefficients is correct. If we had not specified the `vce(cluster clustvar)` option, the (co)variance matrix of the coefficients would have been block-diagonal; that is, the covariances of \_\_\_b\[z1\] and \_\_\_b\[z2\] would have been 0. Then, `test` would have effectively used the invalid formula for the Wald test for two independent samples.

In this example, the two logit models were fit on the same data. The same setup would apply, without modification, when the two logit models were fit on overlapping data that resulted, for instance, if the \_\_\_y or \_\_\_x variables were missing in some observations.

The `suest` command allows us to obtain the above Wald test more efficiently by avoiding the data manipulation, obviating the need to fit a model with twice the number of coefficients. The test statistic produced by the above code fragment is identical to that obtained via `suest` on the original (unstacked) data:

```
. logit y1 x1
. estimates store M1
. logit y2 x2
. estimates store M2
. suest M1 M2
. test [M1]x1=[M2]x2
```

The stacking method can be applied not only to the testing of cross-model hypotheses for `logit` models but also to any estimation command that supports the `vce(cluster clustvar)` option. The stacking approach clearly generalizes to stacking more than two logit or other models, testing more general linear hypotheses, and testing nonlinear cross-model hypotheses (see [R] `testnl`). In all of these cases, `suest` would yield identical statistical results but at smaller costs in terms of data management, computer storage, and computer time.

Is `suest` nothing but a convenience command? No, there are two disadvantages to the stacking method, both of which are resolved via `suest`. First, if the models include ancillary parameters (in a regression model, the residual variance; in an ordinal response model, the cutpoints; and in lognormal survival-time regression, the time scale parameter), these parameters are constrained to be equal between the stacked models. In `suest`, this constraint is relaxed. Second, the stacking method does not generalize to compare different statistical models, such as a probit model and a regression model. As demonstrated in the previous section, `suest` can deal with this situation.
stored results

`suest` stores the following in `e()`:

Scalars
- `e(N)` number of observations
- `e(N_clust)` number of clusters
- `e(rank)` rank of `e(V)`

Macros
- `e(cmd)` `suest`
- `e(eqnames#)` original names of equations of model #
- `e(names)` list of model names
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(clustvar)` name of cluster variable
- `e(vce)` `vcetype` specified in `vce()`
- `e(vcetype)` title used to label Std. err.
- `e(properties)` `b V`

Matrices
- `e(b)` stacked coefficient vector of the models
- `e(V)` variance–covariance matrix of the estimators

Functions
- `e(sample)` marks estimation sample

methods and formulas

The estimation of the simultaneous (co)variance of a series of \( k \) estimators is a nonstandard application of the sandwich estimator, as implemented by the command `[P] `robust`. You may want to read this manual entry before reading further.

The starting point is that we have fit \( k \) different models on the same data—partially overlapping or nonoverlapping data are special cases. We want to derive the simultaneous distribution of these \( k \) estimators, for instance, to test a cross-estimator hypothesis \( H_0 \). As in the framework of Hausman testing, \( H_0 \) will often be of the form that different estimators have the same probability limit under some hypothesis, while the estimators have different limits if the hypothesis is violated.

We consider (vector) estimators \( \hat{\beta}_i \) to be defined as “the” solution of the estimation equations \( \mathbf{G}_i \),

\[
\mathbf{G}_i(b_i) = \sum_j w_{ij} \mathbf{u}_{ij}(b_i) = 0, \quad i = 1, \ldots, k
\]

We refer to the \( \mathbf{u}_{ij} \) as the “scores”. Specifying some weights \( w_{ij} = 0 \) trivially accommodates for partially overlapping or even disjointed data. Under “suitable regularity conditions” (see White [1982; 1996] for details), the \( \hat{\beta}_i \) are asymptotically normally distributed, with the variance estimated consistently by the sandwich estimator

\[
V_i = \text{Var}(\hat{\beta}_i) = \mathbf{D}_i^{-1} \sum_j w_{ij} \mathbf{u}_{ij} \mathbf{u}_{ij}' \mathbf{D}_i^{-1}
\]
where $D_i$ is the Jacobian of $G_i$ evaluated at $\hat{\beta}_i$. In the context of maximum likelihood estimation, $D_i$ can be estimated consistently by (minus) the Hessian of the log likelihood or by the Fisher information matrix. If the model is also well specified, the sandwiched term $(\sum_j w_{ij} u_{ij} u_{ij}' )$ converges in probability to $D_i$, so $V_i$ may be consistently estimated by $D_i^{-1}$.

To derive the simultaneous distribution of the estimators, we consider the “stacked” estimation equation,

$$G(\hat{\beta}) = \left\{ G_1(\hat{\beta}_1)' \ G_1(\hat{\beta}_2)' \ldots \ G_k(\hat{\beta}_k)' \right\}' = 0$$

Under “suitable regularity conditions” (see White [1996] for details), $\hat{\beta}$ is asymptotically jointly normally distributed. The Jacobian and scores of the simultaneous equation are easily expressed in the Jacobian and scores of the separate equations. The Jacobian of $G$,

$$D(\hat{\beta}) = \left. \frac{dG(\beta)}{d\beta} \right|_{\beta=\hat{\beta}}$$

is block diagonal with blocks $D_1, \ldots, D_k$. The inverse of $D(\hat{\beta})$ is again block diagonal, with the inverses of $D_i$ on the diagonal. The scores $u$ of $G$ are simply obtained as the concatenated scores of the separate equations:

$$u_j = (u_{1j}' \ u_{2j}' \ldots \ u_{kj}')'$$

Out-of-sample (that is, where $w_{ij} = 0$) values of the score variables are defined as 0 (thus we drop the $i$ subscript from the common weight variable). The sandwich estimator for the asymptotic variance of $\hat{\beta}$ reads

$$V = \text{Var}(\hat{\beta}) = D(\hat{\beta})^{-1} \left( \sum_j w_{ij} u_{ij} u_{ij}' \right) D(\hat{\beta})^{-1}$$

Taking a “partitioned” look at this expression, we see that $V(\hat{\beta}_i)$ is estimated by

$$D_i^{-1} \left( \sum_j w_{ij} u_{ij} u_{ij}' \right) D_i^{-1}$$

which is, yet again, the familiar sandwich estimator for $\hat{\beta}_i$ based on the separate estimation equation $G_i$. Thus, considering several estimators simultaneously in this way does not affect the estimators of the asymptotic variances of these estimators. However, as a bonus of stacking, we obtained a sandwich-type estimate of the covariance $V_{ih}$ of estimators $\hat{\beta}_i$ and $\hat{\beta}_h$,

$$V_{ih} = \text{Cov}(\hat{\beta}_i, \hat{\beta}_h) = D_i^{-1} \left( \sum_j w_{ij} u_{ij} u_{hj}' \right) D_h^{-1}$$

which is also obtained by White (1982).

This estimator for the covariance of estimators is an application of the cluster modification of the sandwich estimator proposed by Rogers (1993). Consider the stacked data format as discussed in the logit example, and assume that Stata would be able to estimate a “stacked model” in which different models apply to different observations, for example, a probit model for the first half, a regression model for the second half, and a one-to-one cluster relation between the first and second half. If there are no common parameters to both models, the score statistics of parameters for the stacked models are zero in the half of the data in which they do not occur. In Rogers’s method, we have to sum the score statistics over the observations within a cluster. This step boils down to concatenating the score statistics at the level of the cluster.
We compare the sandwich estimator of the (co)variance $V_{12}$ of two estimators with the estimator of variance $\tilde{V}_{12}$ applied in the classic Hausman test. Hausman (1978) showed that if $\hat{\beta}_1$ is consistent under $H_0$ and $\hat{\beta}_2$ is efficient under $H_0$, then asymptotically

$$\text{Cov}(\hat{\beta}_1, \hat{\beta}_2) = \text{Var}(\hat{\beta}_2)$$

and so $\text{var}(\hat{\beta}_1 - \hat{\beta}_2)$ is consistently estimated by $V_1 - V_2$.

Acknowledgment

suest was written by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands. This research is supported by grant PGS 50-370 by The Netherlands Organization for Scientific Research.

An earlier version of suest was published in the Stata Technical Bulletin (1999). The current version of suest is not backward compatible with the 1999 version because of the introduction of new ways to manage estimation results via the estimates command.

**Description**

`summarize` calculates and displays a variety of univariate summary statistics. If no `varlist` is specified, summary statistics are calculated for all the variables in the dataset.

**Quick start**

Basic summary statistics for continuous variable `v1`

```
summarize v1
```

Same as above, and include `v2` and `v3`

```
summarize v1-v3
```

Same as above, and provide additional detail about the distribution

```
summarize v1-v3, detail
```

Summary statistics reported separately for each level of `catvar`

```
by catvar: summarize v1
```

With frequency weight `wvar`

```
summarize v1 [fweight=wvar]
```

**Menu**

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Summary statistics
**Syntax**

```
summarize [varlist] [if] [in] [weight] [, options]
```

<table>

*varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*varlist* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

by, collect, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.

aweights, fweights, and iweights are allowed. However, iweights may not be used with the detail option; see [U] 11.1.6 weight.

**Options**

- **Main**
  - *detail* produces additional statistics, including skewness, kurtosis, the four smallest and four largest values, and various percentiles.
  - *meanonly*, which is allowed only when *detail* is not specified, suppresses the display of results and calculation of the variance. Ado-file writers will find this useful for fast calls.
  - *format* requests that the summary statistics be displayed using the display formats associated with the variables rather than the default g display format; see [U] 12.5 Formats: Controlling how data are displayed.
  - *separator(#)* specifies how often to insert separation lines into the output. The default is separator(5), meaning that a line is drawn after every five variables. separator(10) would draw a line after every 10 variables. separator(0) suppresses the separation line.

- *display_options*: vsquish, noemptycells, baselevels, allbaselevels,nofvlabel, fwrap(#), and fwrapon(style); see [R] Estimation options.

**Remarks and examples**

`summarize` can produce two different sets of summary statistics. Without the detail option, the number of nonmissing observations, the mean and standard deviation, and the minimum and maximum values are presented. With detail, the same information is presented along with the variance, skewness, and kurtosis; the four smallest and four largest values; and the 1st, 5th, 10th, 25th, 50th (median), 75th, 90th, 95th, and 99th percentiles.

Also see [R] `ci` for calculating the standard error and confidence intervals of the mean.
Example 1: summarize with the separator() option

We have data containing information on various automobiles, among which is the variable mpg, the mileage rating. We can obtain a quick summary of the mpg variable by typing

```
. use https://www.stata-press.com/data/r18/auto2
(1978 automobile data)
. summarize mpg
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>5.785503</td>
<td>12</td>
<td>41</td>
</tr>
</tbody>
</table>

We see that we have 74 observations. The mean of mpg is 21.3 miles per gallon, and the standard deviation is 5.79. The minimum is 12, and the maximum is 41.

If we had not specified the variable (or variables) we wanted to summarize, we would have obtained summary statistics on all the variables in the dataset:

```
. summarize, separator(4)
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

There are only 69 observations on rep78, so some of the observations are missing. There are no observations on make because it is a string variable.
The idea of the mean is quite old (Plackett 1958), but its extension to a scheme of moment-based measures was not done until the end of the 19th century. Between 1893 and 1905, Pearson discussed and named the standard deviation, skewness, and kurtosis, but he was not the first to use any of these. Thiele (1889), in contrast, had earlier firmly grasped the notion that the $m_r$ provide a systematic basis for discussing distributions. However, even earlier anticipations can also be found. For example, Euler in 1778 used $m_2$ and $m_3$ in passing in a treatment of estimation (Hald 1998, 87), but seemingly did not build on that.

Similarly, the idea of the median is quite old. The history of the interquartile range is tangled up with that of the probable error, a long-popular measure. Extending this in various ways to a more general approach based on quantiles (to use a later term) occurred to several people in the nineteenth century. Galton (1875) is a nice example, particularly because he seems so close to the key idea of the quantiles as a function, which took another century to reemerge strongly.

Thorvald Nicolai Thiele (1838–1910) was a Danish scientist who worked in astronomy, mathematics, actuarial science, and statistics. He made many pioneering contributions to statistics, several of which were overlooked until recently. Thiele advocated graphical analysis of residuals checking for trends, symmetry of distributions, and changes of sign, and he even warned against overinterpreting such graphs.

---

Example 2: summarize with the detail option

The detail option provides all the information of a normal summarize and more. The format of the output also differs, as shown here:

```
  . summarize mpg, detail

Mileage (mpg)

    Percentiles     Smallest
1%           12          12
5%           14          12
10%          14          14     Obs          74
25%          18          14    Sum of wgt.    74
50%          20          Mean    21.2973
               Largest     Std. dev.   5.785503
75%          25          34
90%          29          35     Variance    33.47205
95%          34          35     Skewness    .9487176
99%          41          41     Kurtosis    3.975005
```

As in the previous example, we see that the mean of mpg is 21.3 miles per gallon and that the standard deviation is 5.79. We also see the various percentiles. The median of mpg (the 50th percentile) is 20 miles per gallon. The 25th percentile is 18, and the 75th percentile is 25.

When we performed summarize, we learned that the minimum and maximum were 12 and 41, respectively. We now see that the four smallest values in our dataset are 12, 12, 14, and 14. The four largest values are 34, 35, 35, and 41. The skewness of the distribution is 0.95, and the kurtosis is 3.98. (A normal distribution would have a skewness of 0 and a kurtosis of 3.)

Skewness is a measure of the lack of symmetry of a distribution. If the distribution is symmetric, the coefficient of skewness is 0. If the coefficient is negative, the median is usually greater than the mean and the distribution is said to be skewed left. If the coefficient is positive, the median is usually less than the mean and the distribution is said to be skewed right. Kurtosis (from the Greek kurtosis, meaning curvature) is a measure of peakedness of a distribution. The smaller the coefficient of kurtosis, the flatter the distribution. The normal distribution has a coefficient of kurtosis of 3 and provides a convenient benchmark.
Technical note

The convention of calculating the median of an even number of values by averaging the central two order statistics is of long standing. (That is, given 8 values, average the 4th and 5th smallest values, or given 42, average the 21st and 22nd smallest.) Stigler (1977) filled a much-needed gap in the literature by naming such paired central order statistics as “comedians”, although it remains unclear how far he was joking.

Example 3: summarize with the by prefix

`summarize` can usefully be combined with the `by varlist:` prefix. In our dataset, we have a variable, `foreign`, that distinguishes foreign and domestic cars. We can obtain summaries of `mpg` and `weight` within each subgroup by typing

```
. by foreign: summarize mpg weight
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mpg</code></td>
<td>52</td>
<td>19.82692</td>
<td>4.743297</td>
<td>12</td>
<td>34</td>
</tr>
<tr>
<td><code>weight</code></td>
<td>52</td>
<td>3317.115</td>
<td>695.3637</td>
<td>1800</td>
<td>4840</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mpg</code></td>
<td>22</td>
<td>24.77273</td>
<td>6.611187</td>
<td>14</td>
<td>41</td>
</tr>
<tr>
<td><code>weight</code></td>
<td>22</td>
<td>2315.909</td>
<td>433.0035</td>
<td>1760</td>
<td>3420</td>
</tr>
</tbody>
</table>

Domestic cars in our dataset average 19.8 miles per gallon, whereas foreign cars average 24.8.

Because `by varlist:` can be combined with `summarize`, it can also be combined with `summarize`, `detail:`
```
2862 summarize — Summary statistics

. by foreign: summarize mpg, detail

-> foreign = Domestic

Mileage (mpg)

<table>
<thead>
<tr>
<th>Percentiles</th>

Sum of wgt. 22

Mean 24.77273

Std. dev. 6.611187

Variance 43.70779

Skewness .657329

Kurtosis 3.10734

Technical note

summarize respects display formats if we specify the format option. When we type summarize price weight, we obtain

```
Variable | Obs  | Mean    | Std. dev. | Min   | Max   |
----------|------|---------|-----------|-------|-------|
price     | 74   | 6,165.26| 2,949.496| 3,291 | 15,906|
weight    | 74   | 3,019.46| 777.19    | 1,760 | 4,840 |
```

The display is accurate but is not as aesthetically pleasing as we may wish, particularly if we plan to use the output directly in published work. By placing formats on the variables, we can control how the table appears:

```
Variable | Obs  | Mean    | Std. dev. | Min   | Max   |
----------|------|---------|-----------|-------|-------|
price     | 74   | 6,165.26| 2,949.50  | 3,291 | 15,906|
weight    | 74   | 3,019.46| 777.19    | 1,760 | 4,840 |
```
If you specify a weight (see [U] 11.1.6 weight), each observation is multiplied by the value of the weighting expression before the summary statistics are calculated so that the weighting expression is interpreted as the discrete density of each observation.

Example 4: summarize with factor variables

You can also use `summarize` to obtain summary statistics for factor variables. For example, if you type

```
. summarize i.rep78
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>Poor</td>
<td>69</td>
<td>.0289855</td>
<td>.1689948</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Fair</td>
<td>69</td>
<td>.115942</td>
<td>.3225009</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Average</td>
<td>69</td>
<td>.4347826</td>
<td>.4993602</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Good</td>
<td>69</td>
<td>.2608696</td>
<td>.4423259</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Excellent</td>
<td>69</td>
<td>.1594203</td>
<td>.3687494</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

you obtain the sample proportions for the five levels of the `rep78` variable. For example, 11.6% of the 69 cars with nonmissing values of `rep78` have a fair repair record.

We could have used `tabulate oneway rep78` to obtain the sample proportions along with the cumulative proportions. Alternatively, we could have used `proportions rep78` to obtain the sample proportions along with the standard errors of the proportions instead of the standard deviations of the proportions.

Example 5: summarize with weights

We have 1980 census data on each of the 50 states. Included in our variables is `medage`, the median age of the population of each state. If we type `summarize medage`, we obtain unweighted statistics:

```
. use https://www.stata-press.com/data/r18/census, clear
   (1980 Census data by state)
. summarize medage
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>medage</td>
<td>50</td>
<td>29.54</td>
<td>1.693445</td>
<td>24.2</td>
<td>34.7</td>
</tr>
</tbody>
</table>

Also among our variables is `pop`, the population in each state. Typing `summarize medage [w=pop]` produces population-weighted statistics:
Summary statistics

To summarize the data, we use the `summarize` command with the population weights:

```
summarize medage [w=pop]
(analytic weights assumed)
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Weight</th>
<th>Mean</th>
<th>Std. Dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>medage</td>
<td>50</td>
<td>225907472</td>
<td>30.11047</td>
<td>1.66933</td>
<td>24.2</td>
<td>34.7</td>
</tr>
</tbody>
</table>

The number listed under `Weight` is the sum of the weighting variable, `pop`, indicating that there are roughly 226 million people in the United States. The `pop`-weighted mean of `medage` is 30.11 (compared with 29.54 for the unweighted statistic), and the weighted standard deviation is 1.67 (compared with 1.69).

Example 6: summarize with weights and the detail option

We can obtain detailed summaries of weighted data as well. When we do this, all the statistics are weighted, including the percentiles.

```
summarize medage [w=pop], detail
(analytic weights assumed)
```

```
Median age

<table>

90%                 32.1          32.1
95%                 32.2          32.2
99%                 34.7          34.7

Variance 2.786661
Skewness .5281972
Kurtosis 4.494223
```

Technical note

If you are writing a program and need to access the mean of a variable, the `meanonly` option provides for fast calls. For example, suppose that your program reads as follows:

```
program mean
    summarize `1', meanonly
    display " mean = " r(mean)
end
```

The result of executing this is

```
. use https://www.stata-press.com/data/r18/auto2
   (1978 automobile data)
. mean price
    mean = 6165.2568
```
Video example

Descriptive statistics in Stata

Stored results

`summarize` stores the following in `r()`:

Scalars

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Methods and formulas

Let \( x \) denote the variable on which we want to calculate summary statistics, and let \( x_i, i = 1, \ldots, n \), denote an individual observation on \( x \). Let \( v_i \) be the weight, and if no weight is specified, define \( v_i = 1 \) for all \( i \).

Define the total number of observations as \( N = n \) if \( v_i \) is an `aweight` and as

\[
N = \sum_{i=1}^{n} v_i
\]

otherwise.

Additionally, define the normalized weight as

\[
w_i = \frac{nv_i}{\sum_{i=1}^{n} v_i}
\]

if \( v_i \) is an `aweight` and as \( w_i = v_i \) otherwise.

The mean, \( \overline{x} \), is defined as

\[
\overline{x} = \frac{1}{N} \sum_{i=1}^{n} w_i x_i
\]

The variance, \( s^2 \), is defined as

\[
s^2 = \frac{1}{N-1} \sum_{i=1}^{n} w_i (x_i - \overline{x})^2
\]

The standard deviation, \( s \), is defined as \( \sqrt{s^2} \).

Define \( m_r \) as the \( r \)th moment about the mean \( \overline{x} \):

\[
m_r = \frac{1}{N} \sum_{i=1}^{n} w_i (x_i - \overline{x})^r
\]
The coefficient of skewness is then defined as \( m_3 m_2^{-3/2} \). The coefficient of kurtosis is defined as \( m_4 m_2^{-2} \).

Let \( x_{(i)} \) refer to the \( x \) in ascending order, and let \( w_{(i)} \) refer to the corresponding weights of \( x_{(i)} \). The four smallest values are \( x_{(1)}, x_{(2)}, x_{(3)}, \) and \( x_{(4)} \). The four largest values are \( x_{(n)}, x_{(n-1)}, x_{(n-2)}, \) and \( x_{(n-3)} \).

To obtain the \( p \)th percentile, which we will denote as \( x[p] \), let \( P = Np/100 \). Let

\[
W(i) = \sum_{j=1}^{i} w(j)
\]

Find the first index \( i \) such that \( W(i) > P \). The \( p \)th percentile is then

\[
x[p] = \begin{cases} 
\frac{x(i-1) + x(i)}{2} & \text{if } W(i-1) = P \\
 x(i) & \text{otherwise}
\end{cases}
\]

Description

`sunflower` draws density-distribution sunflower plots (Plummer and Dupont 2003). Dark sunflowers, light sunflowers, and marker symbols represent high-, medium-, and low-density regions of the data, respectively. These plots are useful for displaying bivariate data whose density is too great for conventional scatterplots to be effective.

Quick start

Density-distribution sunflower plot showing the relationship between \(x\) and \(y\)

```plaintext
sunflower y x
```

Set the center of the reference bin to \(x = 5\) and \(y = 8\)

```plaintext
sunflower y x, xcenter(5) ycenter(8)
```

Same as above, but specify the width of the hexagonal bins to be 1.5

```plaintext
sunflower y x, xcenter(5) ycenter(8) binwidth(1.5)
```

Same as above, but set the minimum number of observations needed for a bin to be represented by a light sunflower to 4

```plaintext
sunflower y x, xcenter(5) ycenter(8) binwidth(1.5) light(4)
```

Use the `s1color` scheme

```plaintext
sunflower y x, scheme(s1color)
```

Specify that only the petals are shown and the hexagons are omitted

```plaintext
sunflower y x, flowersonly
```

Suppress display of the table

```plaintext
sunflower y x, notable
```

Menu

Graphics > Smoothing and densities > Density-distribution sunflower plot
Syntax

```
sunflower  yvar  xvar  [if]  [in]  [weight]  [ ,  options ]
```

All options are rightmost; see [G-4] Concept: repeated options.

fweights are allowed; see [U] 11.1.6 weight.
Options

notograph prevents the graph from being generated.
notable prevents the summary table from being displayed. This option is implied when the by() option is specified.

marker_options affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] marker_options.

binwidth(#) specifies the horizontal width of the hexagonal bins in the same units as xvar. By default,

\[
\text{binwidth} = \max(\text{rbw}, \text{nbw})
\]

where

\[
\text{rbw} = \text{range of } xvar / 40
\]
\[
\text{nbw} = \text{range of } xvar / \max(1, \text{nb})
\]

and

\[
\text{nb} = \text{int}(\min(\sqrt{n}), 10 * \log_{10}(n))
\]

where

\[
\text{n} = \text{the number of observations in the dataset}
\]

binar(#) specifies the aspect ratio for the hexagonal bins. The height of the bins is given by

\[
\text{binheight} = \text{binwidth} \times # \times 2 / \sqrt{3}
\]

where binheight and binwidth are specified in the units of yvar and xvar, respectively. The default is binar(r), where r results in the rendering of regular hexagons.

bin_options affect how the hexagonal bins are rendered.

lbstyle(areastyle) and dbstyle(areastyle) specify the look of the light and dark hexagonal bins, respectively. The options listed below allow you to change each attribute, but lbstyle() and dbstyle() provide the starting points. See [G-4] areastyle for a list of available area styles.

lbcolor(colorstyle) and dbcolor(colorstyle) specify one color to be used both to outline the shape and to fill the interior of the light and dark hexagonal bins, respectively. See [G-4] colorstyle for a list of color choices.

lbfcolor(colorstyle) and dbfcolor(colorstyle) specify the color to be used to fill the interior of the light and dark hexagonal bins, respectively. See [G-4] colorstyle for a list of color choices.

lblstyle(linestyle) and dblblstyle(linestyle) specify the overall style of the line used to outline the area, which includes its pattern (solid, dashed, etc.), thickness, and color. The other options listed below allow you to change the line's attributes, but lbstyle() and dbstyle() are the starting points. See [G-4] linestyle for a list of choices.

lblcolor(colorstyle) and dblblcolor(colorstyle) specify the color to be used to outline the light and dark hexagonal bins, respectively. See [G-4] colorstyle for a list of color choices.
lblwidth(linewidthstyle) and dblwidth(linewidthstyle) specify the thickness of the line to be used to outline the light and dark hexagonal bins, respectively. See [G-4] linewidthstyle for a list of choices.

light(#) specifies the minimum number of observations needed for a bin to be represented by a light sunflower. The default is light(3).

dark(#) specifies the minimum number of observations needed for a bin to be represented by a dark sunflower. The default is dark(13).

xcenter(#) and ycenter(#) specify the center of the reference bin. The default values are the median values of xvar and yvar, respectively. The centers of the other bins are implicitly defined by the location of the reference bin together with the common bin width and height.

petalweight(#) specifies the number of observations represented by each petal of a dark sunflower. The default value is chosen so that the maximum number of petals on a dark sunflower is 14.

petallength(#) specifies the length of petals in the sunflowers. The value specified is interpreted as a percentage of half the bin width. The default is 100%.

petal_options affect how the sunflower petals are rendered.

lflstyle(linestyle) and dflstyle(linestyle) specify the overall style of the light and dark sunflower petals, respectively.

lflcolor(colorstyle) and dflcolor(colorstyle) specify the color of the light and dark sunflower petals, respectively.

lflwidth(linewidthstyle) and dflwidth(linewidthstyle) specify the width of the light and dark sunflower petals, respectively.

flowersonly suppresses rendering of the bins. This option is equivalent to specifying lbcolor(none) and dbcolor(none).

nosinglepetal suppresses flowers from being drawn in light bins that contain only 1 observation and dark bins that contain as many observations as the petal weight (see the petalweight() option).

addplot(plot) provides a way to add other plots to the generated graph; see [G-3] addplot_option.

twoway_options are any of the options documented in [G-3] twoway_options. These include options for titling the graph (see [G-3] title_options), options for saving the graph to disk (see [G-3] saving_option), and the by() option (see [G-3] by_option).

Remarks and examples

A sunflower is several line segments of equal length, called petals, that radiate from a central point. There are two varieties of sunflowers: light and dark. Each petal of a light sunflower represents 1 observation. Each petal of a dark sunflower represents several observations. Dark and light sunflowers represent high- and medium-density regions of the data, and marker symbols represent individual observations in low-density regions.
sunflower divides the plane defined by the variables yvar and xvar into contiguous hexagonal bins. The number of observations contained within a bin determines how the bin will be represented.

- When there are fewer than light(#) observations in a bin, each point is plotted using the usual marker symbols in a scatterplot.
- Bins with at least light(#) but fewer than dark(#) observations are represented by a light sunflower. Each petal of a light sunflower represents one observation in the bin.
- Bins with at least dark(#) observations are represented by a dark sunflower. Each petal of a dark sunflower represents multiple observations.

See Dupont (2009, 87–92) for a discussion of sunflower plots and how to create them using Stata.

### Example 1

Using the auto dataset, we want to examine the relationship between weight and mpg. To do that, we type

```stata
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. sunflower mpg weight, binwid(500) petalw(2) dark(8) scheme(stcolor)
```

| Total       | 75           | 74            |
The two darkly shaded sunflowers immediately catch our eyes, indicating a group of 10 cars that are heavy (nearly 4,000 pounds) and fuel inefficient and a group 16 of cars that get about 20 miles per gallon and weight in the neighborhood of 3,000 pounds. The lighter sunflowers each indicate groups of three to seven cars that share similar weight and fuel economy characteristics. To obtain the number of cars in each group, we count the number of petals in each flower and consult the graph legend to see how many observations each petal represents.

Acknowledgments

We thank William D. Dupont and W. Dale Plummer Jr., both of the Department of Biostatistics at Vanderbilt University, who are the authors of the original sunflower command, for their assistance in producing this version.

References

**Description**

`sureg` fits seemingly unrelated regression models (Zellner 1962; Zellner and Huang 1962; Zellner 1963). The acronyms SURE and SUR are often used for the estimator.

**Quick start**

Model of $y_1$ and $y_2$ as a function of $x_1$, $x_2$, and $x_3$

```
sureg (y1 x1 x2 x3) (y2 x1 x2 x3)
```

Same as above

```
sureg (y1 y2 = x1 x2 x3)
```

Same as above, but obtain small-sample statistics and use small-sample adjustment

```
sureg (y1 y2 = x1 x2 x3), small dfk
```

Also perform Breusch–Pagan test

```
sureg (y1 y2 = x1 x2 x3), small dfk corr
```

Model of $y_1$ as a function of $x_1$ and $x_2$ and $y_2$ as a function of $x_2$ and lag of $x_2$ using `tsset` data

```
sureg (y1 x1 x2) (y2 x2 L.x2)
```

**Menu**

Statistics > Linear models and related > Multiple-equation models > Seemingly unrelated regression
Syntax

Basic syntax

varlist1, ..., varlistN may contain factor variables; see [U] 11.4.3 Factor variables. You must have the same levels of factor variables in all equations that have factor variables.

depvars and the varlists may contain time-series operators; see [U] 11.4.4 Time-series varlists.

bootstrap, by, collect, fp, jackknife, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

aweights are not allowed with the jackknife prefix; see [R] jackknife.

aweights and fweights are allowed; see [U] 11.1.6 weight.

noheader, notable, and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

Model

isure specifies that sureg iterate over the estimated disturbance covariance matrix and parameter estimates until the parameter estimates converge. Under seemingly unrelated regression, this iteration converges to the maximum likelihood results. If this option is not specified, sureg produces two-step estimates.

constraints(constraints); see [R] Estimation options.

SE/Robust

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (unadjusted), that are robust to some kinds of misspecification (robust), and that allow for intragroup correlation (cluster clustvar); see [R] vce_option.

vce(unadjusted), the default, specifies that an unadjusted (nonrobust) VCE matrix be used; this results in efficient estimates when assuming homoskedasticity.

df adj.

small specifies that small-sample statistics be computed. It shifts the test statistics from $\chi^2$ and $z$ statistics to $F$ statistics and $t$ statistics. Although the standard errors from each equation are computed using the degrees of freedom for the equation, the degrees of freedom for the $t$ statistics are all taken to be those for the first equation.

dfk specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. As an asymptotically justified estimator, sureg by default uses the number of sample observations ($n$) as a divisor. When the dfk option is set, a small-sample adjustment is made and the divisor is taken to be $\sqrt{(n - k_i)(n - k_j)}$, where $k_i$ and $k_j$ are the number of parameters in equations $i$ and $j$, respectively.

dfk2 specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. When the dfk2 option is set, the divisor is taken to be the mean of the residual degrees of freedom from the individual equations.

Reporting

level(#); see [R] Estimation options.

corr displays the correlation matrix of the residuals between equations and performs a Breusch–Pagan test for independent equations; that is, the disturbance covariance matrix is diagonal.

nocnsreport; see [R] Estimation options.
display_options: noci, nopvvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrappon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt), and nolstretch; see [R] Estimation options.

Optimization

optimization_options control the iterative process that minimizes the sum of squared errors when isure is specified. These options are seldom used.

iterate(#) specifies the maximum number of iterations. When the number of iterations equals #, the optimizer stops and presents the current results, even if the convergence tolerance has not been reached. The default is the number set using set maxiter, which is 300 by default.

trace adds to the iteration log a display of the current parameter vector.

log and nolog specify whether to display the iteration log. The iteration log is displayed by default unless you used set iterlog off to suppress it; see set iterlog in [R] set iter.

tolerance(#) specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to #, the optimization process is stopped. tolerance(1e-6) is the default.

The following options are available with sureg but are not shown in the dialog box:

noheader suppresses display of the header reporting $F$ statistics, $R^2$, and root mean squared error above the coefficient table.

notable suppresses display of the coefficient table.

coefflegend; see [R] Estimation options.

Remarks and examples

Seemingly unrelated regression models are so called because they appear to be joint estimates from several regression models, each with its own error term. The regressions are related because the (contemporaneous) errors associated with the dependent variables may be correlated. Chapter 6 of Cameron and Trivedi (2022) contains a discussion of the seemingly unrelated regression model and the feasible generalized least-squares estimator underlying it.

Example 1

When we fit models with the same set of right-hand-side variables, the seemingly unrelated regression results (in terms of coefficients and standard errors) are the same as fitting the models separately (using, say, regress). The same is true when the models are nested. Even in such cases, sureg is useful when we want to perform joint tests. For instance, let us assume that we think

\[
\text{price} = \beta_0 + \beta_1 \text{foreign} + \beta_2 \text{length} + u_1 \\
\text{weight} = \gamma_0 + \gamma_1 \text{foreign} + \gamma_2 \text{length} + u_2
\]

Because the models have the same set of explanatory variables, we could estimate the two equations separately. Yet, we might still choose to estimate them with sureg because we want to perform the joint test $\beta_1 = \gamma_1 = 0$. 

We use the small and dfk options to obtain small-sample statistics comparable with \texttt{regress} or \texttt{mvreg}.

\begin{verbatim}
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. sureg (price foreign length) (weight foreign length), small dfk
\end{verbatim}

\begin{verbatim}
Seemingly unrelated regression
Equation Obs Params RMSE "R-squared" F P>F
price 74 2 2474.593 0.3154 16.35 0.0000
weight 74 2 250.2515 0.8992 316.54 0.0000
\end{verbatim}

\begin{verbatim}
| Coefficient Std. err. t P>|t| [95\% conf. interval] |
|-----------------|----------|--------|-------------|---------|------------------|
| price           |
| foreign         | 2801.143 766.117 3.66 0.000 1286.674 4315.611 |
| length          | 90.21239 15.83368 5.70 0.000 58.91219 121.5126 |
| _cons           | -11621.35 3124.436 -3.72 0.000 -17797.77 -5444.93 |
| weight          |
| foreign         | -133.6775 77.47615 -1.73 0.087 -286.8332 19.4782 |
| length          | 31.44455 1.601234 19.64 0.000 28.27921 34.60989 |
| _cons           | -2850.25 315.9691 -9.02 0.000 -3474.861 -2225.639 |
\end{verbatim}

Note: Small-sample degrees-of-freedom adjustment applied when estimating covariance matrix of residuals.

These two equations have a common set of regressors, and we could have used a shorthand syntax to specify the equations:

\begin{verbatim}
. sureg (price weight = foreign length), small dfk
\end{verbatim}

Here the results presented by \texttt{sureg} are the same as if we had estimated the equations separately:

\begin{verbatim}
. regress price foreign length
(output omitted)
. regress weight foreign length
(output omitted)
\end{verbatim}

There is, however, a difference. We have allowed \(u_1\) and \(u_2\) to be correlated and have estimated the full variance–covariance matrix of the coefficients. \texttt{sureg} has estimated the correlations, but it does not report them unless we specify the \texttt{corr} option. We did not remember to specify \texttt{corr} when we fit the model, but we can redisplay the results:

\begin{verbatim}
. sureg, notable noheader corr
Note: Small-sample degrees-of-freedom adjustment applied when estimating covariance matrix of residuals.
Correlation matrix of residuals:
\begin{verbatim}
<table>
<thead>
<tr>
<th>price</th>
<th>weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>1.0000</td>
</tr>
<tr>
<td>weight</td>
<td>0.5840</td>
</tr>
</tbody>
</table>
\end{verbatim}
Breusch-Pagan test of independence: chi2(1) = 25.237, Pr = 0.0000
\end{verbatim}

The \texttt{notable} and \texttt{noheader} options prevented \texttt{sureg} from redisplaying the header and coefficient tables. We find that, for the same cars, the correlation of the residuals in the \texttt{price} and \texttt{weight} equations is 0.5840 and that we can reject the hypothesis that this correlation is zero.
We can test that the coefficients on foreign are jointly zero in both equations—as we set out to do—by typing test foreign; see \texttt{[R] test}. When we type a variable without specifying the equation, that variable is tested for zero in all equations in which it appears:

\begin{verbatim}
. test foreign
  ( 1) [price]foreign = 0
  ( 2) [weight]foreign = 0
  F(  2,  142) = 17.99
  Prob > F = 0.0000
\end{verbatim}

\textbf{Example 2}

When the models do not have the same set of explanatory variables and are not nested, \texttt{sureg} may lead to more efficient estimates than running the models separately as well as allowing joint tests. This time, let us assume that we believe

\[
\begin{align*}
\text{price} &= \beta_0 + \beta_1 \text{foreign} + \beta_2 \text{mpg} + \beta_3 \text{displ} + u_1 \\
\text{weight} &= \gamma_0 + \gamma_1 \text{foreign} + \gamma_2 \text{length} + u_2
\end{align*}
\]

To fit this model, we type

\begin{verbatim}
. sureg (price foreign mpg displ) (weight foreign length), corr
\end{verbatim}

\begin{verbatim}
Seemingly unrelated regression

The coefficients are slightly different, but the standard errors are uniformly larger. This would still be true if we specified the dfk option to make a small-sample adjustment to the estimated covariance of the disturbances.

Technical note

Constraints can be applied to SURE models using Stata’s standard syntax for constraints. For a general discussion of constraints, see [R] constraint; for examples similar to seemingly unrelated regression models, see [R] reg3.

Stored results

sureg stores the following in e():

Scalars

- e(N) number of observations
- e(k) number of parameters
- e(k_eq) number of equations in e(b)
- e(mss_#) model sum of squares for equation #
- e(df_m#) model degrees of freedom for equation #
- e(rss_#) residual sum of squares for equation #
- e(df_r) residual degrees of freedom
- e(r2_#) $R^2$ for equation #
- e(F_#) $F$ statistic for equation # (small only)
- e(rmse_#) root mean squared error for equation #
- e(dfk2_adj) divisor used with VCE when dfk2 specified
- e(ll) log likelihood
- e(N_clust) number of clusters
- e(chi2_#) $\chi^2$ for equation #
- e(p_#) $p$-value for equation #
- e(cons_#) 1 if equation # has a constant, 0 otherwise
- e(chi2_bp) Breusch–Pagan $\chi^2$
- e(df_bp) degrees of freedom for Breusch–Pagan $\chi^2$ test
- e(rank) rank of e(V)
- e(ic) number of iterations
In addition to the above, the following is stored in \( r() \):

Matrices

\[ r(\text{table}) \]

matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in \( r() \) are updated when the command is replayed and will be replaced when any \( r \)-class command is run after the estimation command.

**Methods and formulas**

`sureg` uses the asymptotically efficient, feasible, generalized least-squares algorithm described in Greene (2018, 328–339). The computing formulas are given on page 328–335.

The \( R^2 \) reported is the percent of variance explained by the predictors. It may be used for descriptive purposes, but \( R^2 \) is not a well-defined concept when GLS is used.

`sSureg` will refuse to compute the estimators if the same equation is named more than once or the covariance matrix of the residuals is singular.

The Breusch and Pagan (1980) \( \chi^2 \) statistic—a Lagrange multiplier statistic—is given by

\[
\lambda = T \sum_{m=1}^{M} \sum_{n=1}^{m-1} r_{mn}^2
\]

where \( r_{mn} \) is the estimated correlation between the residuals of the \( M \) equations and \( T \) is the number of observations. It is distributed as \( \chi^2 \) with \( M(M - 1)/2 \) degrees of freedom.
This command supports the Huber/White/sandwich estimator of the variance and its clustered version using vce(robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Introduction and Methods and formulas.

Arnold Zellner (1927–2010) was born in New York. He studied physics at Harvard and economics at Berkeley, and then he taught economics at the Universities of Washington and Wisconsin before settling in Chicago in 1966. Among his many major contributions to econometrics and statistics are his work on seemingly unrelated regression, three-stage least squares, and Bayesian econometrics.

</table>
predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, residuals, and differences between the linear predictions.

Menu for predict

Statistics  >  Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, equation(eqno[,eqno]) statistic]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main</td>
<td></td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction; the default</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
<tr>
<td>residuals</td>
<td>residuals</td>
</tr>
<tr>
<td>difference</td>
<td>difference between the linear predictions of two equations</td>
</tr>
<tr>
<td>stddp</td>
<td>standard error of the difference in linear predictions</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type `predict ... if e(sample) ... if wanted` only for the estimation sample.

Options for predict

- `equation(eqno[,eqno])` specifies to which equation(s) you are referring.

  `equation()` is filled in with one `eqno` for the `xb`, `stdp`, and `residuals` options. `equation(#1)` would mean that the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named income and `equation(hours)` to the equation named hours.

  If you do not specify `equation()`, the results are the same as if you specified `equation(#1)`.

- `difference` and `stddp` refer to between-equation concepts. To use these options, you must specify two equations, for example, `equation(#1,#2)` or `equation(income,hours)`. When two equations must be specified, `equation()` is required.

  `xb`, the default, calculates the linear prediction (fitted values)—the prediction of $x_j b$ for the specified equation.

  `stdp` calculates the standard error of the prediction for the specified equation. It can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern.

  The standard error of the prediction is also referred to as the standard error of the fitted value.

  `residuals` calculates the residuals.
difference calculates the difference between the linear predictions of two equations in the system. With equation(#1,#2), difference computes the prediction of equation(#1) minus the prediction of equation(#2).

stddp is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions \( (x_{1j}b - x_{2j}b) \) between equations 1 and 2 is calculated.

For more information on using predict after multiple-equation estimation commands, see [R] predict.

**margins**

**Description for margins**

margins estimates margins of response for linear predictions and differences between the linear predictions.

**Menu for margins**

Statistics > Postestimation

**Syntax for margins**

```
margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>linear predictions for each equation</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction for a specified equation</td>
</tr>
<tr>
<td>difference</td>
<td>difference between the linear predictions of two equations</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
<tr>
<td>residuals</td>
<td>not allowed with margins</td>
</tr>
<tr>
<td>stddp</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

XB defaults to the first equation.

Statistics not allowed with margins are functions of stochastic quantities other than \( e(b) \).

For the full syntax, see [R] margins.
Remarks and examples

For an example of cross-equation testing of parameters using the `test` command, see example 1 in [R] `sureg`.

Example 1

In example 1 of [R] `sureg`, we fit a seemingly unrelated regressions model of `price` and `weight`. Here we obtain the fitted values.

```
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. sureg (price foreign length) (weight foreign length), small dfk
(output omitted)
. predict phat, equation(price)
  (option xb assumed; fitted values)
. predict what, equation(weight)
  (option xb assumed; fitted values)
. summarize price phat weight what
```

```
<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>74</td>
<td>6165.257</td>
<td>2949.496</td>
<td>3291</td>
<td>15906</td>
</tr>
<tr>
<td>phat</td>
<td>74</td>
<td>6165.257</td>
<td>1656.407</td>
<td>1639.872</td>
<td>9398.138</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>777.1936</td>
<td>1760</td>
<td>4840</td>
</tr>
<tr>
<td>what</td>
<td>74</td>
<td>3019.459</td>
<td>736.9666</td>
<td>1481.199</td>
<td>4476.331</td>
</tr>
</tbody>
</table>
```

Just as in single-equation OLS regression, in a SURE model the sample mean of the fitted values for an equation equals the sample mean of the dependent variable.

Example 2

Suppose that for whatever reason we were interested in the difference between the predicted values of `price` and `weight`. `predict` has an option to compute this difference in one step:

```
. predict diff, equation(price, weight) difference
```

diff is the same as `phat - what`:

```
. generate mydiff = phat - what
. summarize diff mydiff
```

```
<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>diff</td>
<td>74</td>
<td>3145.797</td>
<td>1233.26</td>
<td>-132.2275</td>
<td>5505.914</td>
</tr>
<tr>
<td>mydiff</td>
<td>74</td>
<td>3145.797</td>
<td>1233.26</td>
<td>-132.2275</td>
<td>5505.914</td>
</tr>
</tbody>
</table>
```

[U] 20 Estimation and postestimation commands
swilk — Shapiro–Wilk and Shapiro–Francia tests for normality

**Description**

swilk performs the Shapiro–Wilk $W$ test for normality for each variable in the specified varlist. Likewise, sfrancia performs the Shapiro–Francia $W'$ test for normality. See [MV] mvtest normality for multivariate tests of normality.

**Quick start**

*Shapiro–Wilk test of normality*

Shapiro–Wilk test for v1

```
swilk v1
```

Separate tests of normality for v1 and v2

```
swilk v1 v2
```

Generate new variable w containing $W$ test coefficients

```
swilk v1, generate(w)
```

Specify that average ranks should not be used for tied values

```
swilk v1 v2, noties
```

Test that v3 is distributed lognormally

```
generate lnv3 = ln(v3)
swilk lnv3
```

*Shapiro–Francia test of normality*

Shapiro–Francia test for v1

```
sfrancia v1
```

Separate tests of normality for v1 and v2

```
sfrancia v1 v2
```

Same as above, but use the Box–Cox transformation

```
sfrancia v1 v2, boxcox
```

Specify that average ranks should not be used for tied values

```
sfrancia v1 v2, noties
```
### Menu

**swilk**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Shapiro-Wilk normality test

**sfrancia**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Shapiro-Francia normality test

### Syntax

**Shapiro–Wilk normality test**

```
swilk varlist [if] [in] [, swilk_options]
```

**Shapiro–Francia normality test**

```
sfrancia varlist [if] [in], sfrancia_options
```

#### swilk_options

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Main</strong></td>
</tr>
<tr>
<td><code>generate(newvar)</code></td>
</tr>
<tr>
<td><code>lnnormal</code></td>
</tr>
<tr>
<td><code>noties</code></td>
</tr>
</tbody>
</table>

#### sfrancia_options

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Main</strong></td>
</tr>
<tr>
<td><code>boxcox</code></td>
</tr>
<tr>
<td><code>noties</code></td>
</tr>
</tbody>
</table>

by and collect are allowed with `swilk` and `sfrancia`; see [U] 11.1.10 Prefix commands.

### Options for `swilk`

- **generate(newvar)** creates new variable `newvar` containing the $W$ test coefficients.

- **lnnormal** specifies that the test be for three-parameter lognormality, meaning that $\ln(X - k)$ is tested for normality, where $k$ is calculated from the data as the value that makes the skewness coefficient zero. When simply testing $\ln(X)$ for normality, do not specify this option. See [R] `lnskew0` for estimation of $k$. 

- **noties** suppresses use of averaged ranks for tied values when calculating the $W$ test coefficients.
Options for sfrancia

boxcox specifies that the Box–Cox transformation of Royston (1983) for calculating $W'$ test coefficients be used instead of the default log transformation (Royston 1993a). Under the Box–Cox transformation, the normal approximation to the sampling distribution of $W'$, used by sfrancia, is valid for $5 \leq n \leq 1000$. Under the log transformation, it is valid for $10 \leq n \leq 5000$.

noties suppresses use of averaged ranks for tied values when calculating the $W'$ test coefficients.

Remarks and examples

s威尔k can be used with $4 \leq n \leq 2000$ observations. sfrancia can be used with $10 \leq n \leq 5000$ observations; however, if the boxcox option is specified, it can be used with $5 \leq n \leq 1000$ observations.

Also see [R] sktest for the skewness and kurtosis test described by D’Agostino, Belanger, and D’Agostino (1990) with the empirical correction developed by Royston (1991b). While the Shapiro–Wilk and Shapiro–Francia tests for normality are, in general, preferred for nonaggregated data (Gould and Rogers 1991; Gould 1992b; Royston 1991b), the skewness and kurtosis test will permit more observations. Moreover, a normal quantile plot should be used with any test for normality; see [R] Diagnostic plots for more information.

Example 1

Using our automobile dataset, we will test whether the variables mpg and trunk are normally distributed:

```
. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. swilk mpg trunk
    Shapiro–Wilk W test for normal data
    Variable |     Obs  W   V   z  Prob>z
    -------- | -------- ---- --- ----- -----
             |  74 0.94821 3.335 2.627  0.00430
      mpg |  74 0.97921 1.339 0.637  0.26215
    trunk |  74 0.94872 3.650 2.510  0.00604
. sfrancia mpg trunk
    Shapiro–Francia W' test for normal data
    Variable |     Obs  W'  V'   z  Prob>z
    -------- | -------- ---- --- ----- -----
             |  74 0.94872 3.650 2.510  0.00604
      mpg |  74 0.98446 1.106 0.195  0.42271
    trunk |  74 0.98446 1.106 0.195  0.42271
```

We can reject the hypothesis that mpg is normally distributed, but we cannot reject that trunk is normally distributed.

The values reported under $W$ and $W'$ are the Shapiro–Wilk and Shapiro–Francia test statistics. The tests also report $V$ and $V'$ (Royston 1991d), which are more appealing indexes for departure from normality. The median values of $V$ and $V'$ are 1 for samples from normal populations. Large values indicate nonnormality. There is no more information in $V$ ($V'$) than in $W$ ($W'$)—one is just the transform of the other.
Example 2

We have data on a variable called `studytime`, which we suspect is distributed lognormally:

```stata
. use https://www.stata-press.com/data/r18/cancer (Patient survival in drug trial)
. generate lnstudytime = ln(studytime)
. swilk lnstudytime
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>W</th>
<th>V</th>
<th>z</th>
<th>Prob&gt;z</th>
</tr>
</thead>
<tbody>
<tr>
<td>lnstudytime</td>
<td>48</td>
<td>0.92731</td>
<td>3.311</td>
<td>2.547</td>
<td>0.00543</td>
</tr>
</tbody>
</table>

We can reject the lognormal assumption. We do not specify the `lnnormal` option when testing for lognormality. The `lnnormal` option is for three-parameter lognormality.

Example 3

Having discovered that ln(studytime) is not distributed normally, we now test that ln(studytime – k) is normally distributed, where k is chosen so that the resulting skewness is zero. We obtain the estimate for k from `lnskew0`; see [R] `lnskew0`:

```stata
. lnskew0 lnstudytimek = studytime, level(95)
```

<table>
<thead>
<tr>
<th>Transform</th>
<th>k</th>
<th>[95% conf. interval]</th>
<th>Skewness</th>
</tr>
</thead>
<tbody>
<tr>
<td>ln(studytime-k)</td>
<td>-11.01181</td>
<td>-infinity</td>
<td>-.9477328</td>
</tr>
</tbody>
</table>

```stata
. swilk lnstudytimek, lnnormal
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>W</th>
<th>V</th>
<th>z</th>
<th>Prob&gt;z</th>
</tr>
</thead>
<tbody>
<tr>
<td>lnstudytimek</td>
<td>48</td>
<td>0.97064</td>
<td>1.337</td>
<td>1.261</td>
<td>0.10363</td>
</tr>
</tbody>
</table>

We cannot reject the hypothesis that ln(studytime + 11.01181) is distributed normally. We do specify the `lnnormal` option when using an estimated value of k.

Stored results

`swilk` and `sfrancia` store the following in `r()`:

Scalars

- `r(N)` number of observations
- `r(p)` p-value
- `r(z)` z statistic
- `r(W)` W or W’
- `r(V)` V or V’

Methods and formulas

The Shapiro–Francia test (Shapiro and Francia 1972; Royston 1983; Royston 1993a) is an approximate test that is similar to the Shapiro–Wilk test for very large samples.

The relative merits of the Shapiro–Wilk and Shapiro–Francia tests versus skewness and kurtosis test have been a subject of debate. The interested reader is directed to the articles in the Stata Technical Bulletin. Our recommendation is to use the Shapiro–Francia test whenever possible, that is, whenever dealing with nonaggregated or ungrouped data (Gould and Rogers 1991; Gould 1992b); see [R] swilk. If normality is rejected, use sktest to determine the source of the problem. As both D’Agostino, Belanger, and D’Agostino (1990) and Royston (1991c) mention, researchers should also examine the normal quantile plot to determine normality rather than blindly relying on a few test statistics. See the qnorm command documented in [R] Diagnostic plots for more information on normal quantile plots.

Acknowledgment

swilk and sfrancia were written by Patrick Royston of the MRC Clinical Trials Unit, London and coauthor of the Stata Press book Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model.

### Description

`symmetry` performs asymptotic symmetry and marginal homogeneity tests, as well as an exact symmetry test on $K \times K$ tables where there is a 1-to-1 matching of cases and controls (nonindependence). This testing is used to analyze matched-pair case–control data with multiple discrete levels of the exposure (outcome) variable. In genetics, the test is known as the transmission/disequilibrium test (TDT) and is used to test the association between transmitted and nontransmitted parental marker alleles to an affected child (Spieldman, McGinnis, and Ewens 1993). For $2 \times 2$ tables, the asymptotic test statistics reduce to the McNemar test statistic, and the exact symmetry test produces an exact McNemar test; see [R] Epitab. For many exposure variables, `symmetry` can optionally perform a test for linear trend in the log relative risk.

`symmetry` expects the data to be in the wide format; that is, each observation contains the matched case and control values in variables `casevar` and `controlvar`. Variables can be numeric or string.

`symmi` is the immediate form of `symmetry`. The `symmi` command uses the values specified on the command line; rows are separated by `'\'`, and options are the same as for `symmetry`. See [U] 19 Immediate commands for a general introduction to immediate commands.

### Quick start

Symmetry and marginal homogeneity tests for 1-to-1 matched case–control studies

```bash
symmetry case control
```

Same as above

```bash
symmetry control case
```

Exact test of table symmetry

```bash
symmetry case control, exact
```

Report the contribution from each off-diagonal pair to the overall $\chi^2$-statistic

```bash
symmetry control case, contrib
```

Test for a linear trend in the log of the relative risk

```bash
symmetry control case, trend
```

Request marginal homogeneity statistics that do not require the inversion of the variance–covariance matrix

```bash
symmetry case control, mh
```

Using frequency weight variable `wvar`

```bash
symmetry case control [fweight=wvar]
```

notable                              suppress output of contingency table
contrib                          report contribution of each off-diagonal cell pair
exact                               perform exact test of table symmetry
mh                                  perform two marginal homogeneity tests
trend                               perform a test for linear trend in the (log) relative risk (RR)
cc                                   use continuity correction when calculating test for linear trend

collect is allowed with symmetry; see [U] 11.1.10 Prefix commands.
fweights are allowed; see [U] 11.1.6 weight.

Options

notable suppresses the output of the contingency table. By default, symmetry displays the \( n \times n \) contingency table at the top of the output.

contrib reports the contribution of each off-diagonal cell pair to the overall symmetry \( \chi^2 \).

exact performs an exact test of table symmetry. This option is recommended for sparse tables.

CAUTION: The exact test requires substantial amounts of time and memory for large tables.

mh performs two marginal homogeneity tests that do not require the inversion of the variance–covariance matrix.

By default, symmetry produces the Stuart–Maxwell test statistic, which requires the inversion of the nondiagonal variance–covariance matrix, \( V \). When the table is sparse, the matrix may not be of full rank, and then the command substitutes a generalized inverse \( V^* \) for \( V^{-1} \). mh calculates optional marginal homogeneity statistics that do not require the inversion of the variance–covariance matrix. These tests may be preferred in certain situations. See Methods and formulas and Bickebøller and Clerget-Darpoux (1995) for details on these test statistics.
trend performs a test for linear trend in the (log) relative risk (RR). This option is allowed only for numeric exposure (outcome) variables, and its use should be restricted to measurements on the ordinal or the interval scales.

cc specifies that the continuity correction be used when calculating the test for linear trend. This correction should be specified only when the levels of the exposure variable are equally spaced.

### Remarks and examples

symmetry and symmi may be used to analyze 1-to-1 matched case–control data with multiple discrete levels of the exposure (outcome) variable.

#### Example 1

Consider a survey of 344 individuals (BMDP 1990, 267–270) who were asked in October 1986 whether they agreed with President Reagan’s handling of foreign affairs. In January 1987, after the Iran-Contra affair became public, these same individuals were surveyed again and asked the same question. We would like to know if public opinion changed over this period.

We first describe the dataset and list a few observations.

```
. use https://www.stata-press.com/data/r18/iran
. describe
Contains data from https://www.stata-press.com/data/r18/iran.dta
Observations: 344
Variables: 2

</tr>
<tr>
<td>Disagree</td>
<td>Disagree</td>
</tr>
</tbody>
</table>

Each observation corresponds to one of the 344 individuals. The data are in wide form so that each observation has a before and an after measurement. We now perform the test without options.
The test first tabulates the data in a $K \times K$ table and then performs Bowker’s (1948) test for table symmetry and the Stuart–Maxwell (Stuart 1955; Maxwell 1970) test for marginal homogeneity.

Both the symmetry test and the marginal homogeneity test are highly significant, thus indicating a shift in public opinion.

An exact test of symmetry is provided for use on sparse tables. This test is computationally intensive, so it should not be used on large tables. Because we are working on a fast computer, we will run the symmetry test again and this time include the exact option. We will suppress the output of the contingency table by specifying notable and include the contrib option so that we may further examine the cells responsible for the significant result.

The largest contribution to the symmetry $\chi^2$ is due to cells $n_{12}$ and $n_{21}$. These correspond to changes between the agree and disagree categories. Of the 344 individuals, 56 (16.3%) changed from the agree to the disagree response, whereas only 28 (8.1%) changed in the opposite direction.

For these data, the results from the exact test are similar to those from the asymptotic test.
Example 2

Breslow and Day (1980, 163) reprinted data from Mack et al. (1976) from a case–control study of the effect of exogenous estrogen on the risk of endometrial cancer. The data consist of 59 elderly women diagnosed with endometrial cancer and 59 disease-free control subjects living in the same community as the cases. Cases and controls were matched on age, marital status, and time living in the community. The data collected included information on the daily dose of conjugated estrogen therapy. Breslow and Day analyzed these data by creating four levels of the dose variable. Here are the data as entered into a Stata dataset:

```
use https://www.stata-press.com/data/r18/bd163

</tbody>
</table>

This dataset is in a different format from that of the previous example. Instead of each observation representing one matched pair, each observation represents possibly multiple pairs indicated by the count variable. For instance, the first observation corresponds to six matched pairs where neither the case nor the control was on estrogen, the second observation corresponds to two matched pairs where the case was not on estrogen and the control was on 0.1 to 0.299 mg/day, etc.

To use symmetry to analyze this dataset, we must specify fweight to indicate that in our data there are observations corresponding to more than one matched pair.
Both the test of symmetry and the test of marginal homogeneity are highly significant, thus leading us to reject the null hypothesis that there is no effect of exposure to estrogen on the risk of endometrial cancer.

Breslow and Day perform a test for trend assuming that the estrogen exposure levels were equally spaced by recoding the exposure levels as 1, 2, 3, and 4.

We can easily reproduce their results by recoding our data in this way and by specifying the trend option. Two new numeric variables were created, ca and co, corresponding to the variables case and control, respectively. Below, we list some of the data and our results from symmetry:

```
. encode case, gen(ca)
. encode control, gen(co)
. label values ca
. label values co
. list in 1/4
```

<table>

<td>3</td>
<td>0.0007</td>
</tr>
</tbody>
</table>

| Linear trend in the (log) RR | 14.43 | 1  | 0.0001    |

We requested the continuity correction by specifying cc. Doing so is appropriate because our coded exposure levels are equally spaced.

The test for trend was highly significant, indicating an increased risk of endometrial cancer with increased dosage of conjugated estrogen.

You must be cautious: the way in which you code the exposure variable affects the linear trend statistic. If instead of coding the levels as 1, 2, 3, and 4, we had instead used 0, 0.2, 0.46, and 0.7
(roughly the midpoint in the range of each level), we would have obtained a $\chi^2$ statistic of 11.19 for these data.

**Stored results**

`symmetry` stores the following in `r()`:

Scalars
- `r(N_pair)` number of matched pairs
- `r(chi2)` asymptotic symmetry $\chi^2$
- `r(df)` asymptotic symmetry degrees of freedom
- `r(p)` asymptotic symmetry $p$-value
- `r(chi2_sm)` MH (Stuart–Maxwell) $\chi^2$
- `r(df_sm)` MH (Stuart–Maxwell) degrees of freedom
- `r(p_sm)` MH (Stuart–Maxwell) $p$-value
- `r(chi2_b)` MH (Bickenböller) $\chi^2$
- `r(df_b)` MH (Bickenböller) degrees of freedom
- `r(p_b)` MH (Bickenböller) $p$-value
- `r(chi2_nd)` MH (no diagonals) $\chi^2$
- `r(df_nd)` MH (no diagonals) degrees of freedom
- `r(p_nd)` MH (no diagonals) $p$-value
- `r(chi2_t)` $\chi^2$ for linear trend
- `r(p_trend)` $p$-value for linear trend
- `r(p_exact)` exact symmetry $p$-value

**Methods and formulas**

Methods and formulas are presented under the following headings:

*Asymptotic tests*
*Exact symmetry test*

**Asymptotic tests**

Consider a square table with $K$ exposure categories, that is, $K$ rows and $K$ columns. Let $n_{ij}$ be the count corresponding to row $i$ and column $j$ of the table, $N_{ij} = n_{ij} + n_{ji}$, for $i, j = 1, 2, \ldots, K$, and $n_i$ and $n_j$ be the marginal totals for row $i$ and column $j$, respectively. Asymptotic tests for symmetry and marginal homogeneity for this $K \times K$ table are calculated as follows:

The null hypothesis of complete symmetry $p_{ij} = p_{ji}$, $i \neq j$, is tested by calculating the test statistic (Bowker 1948)

$$T_{cs} = \sum_{i<j} \frac{(n_{ij} - n_{ji})^2}{n_{ij} + n_{ji}}$$

which is asymptotically distributed as $\chi^2$ with $K(K - 1)/2 - R$ degrees of freedom, where $R$ is the number of off-diagonal cells with $N_{ij} = 0$ as discussed in Hoenig, Morgan, and Brown (1995).
The null hypothesis of marginal homogeneity, \( p_i = p_{.i} \), is tested by calculating the Stuart–Maxwell test statistic (Stuart 1955; Maxwell 1970),

\[
T_{sm} = d'V^{-1}d
\]

where \( d \) is a column vector with elements equal to the differences \( d_i = n_i - n_{.i} \) for \( i = 1, 2, \ldots, K \), and \( V \) is the variance–covariance matrix with elements

\[
\begin{align*}
v_{ii} &= n_i + n_{.i} - 2n_{ii} \\v_{ij} &= -(n_{ij} + n_{ji}), \quad i \neq j
\end{align*}
\]

\( T_{sm} \) is asymptotically \( \chi^2 \) with \( K - 1 \) degrees of freedom.

This test statistic properly accounts for the dependence between the table’s rows and columns. When the matrix \( V \) is not of full rank, a generalized inverse \( V^* \) is substituted for \( V^{-1} \).

The Bickeböller and Clerget-Darpoux (1995) marginal homogeneity test statistic is calculated by

\[
T_{mh} = \sum_i \frac{(n_i - n_{.i})^2}{n_i + n_{.i}}
\]

This statistic is asymptotically distributed, under the assumption of marginal independence, as \( \chi^2 \) with \( K - 1 \) degrees of freedom.

The marginal homogeneity (no diagonals) test statistic \( T_{mh}^0 \) is calculated in the same way as \( T_{mh} \), except that the diagonal elements do not enter into the calculation of the marginal totals. Unlike the previous test statistic, \( T_{mh}^0 \) reduces to a McNemar test statistic for \( 2 \times 2 \) tables. The test statistic \( \{(K - 1)/2\}T_{mh}^0 \) is asymptotically distributed as \( \chi^2 \) with \( K - 1 \) degrees of freedom (Cleves, Olson, and Jacobs 1997; Spieldman and Ewens 1996).

Breslow and Day’s test statistic for linear trend in the (log) of RR is

\[
\left\{ \sum_{i<j} (n_{ij} - n_{ji})(X_j - X_i) - cc \right\}^2
\]

\[
\sum_{i<j} (n_{ij} + n_{ji})(X_j - X_i)^2
\]

where the \( X_j \) are the doses associated with the various levels of exposure and \( cc \) is the continuity correction; it is asymptotically distributed as \( \chi^2 \) with 1 degree of freedom.

The continuity correction option is applicable only when the levels of the exposure variable are equally spaced.

**Exact symmetry test**

The exact test is based on a permutation algorithm applied to the null distribution. The distribution of the off-diagonal elements \( n_{ij}, i \neq j \), conditional on the sum of the complementary off-diagonal cells, \( N_{ij} = n_{ij} + n_{ji} \), can be written as the product of \( K(K - 1)/2 \) binomial random variables,

\[
P(n) = \prod_{i<j} \binom{N_{ij}}{n_{ij}} \pi_{ij}^{n_{ij}} (1 - \pi_{ij})^{n_{ij}}
\]

where \( n \) is a vector with elements \( n_{ij} \) and \( \pi_{ij} = E(n_{ij}/N_{ij}|N_{ij}) \). Under the null hypothesis of complete symmetry, \( \pi_{ij} = \pi_{ji} = 1/2 \), and thus the permutation distribution is given by
\[ P_0(n) = \prod_{i<j} \left( \frac{N_{ij}}{n_{ij}} \right) \left( \frac{1}{2} \right)^{N_{ij}} \]

The exact significance test is performed by evaluating

\[ P_{cs} = \sum_{n \in p} P_0(n) \]

where \( p = \{ n : P_0(n) < P_0(n^*) \} \) and \( n^* \) is the observed contingency table data vector. The algorithm evaluates \( p_{cs} \) exactly. For information about permutation tests, see Good (2005, 2006).

Introduction to tables of frequencies, summaries, and command results

Description

Tables allow us to effectively communicate information about our data and results from our analyses. The `table` command is a flexible tool for creating tables. It allows you to create tabulations, tables of summary statistics, tables of results from hypothesis tests, tables of regression results, and more. `table` also allows you to customize the table so that it effectively communicates the results.

Remarks and examples

Remarks are presented under the following headings:

- Overview
- Tabulations
- Tables of summary statistics
- Tables of results from other commands
- Flexible tables combining results
- Formatting, customizing, and exporting tables

Overview

The `table` command allows you to create various types of tables.

1. Tabulations of one, two, or more categorical variables, reporting frequencies, percentages, or proportions.
2. Tables of summary statistics such as means, standard deviations, medians, and the like—perhaps computed across levels of one or more categorical variables.
3. Tables of results from other Stata commands, such as regression results or results of classic hypothesis tests.
4. Tables combining summary statistics and results from other Stata commands.

`table` obtains the statistics it reports in two ways. The `table` command itself can compute summary statistics. `table` also provides a `command()` option that allows you to run any Stata command and include its results in the table.

`table` also provides much flexibility for you to arrange the results in your table in a meaningful way. You can control how the rows, columns, and potentially even separate tables are defined. For instance, you might type

```
  . table (var1) (var2) ...
```

to place the levels of `var1` on the rows and the levels of `var2` on the columns. The first set of parentheses is used to define the rows, and the second set is used to define the columns. The parentheses could be omitted in this case, but for clarity we will use them in our discussion here.
We could use the levels of both `var1` and `var2` to define the rows.

```
.table (var1 var2) ...
```

If we have an additional variable, `var3`, we can define rows by both `var1` and `var2` and the columns by `var3` by typing

```
.table (var1 var2) (var3) ...
```
or we can place the levels of `var2` and `var3` on the columns,

```
.table (var1) (var2 var3) ...
```

We could even create separate tables for the levels of `var3`,

```
.table (var1) (var2) (var3) ...
```

The third set of parentheses defines the separate tables.

If our table reports multiple statistics, say, means and standard deviations, we can use the keyword `result` to specify how they are included in the table layout. To place the statistics on separate rows, we could type

```
.table (var1 result) (var2) ...
```

The flexibility of the table layout goes beyond these examples. You can add additional variables to define rows, columns, and tables as is appropriate for the table you wish to create.

In addition to controlling the layout of your table, you can customize the results by specifying formats, including stars representing significance, and selecting from styles that determine how the headers of the table are displayed.

### Tabulations

Tabulations allow you to examine the distribution of your data across the levels of one or more categorical variables. Tabulations often report frequencies, percentages, and proportions.

With `table`, you can easily create one-way tabulations, two-way tabulations, three-way tabulations, and even more complex tabulations. For example, we could create a two-way tabulation of `region` and `diabetes`, reporting frequencies,

```
.table (region) (diabetes)
```

<table>
<thead>
<tr>
<th>Region</th>
<th>Diabetes status</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Not diabetic</td>
<td>Diabetic</td>
<td>Total</td>

<td>2,648</td>
<td>125</td>
<td>2,773</td>
</tr>
<tr>
<td>S</td>
<td>2,692</td>
<td>161</td>
<td>2,853</td>
</tr>
<tr>
<td>W</td>
<td>2,513</td>
<td>115</td>
<td>2,628</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>9,850</strong></td>
<td><strong>499</strong></td>
<td><strong>10,349</strong></td>
</tr>
</tbody>
</table>
or we can report percentages,

```
.table (region) (diabetes), statistic(percent)
```

<table>
<thead>
<tr>
<th>Region</th>
<th>Not diabetic</th>
<th>Diabetic</th>
<th>Total</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Total</td>
<td>95.18</td>
<td>4.82</td>
<td>100.00</td>
</tr>
</tbody>
</table>

To learn how to create tabulations, see

[R] `table oneway` One-way tabulation
[R] `table twoway` Two-way tabulation
[R] `table multiway` Multiway tables

In these entries, we provide simplified syntax for creating the specific type of tabulation you are interested in, and we provide a number of examples demonstrating how to build these tables and customize the results.

**Tables of summary statistics**

`table` can compute summary statistics such as minimums, maximums, means, standard deviations, medians, and interquartile ranges. Summary statistics can be computed for one or more variables. Summary statistics can also be computed separately for groups of data. For example, we can create a table reporting the means of `age`, `height`, and `bmi`,

```
.table, statistic(mean age height bmi)
```

<table>
<thead>
<tr>
<th>Age (years)</th>
<th>47.57965</th>
</tr>
</thead>
<tbody>
<tr>
<td>Height (cm)</td>
<td>167.6509</td>
</tr>
<tr>
<td>Body mass index (BMI)</td>
<td>25.5376</td>
</tr>
</tbody>
</table>

or we can compute these means separately for males and females,

```
.table () (sex), statistic(mean age height bmi)
```

<table>
<thead>
<tr>
<th>Sex</th>
<th>Age (years)</th>
<th>Height (cm)</th>
<th>Body mass index (BMI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>47.4238</td>
<td>174.7421</td>
<td>25.50999</td>
</tr>
<tr>
<td>Female</td>
<td>47.72057</td>
<td>161.2393</td>
<td>25.56256</td>
</tr>
<tr>
<td>Total</td>
<td>47.57965</td>
<td>167.6509</td>
<td>25.5376</td>
</tr>
</tbody>
</table>

To learn how to create tables of summary statistics, including the simplified `table` syntax and worked examples, see

[R] `table summary` Table of summary statistics

You can also create a table of summary statistics with `dtable`. The advantage of using `dtable` is that you can create a table with a title and notes and export it to a variety of file types, all in a single step. Unlike `table`, however, `dtable` has a predefined layout, and you will not be able to specify how the results should be arranged in the table.
Tables of results from other commands

With table’s command() option, you can run any Stata command and place statistics reported by that command in your table. For instance, you might use test to test for differences in means or use regress to fit a linear regression model. You can include any stored results from these commands in your table. For example, we can create a table to compare coefficients from linear regressions of bpsysol on age and weight fit separately for males and females.

```
.table (colname) (sex result), command(regress bpsystol age weight)
```

<table>
<thead>
<tr>
<th></th>
<th>Male</th>
<th>Female</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years)</td>
<td>.4789361</td>
<td>.7735499</td>
<td>.6379892</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>.3346106</td>
<td>.4586108</td>
<td>.4069041</td>
</tr>
<tr>
<td>Intercept</td>
<td>84.08037</td>
<td>61.70456</td>
<td>71.27096</td>
</tr>
</tbody>
</table>

To learn how to create tables with results from other commands, including simplified table syntax and worked examples, see

[R] table hypothesis tests  Table of hypothesis tests
[R] table regression        Table of regression results

Flexible tables combining results

`table` can create tables with combinations of frequencies, other summary statistics, and results from other table commands. To see the full syntax and discussion of how `table` automates the table layout, see

[R] table  Table of frequencies, summaries, and command results

Formatting, customizing, and exporting tables

`table` allows you to customize your results by specifying the layout and with options that change the numeric formatting, add characters such as percent signs or parentheses to specific types of statistics, add stars representing significance levels, and modify the look of confidence intervals. In addition, Stata provides predefined styles that you may select from using the `style()` option. These styles control which labels are displayed in the headers of the tables, how the labels are aligned, how the statistics are aligned within the cells, and more. To learn about the predefined styles that you can select from, see [TABLES] Predefined styles. Examples of using the `style()` and other formatting options are provided in the entries for specific types of tables listed in the previous sections.

The results from `table` can be customized even beyond what its formatting options allow. `table` is unique in that it stores its results in a format that we refer to as a “collection”. Stata’s `collect` suite of commands can be used to produce highly customized tables from results in a collection and to export those tables to presentation-ready formats such as HTML, Word, LaTeX, PDF, Excel, and more. Examples of using `collect` to modify labels and table layout are also provided in the entries for the specific types of tables listed in the previous sections. To learn more about the `collect` commands, see [TABLES] Intro and the entries discussed therein.

[R] table — Table of frequencies, summaries, and command results
[TABLES] Intro — Introduction
In this entry, we discuss how to use `table` to create a one-way tabulation, including frequencies, percentages, and proportions.

### Quick start

One-way table of frequencies, with rows corresponding to the levels of `a1`

```
table a1
```

Same as above, but with columns corresponding to the levels of `a1`

```
table () a1
```

Same as above, but treat missing values like other values of `a1`

```
table () a1, missing
```

One-way table of frequencies, using the collection style `mystyle`

```
table a1, style(mystyle)
```

One-way table of frequencies and percentages

```
table a1, statistic(frequency) statistic(percent)
```

### Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results
Syntax

**Basic one-way tabulation**

```
table varname [if] [in] [weight] [, options]
```

**Customized one-way tabulation**

```
table [(rowspec)] [(colspec)] [if] [in] [weight] [, options]
```

`rowspec` and `colspec` may be empty or may include `varname`, `result`, or `varname` and `result`, where `result` refers to the requested statistics.

**options**

</tbody>
</table>

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
strL variables are not allowed; see [U] 12.4.8 strL.
markvar() does not appear in the dialog box.
Options

nototals prevents table from displaying the row or column totals.

statistic(stat) specifies the statistic to be displayed. statistic() may be repeated to request multiple statistics.

Available statistics are

<table>
<thead>
<tr>
<th>stat</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>frequency</td>
<td>frequency</td>
</tr>
<tr>
<td>sumw</td>
<td>sum of weights</td>
</tr>
<tr>
<td>proportion</td>
<td>proportion</td>
</tr>
<tr>
<td>percent</td>
<td>percentage</td>
</tr>
<tr>
<td>rawproportion</td>
<td>proportion ignoring optionally specified weights</td>
</tr>
<tr>
<td>rawpercent</td>
<td>percentage ignoring optionally specified weights</td>
</tr>
</tbody>
</table>

nformat(\% fmt [ results ] [, basestyle]) changes the numeric format, such as the number of decimal places, for specified results. If results are not specified, the numeric format is changed for all results.

results may be any statistic named in option statistic() (that is, any stat).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (rowspec and colspec). The default format of these variables is taken from the dataset.

basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

sformat(sfmt [ results ]) changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and \%. Here \% refers to the numeric value that is formatted as specified using nformat(). The text will be placed around the numeric values in your table as it is placed around \% in this option. For instance, to place parentheses around the percent statistics, you can specify sformat("(\%s)" percent).

results may be any statistic named in option statistic() (that is, any stat).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type \%\%. To include \, type \\\. For instance, to place a percent sign following percent statistics, you can specify sformat("%s%%%" percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.
Options

missing specifies that numeric missing values of \texttt{varname} be treated as valid categories. By default, observations with a numeric missing value in \texttt{varname} are omitted.

\texttt{name(cname)} specifies that a collection named \texttt{cname} be associated with the collected statistics and results. The default is \texttt{name(Table)}.

\texttt{append} specifies that \texttt{table} append its collection information into the collection named in \texttt{name(\)}. \texttt{replace} permits \texttt{table} to overwrite an existing collection. This option is implied for \texttt{name(Table)} when \texttt{append} is not specified.

\texttt{label(filename)} specifies the \texttt{filename} containing the collection labels to use for your table. Labels in \texttt{filename} will be loaded for the table, and any labels not specified in \texttt{filename} will be taken from the labels defined in \texttt{c(collect_label)}. The default is to use only the collection labels set in \texttt{c(collect_label)}; see \texttt{[TABLES] set collect_label}.

\texttt{style(filename [, override])} specifies the \texttt{filename} containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in \texttt{filename} will be applied.

If you prefer the default collection styles but also want to apply any styles in \texttt{filename}, specify \texttt{override}. If there are conflicts between the default collection styles and those in \texttt{filename}, the ones in \texttt{filename} will take precedence.

The default is to use only the collection styles set in \texttt{c(table_style)}; see \texttt{[TABLES] set table_style}.

The following option is available with \texttt{table} but is not shown in the dialog box:

\texttt{markvar(newvar)} generates an indicator variable that identifies the observations used in the tabulation.

Remarks and examples

Remarks are presented under the following headings:

\begin{itemize}
  \item Tabulation of one variable
  \item Tabulation, including percentages
  \item Customizing results
  \item Advanced customization
\end{itemize}

Tabulation of one variable

To obtain a one-way tabulation that reports the number of observations for each level of a categorical variable, we need specify only the name of the categorical variable following \texttt{table}.

To demonstrate, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). We tabulate the \texttt{hlthstat} variable, which contains individuals’ self-reported health status categories.
. use https://www.stata-press.com/data/r18/nhanes2l
(Second National Health and Nutrition Examination Survey)
. table hlhsstat

<table>
<thead>
<tr>
<th>Health status</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>2,407</td>
</tr>
<tr>
<td>Very good</td>
<td>2,591</td>
</tr>
<tr>
<td>Good</td>
<td>2,938</td>
</tr>
<tr>
<td>Fair</td>
<td>1,670</td>
</tr>
<tr>
<td>Poor</td>
<td>729</td>
</tr>
<tr>
<td>Total</td>
<td>10,335</td>
</tr>
</tbody>
</table>

We see that more people self-reported having excellent, very good, or good health status than reported having fair or poor health status.

Above, we see frequencies for those who reported a health status. This information is not available for some individuals in the dataset. We can determine how many missing values we have for this variable by adding the missing option

. table hlhsstat, missing

<table>
<thead>
<tr>
<th>Health status</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>2,407</td>
</tr>
<tr>
<td>Very good</td>
<td>2,591</td>
</tr>
<tr>
<td>Good</td>
<td>2,938</td>
</tr>
<tr>
<td>Fair</td>
<td>1,670</td>
</tr>
<tr>
<td>Poor</td>
<td>729</td>
</tr>
<tr>
<td>.</td>
<td>2</td>
</tr>
<tr>
<td>Blank but applicable</td>
<td>14</td>
</tr>
<tr>
<td>Total</td>
<td>10,351</td>
</tr>
</tbody>
</table>

We find that there is missing health status data for 16 individuals—2 with a generic missing value and 14 whose responses were labeled “Blank but applicable”.

Tabulation, including percentages

In addition to frequencies, we can report the proportion or percentage of observations in each health status category. By default, table reports frequencies, which is equivalent to including the statistic(frequency) option. Here we include that option along with the statistic(percent) option to report both frequencies and percentages.

. table hlhsstat, statistic(frequency) statistic(percent)

<table>
<thead>
<tr>
<th>Health status</th>
<th>Frequency</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>2,407</td>
<td>23.29</td>
</tr>
<tr>
<td>Very good</td>
<td>2,591</td>
<td>25.07</td>
</tr>
<tr>
<td>Good</td>
<td>2,938</td>
<td>28.43</td>
</tr>
<tr>
<td>Fair</td>
<td>1,670</td>
<td>16.16</td>
</tr>
<tr>
<td>Poor</td>
<td>729</td>
<td>7.05</td>
</tr>
<tr>
<td>Total</td>
<td>10,335</td>
<td>100.00</td>
</tr>
</tbody>
</table>

Now, it is clear that 28.43% of respondents reported having good health.
Customizing results

There are a number of ways that you can customize the results in your table.

In some cases, you may prefer to place frequencies and percentages on the rows and the levels of the variable being tabulated on the columns. To do this, you can include both the row and column specifications in parentheses following table. Here we use result in the first set of parentheses to request that the statistics be placed on rows and the variable hlthstat in the second set of parentheses to request that the levels of this variable be placed on the columns.

```
. table (result) (hlthstat), statistic(frequency) statistic(percent)
```

<table>
<thead>
<tr>
<th>Health status</th>
<th>Excellent</th>
<th>Very good</th>
<th>Good</th>
<th>Fair</th>
<th>Poor</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frequency</td>
<td>2,407</td>
<td>2,591</td>
<td>2,938</td>
<td>1,670</td>
<td>729</td>
<td>10,335</td>
</tr>
<tr>
<td>Percent</td>
<td>23.29</td>
<td>25.07</td>
<td>28.43</td>
<td>16.16</td>
<td>7.05</td>
<td>100.00</td>
</tr>
</tbody>
</table>

Alternatively, we could have omitted result and typed

```
. table () (hlthstat), statistic(freq) statistic(percent)
```

Because we requested that hlthstat be moved to the columns by specifying it in the second set of parentheses, table automatically moves the requested statistics to the rows.

If instead of a short and wide table, you prefer a tall and narrow table, you can specify that both the levels of hlthstat and the statistics be used to define the rows by including the variable name and result in the first set of parentheses.

```
. table (hlthstat result), statistic(frequency) statistic(percent)
```

<table>
<thead>
<tr>
<th>Health status</th>
<th>Excellent</th>
<th>Very good</th>
<th>Good</th>
<th>Fair</th>
<th>Poor</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frequency</td>
<td>2,407</td>
<td>2,591</td>
<td>2,938</td>
<td>1,670</td>
<td>729</td>
<td>10,335</td>
</tr>
<tr>
<td>Percent</td>
<td>23.29</td>
<td>25.07</td>
<td>28.43</td>
<td>16.16</td>
<td>7.05</td>
<td>100.00</td>
</tr>
</tbody>
</table>

In addition to modifying the layout of the table, we may want to customize the results reported within the cells of the table. For instance, we can specify that the percentages be reported using only one decimal place by using the nformat() option. Here we return to the two-column table layout.
The `table` command produces its output using a default set of styles, typically those defined in the `table_style` but could be any other style that you have set as the default by using `set table_style`. When customizing our tables, we can take advantage of one of the styles described in [TABLES] Predefined styles. For instance, for tables with only one or two row variables, row labels that are right-aligned may be preferred. Here we use the `table-right` style.

```
. table hlthstat, statistic(frequency) statistic(percent) > nformat(\%5.1f percent) style(table-right)
```

<table>
<thead>
<tr>
<th>Health status</th>
<th>Frequency</th>
<th>Percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>2,407</td>
<td>23.3</td>
</tr>
<tr>
<td>Very good</td>
<td>2,591</td>
<td>25.1</td>
</tr>
<tr>
<td>Good</td>
<td>2,938</td>
<td>28.4</td>
</tr>
<tr>
<td>Fair</td>
<td>1,670</td>
<td>16.2</td>
</tr>
<tr>
<td>Poor</td>
<td>729</td>
<td>7.1</td>
</tr>
<tr>
<td>Total</td>
<td>10,335</td>
<td>100.0</td>
</tr>
</tbody>
</table>

**Advanced customization**

Customization can go beyond the predefined styles and options available to you in the `table` command. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to produce highly customized tables and to export those tables to presentation-ready formats such as HTML, Word, \LaTeX, PDF, Excel, and more.

Continuing with our example above, if we want to shorten the labels on the column headings, we could use the `collect label levels` command to define our new labels. After a change using `collect`, we can use `collect preview` to see the results.

```
. collect label levels result frequency "Freq" percent "\%", modify
. collect preview
```

<table>
<thead>
<tr>
<th></th>
<th>Freq</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>2,407</td>
<td>23.3</td>
</tr>
<tr>
<td>Very good</td>
<td>2,591</td>
<td>25.1</td>
</tr>
<tr>
<td>Good</td>
<td>2,938</td>
<td>28.4</td>
</tr>
<tr>
<td>Fair</td>
<td>1,670</td>
<td>16.2</td>
</tr>
<tr>
<td>Poor</td>
<td>729</td>
<td>7.1</td>
</tr>
<tr>
<td>Total</td>
<td>10,335</td>
<td>100.0</td>
</tr>
</tbody>
</table>
We could continue making style edits to this table. When we are happy with the result, we can then export it to the format of our choice using `collect export`.

See `[TABLES] collect label` for details on the `collect label` command we used here, and for an overview of the `collect` suite, see `[TABLES] Intro`.

**Stored results**

`table` stores the following in `r()`:

Scalars

- `r(N)` number of observations

**References**

**Also see**

[R] table — Table of frequencies, summaries, and command results

[R] table twoway — Two-way tabulation

[R] tabulate oneway — One-way table of frequencies

[TABLES] Intro — Introduction
In this entry, we discuss how to use `table` to create a two-way tabulation, including frequencies, percentages, and proportions.

**Quick start**

Table of frequencies, with rows defined by categories of \( a_1 \) and columns defined by categories of \( a_2 \)

```
        table a1 a2
```

Same as above, but treat missing values like other values

```
        table a1 a2, missing
```

Table with the percentage of observations in each cell

```
        table a1 a2, statistic(percent)
```

For each category of \( a_1 \), report the percentage of observations across levels of \( a_2 \)

```
        table a1 a2, statistic(percent, across(a2))
```

Report frequencies and the proportion of observations across categories of \( a_1 \), enclosed within parentheses

```
        table a1 a2, statistic(frequency) ///
        statistic(proportion, across(a1)) sformat("(\%s)" proportion)
```

**Menu**

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results
Syntax

Basic two-way tabulation

```
  table rowvar colvar [if] [in] [weight] [, options]
```

Customized two-way tabulation

```
  table [(rowspec)] [(colspec)] [if] [in] [weight] [, options]
```

*rowspec* may be empty or may include *rowvar*, *result*, or *rowvar* and *result*, where *result* refers to the requested statistics.

*colspec* may be empty or may include *colvar*, *result*, or *colvar* and *result*, where *result* refers to the requested statistics.

```
  options          Description

  totals(totals)  report only the specified totals
  nototals        suppress the marginal totals

  statistic(stat[, statopts])  statistic to be reported; default is statistic(frequency) when no weights are specified and statistic(sumw) otherwise

  nformat(%fmt [results][, basestyle])  specify numeric format
  sformat(%fmt [results])  specify string format

  missing         treat numeric missing values of *rowvar* and *colvar* like other values
  zerocounts      report 0 for empty cell counts
  name(cname)     collect results into a collection named *cname*
  append          append results to an existing collection
  replace         replace results of an existing collection
  label(filename) specify the collection labels
  style(filename [, override])  specify the collection style
  markvar(newvar)  create *newvar* that identifies observations used in the tabulation
```

Fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

strL variables are not allowed; see [U] 12.4.8 strL.

markvar() does not appear in the dialog box.
Options

totals(totals) and nototals control which totals are to be displayed in the table. By default, all totals are reported.

totals(totals) specifies which margin totals to display in the reported table. totals can contain rowvar, colvar, and their interaction. Interactions can be specified by using the # operator.

nototals prevents table from displaying any totals.

statistic(stat[, statopts]) specifies the statistic to be displayed. statistic() may be repeated to request multiple statistics.

Available statistics are

<table>
<thead>
<tr>
<th>stat</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>frequency</td>
<td>frequency</td>
</tr>
<tr>
<td>sumw</td>
<td>sum of weights</td>
</tr>
<tr>
<td>proportion</td>
<td>proportion</td>
</tr>
<tr>
<td>percent</td>
<td>percentage</td>
</tr>
<tr>
<td>rawproportion</td>
<td>proportion ignoring optionally specified weights</td>
</tr>
<tr>
<td>rawpercent</td>
<td>percentage ignoring optionally specified weights</td>
</tr>
</tbody>
</table>

The following options may be specified in combination with statistics proportion, percent, rawproportion, and rawpercent:

<table>
<thead>
<tr>
<th>statopts</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>across(rowvar)</td>
<td>percentages or proportions across rows</td>
</tr>
<tr>
<td>across(colvar)</td>
<td>percentages or proportions across columns</td>
</tr>
<tr>
<td>total</td>
<td>compute overall percentages or proportions</td>
</tr>
</tbody>
</table>

nformat(%,fmt results[, basestyle]) changes the numeric format, such as the number of decimal places, for specified results. If results are not specified, the numeric format is changed for all results.

results may be any statistic named in option statistic() (that is, any stat).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (rowspec and colspec). The default format of these variables is taken from the dataset.

basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

sformat(fmt results) changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and %s. Here %s refers to the numeric value that is formatted as specified using nformat(). The text will be placed around the numeric values in your table as it is placed around %s in this option. For instance, to place parentheses around the percent statistics, you can specify sformat("(%s)" percent).
results may be any statistic named in option statistic() (that is, any stat).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type %%. To include \\
, type \\\. For instance, to place a percent sign following percent statistics, you can specify sformat("%s%%" percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

--- Options ---

missing specifies that numeric missing values of rowvar or colvar be treated as valid categories. By default, observations with a numeric missing value in rowvar or colvar are omitted.

zerocounts specifies that table report a 0 in empty cells for the frequency statistic.

name(cname) specifies that a collection named cname be associated with the collected statistics and results. The default is name(Table).

append specifies that table append its collection information into the collection named in name().

replace permits table to overwrite an existing collection. This option is implied for name(Table) when append is not specified.

label(filename) specifies the filename containing the collection labels to use for your table. Labels in filename will be loaded for the table, and any labels not specified in filename will be taken from the labels defined in c(collect_label). The default is to use only the collection labels set in c(collect_label); see [TABLES] set collect_label.

style(filename [, override]) specifies the filename containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in filename will be applied.

If you prefer the default collection styles but also want to apply any styles in filename, specify override. If there are conflicts between the default collection styles and those in filename, the ones in filename will take precedence.

The default is to use only the collection styles set in c(table_style); see [TABLES] set table_style.

The following option is available with table but is not shown in the dialog box:

markvar(newvar) generates an indicator variable that identifies the observations used in the tabulation.

--- Remarks and examples ---

Remarks are presented under the following headings:

- Tabulation of two variables
- Tabulation, including percentages
- Customizing results

--- Tabulation of two variables ---

To obtain a two-way tabulation that reports the number of observations across the levels of two categorical variables, we need to specify only the names of the categorical variables following table.

To demonstrate, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981) and create a two-way tabulation of self-reported health status (hlthstat) by region of the USA (region).
. use https://www.stata-press.com/data/r18/nhanes2l
(Second National Health and Nutrition Examination Survey)
. table hlthstat region

<table>
<thead>
<tr>
<th>Health status</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>562</td>
<td>730</td>
<td>546</td>
<td>569</td>
<td>2,407</td>
</tr>
<tr>
<td>Very good</td>
<td>558</td>
<td>721</td>
<td>651</td>
<td>661</td>
<td>2,591</td>
</tr>
<tr>
<td>Good</td>
<td>631</td>
<td>735</td>
<td>807</td>
<td>765</td>
<td>2,938</td>
</tr>
<tr>
<td>Fair</td>
<td>257</td>
<td>419</td>
<td>532</td>
<td>462</td>
<td>1,670</td>
</tr>
<tr>
<td>Poor</td>
<td>77</td>
<td>167</td>
<td>317</td>
<td>168</td>
<td>729</td>
</tr>
<tr>
<td>Total</td>
<td>2,085</td>
<td>2,772</td>
<td>2,853</td>
<td>2,625</td>
<td>10,335</td>
</tr>
</tbody>
</table>

We can examine the missing values as well by adding the missing option.
. table hlthstat region, missing

<table>
<thead>
<tr>
<th>Health status</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>562</td>
<td>730</td>
<td>546</td>
<td>569</td>
<td>2,407</td>
</tr>
<tr>
<td>Very good</td>
<td>558</td>
<td>721</td>
<td>651</td>
<td>661</td>
<td>2,591</td>
</tr>
<tr>
<td>Good</td>
<td>631</td>
<td>735</td>
<td>807</td>
<td>765</td>
<td>2,938</td>
</tr>
<tr>
<td>Fair</td>
<td>257</td>
<td>419</td>
<td>532</td>
<td>462</td>
<td>1,670</td>
</tr>
<tr>
<td>Poor</td>
<td>77</td>
<td>167</td>
<td>317</td>
<td>168</td>
<td>729</td>
</tr>
<tr>
<td>.</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>Blank but applicable</td>
<td>10</td>
<td>1</td>
<td>0</td>
<td>3</td>
<td>14</td>
</tr>
<tr>
<td>Total</td>
<td>2,096</td>
<td>2,774</td>
<td>2,853</td>
<td>2,628</td>
<td>10,351</td>
</tr>
</tbody>
</table>

We find that 16 individuals have a missing health status, and the majority of these are from individuals in the Northeast. The empty cells correspond to regions in which all the individuals have a nonmissing health status; we can fill in these empty cells with 0s:
. table hlthstat region, missing zerocounts

<table>
<thead>
<tr>
<th>Health status</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>

<td>14</td>
</tr>
<tr>
<td>Total</td>
<td>2,096</td>
<td>2,774</td>
<td>2,853</td>
<td>2,628</td>
<td>10,351</td>
</tr>
</tbody>
</table>
Tabulation, including percentages

Instead of frequencies, we can request that `table` report the percentage of observations in each cell of the table by specifying the `statistic(percent)` option.

```
. table hlthstat region, statistic(percent)
```

<table>
<thead>
<tr>
<th>Health status</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>5.44</td>
<td>7.06</td>
<td>5.28</td>
<td>5.51</td>
<td>23.29</td>
</tr>
<tr>
<td>Very good</td>
<td>5.40</td>
<td>6.98</td>
<td>6.30</td>
<td>6.40</td>
<td>25.07</td>
</tr>
<tr>
<td>Good</td>
<td>6.11</td>
<td>7.11</td>
<td>7.81</td>
<td>7.40</td>
<td>28.43</td>
</tr>
<tr>
<td>Fair</td>
<td>2.49</td>
<td>4.05</td>
<td>5.15</td>
<td>4.47</td>
<td>16.16</td>
</tr>
<tr>
<td>Poor</td>
<td>0.75</td>
<td>1.62</td>
<td>3.07</td>
<td>1.63</td>
<td>7.05</td>
</tr>
<tr>
<td>Total</td>
<td>20.17</td>
<td>26.82</td>
<td>27.61</td>
<td>25.40</td>
<td>100.00</td>
</tr>
</tbody>
</table>

We see that 5.44% of all observations correspond to individuals in excellent health who live in the Northeast.

Rather than looking at overall percentages, we might want to examine the distribution of observations within each health status level across the four regions. To do this, we can add the `across(region)` option.

```
. table hlthstat region, statistic(percent, across(region))
```

<table>
<thead>
<tr>
<th>Health status</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>23.35</td>
<td>30.33</td>
<td>22.68</td>
<td>23.64</td>
<td>100.00</td>
</tr>
<tr>
<td>Very good</td>
<td>21.54</td>
<td>27.83</td>
<td>25.13</td>
<td>25.51</td>
<td>100.00</td>
</tr>
<tr>
<td>Good</td>
<td>21.48</td>
<td>25.02</td>
<td>27.47</td>
<td>26.04</td>
<td>100.00</td>
</tr>
<tr>
<td>Fair</td>
<td>15.39</td>
<td>25.09</td>
<td>31.86</td>
<td>27.66</td>
<td>100.00</td>
</tr>
<tr>
<td>Poor</td>
<td>10.56</td>
<td>22.91</td>
<td>43.48</td>
<td>23.05</td>
<td>100.00</td>
</tr>
<tr>
<td>Total</td>
<td>20.17</td>
<td>26.82</td>
<td>27.61</td>
<td>25.40</td>
<td>100.00</td>
</tr>
</tbody>
</table>

Of individuals reporting excellent health, 23.35% live in the Northeast, while 30.33% live in the Midwest, 22.68% live in the South, and 23.64% live in the West.

We can also look at the distribution of observations across health status categories within each region.

```
. table hlthstat region, statistic(percent, across(hlthstat))
```

<table>
<thead>
<tr>
<th>Health status</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excellent</td>
<td>26.95</td>
<td>26.33</td>
<td>19.14</td>
<td>21.68</td>
<td>23.29</td>
</tr>
<tr>
<td>Very good</td>
<td>26.76</td>
<td>26.01</td>
<td>22.82</td>
<td>25.18</td>
<td>25.07</td>
</tr>
<tr>
<td>Good</td>
<td>30.26</td>
<td>26.52</td>
<td>28.29</td>
<td>29.14</td>
<td>28.43</td>
</tr>
<tr>
<td>Fair</td>
<td>12.33</td>
<td>15.12</td>
<td>18.65</td>
<td>17.60</td>
<td>16.16</td>
</tr>
<tr>
<td>Poor</td>
<td>3.69</td>
<td>6.02</td>
<td>11.11</td>
<td>6.40</td>
<td>7.05</td>
</tr>
<tr>
<td>Total</td>
<td>100.00</td>
<td>100.00</td>
<td>100.00</td>
<td>100.00</td>
<td>100.00</td>
</tr>
</tbody>
</table>

Of individuals living in the South, 11.11% report having poor health. This is notably higher than the percentage of individuals reporting poor health in the other regions.
It is often helpful to see both frequencies and percentages in the same table. To do this, we can add the `statistic(frequency)` option to our command.

```
. table hlthstat region, statistic(frequency)  
> statistic(percent, across(hlthstat))
```

<table>
<thead>
<tr>
<th>Region</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>

<td>100.00</td>
<td>100.00</td>
<td>100.00</td>
<td>100.00</td>
<td>100.00</td>
</tr>
</tbody>
</table>

**Customizing results**

There are several ways that we can customize the results of our two-way tabulation.

For instance, in some cases, we may prefer to omit the row and column totals. We can specify the `nototals` option to suppress these totals.

```
. table hlthstat region, statistic(frequency)  
> statistic(percent, across(hlthstat)) nototals
```

<table>
<thead>
<tr>
<th>Region</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
</tr>
</thead>
<tbody>
<tr>
<td>Health status</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Excellent</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frequency</td>
<td>562</td>
<td>730</td>
<td>546</td>
<td>569</td>
</tr>
<tr>
<td>Percent</td>
<td>26.95</td>
<td>26.33</td>
<td>19.14</td>
<td>21.68</td>
</tr>
<tr>
<td>Very good</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frequency</td>
<td>558</td>
<td>721</td>
<td>651</td>
<td>661</td>
</tr>
<tr>
<td>Percent</td>
<td>26.76</td>
<td>26.01</td>
<td>22.82</td>
<td>25.18</td>
</tr>
<tr>
<td>Good</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frequency</td>
<td>631</td>
<td>735</td>
<td>807</td>
<td>765</td>
</tr>
<tr>
<td>Percent</td>
<td>30.26</td>
<td>26.52</td>
<td>28.29</td>
<td>29.14</td>
</tr>
<tr>
<td>Fair</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frequency</td>
<td>257</td>
<td>419</td>
<td>532</td>
<td>462</td>
</tr>
<tr>
<td>Percent</td>
<td>12.33</td>
<td>15.12</td>
<td>18.65</td>
<td>17.60</td>
</tr>
<tr>
<td>Poor</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frequency</td>
<td>77</td>
<td>167</td>
<td>317</td>
<td>168</td>
</tr>
<tr>
<td>Percent</td>
<td>3.69</td>
<td>6.02</td>
<td>11.11</td>
<td>6.40</td>
</tr>
</tbody>
</table>
Or perhaps we want to see row totals or column totals but not both. We can include the `totals(region)` option to display only the `region` totals.

```stata
.table hlthstat region, statistic(frequency) statistic(percent, across(hlthstat)) totals(region)
```

<table>
<thead>
<tr>
<th>Health status</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Excellent</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frequency</td>
<td>562</td>
<td>730</td>
<td>546</td>
<td>569</td>
</tr>
<tr>
<td>Percent</td>
<td>26.95</td>
<td>26.33</td>
<td>19.14</td>
<td>21.68</td>
</tr>
<tr>
<td><strong>Very good</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>

<td>30.26</td>
<td>26.52</td>
<td>28.29</td>
<td>29.14</td>
</tr>
<tr>
<td><strong>Fair</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frequency</td>
<td>257</td>
<td>419</td>
<td>532</td>
<td>462</td>
</tr>
<tr>
<td>Percent</td>
<td>12.33</td>
<td>15.12</td>
<td>18.65</td>
<td>17.60</td>
</tr>
<tr>
<td><strong>Poor</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frequency</td>
<td>77</td>
<td>167</td>
<td>317</td>
<td>168</td>
</tr>
<tr>
<td>Percent</td>
<td>3.69</td>
<td>6.02</td>
<td>11.11</td>
<td>6.40</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Frequency</td>
<td>2,085</td>
<td>2,772</td>
<td>2,853</td>
<td>2,625</td>
</tr>
<tr>
<td>Percent</td>
<td>100.00</td>
<td>100.00</td>
<td>100.00</td>
<td>100.00</td>
</tr>
</tbody>
</table>

Once we have the statistics we want in our table, we can format the way that they appear. If, for instance, we want to add a percent sign to each of our percentages, we can specify the `sformat("%s\%\%" percent)` option. The `sformat()` option specifies that we want to add string characters to the numbers in the table. Within it, we refer to the numeric values as `%s` and place any string characters we want around this. The percent sign is unique because it already has special meaning in this context. Therefore, we must type two percent signs, `%%`, to display one. Finally, by adding `percent` within the `sformat()` option, we specify that we want to apply this format only to the percent statistics.
Now that we have added the percent sign, we could argue that the labels Frequency and Percent are unnecessary. If we remove these statistic names from the row labels, we might also want to right-align the remaining labels in row headers. Finally, for readability, we could insert blank lines between levels of hlthstat. We could use the `collect` suite of commands to make these style changes. Fortunately, however, one of our predefined styles, `table-tab2`, includes these style changes, and we can select it using the `style()` option.

```
. table hlthstat region, statistic(frequency)
> statistic(percent, across(hlthstat)) totals(region)
> sformat("%s\%" percent)

<table>
<thead>
<tr>
<th>Health status</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
</tr>
</thead>
<tbody>
<tr>

<td>100.00%</td>
<td>100.00%</td>
</tr>
</tbody>
</table>
```
You can learn more about the predefined styles described at [TABLES] Predefined styles. If none of these provide the exact style you want for your table, you can further customize the results by using the collect suite of commands. To learn more, see [TABLES] Intro.

If you wish to include this table in a paper, on a webpage, or in another format, you can easily export it in \LaTeX, Word, Excel, HTML, and a variety of other formats by using collect export.

Stored results

`table` stores the following in `r()`:

Scalars
- `r(N)` number of observations

Description

In this entry, we discuss how to use the `table` command to create tables displaying frequencies, percentages, and proportions across levels of three or more variables. Additionally, we demonstrate how a single `table` command can create multiple tables corresponding to levels of variables or different statistics.

Quick start

Table of frequencies with rows defined by the levels of `a1` and columns defined by the categories of `a2` and `a3`

```
  table (a1) (a2 a3)
```

Same as above, but with rows defined by levels of `a1` and `a2` and columns defined by levels of `a3`

```
  table (a1 a2) (a3)
```

Separate tables for each level `a3` with the rows of each table defined by the levels of `a1` and the columns defined by levels of `a2`

```
  table (a1) (a2) (a3)
```

Report percentages of observations in each cell rather than frequencies

```
  table (a1) (a2 a3), statistic(percent)
```

Report both frequencies and percentages

```
  table (a1) (a2 a3), statistic(percent) statistic(frequency)
```

Report the percentages across levels of `a3`

```
  table (a1) (a2 a3), statistic(percent, across(a3))
```

Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results
Syntax

Table with rows defined by multiple variables

```
   table rowvars colvar [if] [in] [weight] [, options]
```

Table with columns defined by multiple variables

```
   table rowvar (colvars) [if] [in] [weight] [, options]
```

Table with rows and columns defined by multiple variables

```
   table (rowvars) (colvars) [if] [in] [weight] [, options]
```

Multiple multiway tables

```
   table (rowvars) (colvars) (tabvars) [if] [in] [weight] [, options]
```

Customized multiway tables

```
   table (rowspec) (colspec) (tabspec) [if] [in] [weight] [, options]
```

`rowspec`, `colspec`, and `tabspec` may be empty or may include variable names or any of the following keywords:

<table>

<td>markvar( (\text{newvar}) )</td>
<td></td>
</tr>
</tbody>
</table>

\text{fweights}, \text{aweights}, \text{iweights}, and \text{pweights} are allowed; see [U] 11.1.6 weight.

\text{strL} variables are not allowed; see [U] 12.4.8 strL.

\text{markvar()} does not appear in the dialog box.

---

**Options**

- **Main**
  - **totals\( (\text{totals}) \)** and **nototals** control which totals are to be displayed in the table. By default, all totals are reported.
  - **totals\( (\text{totals}) \)** specifies that totals be displayed only for the variables or interactions specified.
    - totals can contain rowvars, colvars, tabvars, and interactions between any of these variables.
    - Interactions can be specified by using the \# operator.
  - **nototals** prevents \text{table} from displaying any totals.
statistic(stat[, statopts]) specifies the statistic to be displayed. statistic() may be repeated to request multiple statistics.

Available statistics are:

<table>
<thead>
<tr>
<th>stat</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>frequency</td>
<td>frequency</td>
</tr>
<tr>
<td>sumw</td>
<td>sum of weights</td>
</tr>
<tr>
<td>proportion</td>
<td>proportion</td>
</tr>
<tr>
<td>percent</td>
<td>percentage</td>
</tr>
<tr>
<td>rawproportion</td>
<td>proportion ignoring optionally specified weights</td>
</tr>
<tr>
<td>rawpercent</td>
<td>percentage ignoring optionally specified weights</td>
</tr>
</tbody>
</table>

The following options may be specified in combination with statistics proportion, percent, rawproportion, and rawpercent:

<table>
<thead>
<tr>
<th>statopts</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>across(cellspec)</td>
<td>percentages or proportions across levels of variables or interactions</td>
</tr>
<tr>
<td>total</td>
<td>compute overall percentages or proportions</td>
</tr>
</tbody>
</table>

 cellspec may contain rowvars, colvars, tabvars, or an interaction between any of these variables. Interactions can be specified by using the # operator.

nformat(%fmt [ results ][, basestyle]) changes the numeric format, such as the number of decimal places, for specified results. If results are not specified, the numeric format is changed for all results.

results may be any statistic named in option statistic() (that is, any stat).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (rowspec, colspec, and tabspec). The default format of these variables is taken from the dataset.

basestyle indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

sformat(sfmt [ results ]) changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

sfmt may contain a mix of text and %s. Here %s refers to the numeric value that is formatted as specified using nformat(). The text will be placed around the numeric values in your table as it is placed around %s in this option. For instance, to place parentheses around the percent statistics, you can specify sformat("(\%s)" percent).

results may be any statistic named in option statistic() (that is, any stat).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type \%. To include \, type \\%. For instance, to place a percent sign following percent statistics, you can specify sformat("\%s\%" percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.
Options

listwise handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any variable specified in a statistic() option is missing for that observation. By default, table will omit an observation only if all variables specified in all statistic() options are missing for that observation.

missing specifies that numeric missing values of any rowvars, colvars, or tabvars be treated as valid categories. By default, observations with a numeric missing value in rowvars, colvars, or tabvars are omitted.

showcounts specifies that table report the sample size for each variable specified in option statistic().

zerocounts specifies that table report a 0 in empty cells for the frequency statistic.

name(cname) specifies that a collection named cname be associated with the collected statistics and results. The default is name(Table).

append specifies that table append its collection information into the collection named in name().

replace permits table to overwrite an existing collection. This option is implied for name(Table) when append is not specified.

label(filename) specifies the filename containing the collection labels to use for your table. Labels in filename will be loaded for the table, and any labels not specified in filename will be taken from the labels defined in c(collect_label). The default is to use only the collection labels set in c(collect_label); see [TABLES] set collect_label.

style(filename [, override]) specifies the filename containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in filename will be applied.

If you prefer the default collection styles but also want to apply any styles in filename, specify override. If there are conflicts between the default collection styles and those in filename, the ones in filename will take precedence.

The default is to use only the collection styles set in c(table_style); see [TABLES] set table_style.

The following option is available with table but is not shown in the dialog box:

markvar(newvar) generates an indicator variable that identifies the observations used in the tabulation.

Remarks and examples

Remarks are presented under the following headings:

Introduction
Tables with columns defined by multiple variables
Appending tables
Multiple tables with specified totals

Introduction

The table command allows you to create complex tables beyond one- and two-way tabulations. In multiway tabulations, you can display frequencies across levels of two or more variables. You can have levels of one variable nested within levels of another variable in columns, in rows, or in both dimensions. And with a single command, you can create separate tables for levels of one or more variables or for different results.
Tables with columns defined by multiple variables

We use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). The data contain some demographic information, such as the age, sex, and race of participants. The dataset also contains some measures of health, including whether the individual has high blood pressure (highbp).

Before we create any tables, we will modify a few labels in our dataset so that they will appear as we wish in our tables.

```
. use https://www.stata-press.com/data/r18/nhanes2l
(Second National Health and Nutrition Examination Survey)
. label define yesno 0 "No" 1 "Yes"
. label values highbp diabetes heartatk yesno
. label variable diabetes "Diabetes"
```

Suppose we want to examine how many males and females in each age group have high blood pressure. Let’s place the levels of age group on the rows and the levels of high blood pressure and sex on the columns.

```
. table (agegrp) (sex highbp), nototals
```

<table>
<thead>
<tr>
<th>Age group</th>
<th>Male</th>
<th>Female</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>High blood pressure</td>
<td>No</td>
</tr>
<tr>
<td>20-29</td>
<td>825</td>
<td>291</td>
</tr>
<tr>
<td>30-39</td>
<td>480</td>
<td>290</td>
</tr>
<tr>
<td>40-49</td>
<td>336</td>
<td>274</td>
</tr>
<tr>
<td>50-59</td>
<td>255</td>
<td>347</td>
</tr>
<tr>
<td>60-69</td>
<td>568</td>
<td>801</td>
</tr>
<tr>
<td>70+</td>
<td>147</td>
<td>301</td>
</tr>
</tbody>
</table>

By default, `table` includes the totals for each category; we added the `nototals` option to suppress them here.

To better compare the occurrence of high blood pressure, let’s now compute percentages of `highbp`. Below, we create the same table, but within each sex and age group combination, we report the percentage of individuals with and without high blood pressure.

```
. table (agegrp) (sex highbp), nototals
```

<table>
<thead>
<tr>
<th>Age group</th>
<th>Male</th>
<th>Female</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>High blood pressure</td>
<td>No</td>
</tr>
<tr>
<td>20-29</td>
<td>825</td>
<td>291</td>
</tr>
<tr>
<td>30-39</td>
<td>480</td>
<td>290</td>
</tr>
<tr>
<td>40-49</td>
<td>336</td>
<td>274</td>
</tr>
<tr>
<td>50-59</td>
<td>255</td>
<td>347</td>
</tr>
<tr>
<td>60-69</td>
<td>568</td>
<td>801</td>
</tr>
<tr>
<td>70+</td>
<td>147</td>
<td>301</td>
</tr>
</tbody>
</table>
Here we see that 26.08% of males in their 20s have high blood pressure and only 8.39% of females in their 20s have high blood pressure.

If we had simply typed `statistic(percent)`, then we would see the percentage of observations in each cell. With the suboption `across()`, we can compute the percentage within each sex and age group combination (across levels of `highbp`).

Next, let’s request that percentages be calculated across the categories of high blood pressure and sex. We can alternatively think of this as being percentages within age group.

Here we see that 12.54% of individuals in their 20s are males with high blood pressure and 4.35% are females with high blood pressure.

We can reverse the order of our column variables so that we have the levels of `sex` nested within levels of high blood pressure. We will again request percentages across the categories of `highbp`.

<table>
<thead>
<tr>
<th>Age group</th>
<th>Male High blood pressure</th>
<th>Male No</th>
<th>Female High blood pressure</th>
<th>Female No</th>
</tr>
</thead>

<td>18.26</td>
<td>36.31</td>
</tr>
</tbody>
</table>
The last two columns represent the percentage of males with high blood pressure in the age group and the percentage of females with high blood pressure in the age group. We can clearly see that, across all age groups, the percent of males who have high blood pressure is greater than the percentage of females with high blood pressure.

Perhaps we want a table that includes only the two columns on the right. To create a table with the percentages of individuals with high blood pressure, we can take advantage of a unique feature of `table`—its results are automatically stored in a “collection” and can be easily customized. Specifically, when we create a table using the `table` command, the results are stored in a collection named `Table`, and these results replace the results from any previous `table` command. The `collect` suite of commands can be used to change the layout, style, and formatting of tables created from results in collection; see [TABLES] Intro to learn about collections of results and creating customized tables. For our table, we will use the `collect layout` command, which specifies how items from a collection should be arranged. Below, we arrange the percentages in a table with rows defined by the categories of `agegrp` and columns defined by the categories of sex and category 1 of `highbp`.

```
. collect layout (agegrp) (highbp[1]#sex)
Collection: Table
Rows: agegrp
Columns: highbp[1]#sex
Table 1: 7 x 2

<table>
<thead>
<tr>
<th>Age group</th>
<th>Male</th>
<th>Female</th>
</tr>
</thead>
<tbody>
<tr>
<td>20-29</td>
<td>73.92</td>
<td>91.61</td>
</tr>
<tr>
<td>30-39</td>
<td>62.34</td>
<td>80.63</td>
</tr>
<tr>
<td>40-49</td>
<td>55.08</td>
<td>65.56</td>
</tr>
<tr>
<td>50-59</td>
<td>42.36</td>
<td>48.62</td>
</tr>
<tr>
<td>60-69</td>
<td>41.49</td>
<td>41.92</td>
</tr>
<tr>
<td>70+</td>
<td>32.81</td>
<td>33.46</td>
</tr>
</tbody>
</table>
```
Appending tables

When we specify multiple variables for the row or column specification, the levels of one variable are nested within the levels of another. When you simply wish to join rows or columns from multiple tables, this can be easily done with the `append` option.

For example, we first create a table with the percentage of males and females in each age group with diabetes.

```
local sex = 'sex'
local agegrp = 'agegrp'
local diabetes = 'diabetes'
local highbp = 'highbp'
local heartatk = 'heartatk'

. table (`sex' `agegrp') (`diabetes'), nototals statistic(percent, across(`diabetes'))

<table>
<thead>
<tr>
<th>Sex</th>
<th>Diabetes</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Male</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Age group</td>
<td></td>
<td></td>
</tr>
<tr>
<td>20-29</td>
<td>99.64</td>
<td>0.36</td>
</tr>
<tr>
<td>30-39</td>
<td>99.61</td>
<td>0.39</td>
</tr>
<tr>
<td>40-49</td>
<td>97.38</td>
<td>2.62</td>
</tr>
<tr>
<td>50-59</td>
<td>94.68</td>
<td>5.32</td>
</tr>
<tr>
<td>60-69</td>
<td>91.96</td>
<td>8.04</td>
</tr>
<tr>
<td>70+</td>
<td>88.39</td>
<td>11.61</td>
</tr>
<tr>
<td>Female</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Age group</td>
<td></td>
<td></td>
</tr>
<tr>
<td>20-29</td>
<td>99.09</td>
<td>0.91</td>
</tr>
<tr>
<td>30-39</td>
<td>97.88</td>
<td>2.12</td>
</tr>
<tr>
<td>40-49</td>
<td>96.07</td>
<td>3.93</td>
</tr>
<tr>
<td>50-59</td>
<td>94.19</td>
<td>5.81</td>
</tr>
<tr>
<td>60-69</td>
<td>91.42</td>
<td>8.58</td>
</tr>
<tr>
<td>70+</td>
<td>89.03</td>
<td>10.97</td>
</tr>
</tbody>
</table>
```

We want to include the same information for `highbp` and `heartatk` in the same table, which indicates whether someone has had a heart attack. To do this, we will run the `table` command three times, once specifying each of these variables as the column variable. We will use the `name(table1)` option to specify that the results be stored in a collection named `table1`. To the second and third `table` commands, we will add the `append` option so that all the results are stored in the same collection rather than overriding the results from the previous command.

```
. quietly: table (`sex' `agegrp') (`diabetes'), nototals statistic(percent, across(`diabetes')) name(table1)
. quietly: table (`sex' `agegrp') (`highbp'), nototals statistic(percent, across(`highbp')) name(table1) append
. quietly: table (`sex' `agegrp') (`heartatk'), nototals statistic(percent, across(`heartatk')) name(table1) append
```

With the results from all our `table` commands stored in one collection, we can again take advantage of the `collect layout` command to arrange results into a table. We request that `sex` and `agegroup` define the rows. By including the `#` between variable names, we specify that we want the levels of these variables to be interacted to form the rows. We request that levels of `diabetes`, `highbp`, and `heartatk` form the columns. Because we did not include `#` between the variable names, their levels will not be interacted. Instead, they will be listed one after the other.
### Table 1: 17 x 6

</tbody>
</table>

### Multiple tables with specified totals

There may be times when instead of creating one large table for multiple variables, you would prefer to create separate tables for each level of one or more variables or for different statistics. For example, we previously had levels of age group nested within categories of sex. Now, we would like to create tables that show how males and females in each age group rate their own health. The variable `hlthstat` records how individuals self-rate their health. Let’s create a table that shows what percent of males in each age group selected each of the health categories and a separate table to list the percent of females.
We see that 14.77% of males in their 70s and beyond rated their health as excellent and 10.78% of females in their 70s and beyond rated their health as excellent.

Note that we actually created three tables, one for males, one for females, and one for everybody. We are mainly interested in the first two tables and would like to drop the third table. But if we use the nototals option, we will not get the row totals we see above. Instead, we can specify which totals we do want with the totals() option:
```
. table (agegrp) (hlthstat) (sex), statistic(percent, across(hlthstat))
> totals(sex#agegrp sex#hlthstat sex)
Sex = Male

<table>
<thead>
<tr>
<th>Health status</th>
<th>Excellent</th>
<th>Very good</th>
<th>Good</th>
<th>Fair</th>
<th>Poor</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age group</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>20-29</td>
<td>39.61</td>
<td>32.71</td>
<td>20.97</td>
<td>5.82</td>
<td>0.90</td>
<td>100.00</td>
</tr>
<tr>
<td>30-39</td>
<td>36.88</td>
<td>29.61</td>
<td>26.10</td>
<td>5.84</td>
<td>1.56</td>
<td>100.00</td>
</tr>
<tr>

<td>21.29</td>
<td>25.40</td>
<td>29.45</td>
<td>17.47</td>
<td>6.40</td>
<td>100.00</td>
</tr>
</tbody>
</table>
```

sex#agegrp gives us the row totals, the total for each age group within each category of sex. sex#hlthstat provides us with the column totals, one of which would be the total percent of females that rated their health as excellent. Finally, sex gives us the total in the rightmost cell in the bottom of each table.

In all our previous tables, we used variables to define the rows and columns, but you can also use results in the row, column, and table identifiers. For example, suppose that in addition to reporting percentages for males and females in each age group, we wanted to report frequencies. We can create separate tables for the percentages and frequencies by specifying result in the third set of parentheses. To include the totals for each age group and for each category of sex, we specify the interaction of sex and agegrp in the totals() option:
In the table of frequencies, we see that of the 1,204 females in their 20s, only 390 rated their health as excellent. In the table of percentages, we see that this is equal to 32.39% of females in their 20s.

If we wish to include one of these tables, for example, in a paper or on a webpage, we can easily export it in \LaTeX, Word, Excel, HTML, and a variety of other formats by using collect export.
Stored results

table stores the following in r():

Scalars
r(N) number of observations

</table>

**Description**

In this entry, we discuss how to use `table` to create a table of summary statistics.

**Quick start**

Table with the mean of v1, v2, and v3 for each category of a1 and a2; rows are defined by categories of a1 and variables v1, v2, and v3

```
table a1 a2, stat(mean v1 v2 v3)
```

Same as above, but also report standard deviations and suppress the totals; rows are defined by the results for each variable within each category of a1

```
table (a1 var result) (a2), stat(mean v1 v2 v3) ///
    stat(sd v1 v2 v3) nototals
```

Table with number of observations in each category of a2 and a3, for each level of a1

```
table a1, stat(fvfrequency a2 a3)
```

Same as above, and report percentage of observations in each category

```
table a1, stat(fvfrequency a2 a3) ///
    stat(fvpercent a2 a3)
```

Same as above, and report the percentages with a percent sign, using two decimal places, and enclose them in parentheses

```
table (a1) (var result), stat(fvfrequency a2 a3) ///
    stat(fvpercent a2 a3) ///
    nformat(%5.2f fvpercent) sformat("(%s%%)" fvpercent)
```

**Menu**

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results
Syntax

Basic table of summary statistics

```
table [rowvar] [colvar] [if] [in] [weight], statistic(statspec)
   [statistic(statspec) […]] [options]
```

Customized table of summary statistics

```
table [(rowspec)] [(colspec)] [(tabspec)] [if] [in] [weight], statistic(statspec)
   [statistic(statspec) […]] [options]
```

`rowspec`, `colspec`, and `tabspec` may be empty or may include variable names or any of the following keywords:

<table>
<thead>
<tr>
<th>keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>requested statistics</td>
</tr>
<tr>
<td>var</td>
<td>variables from <code>statistic()</code> option</td>
</tr>
<tr>
<td>across</td>
<td>index across() specifications</td>
</tr>
</tbody>
</table>

```
options | Description
---------|-------------|
Main     |
```
```
totals()  | report only the specified totals
nototals  | suppress the marginal totals
```

```
Statistics |
```
```
statistic() | statistic to be reported; default is `statistic(frequency)` when no weights are specified and `statistic(sumw)` otherwise
```

```
Formats    |
```
```
nformat(%,fmt [results], basestyle) | specify numeric format
sformat(sfmt [results])         | specify string format
```

```
Options    |
```
```
listwise | use listwise deletion to handle missing values
missing   | treat numeric missing values of variables in `rowspec`, `colspec`, and `tabspec` like other values
showcounts| show sample size for all variables in `statistic()` option
zerocounts| report 0 for empty cell counts
name(cname)| collect results into a collection named `cname`
append    | append results to an existing collection
replace   | replace results of an existing collection
label(filename) | specify the collection labels
style(filename [, , override]) | specify the collection style
markvar(newvar) | create `newvar` that identifies observations used in the tabulation
```
fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
strL variables are not allowed; see [U] 12.4.8 strL.
markvar() does not appear in the dialog box.

Options

### Main

totals(totals) and nototals control which totals are to be displayed in the table. By default, all totals are reported.

- totals(totals) specifies which margin totals to display in the reported table. totals can contain variables in rowspec, colspec, tabspec, and their interaction. Interactions can be specified by using the # operator.
- nototals prevents table from displaying any totals.

### Statistics

statistic(statistic) specifies the statistic to be displayed. statistic() may be repeated to request multiple statistics. Frequency statistics, summary statistics, and ratio statistics are available by specifying statistic(freqstat), statistic(sumstat varlist), and statistic(ratiostat varlist [ , ratio_options ]), respectively.

statistic() may be repeated to request multiple statistics.

statistic(freqstat) specifies that frequencies be computed.

<table>

</tbody>
</table>
The `statistic(ratiostat [, varlist] [, ratio_options])` command specifies that the ratio statistic `ratiostat` be computed. If `varlist` is specified, ratios are computed based on the totals of the specified variables. If `varlist` is not specified, ratios are computed based on frequencies.

<table>
<thead>

</tbody>
</table>

`cellsoc` may contain any variables in `rowspec`, `colspec`, `tabspec`, or an interaction between any of these variables. Interactions can be specified by using the `#` operator.

The `nformat(fmt [, results] [, basestyle])` command changes the numeric format, such as the number of decimal places, for specified results. If `results` are not specified, the numeric format is changed for all results.

`results` may be any statistic named in option `statistic()` (that is, any `freqstat`, `sumstat`, or `ratiostat`).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (`rowspec`, `colspec`, and `tabspec`) or the format of factor variables specified in the `statistic()` option. The default format of these variables is taken from the dataset.

`basestyle` indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

The `sformat(fmt [, results])` command changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

`fmt` may contain a mix of text and `%s`. Here `%s` refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around `%s` in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s)" percent).

`results` may be any statistic named in option `statistic()` (that is, any `freqstat`, `sumstat`, or `ratiostat`).

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include `%`, type `%%`. To include \, type `\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%" percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.
Options

- **listwise** handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any variable specified in a `statistic()` option is missing for that observation. By default, `table` will omit an observation only if all variables specified in all `statistic()` options are missing for that observation.

- **missing** specifies that numeric missing values of any variables specified in `rowspec`, `colspec`, or `tabspec` be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

This option does not apply to factor variables specified with statistics `fvfrequency`, `fvrawfrequency`, `fvproportion`, `fvrawproportion`, `fvpercent`, or `fvrawpercent`.

- **showcounts** specifies that `table` report the sample size for each variable specified in option `statistic()`.

- **zerocounts** specifies that `table` report a 0 in empty cells for results `count`, `frequency`, `fvfrequency`, and `fvrawfrequency`.

- **name(cname)** specifies that a collection named `cname` be associated with the collected statistics and results. The default is `name(Table)`.

- **append** specifies that `table` append its collection information into the collection named in `name()`.

- **replace** permits `table` to overwrite an existing collection. This option is implied for `name(Table)` when `append` is not specified.

- **label(filename)** specifies the `filename` containing the collection labels to use for your table. Labels in `filename` will be loaded for the table, and any labels not specified in `filename` will be taken from the labels defined in `c(collect_label)`. The default is to use only the collection labels set in `c(collect_label)`; see [TABLES] set collect_label.

- **style(filename [, override])** specifies the `filename` containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in `filename` will be applied.

  If you prefer the default collection styles but also want to apply any styles in `filename`, specify `override`. If there are conflicts between the default collection styles and those in `filename`, the ones in `filename` will take precedence.

  The default is to use only the collection styles set in `c(table_style)`; see [TABLES] set table_style.

The following option is available with `table` but is not shown in the dialog box:

- **markvar(newvar)** generates an indicator variable that identifies the observations used in the tabulation.

Remarks and examples

Remarks are presented under the following headings:

- Basic summary statistic tables
- Classic Table 1
Basic summary statistic tables

The `table` command can be used to compute a variety of summary statistics and display them in a table. Summary statistics can be computed for the full dataset or across levels of one or more categorical variables.

To demonstrate, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981) and create a table reporting the mean body mass index (BMI) of individuals across four regions of the USA. We use the `statistic()` option to request that means be computed, and we specify `region` as our row variable for the table. Thus, means are computed for each region separately and for all the regions combined (Total).

```
. use https://www.stata-press.com/data/r18/nhanes2l
(Second National Health and Nutrition Examination Survey)
. table region, statistic(mean bmi)
```

<table>
<thead>
<tr>
<th>Region</th>
<th>Mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>NE</td>
<td>25.57535</td>
</tr>
<tr>
<td>MW</td>
<td>25.51936</td>
</tr>
<tr>
<td>S</td>
<td>25.63317</td>
</tr>
<tr>
<td>W</td>
<td>25.42299</td>
</tr>
<tr>
<td>Total</td>
<td>25.5376</td>
</tr>
</tbody>
</table>

The mean BMI is very similar across regions. We might want to look at some additional statistics. We can add the minimums and maximums in our table by repeating our `statistic()` option for each statistic; we will use the `stat()` abbreviation.

```
. table region, stat(mean bmi) stat(min bmi) stat(max bmi)
```

<table>
<thead>
<tr>
<th>Region</th>
<th>Mean</th>
<th>Minimum value</th>
<th>Maximum value</th>
</tr>
</thead>
<tbody>
<tr>
<td>NE</td>
<td>25.57535</td>
<td>15.36715</td>
<td>57.10803</td>
</tr>
<tr>
<td>MW</td>
<td>25.51936</td>
<td>14.1351</td>
<td>61.1297</td>
</tr>
<tr>
<td>S</td>
<td>25.63317</td>
<td>12.3856</td>
<td>55.43552</td>
</tr>
<tr>
<td>W</td>
<td>25.42299</td>
<td>15.69046</td>
<td>54.05056</td>
</tr>
<tr>
<td>Total</td>
<td>25.5376</td>
<td>12.3856</td>
<td>61.1297</td>
</tr>
</tbody>
</table>

If we want to include even more statistics, the table will become very wide. We can move the statistics to the rows of our table by specifying the keyword `result` in the first set of parentheses. We place `region` on the columns by specifying this variable in the second set of parentheses.
. table (result) (region),
> stat(mean bmi) stat(median bmi) stat(sd bmi)
> stat(min bmi) stat(max bmi)

<table>
<thead>
<tr>
<th></th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean</td>
<td>25.57535</td>
<td>25.51936</td>
<td>25.63317</td>
<td>25.42299</td>
<td>25.5376</td>
</tr>
<tr>
<td>Standard deviation</td>
<td>4.72798</td>
<td>4.905965</td>
<td>5.084678</td>
<td>4.883534</td>
<td>4.914969</td>
</tr>
<tr>
<td>Minimum value</td>
<td>15.36715</td>
<td>14.1351</td>
<td>12.3856</td>
<td>15.69046</td>
<td>12.3856</td>
</tr>
<tr>
<td>Maximum value</td>
<td>57.10803</td>
<td>61.1297</td>
<td>55.43552</td>
<td>54.05056</td>
<td>61.1297</td>
</tr>
</tbody>
</table>

Instead of computing many statistics for one variable, we might want to compute one statistic for multiple variables. To do this, we can include a list of variables within a single `statistic()` option. Let's compute the means of age, BMI, and systolic blood pressure (bpsystol).

. table (result) (region), stat(mean age bmi bpsystol)

<table>
<thead>
<tr>
<th></th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years)</td>
<td>47.81584</td>
<td>46.52776</td>
<td>48.19068</td>
<td>47.83828</td>
<td>47.57965</td>
</tr>
<tr>
<td>Body mass index (BMI)</td>
<td>25.57535</td>
<td>25.51936</td>
<td>25.63317</td>
<td>25.42299</td>
<td>25.5376</td>
</tr>
<tr>
<td>Systolic blood pressure</td>
<td>131.3836</td>
<td>130.4863</td>
<td>131.1626</td>
<td>130.5936</td>
<td>130.8817</td>
</tr>
</tbody>
</table>

**Classic Table 1**

In many reports, the first discussion of the data is accompanied by a “Table 1”, a reporting of summary statistics for all variables of interest. Often the table includes a mixture of continuous and categorical variables. We may also want to specify these in a particular order based on importance. In many cases, the table has multiple columns with the summary statistics reported for each level of a categorical variable of interest.

Here we will demonstrate how to create one variety of such a table. We have two factor variables of interest, diabetes and hlthstat, for which we would like to compute the percentage of individuals in each category. We will use the `fvpercent` statistic to obtain these percentages. We also have three continuous variables, age, bmi, and bpsystol, for which we would like to compute means. We specify the `statistic()` options in the order we wish to see the results in the table. To specify that the variables in the `statistic()` options appear on the rows, we include the keyword `var` in the first set of parentheses. We place `region` on the columns by listing it in the second set of parentheses.
We have the statistics we want, but clearly our table could be improved. Let’s start by applying one of the predefined styles, `table-1`, by adding the `style()` option.
This style removes the labels for the type of statistic being reported, cleans up the reporting of factor variables in the row headers, and right-aligns the content in the row headers. In addition, we may want to specify that the means be reported to two decimal places using the `nformat(%6.2f mean)` option.

```
.table (var) (region),
> statistic(fvpercent diabetes)
> statistic(mean age bmi)
> statistic(fvpercent hlthstat )
> statistic(mean bpsystol) style(table-1) nformat(%6.2f mean)
```

<table>
<thead>
<tr>
<th>Region</th>
<th>NE</th>
<th>MW</th>
<th>S</th>
<th>W</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diabetes status</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Not diabetic</td>
<td>95.32</td>
<td>95.49</td>
<td>94.36</td>
<td>95.62</td>
<td>95.18</td>
</tr>
<tr>
<td>Diabetic</td>
<td>4.68</td>
<td>4.51</td>
<td>5.64</td>
<td>4.38</td>
<td>4.82</td>
</tr>
<tr>
<td>Age (years)</td>
<td>47.82</td>
<td>46.53</td>
<td>48.19</td>
<td>47.84</td>
<td>47.58</td>
</tr>
<tr>
<td>Body mass index (BMI)</td>
<td>25.58</td>
<td>25.52</td>
<td>25.63</td>
<td>25.42</td>
<td>25.54</td>
</tr>
<tr>
<td>Health status</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Excellent</td>
<td>26.95</td>
<td>26.33</td>
<td>19.14</td>
<td>21.68</td>
<td>23.29</td>
</tr>
<tr>
<td>Very good</td>
<td>26.76</td>
<td>26.01</td>
<td>22.82</td>
<td>25.18</td>
<td>25.07</td>
</tr>
<tr>
<td>Good</td>
<td>30.26</td>
<td>26.52</td>
<td>28.29</td>
<td>29.14</td>
<td>28.43</td>
</tr>
<tr>
<td>Fair</td>
<td>12.33</td>
<td>15.12</td>
<td>18.65</td>
<td>17.60</td>
<td>16.16</td>
</tr>
<tr>
<td>Poor</td>
<td>3.69</td>
<td>6.02</td>
<td>11.11</td>
<td>6.40</td>
<td>7.05</td>
</tr>
<tr>
<td>Systolic blood pressure</td>
<td>131.38</td>
<td>130.49</td>
<td>131.16</td>
<td>130.59</td>
<td>130.88</td>
</tr>
</tbody>
</table>
Let's go one step further. Perhaps we want the mean and standard deviation of each continuous variable, and we want the frequency and percent for each factor variable. We need to specify a few more statistic() options.

\[ \text{. table (var) (region),} \]
\[ > \text{stat(fvfreq diabetes) statistic(sd age bmi)} \]
\[ > \text{statistic(fvfreq hlthstat) statistic(fvpercent hlthstat)} \]
\[ > \text{statistic(mean bpsystol) statistic(sd bpsystol)} \]
\[ > \text{style(table-1) nformat(%6.2f mean sd)} \]

<table>

</tr>
</tbody>
</table>
Finally, to distinguish among our statistics, we can use the `sformat()` option to add parentheses around our standard deviations and percent signs to our percentages.

```
. table (var) (region),
> stat(fvfreq diabetes) statistic(fvpercent diabetes)
> statistic(mean age bmi) statistic(sd age bmi)
> statistic(fvfreq hlthstat) statistic(fvpercent hlthstat)
> statistic(mean bpsystol) statistic(sd bpsystol)
> style(table-1) nformat(%6.2f mean sd)
> sformat("(%s)" sd) sformat("%s%%" fvpercent)
```

</tbody>
</table>

We have added many customizations to our table. However, you may prefer a different look. For another style, you can select from the predefined styles described in [TABLES] Predefined styles. If none of these provide the exact style you want for your table, you can further customize the results by using the collect suite of commands. To learn more, see [TABLES] Intro.

If you wish to include this table in a paper, on a webpage, or in another format, you can easily export it in LaTeX, Word, Excel, HTML, and a variety of other formats by using `collect export`.

### Stored results

`table` stores the following in `r()`:

- **Scalars**
  - `r(N)` number of observations

[R] dtable — Create a table of descriptive statistics
[R] table intro — Introduction to tables of frequencies, summaries, and command results
[R] tabstat — Compact table of summary statistics
[TABLES] Intro — Introduction
In this entry, we discuss how to use `table` to create tables with results of hypothesis tests.

**Quick start**

Table with pairwise correlations stored in matrix `r(C)`
```
table (rowname) (colname), command(r(C): pwcorr v1 v2 v3)
```

Table with all the numeric scalars returned by `ttest`; rows correspond to the different results
```
table (result) (command), command(ttest v1, by(catvar))
```

Table with means and two-sided \(p\)-values; columns correspond to the different results
```
table (command) (result), ///
   command(r(mu_1) r(mu_2) r(p): ttest v1, by(catvar))
```

Same as above, but with statistics for `v1` and `v2`
```
table (command) (result), ///
   command(r(mu_1) r(mu_2) r(p): ttest v1, by(catvar)) ///
   command(r(mu_1) r(mu_2) r(p): ttest v2, by(catvar))
```

Options

**Commands**

`command(cmdspec)` specifies the Stata commands from which to collect results. `command()` may be repeated to collect results from multiple commands.

`cmdspec` is `[ explist: ] command [ arguments ] [ , cmdoptions ]`

- `explist` specifies which results to collect and report in the table. `explist` may include *result identifiers* and *named expressions*.

  - *result identifiers* are results stored in `r()` and `e()` by the *command*. For instance, *result identifiers* could be `r(mean)`, `r(C)`, or `e(chi2)`. After estimation commands, *result identifiers* also include the following:

    | Identifier | Result |
    |------------|--------|
    | _r_b       | coefficients or transformed coefficients reported by *command* |
    | _r_se      | standard errors of _r_b |
    | _r_z       | test statistics for _r_b |
    | _r_z_abs   | absolute value of _r_z |
    | _r_p       | p-values for _r_b |
    | _r_lb      | lower bounds of confidence intervals for _r_b |
    | _r_ub      | upper bounds of confidence intervals for _r_b |
    | _r_ci      | confidence intervals for _r_b |
    | _r_crlb    | lower bounds of credible intervals for _r_b |
    | _r_crub    | upper bounds of credible intervals for _r_b |
    | _r_cri     | credible intervals for _r_b |
    | _r_df      | degrees of freedom for _r_b |

  - *named expressions* are specified as `name = exp`, where `name` may be any valid Stata name and `exp` is an expression, typically an expression that involves one or more *result identifiers*.

    An example of a named expression is `sd = sqrt(r(variance))`.

For `r-class` commands, the default is to include all numeric scalars posted to `r()` in the table results. For `e-class` commands, the default is to include `_r_b` in the table results.

- `command` is any command that follows standard Stata syntax.

- `arguments` may be anything so long as they do not include an `if` clause, `in` range, or weight specification.

  Any `if` or `in` qualifier and weights should be specified directly with `table`, not within the `command()` option. Weights are passed to *command* only if they are specified.

- `cmdoptions` may be anything supported by *command*.

**Formats**

`nformat(%, fmt [ results ] [ , basestyle ])` changes the numeric format, such as the number of decimal places, for specified results. If `results` are not specified, the numeric format is changed for all results.

- `results` may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.
This option does not affect the format of numeric layout variables (rowspec, colspec, and tabspec). The default format of these variables is taken from the dataset.

**basestyle** indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt results)` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

`sfmt` may contain a mix of text and `%s`. Here `%s` refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around `%s` in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(\%)" percent).

`results` may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type \%. To include \, type \\%. For instance, to place a percent sign following percent statistics, you can specify `sformat("%\%" percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

**Stars**

`sstars(starspec)` specifies that stars representing statistical significance be included in the table. `starspec` identifies the result whose values determine significance, which characters should represent each significance level, and where these characters should be displayed in the table. `starspec` is `starres [ #1 "label1" [ #2 "label2" [ #3 "label3" [ #4 "label4" [ #5 "label5" ] ] ] ] ] [ , attach(attachres) result dimension starsnoteopts ]`

`starres` is the name of the result whose values determine which characters, typically which number of stars, are to be displayed.

`label1` specifies the characters to be displayed when `starres` < #1.

`label2` specifies the characters to be displayed when `starres` < #2.

`label3` specifies the characters to be displayed when `starres` < #3.

`label4` specifies the characters to be displayed when `starres` < #4.

`label5` specifies the characters to be displayed when `starres` < #5.

`attach(attachres)` specifies the name of the result to which the characters defined by `label1`, ..., `label5` are to be attached. If `attach()` is not specified, a new result named `stars` is created and is automatically added to the table.

`result` and `dimension` control how `collect stars` adds items when labeling significant results. These options are mutually exclusive.

`result` specifies the default behavior, and this option is necessary only if the following `dimension` behavior is in effect and you want to change back to the `result` behavior.

`dimension` specifies that dimension `stars` be added to the collection. Items will be tagged with `stars[value]`, and the labels will be tagged with `stars[label]`. Use this option for layouts where results are to be stacked within columns, and use new dimension `stars` in the column specification of the layout.

`sstarsnoteopts` control the display and composition of the stars note.
noshownote and shownote control whether to display the stars note.

increasing and decreasing control the order of $p$-values in the stars note.

pvname(string) specifies a name for the $p$-value in the stars note. The default is pvname(p).

delimiter(string) specifies the delimiter between labels in the stars note. The default is delimiter(" ").

nformat(\%%f) specifies the numeric format for the cutoff values in the stars note. The default is nformat(\%9.0g).

prefix(string) specifies the prefix for the stars note. The prefix is empty by default.

suffix(string) specifies the suffix for the stars note. The suffix is empty by default.

For example, \texttt{stars(_r_p 0.01 "***" 0.05 "**" 0.1 ", attach(_r_b))} could be added to a table of regression results to specify that stars be defined based on the $p$-values in \_r\_p and be attached to the reported coefficients (\_r\_b).

### Options

**missing** specifies that numeric missing values of any variables specified in \texttt{rowspec}, \texttt{colspec}, or \texttt{tabspec} be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

**name(cname)** specifies that a collection named \texttt{cname} be associated with the collected statistics and results. The default is \texttt{name(Table)}.

**append** specifies that \texttt{table} append its collection information into the collection named in \texttt{name()}. **replace** permits \texttt{table} to overwrite an existing collection. This option is implied for \texttt{name(Table)} when \texttt{append} is not specified.

**label(filename)** specifies the \texttt{filename} containing the collection labels to use for your table. Labels in \texttt{filename} will be loaded for the table, and any labels not specified in \texttt{filename} will be taken from the labels defined in \texttt{c(collect_label)}. The default is to use only the collection labels set in \texttt{c(collect_label)}; see \texttt{[TABLES] set collect_label}. **style(filename[, override])** specifies the \texttt{filename} containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in \texttt{filename} will be applied.

If you prefer the default collection styles but also want to apply any styles in \texttt{filename}, specify \texttt{override}. If there are conflicts between the default collection styles and those in \texttt{filename}, the ones in \texttt{filename} will take precedence.

The default is to use only the collection styles set in \texttt{c(table_style)}; see \texttt{[TABLES] set table_style}.

The following option is available with \texttt{table} but is not shown in the dialog box:

**noisily** specifies that output from the commands specified in \texttt{command()} options be displayed. By default, output from commands is suppressed.
Remarks and examples

Remarks are presented under the following headings:

Introduction
Creating tables from scalars
Creating tables from matrices

Introduction

The `table` command can be used to create tables with results of hypothesis tests. For example, you can create a table with results from a mean-comparison test, a test of proportions, or a test of normality.

`table` does not perform hypothesis tests directly. Rather, `table` will run any Stata command that you include in its `command()` option and place results from that command into the table. You determine which results you would like to see in the table. You can select any of the results stored by the command.

Creating tables from scalars

We have data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). The data contain some demographic information, such as the age, sex, and race of participants. The data also contain some measures of health, including whether the individual has high blood pressure (`highbp`), has diabetes, or has had a heart attack previously (`hearthatk`).

Suppose we want to examine the proportion of males and females that have high blood pressure, that have diabetes, and that have had a heart attack previously. With `prtest`, we can test whether the proportions are equal between males and females. For example, let’s perform a test of proportions for diabetes:

```stata
. use https://www.stata-press.com/data/r18/nhanes2l
(Second National Health and Nutrition Examination Survey)
. prtest diabetes, by(sex)
Two-sample test of proportions

|        | Number of obs | Mean | Std. err. | z    | P>|z|    | [95% conf. interval] |
|--------|---------------|------|-----------|------|--------|---------------------|
| Male   | 4915          | .0441506 | .0029302  | .0384074 | .0498937 |                   |
| Female | 5434          | .0518955 | .0030091  | .0459978 | .0577932 |                   |
| diff   |               | -.0077449 | .0042001  | -.0159769 | .0004871 |                   |

under H0: .0042169 -1.84 0.066

z = -1.8366

Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0331 Pr(|Z| > |z|) = 0.0663 Pr(Z > z) = 0.9669
```

We would like to create a table that includes the proportion of men who have diabetes, the proportion of women who have diabetes, the difference in these proportions, and the $p$-value for a two-sided test. First, we need to determine how to refer to these statistics.
The statistics we want to see are stored as $r(P1)$, $r(P2)$, $r(P\_diff)$, and $r(p)$. We can specify this in the `command()` option by typing

```
.table ..., command(r(P1) r(P2) r(P\_diff) r(p): prtest diabetes, by(sex))
```

This will get the results we want into our table. Furthermore, because we know what these values represent, we can give them names that will appear in the table headers. We can, for instance, type

```
.table ..., command(Males=r(P1) Females=r(P2) Difference=r(P\_diff) ///
    r(p): prtest diabetes, by(sex))
```

We can specify similar `command()` options for `heartatk` and `highbp` as well.

In addition, we need to specify how our results will be laid out in the table. Below, we type `command` in the first set of parentheses so that the rows correspond to the different commands. We type `result` in the second set of parentheses to specify that statistics appear in the columns.

Finally, we add two options to customize the results. We specify a numeric format so that the statistics be displayed only with three digits after the decimal. We also choose the predefined style `table-right` so that our row headers will be right-aligned. See [TABLES] Predefined styles for information on this and other styles.

```
.table (command) (result),
> command(Males=r(P1) Females=r(P2) Difference=r(P\_diff) r(p): prtest diabetes, by(sex))
> command(Males=r(P1) Females=r(P2) Difference=r(P\_diff) r(p): prtest heartatk, by(sex))
> command(Males=r(P1) Females=r(P2) Difference=r(P\_diff) r(p): prtest highbp, by(sex))
> nformat(%5.3f) style(table-right)
```

<table>
<thead>
<tr>
<th></th>
<th>Males</th>
<th>Females</th>
<th>Difference</th>
<th>Two-sided p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>prtest diabetes, by(sex)</td>
<td>0.044</td>
<td>0.052</td>
<td>-0.008</td>
<td>0.066</td>
</tr>
<tr>
<td>prtest heartatk, by(sex)</td>
<td>0.065</td>
<td>0.029</td>
<td>0.036</td>
<td>0.000</td>
</tr>
<tr>
<td>prtest highbp, by(sex)</td>
<td>0.469</td>
<td>0.381</td>
<td>0.088</td>
<td>0.000</td>
</tr>
</tbody>
</table>
Our table now includes all the statistics we want. Yet we might want to make some modifications. Table customization can go beyond the predefined styles and options available to you in the `table` command. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to produce highly customized tables and to export those tables to presentation-ready formats, such as HTML, Word, LaTeX, PDF, Excel, and more.

For this table, we want to modify the labels in our row headers. Instead of showing the full command that was run, row headers will identify the variable we are testing. In addition, we will modify the label for our p-value. We want to use the label `p-value`. Because this is not a valid Stata name, we could not specify it in the `table` command as we did with `Males`. However, we can use `collect label levels` to modify the label on our p-values.

After applying the label updates, we use `collect preview` to see our updated table.

```
. collect label levels command 1 "Diabetes" 2 "Heart attack" 3 "High BP", modify
. collect label levels result p "p-value", modify
. collect preview

<table>
<thead>
<tr>
<th></th>
<th>Males</th>
<th>Females</th>
<th>Difference</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diabetes</td>
<td>0.044</td>
<td>0.052</td>
<td>-0.008</td>
<td>0.066</td>
</tr>
<tr>
<td>Heart attack</td>
<td>0.065</td>
<td>0.029</td>
<td>0.036</td>
<td>0.000</td>
</tr>
<tr>
<td>High BP</td>
<td>0.469</td>
<td>0.381</td>
<td>0.088</td>
<td>0.000</td>
</tr>
</tbody>
</table>
```

**Creating tables from matrices**

You may find that the results you want to include in your table are stored in a matrix; these results can also be easily included in a table.

To demonstrate, we create a table with p-values for tests of normality for `height`, `weight`, and diastolic blood pressure (`bpdiast`). The command `sktest` performs tests based on skewness, kurtosis, and a combined test statistic.

```
. sktest height weight bpdiast
Skewness and kurtosis tests for normality

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Pr(skewness)</th>
<th>Pr(kurtosis)</th>
<th>Adj chi2(2)</th>
<th>Prob&gt;chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>height</td>
<td>10,351</td>
<td>0.0000</td>
<td>0.0000</td>
<td>147.47</td>
<td>0.0000</td>
</tr>
<tr>
<td>weight</td>
<td>10,351</td>
<td>0.0000</td>
<td>0.0000</td>
<td>801.40</td>
<td>0.0000</td>
</tr>
<tr>
<td>bpdiast</td>
<td>10,351</td>
<td>0.0000</td>
<td>0.0000</td>
<td>362.54</td>
<td>0.0000</td>
</tr>
</tbody>
</table>
```

Let's look at the returned results.

```
. return list
scalars:
   r(N) = 10351
   r(p_skew) = 1.58706287446e-72
   r(p_kurt) = 6.22330331716e-26
   r(chi2) = 362.5385838320567
   r(p_ch2) = 1.88689086684e-79

matrices:
   r(table) : 3 x 5
```

The statistics we want plus a few others are stored in `r(table)`. 
Now, let's place these values in a table. We specify that our table be arranged with the row names (rowname) of the matrix defining the rows of the table. Similarly, the column names (colname) of the matrix define the columns of the table. Then, we specify that we want to collect the results from the matrix r(table) from the sktest command.

```
.table (rowname) (colname),
> command(r(table): sktest height weight bpdiast)
```

<table>
<thead>
<tr>
<th></th>
<th>N</th>
<th>p_skew</th>
<th>p_kurt</th>
<th>chi2</th>
<th>p_chi2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Height (cm)</td>
<td>10351</td>
<td>.0000179</td>
<td>1.87e-35</td>
<td>147.4712</td>
<td>9.48e-33</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>10351</td>
<td>1.6e-166</td>
<td>1.63e-49</td>
<td>801.3958</td>
<td>9.5e-175</td>
</tr>
<tr>
<td>Diastolic blood pressure</td>
<td>10351</td>
<td>1.59e-72</td>
<td>6.22e-26</td>
<td>362.5386</td>
<td>1.89e-79</td>
</tr>
</tbody>
</table>

Because the row names in r(table) corresponded to variables, our table automatically put the variable labels in the row headers. However, the column headers are not nicely labeled.

We can create better labels and modify our table in many other ways. table creates a collection of results that can be used in combination with the collect suite of commands to further customize tables.

To clean up our table, let's use collect label levels to modify the labels for the p-values for the skewness, kurtosis, and joint tests; these are the statistics we will include in our table below. To use collect label levels, we need to know just a little about the collect system. In collections, values are organized according to dimensions and levels within those dimensions. In fact, we use these dimensions in table. The keywords that we can use to define our rows and columns are dimensions. Here colname is our dimension that defines the columns, and its levels are N, p_skew, .... To modify labels, we need to tell collect label levels which dimension (colname) we would like to change and then specify labels for levels of that dimension.

We specify the dimension and then the label for each level:

```
. collect label levels colname p_skew "Skewness p-value"
> p_kurt "Kurtosis p-value" p_chi2 "Joint p-value", modify
```

To learn more about modifying labels, see [TABLES] collect label.

Let's also change the numeric format of our p-values. With collect style cell, we can modify all cells in the table, all cells in a particular dimension, or particular cells of a particular dimension. Below, we specify the numeric formatting for only three levels of colname.

```
. collect style cell colname[p_skew p_kurt p_chi2], nformat(%7.3f)
```

Finally, we want to show only the three p-values in our table. We can use collect layout to specify the statistics we want to include in our final table.

```
. collect layout (rowname) (colname[p_skew p_kurt p_chi2])
```

```
Collection: Table
Rows: rowname
Columns: colname[p_skew p_kurt p_chi2]
Table 1: 3 x 3

<table>
<thead>
<tr>
<th></th>
<th>Skewness p-value</th>
<th>Kurtosis p-value</th>
<th>Joint p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Height (cm)</td>
<td>0.000</td>
<td>0.000</td>
<td>0.000</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>0.000</td>
<td>0.000</td>
<td>0.000</td>
</tr>
<tr>
<td>Diastolic blood pressure</td>
<td>0.000</td>
<td>0.000</td>
<td>0.000</td>
</tr>
</tbody>
</table>
```
Notably, all $p$-values for all tests are very small, so this is not a particularly exciting table. However, our table customizations made it easy to quickly see the results of tests of normality for all our variables.

**Stored results**

`table` stores the following in `r()`:

Scalars

- `r(N)` number of observations

**Reference**

**Also see**

[R] `table` — Table of frequencies, summaries, and command results

[R] `table intro` — Introduction to tables of frequencies, summaries, and command results

[R] `table regression` — Table of regression results

[TABLES] `Intro` — Introduction
Description

In this entry, we discuss how to create tables of regression results. These tables can include coefficients, standard errors, confidence intervals, and many more results stored by estimation commands.

Quick start

Table of regression coefficients; rows correspond to covariates (colname)
```
table colname, command(regress y x1 x2 x3)
```

Table of coefficients and confidence intervals; columns correspond to the statistics (result)
```
table (colname) (result), command(_r_b _r_ci: regress y x1 x2 x3)
```

Same as above, but use the labels defined in mylabels.stjson and the styles in mystyle.stjson
```
table (colname) (result), ///
    command(_r_b _r_ci: regress y x1 x2 x3) ///
    label(mylabels) style(mystyle)
```

Menu

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results
Syntax

```
table ([rowspec]) ([colspec]) ([tabspec]) [if] [in] [weight],
command(cmdspec) [command(cmdspec) ...] [options]
```

`rowspec`, `colspec`, and `tabspec` may be empty or may include variable names or any of the following keywords:

<table>
<thead>
<tr>
<th>keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>requested statistics</td>
</tr>
<tr>
<td>stars</td>
<td>stars denoting statistical significance</td>
</tr>
<tr>
<td>command</td>
<td>index option command()</td>
</tr>
<tr>
<td>colname</td>
<td>column names for matrix statistics</td>
</tr>
<tr>
<td>rowname</td>
<td>row names for matrix statistics</td>
</tr>
<tr>
<td>coleq</td>
<td>column equation names for matrix statistics</td>
</tr>
<tr>
<td>roweq</td>
<td>row equation names for matrix statistics</td>
</tr>
</tbody>
</table>

```
options
```

<table>

</tr>
</tbody>
</table>

`fweights, aweights, iweights, and pweights` are allowed; see [U] 11.1.6 weight.

`strL` variables are not allowed; see [U] 12.4.8 strL.

`noisily` does not appear in the dialog box.
Options

\texttt{command(cmdspec)} specifies the Stata commands from which to collect results. \texttt{command()} may be repeated to collect results from multiple commands.

\texttt{cmdspec} is \texttt{[ explist: ] command [ arguments ] [ , cmdoptions ]}

\texttt{explist} specifies which results to collect and report in the table. \texttt{explist} may include result identifiers and named expressions.

result identifiers are results stored in \texttt{r()} and \texttt{e()} by the \texttt{command}. For instance, result identifiers could be \texttt{r(mean)}, \texttt{r(C)}, or \texttt{e(chi2)}. After estimation commands, result identifiers also include the following:

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>_r_b</td>
<td>coefficients or transformed coefficients reported by \texttt{command}</td>
</tr>
<tr>
<td>_r_se</td>
<td>standard errors of _r_b</td>
</tr>
<tr>
<td>_r_z</td>
<td>test statistics for _r_b</td>
</tr>
<tr>
<td>_r_z_abs</td>
<td>absolute value of _r_z</td>
</tr>
<tr>
<td>_r_p</td>
<td>(p)-values for _r_b</td>
</tr>
<tr>
<td>_r_lb</td>
<td>lower bounds of confidence intervals for _r_b</td>
</tr>
<tr>
<td>_r_ub</td>
<td>upper bounds of confidence intervals for _r_b</td>
</tr>
<tr>
<td>_r_ci</td>
<td>confidence intervals for _r_b</td>
</tr>
<tr>
<td>_r_crlb</td>
<td>lower bounds of credible intervals for _r_b</td>
</tr>
<tr>
<td>_r_crub</td>
<td>upper bounds of credible intervals for _r_b</td>
</tr>
<tr>
<td>_r_cri</td>
<td>credible intervals for _r_b</td>
</tr>
<tr>
<td>_r_df</td>
<td>degrees of freedom for _r_b</td>
</tr>
</tbody>
</table>

named expressions are specified as \texttt{name = exp}, where \texttt{name} may be any valid Stata name and \texttt{exp} is an expression, typically an expression that involves one or more result identifiers.

An example of a named expression is \texttt{sd = sqrt(r(variance))}.

For \texttt{r}-class commands, the default is to include all numeric scalars posted to \texttt{r()} in the table results. For \texttt{e}-class commands, the default is to include \_r\_b in the table results.

\texttt{command} is any command that follows standard Stata syntax.

\texttt{arguments} may be anything so long as they do not include an \texttt{if} clause, \texttt{in} range, or weight specification.

Any \texttt{if} or \texttt{in} qualifier and weights should be specified directly with \texttt{table}, not within the \texttt{command()} option. Weights are passed to \texttt{command} only if they are specified.

\texttt{cmdoptions} may be anything supported by \texttt{command}.

\texttt{nformat(\%fmt [ results ] , basestyle])} changes the numeric format, such as the number of decimal places, for specified results. If \texttt{results} are not specified, the numeric format is changed for all results.

\texttt{results} may be any name in the \texttt{e()} or \texttt{r()} results produced by commands specified in option \texttt{command()}. This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.
This option does not affect the format of numeric layout variables (rowspec, colspec, and tabspec). The default format of these variables is taken from the dataset.

`basestyle` indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

`sformat(sfmt results)` changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

`sfmt` may contain a mix of text and %s. Here %s refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around %s in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s)" percent)`.

`results` may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include %, type %%. To include \, type \. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%" percent)`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

`cidelimiter(char)` changes the delimiter between confidence interval limits to char. The default is `cidelimiter(" ")`, that is, two spaces.

`cridelimiter(char)` changes the delimiter between credible interval limits to char. The default is `cridelimiter(" ")`, that is, two spaces.

`stars(starspec)` specifies that stars representing statistical significance be included in the table. `starspec` identifies the result whose values determine significance, which characters should represent each significance level, and where these characters should be displayed in the table. `starspec` is `starres[#1 "label1" [#2 "label2" [#3 "label3" [#4 "label4" [#5 "label5"]]]]]` `[, attach(attachres) result dimension starsnoteopts]`

`starres` is the name of the result whose values determine which characters, typically which number of stars, are to be displayed.

`label1` specifies the characters to be displayed when `starres < #1`.

`label2` specifies the characters to be displayed when `starres < #2`.

`label3` specifies the characters to be displayed when `starres < #3`.

`label4` specifies the characters to be displayed when `starres < #4`.

`label5` specifies the characters to be displayed when `starres < #5`.

`attach(attachres)` specifies the name of the result to which the characters defined by `label1`, ..., `label5` are to be attached. If `attach()` is not specified, a new result named `stars` is created and is automatically added to the table.

`result` and `dimension` control how `collect stars` adds items when labeling significant results. These options are mutually exclusive.

`result` specifies the default behavior, and this option is necessary only if the following `dimension` behavior is in effect and you want to change back to the `result` behavior.
dimension specifies that dimension stars be added to the collection. Items will be tagged with stars[value], and the labels will be tagged with stars[label]. Use this option for layouts where results are to be stacked within columns, and use new dimension stars in the column specification of the layout.

starsnoteopts control the display and composition of the stars note.

noshownote and shownote control whether to display the stars note.

increasing and decreasing control the order of p-values in the stars note.

pvname(string) specifies a name for the p-value in the stars note. The default is pvname(p).

delimiter(string) specifies the delimiter between labels in the stars note. The default is delimiter("","").

nformat[%fnt] specifies the numeric format for the cutoff values in the stars note. The default is nformat(%9.0g).

prefix(string) specifies the prefix for the stars note. The prefix is empty by default.

suffix(string) specifies the suffix for the stars note. The suffix is empty by default.

For example, stars(_r_p 0.01 "***" 0.05 "**" 0.1 ",", attach(_r_b)) could be added to a table of regression results to specify that stars be defined based on the p-values in _r_p and be attached to the reported coefficients (_r_b).

Options

missing specifies that numeric missing values of any variables specified in rowspec, colspec, or tabspec be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.

name(cname) specifies that a collection named cname be associated with the collected statistics and results. The default is name(Table).

append specifies that table append its collection information into the collection named in name(). replace permits table to overwrite an existing collection. This option is implied for name(Table) when append is not specified.

label(filename) specifies the filename containing the collection labels to use for your table. Labels in filename will be loaded for the table, and any labels not specified in filename will be taken from the labels defined in c(collect_label). The default is to use only the collection labels set in c(collect_label); see [TABLES] set collect_label.

style(filename [, , override]) specifies the filename containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in filename will be applied.

If you prefer the default collection styles but also want to apply any styles in filename, specify override. If there are conflicts between the default collection styles and those in filename, the ones in filename will take precedence.

The default is to use only the collection styles set in c(table_style); see [TABLES] set table_style.

The following option is available with table but is not shown in the dialog box:

noisily specifies that output from the commands specified in command() options be displayed. By default, output from commands is suppressed.
Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Tables with results from a single command
- Tables with results from multiple estimation commands
- Regression results with factor variables

Introduction

The `table` command allows us to create tables of regression results. You can create a table that reports coefficients, standard errors, test statistics, confidence intervals, and other statistics from a single model or a table that compares results from multiple models.

`table` does not fit models directly. Rather, `table` will run any Stata command that you include in its `command()` option and place results from that command into the table. You determine which results you would like to see in the table. You can select any of the results stored by the command.

You can also create a table of regression results with `etable`. However, `etable` will create tables only with active estimation results, results from `margins`, or results stored with `estimates store`. If you are working with any of these results, you can use `etable` to create and export a table of regression results. However, if you want to include results from other commands, you should use the `table` command.

Tables with results from a single command

We have data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). The data contain some demographic information, such as the participants’ age. The data also contain some measures of health, including the individual’s weight, systolic blood pressure (bpsystol), and whether the individual has diabetes.

Here we will create a table with results from a linear regression model for systolic blood pressure as a function of age and weight. We type the command to fit the model in the `command()` option. In the first set of parentheses following `table`, we specify that we want the rows to correspond to the levels of `colname`—this is how we refer to the list of covariates in our regression model. In the second set of parentheses, we specify that we want the columns to correspond to the statistics (result).

```
use https://www.stata-press.com/data/r18/nhanes2l
(Second National Health and Nutrition Examination Survey)
.table (colname) (result), command(regress bpsystol age weight)
```

<table>
<thead>
<tr>
<th>Coefficient</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years)</td>
</tr>
<tr>
<td>Weight (kg)</td>
</tr>
<tr>
<td>Intercept</td>
</tr>
</tbody>
</table>

Our table is fairly simple. By default, `table` includes only the reported coefficients when an estimation command is specified in the `command()` option.
The `table` command can easily be used to compare results across groups in our data. For instance, if we want to fit the same model for males and females, we can add `sex` to our column specification.

```
. table (colname) (sex result), command(regress bpsystol age weight)
```

<table>
<thead>
<tr>
<th></th>
<th>Male</th>
<th>Female</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years)</td>
<td>.4789361</td>
<td>.7735499</td>
<td>.6379892</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>.3346106</td>
<td>.4586108</td>
<td>.4069041</td>
</tr>
<tr>
<td>Intercept</td>
<td>84.08037</td>
<td>61.70456</td>
<td>71.27096</td>
</tr>
</tbody>
</table>

We can now easily compare results for males, females, and both together.

We may want to see additional statistics reported. Let’s extend our table to include both coefficients and standard errors. We can refer to the reported coefficients using the keyword `r_b` and to the reported standard errors as `r_se`, and we can list these in the `command()` option before our regression command. Here we also move `result` to the first set of parentheses so that coefficients and standard errors will be displayed on separate rows.

```
. table (colname result) (sex),
> command(_r_b _r_se: regress bpsystol age weight)
```

<table>
<thead>
<tr>
<th></th>
<th>Male</th>
<th>Female</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years)</td>
<td>.4789361</td>
<td>.7735499</td>
<td>.6379892</td>
</tr>
<tr>
<td>Coefficient</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Std. error</td>
<td>.0156578</td>
<td>.0155743</td>
<td>.0111315</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>.3346106</td>
<td>.4586108</td>
<td>.4069041</td>
</tr>
<tr>
<td>Coefficient</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Std. error</td>
<td>.0197112</td>
<td>.0182401</td>
<td>.0124786</td>
</tr>
<tr>
<td>Intercept</td>
<td>84.08037</td>
<td>61.70456</td>
<td>71.27096</td>
</tr>
<tr>
<td>Coefficient</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Std. error</td>
<td>1.74867</td>
<td>1.376067</td>
<td>1.041742</td>
</tr>
</tbody>
</table>

We now have the statistics we want in this table, but we may want to modify the look a bit. `table` allows us to customize the results in our table in a number of ways. We can use the `nformat()` option to report all results to two decimal places, and we can use the `sformat()` option to place parentheses around our standard errors.

```
. table (colname result) (sex),
> command(_r_b _r_se: regress bpsystol age weight)
> nformat(%6.2f) sformat("(%s)" _r_se)
```

<table>
<thead>
<tr>
<th></th>
<th>Male</th>
<th>Female</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years)</td>
<td>.48</td>
<td>.77</td>
<td>.64</td>
</tr>
<tr>
<td>Coefficient</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Std. error</td>
<td>.02</td>
<td>.02</td>
<td>.01</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>.33</td>
<td>.46</td>
<td>.41</td>
</tr>
<tr>
<td>Coefficient</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Std. error</td>
<td>.02</td>
<td>.02</td>
<td>.01</td>
</tr>
<tr>
<td>Intercept</td>
<td>84.08</td>
<td>61.70</td>
<td>71.27</td>
</tr>
<tr>
<td>Coefficient</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Std. error</td>
<td>1.75</td>
<td>1.38</td>
<td>1.04</td>
</tr>
</tbody>
</table>
Now that we have the parentheses to distinguish standard errors from coefficients, we may not want to see those labels in the row header. We add the `style(table-reg3)` option to use the predefined style `table-reg3`, which hides the names of these statistics, right-aligns the names of the variables in the row headers, center aligns the statistics horizontally within each column, and adds vertical space between variables.

```
. table (colname result) (sex),
   > command(_r_b _r_se: regress bpsystol age weight)
   > nformat(%05.3f) sformat("(%s)" _r_se) style(table-reg3)
```

<table>
<thead>
<tr>
<th></th>
<th>Sex</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Male</td>
<td>Female</td>
</tr>
<tr>
<td>Age (years)</td>
<td>0.479</td>
<td>0.774</td>
</tr>
<tr>
<td></td>
<td>(0.016)</td>
<td>(0.016)</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>0.335</td>
<td>0.459</td>
</tr>
<tr>
<td></td>
<td>(0.020)</td>
<td>(0.018)</td>
</tr>
<tr>
<td>Intercept</td>
<td>84.080</td>
<td>61.705</td>
</tr>
<tr>
<td></td>
<td>(1.749)</td>
<td>(1.376)</td>
</tr>
</tbody>
</table>

### Tables with results from multiple estimation commands

Above, we fit the same model to the full dataset and then to groups of observations within that dataset. We may alternatively want to fit different models and display their results in a single table. To do this, we specify multiple `command()` options.

```
. table (colname result) (command),
   > command(_r_b _r_se: regress bpsystol age weight)
   > command(_r_b _r_se: regress bpsystol age weight iron vitaminc zinc)
   > nformat(%6.2f) sformat("(%s)" _r_se) style(table-reg3)
```

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years)</td>
<td>0.64</td>
<td>0.64</td>
</tr>
<tr>
<td></td>
<td>(0.01)</td>
<td>(0.01)</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>0.41</td>
<td>0.40</td>
</tr>
<tr>
<td></td>
<td>(0.01)</td>
<td>(0.01)</td>
</tr>
<tr>
<td>Serum iron (mcg/dL)</td>
<td>-0.01</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(0.01)</td>
<td></td>
</tr>
<tr>
<td>Serum vitamin C (mg/dL)</td>
<td>-0.79</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(0.36)</td>
<td></td>
</tr>
<tr>
<td>Serum zinc (mcg/dL)</td>
<td>-0.05</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(0.01)</td>
<td></td>
</tr>
<tr>
<td>Intercept</td>
<td>71.27</td>
<td>77.50</td>
</tr>
<tr>
<td></td>
<td>(1.04)</td>
<td>(1.75)</td>
</tr>
</tbody>
</table>

We may want to modify this table a bit further. Customization of tables can go beyond the predefined styles and options available to you in the `table` command. `table` creates a collection of results that can be used in combination with the `collect` suite of commands to produce highly customized tables.
If we want to add more descriptive labels for the two models, we can use the `collect label levels` command to define our new labels. After a change using `collect`, we can type `collect preview` to see the results.

```
. collect label levels command 1 "Model 1" 2 "Model 2", modify
. collect style header command, level(label)
. collect preview
```

<table>
<thead>
<tr>
<th></th>
<th>Model 1</th>
<th>Model 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age (years)</td>
<td>0.64</td>
<td>0.64</td>
</tr>
<tr>
<td></td>
<td>(0.01)</td>
<td>(0.01)</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>0.41</td>
<td>0.40</td>
</tr>
<tr>
<td></td>
<td>(0.01)</td>
<td>(0.01)</td>
</tr>
<tr>
<td>Serum iron (mcg/dL)</td>
<td>-0.01</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(0.01)</td>
<td></td>
</tr>
<tr>
<td>Serum vitamin C (mg/dL)</td>
<td>-0.79</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(0.36)</td>
<td></td>
</tr>
<tr>
<td>Serum zinc (mcg/dL)</td>
<td>-0.05</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(0.01)</td>
<td></td>
</tr>
<tr>
<td>Intercept</td>
<td>71.27</td>
<td>77.50</td>
</tr>
<tr>
<td></td>
<td>(1.04)</td>
<td>(1.75)</td>
</tr>
</tbody>
</table>

Regression results with factor variables

The examples above included only continuous covariates in the models. When we include factor variables, there are a variety of ways that they can be displayed in the headers of the tables. In [TABLES] Predefined styles, you will find a number of styles that you can choose from. We demonstrate a few here.

We will start with the `table-reg1` style. This style is our default table style, except that it identifies the commands in the headers using values 1, 2, ... rather than labeling them with the full command we typed in the `command()` option.
In some cases, for clarity, it is helpful to see both the factor variables and their levels. The `table-reg1` style provides this in the output.

When we have nice value labels on our factor variables, we may want to see only those. The `table-reg1-fv1` style removes the extra labels. Our table above also reports zero-valued coefficients for base categories in both the main effects of the factor variables and in their interactions. The `table-reg1-fv1` style omits the rows for the base categories in the interactions.
Sometimes, the tables are more readable when the row headers are right aligned. We can use the \texttt{table-reg2-fv1} style in this case. Let’s also change the numeric format of all the results so that they report only two decimal places.

\begin{verbatim}
> . table (colname) (command result),
> command(regress bpsystol i.agegrp i.sex weight)
> command(regress bpsystol i.agegrp##i.sex weight)
> style(table-reg2-fv1) nformat(%6.2f)
\end{verbatim}

\begin{verbatim}
<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>20-29</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>30-39</td>
<td>1.20</td>
<td>-0.78</td>
</tr>
<tr>
<td>40-49</td>
<td>7.25</td>
<td>2.75</td>
</tr>
<tr>
<td>50-59</td>
<td>15.94</td>
<td>10.44</td>
</tr>
<tr>
<td>60-69</td>
<td>22.84</td>
<td>16.53</td>
</tr>
<tr>
<td>70+</td>
<td>30.47</td>
<td>23.31</td>
</tr>
<tr>
<td>Male</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>Female</td>
<td>1.04</td>
<td>-6.78</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>0.44</td>
<td>0.42</td>
</tr>
<tr>
<td>30-39 # Female</td>
<td>3.94</td>
<td></td>
</tr>
<tr>
<td>40-49 # Female</td>
<td>8.79</td>
<td></td>
</tr>
<tr>
<td>50-59 # Female</td>
<td>10.65</td>
<td></td>
</tr>
<tr>
<td>60-69 # Female</td>
<td>12.21</td>
<td></td>
</tr>
<tr>
<td>70+ # Female</td>
<td>13.52</td>
<td></td>
</tr>
<tr>
<td>Intercept</td>
<td>86.71</td>
<td>91.58</td>
</tr>
</tbody>
</table>
\end{verbatim}

There are many ways that we can further customize our table using the \texttt{collect} suite of commands. We can add column titles for our models as we did above. In addition, we can use \texttt{collect style row} to specify a character to be used between terms in an interaction.

\begin{verbatim}
> . collect label levels command 1 "Model 1" 2 "Model 2", modify
> . collect style header command, level(label)
> . collect style row stack, delimiter(" X ")
> . collect preview
\end{verbatim}

\begin{verbatim}
<table>
<thead>
<tr>
<th></th>
<th>Model 1</th>
<th>Model 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>20-29</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>30-39</td>
<td>1.20</td>
<td>-0.78</td>
</tr>
<tr>
<td>40-49</td>
<td>7.25</td>
<td>2.75</td>
</tr>
<tr>
<td>50-59</td>
<td>15.94</td>
<td>10.44</td>
</tr>
<tr>
<td>60-69</td>
<td>22.84</td>
<td>16.53</td>
</tr>
<tr>
<td>70+</td>
<td>30.47</td>
<td>23.31</td>
</tr>
<tr>
<td>Male</td>
<td>0.00</td>
<td>0.00</td>
</tr>
<tr>
<td>Female</td>
<td>1.04</td>
<td>-6.78</td>
</tr>
<tr>
<td>Weight (kg)</td>
<td>0.44</td>
<td>0.42</td>
</tr>
<tr>
<td>30-39 X Female</td>
<td>3.94</td>
<td></td>
</tr>
<tr>
<td>40-49 X Female</td>
<td>8.79</td>
<td></td>
</tr>
<tr>
<td>50-59 X Female</td>
<td>10.65</td>
<td></td>
</tr>
<tr>
<td>60-69 X Female</td>
<td>12.21</td>
<td></td>
</tr>
<tr>
<td>70+ X Female</td>
<td>13.52</td>
<td></td>
</tr>
<tr>
<td>Intercept</td>
<td>86.71</td>
<td>91.58</td>
</tr>
</tbody>
</table>
\end{verbatim}

If one of the predefined styles in \texttt{[TABLES] Predefined styles} does not suit your needs for factor-variable results (or for any other table customization), you can create your own style. To do this, you will use series of \texttt{collect style} commands, and then you can save the style to use later; see \texttt{[TABLES] collect style save}.  

\textbf{Predefined styles}
If you wish to include your table in a paper, on a webpage, or in another format, you can easily export it in \LaTeX, Word, Excel, HTML, and a variety of other formats by using `collect export`.

**Stored results**

`table` stores the following in `r()`:

Scalars:

- `r(N)` number of observations

**References**

**Table**

**Description**

`table` is a flexible command for creating tables of many types—tabulations, tables of summary statistics, tables of regression results, and more. `table` can calculate summary statistics to display in the table. `table` can also include results from other Stata commands.

**Quick start**

Two-way tabulation of `a1` and `a2`

```
table a1 a2
```

Table of means for `v1` and `v2` across the levels of `a1`

```
table a1, statistic(mean v1 v2)
```

Two-way table with `a1` defining rows and `a2` defining columns, with frequencies and pairwise correlation coefficients between `v3` and `v4` computed for every cell

```
table a1 a2, command(pwcorr v3 v4)
```

Table of regression coefficients with means of the covariates; rows correspond to covariates and columns correspond to the statistics

```
table (colname) (statcmd result),
    command(regress y x1 x2)
    statistic(mean x1 x2)
```

Same as above, and include standard deviations for the covariates

```
table (colname) (statcmd result),
    command(regress y x1 x2)
    statistic(mean x1 x2)
    statistic(sd x1 x2)
```

**Menu**

Statistics > Summaries, tables, and tests > Tables of frequencies, summaries, and command results
Syntax

Basic syntax for a one-way table

```
table rowvar
```

```
table () colvar
```

Basic syntax for a two-way table

```
table rowvar colvar
```

Basic syntax for an n-way table

```
table rowvars colvar
```
```
table rowvar (colvars)
```
```
table (rowvars) (colvars)
```

Basic syntax for multiple n-way tables

```
table (rowvars) (colvars) (tabvars)
```

Full syntax

```
table (rowspec) (colspec) [(tabspec)] [ if ] [ in ] [ weight ] [ , options ]
```

rowspec, collspec, and tabspec may be empty or may include variable names or any of the following keywords:

<table>
<thead>
<tr>
<th>keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>requested statistics</td>
</tr>
<tr>
<td>stars</td>
<td>stars denoting statistical significance</td>

</table>

fweights, aweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
strL variables are not allowed; see [U] 12.4.8 strL.
markvar() and noisily do not appear in the dialog box.
Options

**Main**

totals(*totals*) and nototals control which totals are to be displayed in the table. By default, all totals are reported.

totals(*totals*) specifies which margin totals to display in the reported table. *totals* can contain variables in rowspec, colspec, tabspec, and their interaction. Interactions can be specified by using the $# operator.

nototals prevents table from displaying any totals.

**Statistics**

statistic(*statspec*) specifies the statistic to be displayed. Frequency statistics, summary statistics, and ratio statistics are available by specifying statistic(*freqstat*), statistic(*sumstat varlist*), and statistic(*ratiostat [varlist [ , ratio_options ]]*), respectively.

statistic() may be repeated to request multiple statistics.

statistic(*freqstat*) specifies that frequencies be computed.

</tr>
</tbody>
</table>

cellspec may contain rowvars, colvars, tabvars, or an interaction between any of these variables. Interactions can be specified by using the # operator.

command(cmdspec) specifies the Stata commands from which to collect results. command() may be repeated to collect results from multiple commands.

cmdspec is [ explist: ] command [ arguments ] [ , cmdoptions ]

explist specifies which results to collect and report in the table. explist may include result identifiers and named expressions.

result identifiers are results stored in r() and e() by the command. For instance, result identifiers could be r(mean), r(C), or e(chi2). After estimation commands, result identifiers also include the following:

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>_r_b</td>
<td>coefficients or transformed coefficients reported by command</td>
</tr>
<tr>
<td>_r_se</td>

</tr>
<tr>
<td>_r_df</td>
<td>degrees of freedom for _r_b</td>
</tr>
</tbody>
</table>

named expressions are specified as name = exp, where name may be any valid Stata name and exp is an expression, typically an expression that involves one or more result identifiers. An example of a named expression is sd = sqrt(r(variance)).

For r-class commands, the default is to include all numeric scalars posted to r() in the table results. For e-class commands, the default is to include _r_b in the table results.
`command` is any command that follows standard Stata syntax.

arguments may be anything so long as they do not include an if clause, in range, or weight specification.

Any if or in qualifier and weights should be specified directly with `table`, not within the `command()` option.

cmdoptions may be anything supported by `command`.

**Formats**

```
nformat( %fmt [ results ][, basestyle] )
```

changes the numeric format, such as the number of decimal places, for specified results. If `results` are not specified, the numeric format is changed for all results.

`results` may be any statistic named in option `statistic()` (that is, any `freqstat`, `sumstat`, or `ratiostat`) or may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

This option does not affect the format of numeric layout variables (rowspec, colspec, and tabspec) or the format of factor variables specified in the `statistic()` option. The default format of these variables is taken from the dataset.

`basestyle` indicates that the format be applied to results that do not already have their own format instead of overriding the format for all results.

```
sformat( sfmt [ results ] )
```

changes the string format for specified results. You can, for instance, add symbols or text to the values reported in the table by modifying the string format.

`sfmt` may contain a mix of text and `%s`. Here `%s` refers to the numeric value that is formatted as specified using `nformat()`. The text will be placed around the numeric values in your table as it is placed around `%s` in this option. For instance, to place parentheses around the percent statistics, you can specify `sformat("(%s)\%" percent).

`results` may be any statistic named in option `statistic()` (that is, any `freqstat`, `sumstat`, or `ratiostat`) or may be any name in the `e()` or `r()` results produced by commands specified in option `command()`.

Two text characters must be specified using a special character sequence if you want them to be displayed in your table. To include `%`, type `%%`. To include `\`, type `\\`. For instance, to place a percent sign following percent statistics, you can specify `sformat("%s%%" percent).

This option is repeatable, and when multiple formats apply to one result, the rightmost specification is applied.

```
cidelimiter( char )
```

changes the delimiter between confidence interval limits to `char`. The default is `cidelimiter(" "), that is, two spaces.

```
cridelimiter( char )
```

changes the delimiter between credible interval limits to `char`. The default is `cridelimiter(" "), that is, two spaces.

**Stars**

```
stars( starspec )
```

specifies that stars representing statistical significance be included in the table. `starspec` identifies the result whose values determine significance, which characters should represent each significance level, and where these characters should be displayed in the table. `starspec` is
starres [ #1 "label1" [ #2 "label2" [ #3 "label3" [ #4 "label4" [ #5 "label5" ] ] ] ] ] [, attach(attachres) result dimension starsnoteopts]

starres is the name of the result whose values determine which characters, typically which number of stars, are to be displayed.

label1 specifies the characters to be displayed when starres < #1.

label2 specifies the characters to be displayed when starres < #2.

label3 specifies the characters to be displayed when starres < #3.

label4 specifies the characters to be displayed when starres < #4.

label5 specifies the characters to be displayed when starres < #5.

attach(attachres) specifies the name of the result to which the characters defined by label1, ..., label5 are to be attached. If attach() is not specified, a new result named stars is created and is automatically added to the table.

result and dimension control how collect stars adds items when labeling significant results. These options are mutually exclusive.

result specifies the default behavior, and this option is necessary only if the following dimension behavior is in effect and you want to change back to the result behavior.

dimension specifies that dimension stars be added to the collection. Items will be tagged with stars[value], and the labels will be tagged with stars[label]. Use this option for layouts where results are to be stacked within columns, and use new dimension stars in the column specification of the layout.

starsnoteopts control the display and composition of the stars note.

noshownote and shownote control whether to display the stars note.

increasing and decreasing control the order of p-values in the stars note.

pvname(string) specifies a name for the p-value in the stars note. The default is pvname(p).

delimiter(string) specifies the delimiter between labels in the stars note. The default is delimiter(",").

nformat(\%fmt) specifies the numeric format for the cutoff values in the stars note. The default is nformat(\%9.0g).

prefix(string) specifies the prefix for the stars note. The prefix is empty by default.

suffix(string) specifies the suffix for the stars note. The suffix is empty by default.

For example, stars(_r_p 0.01 "***" 0.05 "**" 0.1 "*", attach(_r_b)) could be added to a table of regression results to specify that stars be defined based on the p-values in _r_p and be attached to the reported coefficients (_r_b).

Options

listwise handles missing values through listwise deletion, meaning that the entire observation is omitted from the sample if any variable specified in a statistic() option is missing for that observation. By default, table will omit an observation only if all variables specified in all statistic() options are missing for that observation.

missing specifies that numeric missing values of any variables specified in rowspec, colspec, or tabspec be treated as valid categories. By default, observations with a numeric missing value in any of these variables are omitted.
This option does not apply to factor variables specified with statistics \texttt{fvfrequency}, \texttt{fvrawfrequency}, \texttt{fvproportion}, \texttt{fvrawproportion}, \texttt{fvpercent}, or \texttt{fvrawpercent}.

\texttt{showcounts} specifies that \texttt{table} report the sample size for each variable specified in option \texttt{statistic()}.\texttt{zerocounts} specifies that \texttt{table} report a 0 in empty cells for results \texttt{count}, \texttt{frequency}, \texttt{fvfrequency}, and \texttt{fvrawfrequency}.

\texttt{name(cname)} specifies that a collection named \texttt{cname} be associated with the collected statistics and results. The default is \texttt{name(Table)}.

\texttt{append} specifies that \texttt{table} append its collection information into the collection named in \texttt{name()}. \texttt{replace} permits \texttt{table} to overwrite an existing collection. This option is implied for \texttt{name(Table)} when \texttt{append} is not specified.

\texttt{label(filename)} specifies the \texttt{filename} containing the collection labels to use for your table. Labels in \texttt{filename} will be loaded for the table, and any labels not specified in \texttt{filename} will be taken from the labels defined in \texttt{c(collect_label)}. The default is to use only the collection labels set in \texttt{c(collect_label)}; see [TABLES] \texttt{set collect_label}.

\texttt{style(filename [, override])} specifies the \texttt{filename} containing the collection styles to use for your table. The default collection styles will be discarded, and only the collection styles in \texttt{filename} will be applied.

If you prefer the default collection styles but also want to apply any styles in \texttt{filename}, specify \texttt{override}. If there are conflicts between the default collection styles and those in \texttt{filename}, the ones in \texttt{filename} will take precedence.

The default is to use only the collection styles set in \texttt{c(table_style)}; see [TABLES] \texttt{set table_style}.

The following options are available with \texttt{table} but are not shown in the dialog box:

\texttt{markvar(newvar)} generates an indicator variable that identifies the observations used in the tabulation.

\texttt{noisily} specifies that output from the commands specified in \texttt{command()} options be displayed. By default, output from commands is suppressed.

### Remarks and examples

Remarks are presented under the following headings:

- Introduction
- Specifying the table layout
- Advanced table customization

### Introduction

The \texttt{table} command can create many customized tables, ranging from simple one-way tabulations to multiple $n$-way tables with summary statistics and estimation results. \texttt{table} can compute and report frequencies, proportions, percentiles, and other summary statistics. It can also run other Stata commands and include their results in the table. This means you can combine the summary statistics computed by \texttt{table} with test statistics, correlations, regression coefficients, and other results collected from Stata commands. In addition to building tables with the desired statistics, you can customize them by formatting the values in the table and applying predefined styles and labels that affect how the row headers, column headers, and values are displayed in the table.
`table` can accommodate a variety of layouts. You can define the rows, columns, and even separate tables by levels of categorical variables, statistics, or Stata commands.

If your goal is simply to create a table of estimation results or descriptive statistics, you can use the `etable` and `dtable` commands, respectively. These commands allow you to create these tables and export them to a variety of file types in a single step. However, unlike `table`, these commands create tables with a predefined layout. Therefore, if you want control over the layout or you wish to include a combination of summary statistics, estimation results, and results from other Stata commands, you should use the `table` command.

In the following entries, we provide simplified syntax, examples, and discussion for specialized types of tables that can be created using `table`. If you are interested in creating one of these types of tables, we suggest reading the corresponding entry.

[R] `table oneway` One-way tabulation
[R] `table twoway` Two-way tabulation
[R] `table multiway` Multiway tables
[R] `table summary` Table of summary statistics
[R] `table hypothesis tests` Table of hypothesis tests
[R] `table regression` Table of regression results

All the concepts demonstrated in the entries above can be combined to create tables including combinations of tabulations, summary statistics, hypothesis tests, and regression results.

In this entry, we provide additional information on specifying the table layout and which portions of the layout `table` will automate for you. In addition, we provide resources for customizing the table and exporting the results to your preferred format.

### Specifying the table layout

A table’s layout is determined by our row, column, and table dimension specifications. For example, we specify variable names to define the rows and place statistics in the columns, or vice versa. Because we can include so many different statistics, we can specify keywords that we use to identify the results we have collected from commands and the statistics that `table` has calculated.

The syntax for specifying the table layout is

```
table ([rowspec]) ([colspec]) ([tabspec])
```

We refer to `rowspec`, `colspec`, and `tabspec` collectively as the “layout”. For some tables, keywords are required in the layout to uniquely identify the values that we want to include in our table. If you omit a necessary keyword from the layout, `table` will fill one in for you.

The rules determining whether a keyword is necessary to uniquely identify values in the table are as follows:

1. If more than one statistic is specified, then `result` is needed in the layout.
2. If more than one variable is specified in option `statistic()` and option `command()` is not specified, then `var` is needed in the layout.
3. If more than one `across()` specification is used for ratio statistics, then `across` is needed in the layout.
4. If option `command()` is specified, then `colname` is needed in the layout. If, in addition, more than one variable is specified in option `statistic()`, then `colname` is needed instead of `var`, which was required in 2.
5. If multiple command() options are specified and option statistic() is not specified, then command is needed in the layout.

6. If both options command() and statistic() are specified, then statcmd is needed in the layout.

If we do not directly specify a necessary keyword in one of rowspec, colspec, or tabspec, the missing keywords will be automatically added to the layout as follows:

1. If the row specification is empty, then put the missing keywords in rowspec.
2. If the row specification is not empty but the column specification is empty, then put the missing keywords in colspec.
3. If the row and column specifications are not empty but the table specification is empty and if result is the only missing keyword and there is only one statistic (result), then put result in tabspec.
4. Otherwise, append the missing keywords to rowvars.

Below, we demonstrate how missing keywords are added to the layout.

Using auto.dta, we create a table with the minimum and maximum mpg for each level of rep78. The keyword result identifies the statistics we computed. By listing an empty set of parentheses followed by rep78, we request that the levels of rep78 be placed on the columns.

```
use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
table () rep78, statistic(min mpg) statistic(max mpg)
```

<table>
<thead>
<tr>
<th>Repair record 1978</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum value</td>
<td>18</td>
<td>14</td>
<td>12</td>
<td>14</td>
<td>17</td>
<td>12</td>
</tr>
<tr>
<td>Maximum value</td>
<td>24</td>
<td>24</td>
<td>29</td>
<td>30</td>
<td>41</td>
<td>41</td>
</tr>
</tbody>
</table>

Based on rule 1, if we request more than one statistic, result must be in the layout. Based on situation 1, if the row specification is empty, then the missing keyword will be placed in the row specification. We could have created the same table by typing

```
table (result) (rep78), statistic(min mpg) statistic(max mpg)
```

Now, let's include multiple variables in our statistic() option. We also type rep78 immediately after table to specify that the levels of rep78 be placed on the rows.

```
table rep78, statistic(mean mpg price)
```

<table>
<thead>
<tr>
<th>Mileage (mpg)</th>
<th>Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repair record 1978</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>21</td>
</tr>
<tr>
<td>2</td>
<td>19.125</td>
</tr>
<tr>
<td>3</td>
<td>19.43333</td>
</tr>
<tr>
<td>4</td>
<td>21.66667</td>
</tr>
<tr>
<td>5</td>
<td>27.36364</td>
</tr>
<tr>
<td>Total</td>
<td>21.28986</td>
</tr>
</tbody>
</table>

Because we have more than one variable in the statistic() option, then keyword var must be in the layout (rule 2). If we include a row specification but leave the column specification empty, table will treat var as the column identifier. We could have equivalently typed
Next, let’s include both a `command()` option and a `statistic()` option with multiple variables in the same table. We want a table with coefficients and means of the independent variables. We use the `command()` option to fit the regression and obtain the means with the `statistic()` option. Now, we need both `colname` and `statcmd` to uniquely identify the values in the table. Let’s omit `statcmd` from our command.

```
. table (colname) (result[_r_b mean]),
    command(regress mpg turn trunk) statistic(mean turn trunk)
```

<table>
<thead>
<tr>
<th></th>
<th>Coefficient</th>
<th>Mean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Turn circle (ft.)</td>
<td>-.7610113</td>
<td>39.64865</td>
</tr>
<tr>
<td>Trunk space (cu. ft.)</td>
<td>-.3161825</td>
<td>13.75676</td>
</tr>
<tr>
<td>Intercept</td>
<td>55.82001</td>
<td></td>
</tr>
</tbody>
</table>

But based on situation 4, `table` will add `statcmd` to the row specification if we leave it out. So we could have also typed the following to create the same table:

```
. table (colname statcmd) (result[_r_b mean]),
    command(regress mpg turn trunk) statistic(mean turn trunk)
```

This table displays each of the statistics that we requested. If we simply wanted to compute some statistics quickly, it has served its purpose. However, if we wish to share these results with others or include a table in a report, we will want to make some modifications.

**Advanced table customization**

`table` allows you to customize the results of your table using the `stars()`, `nformat()`, `sformat()`, `cidelimiter()`, `label()`, and `style()` options. With these, you can add significance stars, change the numeric format, and attach characters such as percent signs or parentheses to values in the table, use a stored set of labels, or use a predefined style. See [TABLES] Predefined styles for more information on selecting a style that adjusts elements of the table such as row header alignment, alignment of values within the cells, and which labels are included in the headers.

Customization can also go beyond the predefined styles and options available to you in the `table` command. `table` stores all of its results in a collection named `Table`. This means that you can use the specialized tools available in the `collect` suite of commands to further customize your table. With `collect`, you can modify specific labels, add borders, change the style of the headers, and the like. Once you have a publication-ready table, you can use `collect export` to export your table to HTML, Word, LaTeX, PDF, Excel, or another format appropriate for your report.

**Stored results**

`table` stores the following in `r()`:

Scalars

- `r(N)` number of observations
Methods and formulas

Variables specified in rowspec, colspec, and tabspec identify groups of observations within the dataset. These groups are represented in the table by cells and cell margins (totals). For a given cell or cell margin, let \( n \) denote the number of observations (frequency). Let \( x \) denote the variable on which we want to calculate summary statistics, and let \( x_i, i = 1, \ldots, n \), denote an individual observation on \( x \). count is the number of nonmissing values of \( x \). first is \( x_1 \) and last is \( x_n \). Let \( a \) be the smallest \( i \) such that \( x_i \) is not missing, and then \( \text{first}_nm \) is \( x_a \). Let \( b \) be the largest \( i \) such that \( x_i \) is not missing, and then \( \text{last}_nm \) is \( x_b \).

Let \( v_i \) be the weight, and if no weight is specified, define \( v_i = 1 \) for all \( i \). Let \( v. \) denote the sum of the weights (sumw):

\[
v. = \sum_{i=1}^{n} v_i
\]

When aweights or pweights are specified, the normalized weights are given by \( w_i = v_i(n/v. \) with \( w. = n \); otherwise, \( w_i = v_i \) and \( w. = v. \).

The remaining summary statistics are computed according to the following formulas:

**total**

\[
x. = \begin{cases} \sum_{i=1}^{n} v_i x_i & \text{if pweights} \\ \sum_{i=1}^{n} w_i x_i & \text{otherwise} \end{cases}
\]

**rawtotal**

\[
\sum_{i=1}^{n} x_i
\]

**mean**

\[
\bar{x} = \frac{1}{w.} \sum_{i=1}^{n} w_i x_i
\]

Define \( m_r \) as the \( r \)th moment about the mean:

\[
m_r = \frac{1}{w.} \sum_{i=1}^{n} w_i (x_i - \bar{x})^r
\]

**variance**

\[
s^2 = w. \left( m_2 - \frac{1}{w. - 1} \sum_{i=1}^{n} w_i (x_i - \bar{x})^2 \right)
\]
sd (standard deviation)
\[ s = \sqrt{s^2} \]

semean (standard error of the mean)
\[ se(\bar{x}) = \frac{s}{\sqrt{w}}. \]

sebinomial (standard error of the mean, binomial distribution)
\[ \sqrt{\frac{\bar{x}(1-\bar{x})}{w}}. \]

sepoisson (standard error of the mean, Poisson distribution)
\[ \sqrt{\frac{\bar{x}}{w}}. \]

When pweights are specified, semean, sebinomial, and sepoisson are all computed as
\[ se_{pw}(\bar{x}) = \sqrt{\frac{n}{n-1} \sum_{i=1}^{n} \left\{ \frac{w_i}{v_i} (x_i - \bar{x}) \right\}^2} \]

skewness
\[ m_3 m_2^{-3/2} \]

kurtosis
\[ m_4 m_2^{-2} \]

cv (coefficient of variation)
\[ \frac{s}{\bar{x}} \]

svycv (coefficient of variation, survey literature)
\[ 100 \frac{se(\bar{x})}{|\bar{x}|} \]

svycv with pweights
\[ 100 \frac{se_{pw}(\bar{x})}{|\bar{x}|} \]
geomean (geometric mean)

$$\bar{x}_g = \exp \left( \frac{1}{w} \sum_{i=1}^{n} w_i \ln x_i \right)$$

geosd (geometric standard deviation)

$$\exp \left( \sqrt{\frac{1}{w - 1} \sum_{i=1}^{n} w_i (\ln x_i - \ln \bar{x}_g)^2} \right)$$

Let $x_{(i)}$ refer to the $x$ in ascending order, and let $w_{(i)}$ refer to the corresponding weights of $x_{(i)}$.

minimum

$$x_{(1)}$$

maximum

$$x_{(n)}$$

range

$$x_{(n)} - x_{(1)}$$

To obtain the $p$th percentile, which we will denote as $x_{[p]}$, let $P = np/100$ and

$$W(i) = \frac{n}{w} \sum_{j=1}^{i} w(j)$$

Find the first index $i$ such that $W(i) > P$. The $p$th percentile is then

$$x_{[p]} = \begin{cases} \frac{x_{(i-1)} + x_{(i)}}{2} & \text{if } W_{(i-1)} = P \\ x_{(i)} & \text{otherwise} \end{cases}$$

q1 (first quartile)

$$x_{[25]}$$

q2 (second quartile)

$$x_{[50]}$$

q3 (third quartile)

$$x_{[75]}$$
iqr (interquartile range)

\[ x[75] - x[25] \]

Let \( f \) be an indicator for a specific level of a factor variable and \( f_i \) denote an individual observation on \( f \).

**fvfrequency** (frequency of the factor variable’s level)

\[ \sum_{i=1}^{n} w_i f_i \]

**fvrawfrequency** (unweighted frequency of the factor variable’s level)

\[ \sum_{i=1}^{n} f_i \]

**fvproportion** (proportion of the factor variable’s level)

\[ \frac{1}{w} \sum_{i=1}^{n} w_i f_i \]

**fvrawproportion** (unweighted proportion of the factor variable’s level)

\[ \frac{1}{n} \sum_{i=1}^{n} f_i \]

**fvpercent** (percentage of the factor variable’s level)

\[ \frac{100}{w} \sum_{i=1}^{n} w_i f_i \]

**fvrawpercent** (unweighted percentage of the factor variable’s level)

\[ \frac{100}{n} \sum_{i=1}^{n} f_i \]

Proportion is computed from ratios of totals. The numerator is taken from the total for the given cell or cell margin, and the denominator is taken from the total for a cell margin that contains the given cell or cell margin. Percent is proportion multiplied by 100.

Rawproportion and rawpercent are similarly computed using unweighted totals.

[TABLES] Intro — Introduction
tabstat — Compact table of summary statistics

Description

tabstat displays summary statistics for a series of numeric variables in one table. It allows you to specify the list of statistics to be displayed. Statistics can be calculated (conditioned on) another variable. tabstat allows substantial flexibility in terms of the statistics presented and the format of the table.

Quick start

Mean of v1 displayed using v1’s display format
   tabstat v1, format

Same as above, but use format with 2 significant digits and a comma
   tabstat v1, format(%9.2fc)

Nonmissing observations, mean, standard error, and coefficient of variation for v1
   tabstat v1, statistics(n mean semean cv)

Quartiles and interquartile range of v1 and v2
   tabstat v1 v2, statistics(q iqr)

Same as above, but report statistics separately for each level of catvar
   tabstat v1 v2, by(catvar) statistics(q iqr)

Same as above, but display a separate column for each statistic
   tabstat v1 v2, by(catvar) statistics(q iqr) columns(statistics)

Menu

Statistics > Summaries, tables, and tests > Other tables > Compact table of summary statistics
## Syntax

```
tabstat varlist [if] [in] [weight] [ , options ]
```

### options

<table>
<thead>
<tr>
<th>Main</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>by(varname)</code></td>
<td>group statistics by variable</td>
</tr>
<tr>
<td><code>statistics(statname[...])</code></td>
<td>report specified statistics</td>
</tr>
</tbody>
</table>

### Options

- `labelwidth(#)` width for `by()` variable labels; default is `labelwidth(16)`
- `varwidth(#)` variable width; default is `varwidth(12)`
- `columns(variables)` display variables in table columns; the default
- `columns(statistics)` display statistics in table columns
- `format(%fmt)` display format for statistics; default format is `%9.0g`
- `casewise` perform casewise deletion of observations
- `nototal` do not report overall statistics; use with `by()`
- `missing` report statistics for missing values of `by()` variable
- `noseparator` do not use separator line between `by()` categories
- `longstub` make left table stub wider
- `save` store summary statistics in `r()`

`by` is allowed; see [D] `by`

`aweights` and `fweights` are allowed; see [U] `11.1.6 weight`.

## Options

- `by(varname)` specifies that the statistics be displayed separately for each unique value of `varname`; `varname` may be numeric or string. For instance, `tabstat height` would present the overall mean of height. `tabstat height, by(sex)` would present the mean height of males, and of females, and the overall mean height. Do not confuse the `by()` option with the `by` prefix (see [D] `by`); both may be specified.

- `statistics(statname[...])` specifies the statistics to be displayed; the default is equivalent to specifying `statistics(mean)`. `(stats()) is a synonym for `statistics()`.) Multiple statistics may be specified and are separated by white space, such as `statistics(mean sd)`. Available statistics are

</tbody>
</table>

**Options**

- `labelwidth(#)`: specifies the maximum width to be used within the stub to display the labels of the `by()` variable. The default is `labelwidth(16)`. $8 \leq # \leq 32$.
- `varwidth(#)`: specifies the maximum width to be used within the stub to display the names of the variables. The default is `varwidth(12)`. `varwidth()` is effective only with `columns(statistics)`. Setting `varwidth()` implies `longstub`. $8 \leq # \leq 32$.
- `columns(variables|statistics)`: specifies whether to display variables or statistics in the columns of the table. `columns(variables)` is the default when more than one variable is specified.
- `format` and `format(\%fmt)` specify how the statistics are to be formatted. The default is to use a `%9.0g` format.
  - `format`: specifies that each variable’s statistics be formatted with the variable’s display format; see `[D] format`.
  - `format(\%fmt)`: specifies the format to be used for all statistics.
- The column width is the maximum width of these formats. The minimum column width is nine display characters.
- `casewise`: specifies casewise deletion of observations. Statistics are to be computed for the sample that is not missing for any of the variables in `varlist`. The default is to use all the nonmissing values for each variable.
- `nototal` is for use with `by()`; it specifies that the overall statistics not be reported.
- `missing`: specifies that missing values of the `by()` variable be treated just like any other value and that statistics should be displayed for them. The default is not to report the statistics for the `by()==missing` group. If the `by()` variable is a string variable, `by()==""` is considered to mean missing.
- `noseparator`: specifies that a separator line between the `by()` categories not be displayed.
- `longstub`: specifies that the left stub of the table be made wider so that it can include names of the statistics or variables in addition to the categories of `by(varname)`. The default is to describe the statistics or variables in a header. `longstub` is ignored if `by(varname)` is not specified.
- `save`: specifies that the summary statistics be returned in `r()`. The overall (unconditional) statistics are returned in matrix `r(StatTotal)` (rows are statistics, columns are variables). The conditional statistics are returned in the matrices `r(Stat1), r(Stat2), ...`, and the names of the corresponding variables are returned in the macros `r(name1), r(name2), ...`. 
Remarks and examples

This command is probably most easily understood by going through a series of examples.

Example 1

We have data on the price, weight, mileage rating, and repair record of 22 foreign and 52 domestic 1978 automobiles. We want to summarize these variables for the different origins of the automobiles.

```stata
use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
.tabstat price weight mpg rep78, by(foreign)
Summary statistics: Mean
Group variable: foreign (Car origin)

<table>
<thead>
<tr>
<th></th>
<th>price</th>
<th>weight</th>
<th>mpg</th>
<th>rep78</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>6072.423</td>
<td>3317.115</td>
<td>19.82692</td>
<td>3.020833</td>
</tr>
<tr>
<td>Foreign</td>
<td>6384.682</td>
<td>2315.909</td>
<td>24.77273</td>
<td>4.285714</td>
</tr>
<tr>
<td>Total</td>
<td>6165.257</td>
<td>3019.459</td>
<td>21.2973</td>
<td>3.405797</td>
</tr>
</tbody>
</table>
```

More summary statistics can be requested via the `statistics()` option. The group totals can be suppressed with the `nototal` option.

```stata
.tabstat price weight mpg rep78, by(foreign) stat(mean sd min max) nototal
Summary statistics: Mean, SD, Min, Max
Group variable: foreign (Car origin)

<table>
<thead>
<tr>
<th></th>
<th>price</th>
<th>weight</th>
<th>mpg</th>
<th>rep78</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>6072.423</td>
<td>3317.115</td>
<td>19.82692</td>
<td>3.020833</td>
</tr>
<tr>
<td></td>
<td>3097.104</td>
<td>695.3637</td>
<td>4.743297</td>
<td>.837666</td>
</tr>
<tr>

<td>6384.682</td>
<td>2315.909</td>
<td>24.77273</td>
<td>4.285714</td>
</tr>
<tr>
<td></td>
<td>2621.915</td>
<td>433.0035</td>
<td>6.611187</td>
<td>.7171372</td>
</tr>
<tr>
<td></td>
<td>3748</td>
<td>1760</td>
<td>14</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td>12990</td>
<td>3420</td>
<td>41</td>
<td>5</td>
</tr>
</tbody>
</table>
```

Although the header of the table describes the statistics running vertically in the “cells”, the table may become hard to read, especially with many variables or statistics. The `longstub` option specifies that a column be added describing the contents of the cells. The `format` option can be issued to specify that `tabstat` display the statistics by using the display format of the variables rather than the overall default `%9.0g`. 
. tabstat price weight mpg rep78, by(foreign) stat(mean sd min max) long format

<table>
<thead>
<tr>

<td>41</td>
</tr>
<tr>
<td></td>
<td>rep78</td>
<td>1</td>
<td>3.405797</td>
<td>5</td>
</tr>
</tbody>
</table>

Finally, `tabstat` can also be used to enhance `summarize` so we can specify the statistics to be displayed. For instance, we can display the number of observations, the mean, the coefficient of variation, and the 25%, 50%, and 75% quantiles for a list of variables.

. tabstat price weight mpg rep78, stat(n mean cv q) col(stat) long

<table>
<thead>
<tr>
<th>variable</th>
<th>N</th>
<th>mean</th>
<th>cv</th>
<th>p25</th>
<th>p50</th>
<th>p75</th>
</tr>
</thead>
<tbody>
<tr>
<td>price</td>
<td>74</td>
<td>6165.257</td>
<td>.478406</td>
<td>4195</td>
<td>5006.5</td>
<td>6342</td>
</tr>
<tr>
<td>weight</td>
<td>74</td>
<td>3019.459</td>
<td>.2573949</td>
<td>2240</td>
<td>3190</td>
<td>3600</td>
</tr>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>.2716543</td>
<td>18</td>
<td>20</td>
<td>25</td>
</tr>
<tr>
<td>rep78</td>
<td>69</td>
<td>3.405797</td>
<td>.290661</td>
<td>3</td>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

Because we did not specify the `by()` option, these statistics were not displayed for the subgroups of the data formed by the categories of the `by()` variable.
Video example

Descriptive statistics in Stata

Acknowledgments

The `tabstat` command was written by Jeroen Weesie and Vincent Buskens both of the Department of Sociology at Utrecht University, The Netherlands.

[R] `table summary` — Table of summary statistics

[R] `tabulate, summarize()` — One- and two-way tables of summary statistics

[D] `collapse` — Make dataset of summary statistics
Description

`tabulate` produces a one-way table of frequency counts.

For information on a two-way table of frequency counts along with measures of association, including the common Pearson $\chi^2$, the likelihood-ratio $\chi^2$, Cramér’s $V$, Fisher’s exact test, Goodman and Kruskal’s gamma, and Kendall’s $\tau_b$, see [R] `tabulate twoway`.

`tab1` produces a one-way tabulation for each variable specified in `varlist`.

Also see [R] `table` and [R] `tabstat` if you want one-, two-, or $n$-way table of frequencies and a wide variety of statistics. See [R] `tabulate, summarize()` for a description of `tabulate` with the `summarize()` option; it produces a table (breakdowns) of means and standard deviations. `table` is better than `tabulate, summarize()`, but `tabulate, summarize()` is faster. See [R] `Epitab` for a $2 \times 2$ table with statistics of interest to epidemiologists.

Quick start

One-way table of frequencies for `v1`

```
tabulate v1
```

Sort table in descending order of frequency

```
tabulate v1, sort
```

Generate indicator variables `v1_1, v1_2, ...` representing the levels of `v1`

```
tabulate v1, generate(v1_)
```

Treat missing values like other values of `v1`

```
tabulate v1, missing
```

Display numeric values of `v1` rather than value labels

```
tabulate v1, nolabel
```

Create one-way tables for `v1, v2, and v3`

```
tab1 v1 v2 v3
```

Menu

`tabulate oneway`

Statistics > Summaries, tables, and tests > Frequency tables > One-way table

`tabulate ..., generate()`

Data > Create or change data > Other variable-creation commands > Create indicator variables

`tab1`

by is allowed with `tabulate` and `tabl`, and `collect` is allowed with `tabulate`; see [U] 11.1.10 Prefix commands.

`fweight`, `aweights`, and `iweight` are allowed; see [U] 11.1.6 weight.

Options

`subpop(varname)` excludes observations for which `varname = 0` in tabulating frequencies. The mathematical results of `tabulate...`, `subpop(myvar)` are the same as `tabulate... if myvar !=0`, but the table may be presented differently. The identities of the rows and columns will be determined from all the data, including the `myvar = 0` group, so there may be entries in the table with frequency 0.
Consider tabulating \texttt{answer}, a variable that takes on values 1, 2, and 3, but consider tabulating it just for the \texttt{male==1} subpopulation. Assume that \texttt{answer} is never 2 in this group. \texttt{tabulate answer if male==1} produces a table with two rows: one for answer 1 and one for answer 3. There will be no row for answer 2 because answer 2 was never observed. \texttt{tabulate answer, subpop(male)} produces a table with three rows. The row for answer 2 will be shown as having 0 frequency.

\texttt{missing} requests that missing values be treated like other values in calculations of counts, percentages, and other statistics.

\texttt{nofreq} suppresses the printing of the frequencies.

\texttt{nolabel} causes the numeric codes to be displayed rather than the value labels.

\texttt{plot} produces a bar chart of the relative frequencies in a one-way table. (Also see \texttt{[R] histogram}.)

\texttt{sort} puts the table in descending order of frequency (and ascending order of the variable within equal values of frequency).

\texttt{generate(stubname)} creates a set of indicator variables (\texttt{stubname1}, \texttt{stubname2}, ...) reflecting the observed values of the tabulated variable. The \texttt{generate()} option may not be used with the by prefix.

\texttt{matcell(matname)} saves the reported frequencies in \texttt{matname}. This option is for use by programmers.

\texttt{matrow(matname)} saves the numeric values of the $r \times 1$ row stub in \texttt{matname}. This option is for use by programmers. \texttt{matrow()} may not be specified if the row variable is a string.

\textbf{Limits}

A one-way table may have a maximum of 12,000 rows (Stata/MP and Stata/SE) or 3,000 rows (Stata/BE).

\section*{Remarks and examples}

Remarks are presented under the following headings:

\begin{itemize}
  \item \texttt{tabulate}
  \item \texttt{tab1}
  \item \texttt{Video example}
\end{itemize}

For each value of a specified variable, \texttt{tabulate} reports the number of observations with that value. The number of times a value occurs is called its \textit{frequency}.

\texttt{tabulate}

\textbf{Example 1}

We have data summarizing the speed limit and the accident rate per million vehicle miles along various Minnesota highways in 1973. The variable containing the speed limit is called \texttt{spdlimit}. If we \texttt{summarize} the variable, we obtain its mean and standard deviation:
The average speed limit is 55 miles per hour. We can learn more about this variable by tabulating it:

```
. tabulate spdlimit

<table>
<thead>
<tr>
<th>Speed limit</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>1</td>
<td>2.56</td>
<td>2.56</td>
</tr>
<tr>
<td>45</td>
<td>3</td>
<td>7.69</td>
<td>10.26</td>
</tr>
<tr>
<td>50</td>
<td>7</td>
<td>17.95</td>
<td>28.21</td>
</tr>
<tr>
<td>55</td>
<td>15</td>
<td>38.46</td>
<td>66.67</td>
</tr>
<tr>
<td>60</td>
<td>11</td>
<td>28.21</td>
<td>94.87</td>
</tr>
<tr>
<td>65</td>
<td>1</td>
<td>2.56</td>
<td>97.44</td>
</tr>
<tr>
<td>70</td>
<td>1</td>
<td>2.56</td>
<td>100.00</td>
</tr>
<tr>
<td>Total</td>
<td>39</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>
```

We see that one highway has a speed limit of 40 miles per hour, three have speed limits of 45, 7 of 50, and so on. The column labeled Percent shows the percentage of highways in the dataset that have the indicated speed limit. For instance, 38.46% of highways in our dataset have a speed limit of 55 miles per hour. The final column shows the cumulative percentage. We see that 66.67% of highways in our dataset have a speed limit of 55 miles per hour or less.

**Example 2**

The plot option places a sideways histogram alongside the table:

```
. tabulate spdlimit, plot

<table>
<thead>
<tr>
<th>Speed limit</th>
<th>Freq.</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>1</td>
</tr>
<tr>
<td>45</td>
<td>3</td>
</tr>
<tr>
<td>50</td>
<td>7</td>
</tr>
<tr>
<td>55</td>
<td>15</td>
</tr>
<tr>
<td>60</td>
<td>11</td>
</tr>
<tr>
<td>65</td>
<td>1</td>
</tr>
<tr>
<td>70</td>
<td>1</td>
</tr>
<tr>
<td>Total</td>
<td>39</td>
</tr>
</tbody>
</table>
```

Of course, graph can produce better-looking histograms; see [R] histogram.

**Example 3**

`tabulate` labels tables using `variable` and `value labels` if they exist. To demonstrate how this works, let's add a new variable to our dataset that categorizes `spdlimit` into three categories. We will call this new variable `spdcat`:

```
. generate spdcat=recode(spdlimit,50,60,70)
```
The `recode()` function divides `spdlimit` into 50 miles per hour or below, 51–60, and above 60; see [FN] Programming functions. We specified the breakpoints in the arguments (`spdlimit, 50, 60, 70`). The first argument is the variable to be recoded. The second argument is the first breakpoint, the third argument is the second breakpoint, and so on. We can specify as many breakpoints as we wish.

`recode()` used our arguments not only as the breakpoints but also to label the results. If `spdlimit` is less than or equal to 50, `spdcat` is set to 50; if `spdlimit` is between 51 and 60, `spdcat` is 60; otherwise, `spdcat` is arbitrarily set to 70. (See [U] 26 Working with categorical data and factor variables.)

Because we just created the variable `spdcat`, it is not yet labeled. When we make a table using this variable, `tabulate` uses the variable’s name to label it:

```stata
. tabulate spdcat

<table>
<thead>
<tr>
<th>spdcat</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>50</td>
<td>11</td>
<td>28.21%</td>
<td>28.21%</td>
</tr>
<tr>
<td>60</td>
<td>26</td>
<td>66.67%</td>
<td>94.87%</td>
</tr>
<tr>
<td>70</td>
<td>2</td>
<td>5.13%</td>
<td>100.00%</td>
</tr>
<tr>
<td>Total</td>
<td>39</td>
<td>100.00%</td>
<td></td>
</tr>
</tbody>
</table>
```

Even through the table is not well labeled, `recode()`’s coding scheme provides us with clues as to the table’s meaning. The first line of the table corresponds to 50 miles per hour and below, the next to 51 through 60 miles per hour, and the last to above 60 miles per hour.

We can improve this table by labeling the values and variables:

```stata
. label define scat 50 "40 to 50" 60 "55 to 60" 70 "Above 60"
. label values spdcat scat
. label variable spdcat "Speed Limit Category"
```

We define a value label called `scat` that attaches labels to the numbers 50, 60, and 70 using the `label define` command; see [U] 12.6.3 Value labels. We label the value 50 as “40 to 50”, because we looked back at our original tabulation in the first example and saw that the speed limit was never less than 40. Similarly, we could have labeled the last category “65 to 70” because the speed limit is never greater than 70 miles per hour.

Next, we requested that Stata label the values of the new variable `spdcat` using the value label `scat`. Finally, we labeled our variable Speed Limit Category. We are now ready to `tabulate` the result:

```stata
. tabulate spdcat

<table>
<thead>
<tr>
<th>Speed Limit</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>40 to 50</td>
<td>11</td>
<td>28.21%</td>
<td>28.21%</td>
</tr>
<tr>
<td>55 to 60</td>
<td>26</td>
<td>66.67%</td>
<td>94.87%</td>
</tr>
<tr>
<td>Above 60</td>
<td>2</td>
<td>5.13%</td>
<td>100.00%</td>
</tr>
<tr>
<td>Total</td>
<td>39</td>
<td>100.00%</td>
<td></td>
</tr>
</tbody>
</table>
```

➢ Example 4

If we have missing values in our dataset, `tabulate` ignores them unless we explicitly indicate otherwise. We have no missing data in our example, so let’s add some:

```stata
. replace spdcat=. in 39
(1 real change made, 1 to missing)
```
We changed the first observation on `spdcat` to `missing`. Let’s now `tabulate` the result:

```
. tabulate spdcat
```

<table>
<thead>
<tr>
<th>Speed Limit Category</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>40 to 50</td>
<td>11</td>
<td>28.95</td>
<td>28.95</td>
</tr>
<tr>
<td>55 to 60</td>
<td>26</td>
<td>68.42</td>
<td>97.37</td>
</tr>
<tr>
<td>Above 60</td>
<td>1</td>
<td>2.63</td>
<td>100.00</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>38</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>

Comparing this output with that in the previous example, we see that the total frequency count is now one less than it was—38 rather than 39. Also, the ‘Above 60’ category now has only one observation where it used to have two, so we evidently changed a road with a high speed limit.

We want `tabulate` to treat missing values just as it treats numbers, so we specify the `missing` option:

```
. tabulate spdcat, missing
```

<table>
<thead>
<tr>
<th>Speed Limit Category</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>40 to 50</td>
<td>11</td>
<td>28.21</td>
<td>28.21</td>
</tr>
<tr>
<td>55 to 60</td>
<td>26</td>
<td>66.67</td>
<td>94.87</td>
</tr>
<tr>
<td>Above 60</td>
<td>1</td>
<td>2.56</td>
<td>97.44</td>
</tr>
<tr>
<td>.</td>
<td>1</td>
<td>2.56</td>
<td>100.00</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>39</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>

We now see our missing value—the last category, labeled ‘.’, shows a frequency count of 1. The table sum is once again 39.

Let’s put our dataset back as it was originally:

```
. replace spdcat=70 in 39
   (1 real change made)
```

⚠️ **Technical note**

`tabulate` also can automatically create indicator variables from categorical variables. We will briefly review that capability here, but see [U] 26 Working with categorical data and factor variables for a complete description. Let’s begin by describing our highway dataset:

```
. describe
```

```
Contains data from https://www.stata-press.com/data/r18/hiway.dta
Observations: 39 Minnesota highway data, 1973
Variables: 3 16 Nov 2022 12:39

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Storage type</th>
<th>Display format</th>
<th>Value label</th>
</tr>
</thead>
<tbody>
<tr>
<td>spdlimit</td>
<td>byte</td>
<td>%8.0g</td>
<td>Speed limit</td>
</tr>
<tr>
<td>rate</td>
<td>byte</td>
<td>%9.0g</td>
<td>Accident rate per million vehicle miles</td>
</tr>
<tr>
<td>spdcat</td>
<td>float</td>
<td>%9.0g</td>
<td>Speed Limit Category</td>
</tr>
</tbody>
</table>

Sorted by:
Note: Dataset has changed since last saved.
```
Our dataset contains three variables. We will type `tabulate spdcat, generate(spd)`, `describe` our data, and then explain what happened.

```
tabulate spdcat, generate(spd)

Speed Limit Category | Freq. | Percent | Cum. |
---------------------|-------|---------|------|
40 to 50             | 11    | 28.21   | 28.21|
55 to 60             | 26    | 66.67   | 94.87|
Above 60             | 2     | 5.13    | 100.00|

Total                | 39    | 100.00  |
```

`. describe

Sorted by: 
Note: Dataset has changed since last saved.

When we typed `tabulate` with the `generate()` option, Stata responded by producing a one-way frequency table, so it appeared that the option did nothing. Yet when we `describe` our dataset, we find that we now have six variables instead of the original three. The new variables are named `spd1`, `spd2`, and `spd3`.

When we specify the `generate()` option, we are telling Stata to not only produce the table but also create a set of indicator variables that correspond to that table. Stata adds a numeric suffix to the name we specify in the parentheses. `spd1` refers to the first line of the table, `spd2` to the second line, and so on. Also, Stata labels the variables so that we know what they mean. `spd1` is an indicator variable that is true (takes on the value 1) when `spdcat` is between 40 and 50; otherwise, it is zero. (There is an exception: if `spdcat` is missing, so are the `spd1`, `spd2`, and `spd3` variables. This did not happen in our dataset.)

We want to prove our claim. Because we have not yet introduced two-way tabulations, we will use the `summarize` statement:

```
. summarize spdlimit if spd1==1

Variable | Obs | Mean   | Std. dev. | Min  | Max  |
----------|-----|--------|-----------|------|------|
 spdlimit  | 11  | 47.72727 | 3.437758  | 40   | 50   |
```

```
. summarize spdlimit if spd2==1

Variable | Obs | Mean   | Std. dev. | Min  | Max  |
----------|-----|--------|-----------|------|------|
 spdlimit  | 26  | 57.11538 | 2.519157  | 55   | 60   |
```
Notice the indicated minimum and maximum in each of the tables above. When we restrict the sample to spd1, spdlimit is between 40 and 50; when we restrict the sample to spd2, spdlimit is between 55 and 60; when we restrict the sample to spd3, spdlimit is between 65 and 70.

Thus `tabulate` provides an easy way to create indicator (sometimes called dummy) variables. For an overview of indicator and categorical variables, see [U] 26 Working with categorical data and factor variables.

---

### tab1

`tab1` is a convenience tool. Typing

```
    . tab1 myvar thisvar thatvar, plot
```

is equivalent to typing

```
    . tabulate myvar, plot
    . tabulate thisvar, plot
    . tabulate thatvar, plot
```

---

### Video example

Tables and cross-tabulations in Stata

---

### Stored results

`tabulate` and `tab1` store the following in `r()`:

Scalars

- `r(N)` number of observations
- `r(r)` number of rows

---

**Description**

`tabulate` produces a two-way table of frequency counts, along with various measures of association, including the common Pearson’s $\chi^2$, the likelihood-ratio $\chi^2$, Cramér’s $V$, Fisher’s exact test, Goodman and Kruskal’s gamma, and Kendall’s $\tau_b$.

Line size is respected. That is, if you resize the Results window before running `tabulate`, the resulting two-way tabulation will take advantage of the available horizontal space. Stata for Unix(console) users can instead use the `set linesize` command to take advantage of this feature.

`tab2` produces all possible two-way tabulations of the variables specified in `varlist`.

`tabi` displays the $r \times c$ table, using the values specified; rows are separated by ‘\’. If no options are specified, it is as if `exact` were specified for a $2 \times 2$ table and `chi2` were specified otherwise. See [U] 19 Immediate commands for a general description of immediate commands. See Tables with immediate data below for examples using `tabi`.

See [R] `tabulate oneway` if you want a one-way table of frequencies. See [R] `table` and [R] `tabstat` if you want one-, two-, or $n$-way table of frequencies and a wide variety of summary statistics. See [R] `tabulate, summarize()` for a description of `tabulate` with the `summarize()` option; it produces a table (breakdowns) of means and standard deviations. `table` is better than `tabulate, summarize()`, but `tabulate, summarize()` is faster. See [R] `Epitab` for a $2 \times 2$ table with statistics of interest to epidemiologists.

**Quick start**

Two-way table of frequencies for v1 and v2

```
tabulate v1 v2
```

Add row percentages

```
tabulate v1 v2, row
```

Frequencies only for observations where v3 = 1

```
tabulate v1 v2 if v3==1
```

Weighted cell counts using frequency weights defined by wvar

```
tabulate v1 v2 [fweight=wvar]
```

Pearson’s $\chi^2$ test and each cell’s contribution

```
tabulate v1 v2, chi2 cchi2
```

All available measures of association

```
tabulate v1 v2, all
```
All possible two-way tables for v1, v2, and v3
   tab2 v1 v2 v3

Input cell frequencies and perform $\chi^2$ test

*firstonly is available only for tab2.
‡replace is available only for tabi.
by is allowed with tabulate and tab2, and collect is allowed with tabulate and tabi; see [U] 11.1.10 Prefix commands.

fweights, aweights, and iweights are allowed by tabulate. fweights are allowed by tab2. See [U] 11.1.6 weight. all does not appear in the dialog box.

Options

- **Main**
  - **chi2** calculates and displays Pearson’s $\chi^2$ for the hypothesis that the rows and columns in a two-way table are independent. chi2 may not be specified if aweights or iweights are specified.
  - **exact[(#)]** displays the significance calculated by Fisher’s exact test and may be applied to $r \times c$ as well as to $2 \times 2$ tables. For $2 \times 2$ tables, both one- and two-sided probabilities are displayed. For $r \times c$ tables, two-sided probabilities are displayed. The optional positive integer # is a multiplier on the amount of memory that the command is permitted to consume. The default is 1. This option should not be necessary for reasonable $r \times c$ tables. If the command terminates with error 910, try exact(2). The maximum row or column dimension allowed when computing Fisher’s exact test is the maximum row or column dimension for tabulate (see [R] Limits).
  - **gamma** displays Goodman and Kruskal’s gamma along with its asymptotic standard error. gamma is appropriate only when both variables are ordinal. gamma may not be specified if aweights or iweights are specified.
  - **lrchi2** displays the likelihood-ratio $\chi^2$ statistic. lrchi2 may not be specified if aweights or iweights are specified.
  - **taub** displays Kendall’s $\tau_b$ along with its asymptotic standard error. taub is appropriate only when both variables are ordinal. taub may not be specified if aweights or iweights are specified.
  - **V** (note capitalization) displays Cramér’s $V$. V may not be specified if aweights or iweights are specified.
  - **cchi2** displays each cell’s contribution to Pearson’s $\chi^2$ in a two-way table.
  - **column** displays the relative frequency of each cell within its column in a two-way table.
  - **row** displays the relative frequency of each cell within its row in a two-way table.
  - **clrchi2** displays each cell’s contribution to the likelihood-ratio $\chi^2$ in a two-way table.
  - **cell** displays the relative frequency of each cell in a two-way table.
  - **expected** displays the expected frequency of each cell in a two-way table.
  - **nofreq** suppresses the printing of the frequencies.

- **rowsort and colsort** specify that the rows and columns, respectively, be presented in order of observed frequency.

By default, rows and columns are presented in ascending order of the row and column variable. For instance, if you type `tabulate a b` and `a` takes on the values 2, 3, and 5, then the first row of the table will correspond to `a = 2`; the second row will correspond to `a = 3`; and the third row will correspond to `a = 5`.

rowsort specifies that the rows instead be presented in descending order of observed frequency of the values. If you type `twoway a b, rowsort`, the most frequently observed value of `a` will be listed in the first row, the second most frequently observed value of `a` in the second row, and
so on. If there are rows with equal frequencies, they will be presented in ascending order of the values of \( a \). If \( a = 5 \) occurs with frequency 1,000 and values \( a = 2 \) and \( a = 3 \) each occur with frequency 500, the rows will be presented in the order \( a = 5 \), \( a = 2 \), and \( a = 3 \).

colsort does the same as rowsort, except with the columns and the column variable.

rowsort and colsort may be specified together.

**missing** requests that missing values be treated like other values in calculations of counts, percentages, and other statistics.

**wrap** requests that Stata take no action on wide, two-way tables to make them readable. Unless wrap is specified, wide tables are broken into pieces to enhance readability.

[no]key suppresses or forces the display of a key above two-way tables. The default is to display the key if more than one cell statistic is requested, and otherwise to omit it. key forces the display of the key. nokey suppresses its display.

**nolabel** causes the numeric codes to be displayed rather than the value labels.

**nolog** suppresses the display of the log for Fisher’s exact test. Using Fisher’s exact test requires counting all tables that have a probability exceeding that of the observed table given the observed row and column totals. The log counts down each stage of the network computations, starting from the number of columns and counting down to 1, displaying the number of nodes in the network at each stage. A log is not displayed for \( 2 \times 2 \) tables.

**firstonly**, available only with `tab2`, restricts the output to only those tables that include the first variable in `varlist`. Use this option to interact one variable with a set of others.

**Advanced**

**matcell(matname)** saves the reported frequencies in `matname`. This option is for use by programmers.

**matrow(matname)** saves the numeric values of the \( r \times 1 \) row stub in `matname`. This option is for use by programmers. **matrow()** may not be specified if the row variable is a string.

**matcol(matname)** saves the numeric values of the \( 1 \times c \) column stub in `matname`. This option is for use by programmers. **matcol()** may not be specified if the column variable is a string.

**replace** indicates that the immediate data specified as arguments to the `tabi` command be left as the current data in place of whatever data were there.

The following option is available with `tabulate` but is not shown in the dialog box:

**all** is equivalent to specifying `chi2 lrchi2 V gamma taub`. Note the omission of `exact`. When `all` is specified, `no` may be placed in front of the other options. **all noV** requests all association measures except Cramér’s \( V \) (and Fisher’s exact). **all exact** requests all association measures, including Fisher’s exact test. **all** may not be specified if `aweights` or `iweights` are specified.

**Limits**

Two-way tables may have a maximum of 1,200 rows and 80 columns (Stata/MP and Stata/SE) or 300 rows and 20 columns (Stata/BE). If larger tables are needed, see \[R\] table.
Remarks and examples

Remarks are presented under the following headings:

- tabulate
- Measures of association
- N-way tables
- Weighted data
- Tables with immediate data
- tab2
- Video examples

For each value of a specified variable (or a set of values for a pair of variables), tabulate reports the number of observations with that value. The number of times a value occurs is called its frequency.

Example 1

Example 1 will make two-way tables if we specify two variables following the word tabulate. In our highway dataset, we have a variable called rate that divides the accident rate into three categories: below 4, 4–7, and above 7 per million vehicle miles. Let’s make a table of the speed limit category and the accident-rate category:

```stata
.use https://www.stata-press.com/data/r18/hiway2
(Minnesota highway data, 1973)
.tabulate spdcat rate
```

<table>
<thead>
<tr>
<th>Speed limit category</th>
<th>Accident rate per million vehicle miles</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Below 4</td>
<td>4-7</td>
</tr>
<tr>
<td>40 to 50</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>55 to 50</td>
<td>19</td>
<td>6</td>
</tr>
<tr>
<td>Above 60</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Total</td>
<td>24</td>
<td>11</td>
</tr>
</tbody>
</table>

The table indicates that three stretches of highway have an accident rate below 4 and a speed limit of 40 to 50 miles per hour. The table also shows the row and column sums (called the marginals). The number of highways with a speed limit of 40 to 50 miles per hour is 11, which is the same result we obtained in our previous one-way tabulations.

Stata can present this basic table in several ways—16, to be precise—and we will show just a few below. It might be easier to read the table if we included the row percentages. For instance, of 11 highways in the lowest speed limit category, three are also in the lowest accident-rate category. Three-elevenths amounts to some 27.3%. We can ask Stata to fill in this information for us by using the row option:
The number listed below each frequency is the percentage of cases that each cell represents out of its row. That is easy to remember because we see 100% listed in the “Total” column. The bottom row is also informative. We see that 61.54% of all the highways in our dataset fall into the lowest accident-rate category, that 28.21% are in the middle category, and that 10.26% are in the highest.

*tabulate* can calculate column percentages and cell percentages, as well. It does so when we specify the column or cell options, respectively. We can even specify them together. Below is a table that includes everything:
The number at the top of each cell is the frequency count. The second number is the row percentage—they sum to 100% going across the table. The third number is the column percentage—they sum to 100% going down the table. The bottom number is the cell percentage—they sum to 100% going down all the columns and across all the rows. For instance, highways with a speed limit above 60 miles per hour and in the lowest accident rate category account for 100% of highways with a speed limit above 60 miles per hour; 8.33% of highways in the lowest accident-rate category; and 5.13% of all our data.

A fourth option, `nofreq`, tells Stata not to print the frequency counts. To construct a table consisting of only row percentages, we type

```
. tabulate spdcat rate, row nofreq
```

<table>
<thead>
<tr>
<th>Speed limit category</th>
<th>Accident rate per million vehicle miles</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Below 4</td>
<td>4-7</td>
</tr>
<tr>
<td>40 to 50</td>
<td>27.27</td>
<td>45.45</td>
</tr>
<tr>
<td>55 to 50</td>
<td>73.08</td>
<td>23.08</td>
</tr>
<tr>
<td>Above 60</td>
<td>100.00</td>
<td>0.00</td>
</tr>
<tr>
<td>Total</td>
<td>61.54</td>
<td>28.21</td>
</tr>
</tbody>
</table>
Measures of association

Example 2

`tabulate` will calculate the Pearson $\chi^2$ test for the independence of the rows and columns if we specify the `chi2` option. Suppose that we have 1980 census data on 956 cities in the United States and wish to compare the age distribution across regions of the country. Assume that `agecat` is the median age in each city and that `region` denotes the region of the country in which the city is located.

```
. use https://www.stata-press.com/data/r18/citytemp2
(City temperature data)
. tabulate region agecat, chi2

<table>
<thead>
<tr>
<th>Census region</th>
<th>Age category</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>19-29</td>
<td>30-34</td>
</tr>
<tr>
<td>NE</td>
<td>46</td>
<td>83</td>
</tr>
<tr>
<td>N Cntrl</td>
<td>162</td>
<td>92</td>
</tr>
<tr>
<td>South</td>
<td>139</td>
<td>68</td>
</tr>
<tr>
<td>West</td>
<td>160</td>
<td>73</td>
</tr>
<tr>
<td>Total</td>
<td>507</td>
<td>316</td>
</tr>
</tbody>
</table>
```

Pearson $\chi^2(6) = 61.2877$ Pr = 0.000

We obtain the standard two-way table and, at the bottom, a summary of the $\chi^2$ test. Stata informs us that the $\chi^2$ associated with this table has 6 degrees of freedom and is 61.29. The observed differences are significant.

The table is, perhaps, easier to understand if we suppress the frequencies and print just the row percentages:

```
. tabulate region agecat, row nofreq chi2

<table>
<thead>
<tr>
<th>Census region</th>
<th>Age category</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>19-29</td>
<td>30-34</td>
</tr>
<tr>
<td>NE</td>
<td>27.71</td>
<td>50.00</td>
</tr>
<tr>
<td>N Cntrl</td>
<td>57.04</td>
<td>32.39</td>
</tr>
<tr>
<td>South</td>
<td>55.60</td>
<td>27.20</td>
</tr>
<tr>
<td>West</td>
<td>62.50</td>
<td>28.52</td>
</tr>
<tr>
<td>Total</td>
<td>53.03</td>
<td>33.05</td>
</tr>
</tbody>
</table>
```

Pearson $\chi^2(6) = 61.2877$ Pr = 0.000

Example 3

We have data on dose level and outcome for a set of patients and wish to evaluate the association between the two variables. We can obtain all the association measures by specifying the `all` and `exact` options:
. use https://www.stata-press.com/data/r18/dose
. tabulate dose function, all exact

Enumerating sample-space combinations:
stage 3: enumerations = 1
stage 2: enumerations = 9
stage 1: enumerations = 0

<table>
<thead>
<tr>
<th>Dosage</th>
<th>Function &lt; 1 hr</th>
<th>1 to 4</th>
<th>4+</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/day</td>
<td>20</td>
<td>10</td>
<td>2</td>
<td>32</td>
</tr>
<tr>
<td>2/day</td>
<td>16</td>
<td>12</td>
<td>4</td>
<td>32</td>
</tr>
<tr>
<td>3/day</td>
<td>10</td>
<td>16</td>
<td>6</td>
<td>32</td>
</tr>
<tr>
<td>Total</td>
<td>46</td>
<td>38</td>
<td>12</td>
<td>96</td>
</tr>
</tbody>
</table>

Pearson chi2(4) = 6.7780 Pr = 0.148
Likelihood-ratio chi2(4) = 6.9844 Pr = 0.137
Cramér's V = 0.1879
gamma = 0.3689 ASE = 0.129
Kendall’s tau-b = 0.2378 ASE = 0.086
Fisher’s exact = 0.145

We find evidence of association but not enough to be truly convincing.

If we had not also specified the exact option, we would not have obtained Fisher’s exact test. Stata can calculate this statistic both for $2 \times 2$ tables and for $r \times c$. For $2 \times 2$ tables, the calculation is almost instant. On more general tables, however, the calculation can take longer.

We carefully constructed our example so that all would be meaningful. Kendall’s $\tau_b$ and Goodman and Kruskal’s gamma are relevant only when both dimensions of the table can be ordered, say, from low to high or from worst to best. The other statistics, however, are always applicable.

Technical note

Be careful when attempting to compute the $p$-value for Fisher’s exact test because the number of tables that contribute to the $p$-value can be extremely large and a solution may not be feasible. The errors that are indicative of this situation are errors 910, exceeded memory limitations, and 1401, integer overflow due to large row-margin frequencies. If execution terminates because of memory limitations, use exact(2) to permit the algorithm to consume twice the memory, exact(3) for three times the memory, etc. The default memory usage should be sufficient for reasonable tables.

N-way tables

If you need more than two-way tables, your best alternative to is use table, not tabulate; see [R] table.

The technical note below shows you how to use tabulate to create a sequence of two-way tables that together form, in effect, a three-way table, but using table is easy and produces prettier results:
. use https://www.stata-press.com/data/r18/birthcat
     (City data)
. table (agecat birthcat) (region), nototals

<table>
<thead>
<tr>
<th>Age category</th>
<th>Census region</th>

<td></td>
</tr>
<tr>
<td>196-529</td>
<td>4</td>
<td></td>
<td></td>
<td></td>
<td>37</td>
<td></td>
</tr>
</tbody>
</table>

Technical note

We can make n-way tables by combining the by varlist: prefix with tabulate. Continuing with the dataset of 956 cities, say that we want to make a table of age category by birth-rate category by region of the country. The birth-rate category variable is named birthcat in our dataset. To make separate tables for each age category, we would type

. by agecat, sort: tabulate birthcat region

-> agecat = 19-29

<table>
<thead>
<tr>
<th>Birth-rate category</th>
<th>Census region</th>
<th>NE</th>
<th>N Ctrl</th>
<th>South</th>
<th>West</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>29-136</td>
<td>11</td>
<td>23</td>
<td>11</td>
<td>11</td>
<td>56</td>
<td></td>
</tr>
<tr>
<td>137-195</td>
<td>31</td>
<td>97</td>
<td>65</td>
<td>46</td>
<td>239</td>
<td></td>
</tr>
<tr>
<td>196-529</td>
<td>4</td>
<td>38</td>
<td>59</td>
<td>91</td>
<td>192</td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>46</td>
<td>158</td>
<td>135</td>
<td>148</td>
<td>487</td>
<td></td>
</tr>
</tbody>
</table>

-> agecat = 30-34

<table>
<thead>
<tr>
<th>Birth-rate category</th>
<th>Census region</th>
<th>NE</th>
<th>N Ctrl</th>
<th>South</th>
<th>West</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>29-136</td>
<td>34</td>
<td>27</td>
<td>10</td>
<td>8</td>
<td>79</td>
<td></td>
</tr>
<tr>
<td>137-195</td>
<td>48</td>
<td>58</td>
<td>45</td>
<td>42</td>
<td>193</td>
<td></td>
</tr>
<tr>
<td>196-529</td>
<td>1</td>
<td>3</td>
<td>12</td>
<td>21</td>
<td>37</td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>83</td>
<td>88</td>
<td>67</td>
<td>71</td>
<td>309</td>
<td></td>
</tr>
</tbody>
</table>
-> agecat = 35+

<table>
<thead>
<tr>
<th>Birth-rate category</th>
<th>NE</th>
<th>N Cntrl</th>
<th>South</th>
<th>West</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>29-136</td>
<td>34</td>
<td>26</td>
<td>27</td>
<td>18</td>
<td>105</td>

<td>4</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>37</td>
<td>30</td>
<td>38</td>
<td>22</td>
<td>127</td>
</tr>
</tbody>
</table>

**Weighted data**

Example 4

`tabulate` can process weighted as well as unweighted data. As with all Stata commands, we indicate the weight by specifying the `[weight]` modifier; see [U] 11.1.6 weight.

Continuing with our dataset of 956 cities, we also have a variable called `pop`, the population of each city. We can make a table of region by age category, weighted by population, by typing

```
.tabulate region agecat [fweight=pop]
```

<table>
<thead>
<tr>
<th>Census region</th>
<th>19-29</th>
<th>30-34</th>
<th>35+</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>NE</td>
<td>4721387</td>
<td>10421387</td>
<td>5323610</td>
<td>20466384</td>
</tr>
<tr>
<td>N Cntrl</td>
<td>16901550</td>
<td>8964756</td>
<td>4015593</td>
<td>29881899</td>
</tr>
<tr>
<td>South</td>
<td>13894254</td>
<td>7686531</td>
<td>4141863</td>
<td>25722648</td>
</tr>
<tr>
<td>West</td>
<td>16698276</td>
<td>7755255</td>
<td>2375118</td>
<td>26828649</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>52215467</td>
<td>34827929</td>
<td>15856184</td>
<td>102899580</td>
</tr>
</tbody>
</table>

If we specify the `cell`, column, or `row` options, they will also be appropriately weighted. Below, we repeat the table, suppressing the counts and substituting row percentages:

```
.tabulate region agecat [fweight=pop], nofreq row
```

<table>
<thead>
<tr>
<th>Census region</th>
<th>19-29</th>
<th>30-34</th>
<th>35+</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>NE</td>
<td>23.07</td>
<td>50.92</td>
<td>26.01</td>
<td>100.00</td>
</tr>
<tr>
<td>N Cntrl</td>
<td>56.56</td>
<td>30.00</td>
<td>13.44</td>
<td>100.00</td>
</tr>
<tr>
<td>South</td>
<td>54.02</td>
<td>29.88</td>
<td>16.10</td>
<td>100.00</td>
</tr>
<tr>
<td>West</td>
<td>62.24</td>
<td>28.91</td>
<td>8.85</td>
<td>100.00</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>50.74</td>
<td>33.85</td>
<td>15.41</td>
<td>100.00</td>
</tr>
</tbody>
</table>
## Tables with immediate data

### Example 5

`tabi` ignores the dataset in memory and uses as the table the values that we specify on the command line:

```plaintext
.tabi 30 18 \ 38 14
```

<table>
<thead>
<tr>
<th>row</th>
<th>col 1</th>
<th>col 2</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>30</td>
<td>18</td>
<td>48</td>
</tr>
<tr>
<td>2</td>
<td>38</td>
<td>14</td>
<td>52</td>
</tr>
<tr>
<td>Total</td>
<td>68</td>
<td>32</td>
<td>100</td>
</tr>
</tbody>
</table>

Fisher's exact = 0.289
1-sided Fisher's exact = 0.179

We may specify any of the options of `tabulate` and are not limited to $2 \times 2$ tables:

```plaintext
.tabi 30 18 38 \ 13 7 22, chi2 exact
```

Enumerating sample-space combinations:
stage 3: enumerations = 1
stage 2: enumerations = 3
stage 1: enumerations = 0

<table>
<thead>
<tr>
<th>row</th>
<th>col 1</th>
<th>col 2</th>
<th>col 3</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>30</td>
<td>18</td>
<td>38</td>
<td>86</td>
</tr>
<tr>
<td>2</td>
<td>13</td>
<td>7</td>
<td>22</td>
<td>42</td>
</tr>
<tr>
<td>Total</td>
<td>43</td>
<td>25</td>
<td>60</td>
<td>128</td>
</tr>
</tbody>
</table>

Pearson chi2(2) = 0.7967 Pr = 0.671
Fisher's exact = 0.707

```plaintext
.tabi 30 13 \ 18 7 \ 38 22, all exact col
```

### Key

<table>
<thead>
<tr>
<th>frequency</th>
<th>column percentage</th>
</tr>
</thead>
</table>

Enumerating sample-space combinations:
stage 3: enumerations = 1
stage 2: enumerations = 3
stage 1: enumerations = 0

<table>
<thead>
<tr>
<th>row</th>
<th>col 1</th>
<th>col 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>30</td>
<td>13</td>
</tr>
<tr>
<td></td>
<td>34.88</td>
<td>30.95</td>
</tr>
<tr>
<td></td>
<td>33.59</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>18</td>
<td>7</td>
</tr>
<tr>
<td></td>
<td>20.93</td>
<td>16.67</td>
</tr>
<tr>
<td></td>
<td>19.53</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>38</td>
<td>22</td>
</tr>
<tr>
<td></td>
<td>44.19</td>
<td>52.38</td>
</tr>
<tr>
<td></td>
<td>46.88</td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>86</td>
<td>42</td>
</tr>
<tr>
<td></td>
<td>100.00</td>
<td>100.00</td>
</tr>
</tbody>
</table>
tabulate twoway — Two-way table of frequencies

Pearson chi2(2) = 0.7967 Pr = 0.671
Likelihood-ratio chi2(2) = 0.7985 Pr = 0.671
Cramér's V = 0.0789
gamma = 0.1204 ASE = 0.160
Kendall's tau-b = 0.0630 ASE = 0.084
Fisher's exact = 0.707

For 2 × 2 tables, both one- and two-sided Fisher's exact probabilities are displayed; this is true of both tabulate and tabi. See Cumulative incidence data and Case–control data in [R] Epitab for more discussion on the relationship between one- and two-sided probabilities.

Technical note

tabi, as with all immediate commands, leaves any data in memory undisturbed. With the replace option, however, the data in memory are replaced by the data from the table:

```
.tabi 30 18 \ 38 14, replace

<table>
<thead>
<tr>
<th>row</th>
<th>col</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>30</td>
<td>18</td>
</tr>
<tr>
<td>2</td>
<td>38</td>
<td>14</td>
</tr>
<tr>
<td>Total</td>
<td>68</td>
<td>32</td>
</tr>
</tbody>
</table>
```

Fisher's exact = 0.289
1-sided Fisher's exact = 0.179

```
.list

<table>
<thead>
<tr>
<th>row</th>
<th>col</th>
<th>pop</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>30</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>18</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>38</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>14</td>
</tr>
</tbody>
</table>
```

With this dataset, you could re-create the above table by typing

```
.tabulate row col [fweight=pop], exact

<table>
<thead>
<tr>
<th>row</th>
<th>col</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>30</td>
<td>18</td>
</tr>
<tr>
<td>2</td>
<td>38</td>
<td>14</td>
</tr>
<tr>
<td>Total</td>
<td>68</td>
<td>32</td>
</tr>
</tbody>
</table>
```

Fisher's exact = 0.289
1-sided Fisher's exact = 0.179
**tab2**

*tab2* is a convenience tool. Typing

```
.tab2 myvar thisvar thatvar, chi2
```

is equivalent to typing

```
.tabulate myvar thisvar, chi2
.tabulate myvar thatvar, chi2
.tabulate thisvar thatvar, chi2
```

**Video examples**

- Tables and cross-tabulations in Stata
- Cross-tabulations and chi-squared tests calculator

**Stored results**

*tabulate, tab2, and tabi* store the following in *r()*:

<table>
<thead>
<tr>
<th>Scalar</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>r(N)</td>
<td>number of observations</td>
</tr>
<tr>
<td>r(r)</td>
<td>number of rows</td>
</tr>
<tr>
<td>r(c)</td>
<td>number of columns</td>
</tr>
<tr>
<td>r(chi2)</td>
<td>Pearson’s $\chi^2$ test</td>
</tr>
<tr>
<td>r(p)</td>
<td>p-value for of Pearson’s $\chi^2$ test</td>
</tr>
<tr>
<td>r(gamma)</td>
<td>gamma</td>
</tr>
<tr>
<td>r(p1_exact)</td>
<td>one-sided Fisher’s exact p</td>
</tr>
<tr>
<td>r(ase_gam)</td>
<td>ASE of gamma</td>
</tr>
<tr>
<td>r(ase_taub)</td>
<td>ASE of $\tau_b$</td>
</tr>
<tr>
<td>r(chi2_lr)</td>
<td>likelihood-ratio $\chi^2$</td>
</tr>
<tr>
<td>r(p_lr)</td>
<td>p-value for likelihood-ratio test</td>
</tr>
<tr>
<td>r(CramersV)</td>
<td>Cramér’s $V$</td>
</tr>
<tr>
<td>r(1_exact)</td>
<td>one-sided Fisher’s exact p</td>
</tr>
<tr>
<td>r(taub)</td>
<td>$\tau_b$</td>
</tr>
</tbody>
</table>

$r(p1\_exact)$ is defined only for $2 \times 2$ tables. Also, the *matrow(), matcol(), and matcell()* options allow you to obtain the row values, column values, and frequencies, respectively.

**Methods and formulas**

Let $n_{ij}$, $i = 1, \ldots, I$ and $j = 1, \ldots, J$, be the number of observations in the $i$th row and $j$th column. If the data are not weighted, $n_{ij}$ is just a count. If the data are weighted, $n_{ij}$ is the sum of the weights of all data corresponding to the $(i, j)$ cell.

Define the row and column marginals as

$$n_{i.} = \sum_{j=1}^{J} n_{ij} \quad \text{and} \quad n_{.j} = \sum_{i=1}^{I} n_{ij}$$

and let $n = \sum_{i} \sum_{j} n_{ij}$ be the overall sum. Also, define the concordance and discordance as

$$A_{ij} = \sum_{k>i} \sum_{l>j} n_{kl} + \sum_{k<i} \sum_{l<j} n_{kl}$$
$$D_{ij} = \sum_{k>i} \sum_{l<j} n_{kl} + \sum_{k<i} \sum_{l>j} n_{kl}$$

along with twice the number of concordances $P = \sum_{i} \sum_{j} n_{ij} A_{ij}$ and twice the number of discordances $Q = \sum_{i} \sum_{j} n_{ij} D_{ij}$. 
The Pearson $\chi^2$ statistic with $(I - 1)(J - 1)$ degrees of freedom (so called because it is based on Pearson (1900); see Conover [1999, 240] and Fienberg [1980, 9]) is defined as

$$X^2 = \sum_i \sum_j \frac{(n_{ij} - m_{ij})^2}{m_{ij}}$$

where $m_{ij} = n_i n_j / n$.

The likelihood-ratio $\chi^2$ statistic with $(I - 1)(J - 1)$ degrees of freedom (Fienberg 1980, 40) is defined as

$$G^2 = 2 \sum_i \sum_j n_{ij} \ln(n_{ij} / m_{ij})$$

Cramér’s $V$ (Cramér 1946) is a measure of association designed so that the attainable upper bound is 1. For $2 \times 2$ tables, $-1 \leq V \leq 1$, and otherwise, $0 \leq V \leq 1$.

$$V = \begin{cases} 
\left\{ \frac{(n_{11}n_{22} - n_{12}n_{21})}{(n_1 n_2 n_1 n_2)^{1/2}} \right\}^{1/2} & \text{for } 2 \times 2 \\
\left\{ \frac{(X^2/n)}{\min(I - 1, J - 1)} \right\}^{1/2} & \text{otherwise}
\end{cases}$$

Gamma (Goodman and Kruskal 1954, 1959, 1963, 1972; also see Agresti [2010,186–188]) ignores tied pairs and is based only on the number of concordant and discordant pairs of observations, $-1 \leq \gamma \leq 1$,

$$\gamma = (P - Q)/(P + Q)$$

with asymptotic variance

$$16 \sum_i \sum_j n_{ij} (QA_{ij} - PD_{ij})^2 / (P + Q)^4$$

Kendall’s $\tau_b$ (Kendall 1945; also see Agresti 2010, 188–189), $-1 \leq \tau_b \leq 1$, is similar to gamma, except that it uses a correction for ties,

$$\tau_b = (P - Q)/(w_r w_c)^{1/2}$$

with asymptotic variance

$$\frac{\sum_i \sum_j n_{ij} (2w_r w_c d_{ij} + \tau_b v_{ij})^2 - n^3 \tau_b^2 (w_r + w_c)^2}{(w_r w_c)^4}$$
where

\[ w_r = n^2 - \sum_i n_i^2 \]
\[ w_c = n^2 - \sum_j n_j^2 \]
\[ d_{ij} = A_{ij} - D_{ij} \]
\[ v_{ij} = n_i w_c + n_j w_r \]

Fisher’s exact test (Fisher 1935; Finney 1948; see Zelterman and Louis [1992, 293–301] for the 2 × 2 case) yields the probability of observing a table that gives at least as much evidence of association as the one actually observed under the assumption of no association. Holding row and column marginals fixed, the hypergeometric probability \( P \) of every possible table \( A \) is computed, and the

\[ P = \sum_{T \in A} \Pr(T) \]

where \( A \) is the set of all tables with the same marginals as the observed table, \( T^* \), such that \( \Pr(T) \leq \Pr(T^*) \). For 2 × 2 tables, the one-sided probability is calculated by further restricting \( A \) to tables in the same tail as \( T^* \). The first algorithm extending this calculation to \( r \times c \) tables was Pagano and Halvorsen (1981); the one implemented here is the FEXACT algorithm by Mehta and Patel (1986). This is a search-tree clipping method originally published by Mehta and Patel (1983) with further refinements by Joe (1988) and Clarkson, Fan, and Joe (1993). Fisher’s exact test is a permutation test. For more information on permutation tests, see Good (2005 and 2006) and Pesarin (2001).

tabulate, summarize() — One- and two-way tables of summary statistics

Description

`tabulate, summarize()` produces one- and two-way tables (breakdowns) of means and standard deviations. See [R] tabulate oneway and [R] tabulate twoway for one- and two-way frequency tables. See [R] table for a more flexible command that produces one-, two-, and n-way tables of frequencies and a wide variety of summary statistics. `table` is better, but `tabulate, summarize()` is faster. Also see [R] tabstat for yet another alternative.

Quick start

Tabulation of `v1`, reporting means and standard deviations of `x` and frequencies

```
tabulate v1, summarize(x)
```

Same as above, but report summary statistics for the two-way tabulation of `v1` and `v2`

```
tabulate v1 v2, summarize(x)
```

Weighted summary statistics using frequency weight `wvar`

```
tabulate v1 v2 [fweight=wvar], summarize(x)
```

Report only the mean of `x` for each group

```
tabulate v1 v2, summarize(x) means
```

Do not report standard deviations

```
tabulate v1 v2, summarize(x) nostandard
```

Show numeric values of `v1` and `v2` rather than value labels

```
tabulate v1 v2, summarize(x) nolabel
```

Menu

Statistics > Summaries, tables, and tests > Other tables > Table of means, std. dev., and frequencies
tabulate, summarize() — One- and two-way tables of summary statistics

Syntax

```
   tabulate varname1 [ varname2 ] [ if ] [ in ] [ weight ] [ , options ]
```

<table>

</tbody>
</table>

by and collect are allowed; see [U] 11.1.10 Prefix commands. aweights and fweights are allowed; see [U] 11.1.6 weight.

Options

```
   summarize(varname3) identifies the name of the variable for which summary statistics are to be reported. If you do not specify this option, a table of frequencies is produced; see [R] tabulate oneway and [R] tabulate twoway. The description here concerns tabulate when this option is specified.

   [no] means includes or suppresses only the means from the table.

   The summarize() table normally includes the mean, standard deviation, frequency, and, if the data are weighted, number of observations. Individual elements of the table may be included or suppressed by the [no] means, [no] standard, [no] freq, and [no] obs options. For example, typing

   . tabulate category, summarize(myvar) means standard

   produces a summary table by category containing only the means and standard deviations of myvar. You could also achieve the same result by typing

   . tabulate category, summarize(myvar) nofreq

   [no] standard includes or suppresses only the standard deviations from the table; see [no] means option above.

   [no] freq includes or suppresses only the frequencies from the table; see [no] means option above.

   [no] obs includes or suppresses only the reported number of observations from the table. If the data are not weighted, the number of observations is identical to the frequency, and by default only the frequency is reported. If the data are weighted, the frequency refers to the sum of the weights. See [no] means option above.

   nolabel causes the numeric codes to be displayed rather than the label values.

   wrap requests that no action be taken on wide tables to make them readable. Unless wrap is specified, wide tables are broken into pieces to enhance readability.

   missing requests that missing values of varname1 and varname2 be treated as categories rather than as observations to be omitted from the analysis.
```
Remarks and examples

`tabulate` with the `summarize()` option produces one- and two-way tables of summary statistics. When combined with the by prefix, it can produce n-way tables as well.

Remarks are presented under the following headings:

One-way tables

Example 1

We have data on 74 automobiles. Included in our dataset are the variables `foreign`, which marks domestic and foreign cars, and `mpg`, the car’s mileage rating. Typing `tabulate foreign` displays a breakdown of the number of observations we have by the values of the `foreign` variable.

```
. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. tabulate foreign

<table>
<thead>
<tr>
<th>Car origin</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>52</td>
<td>70.27</td>
<td>70.27</td>
</tr>
<tr>
<td>Foreign</td>
<td>22</td>
<td>29.73</td>
<td>100.00</td>
</tr>
<tr>
<td>Total</td>
<td>74</td>
<td>100.00</td>
<td></td>
</tr>
</tbody>
</table>
```

We discover that we have 52 domestic cars and 22 foreign cars in our dataset. If we add the `summarize(varname)` option, however, `tabulate` produces a table of summary statistics for `varname`:

```
. tabulate foreign, summarize(mpg)

<table>
<thead>
<tr>
<th>Car origin</th>
<th>Summary of Mileage (mpg)</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Mean</td>
<td>Std. dev.</td>
<td>Freq.</td>
<td>Summary of Mileage (mpg)</td>
<td></td>
</tr>
<tr>
<td>Domestic</td>
<td>19.826923</td>
<td>4.7432972</td>
<td>52</td>
<td>19.826923</td>
<td>4.7432972</td>
</tr>
<tr>
<td>Foreign</td>
<td>24.772727</td>
<td>6.611869</td>
<td>22</td>
<td>24.772727</td>
<td>6.611869</td>
</tr>
<tr>
<td>Total</td>
<td>21.297297</td>
<td>5.7855032</td>
<td>74</td>
<td>21.297297</td>
<td>5.7855032</td>
</tr>
</tbody>
</table>
```

We also discover that the average gas mileage for domestic cars is about 20 mpg and the average foreign is almost 25 mpg. Overall, the average is 21 mpg in our dataset.

Technical note

We might now wonder if the difference in gas mileage between foreign and domestic cars is statistically significant. We can use the `oneway` command to find out; see [R] oneway. To obtain an analysis-of-variance table of `mpg` on `foreign`, we type

```
. oneway mpg foreign

<table>
<thead>
<tr>
<th>Source</th>
<th>Analysis of variance</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>SS</td>
<td>df</td>
<td>MS</td>
<td>F</td>
<td>Prob &gt; F</td>
</tr>
<tr>
<td>Between groups</td>
<td>378.153515</td>
<td>1</td>
<td>378.153515</td>
<td>13.18</td>
<td>0.0005</td>
</tr>
<tr>
<td>Within groups</td>
<td>2065.30594</td>
<td>72</td>
<td>28.6848048</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>2443.45946</td>
<td>73</td>
<td>33.4720474</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Bartlett’s equal-variances test: chi2(1) =</td>
<td>3.4818</td>
<td>Prob&gt;chi2 = 0.062</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
The $F$ statistic is 13.18, and the difference between foreign and domestic cars’ mileage ratings is significant at the 0.05% level.

There are several ways that we could have statistically compared mileage ratings—see, for instance, \texttt{[R] anova}, \texttt{[R] oneway}, \texttt{[R] regress}, and \texttt{[R] ttest}—but \texttt{oneway} seemed the most convenient.

\section*{Two-way tables}

\subsection*{Example 2}

\texttt{tabulate, summarize} can be used to obtain two-way as well as one-way breakdowns. For instance, we obtained summary statistics on \texttt{mpg} decomposed by \texttt{foreign} by typing \texttt{tabulate foreign, summarize(mpg)}. We can specify up to two variables before the comma:

\begin{verbatim}
. generate wgtcat = autocode(weight,4,1760,4840)
. tabulate wgtcat foreign, summarize(mpg)
\end{verbatim}

\begin{table}[h]
\centering
\begin{tabular}{lrrr}
\hline
\textbf{Car origin} & \multicolumn{2}{c}{\textbf{Means, Standard Deviations and Frequencies of Mileage (mpg)}} \\
\hline
\textbf{wgtcat} & \textbf{Domestic} & \textbf{Foreign} & \textbf{Total} \\
\hline
2530 & 28.285714 & 27.0625 & 27.434783 \\
 & 3.0937725 & 5.9829619 & 5.2295149 \\
 & 7 & 16 & 23 \\
3300 & 21.75 & 19.6 & 21.238095 \\
 & 2.4083189 & 3.4351128 & 2.7550819 \\
 & 16 & 5 & 21 \\
4070 & 17.26087 & 14 & 17.125 \\
 & 1.8639497 & 0 & 1.9406969 \\
 & 23 & 1 & 24 \\
4840 & 14.666667 & . & 14.66667 \\
 & 3.32666 & . & 3.32666 \\
 & 6 & 0 & 6 \\
\hline
\textbf{Total} & 19.826923 & 24.772727 & 21.297297 \\
 & 4.7432972 & 6.6111869 & 5.7855032 \\
 & 52 & 22 & 74 \\
\hline
\end{tabular}
\end{table}

In addition to the means, standard deviations, and frequencies for each weight–mileage cell, also reported are the summary statistics by weight, by mileage, and overall. For instance, the last row of the table reveals that the average mileage of domestic cars is 19.83 and that of foreign cars is 24.77—domestic cars yield poorer mileage than foreign cars. But we now see that domestic cars yield better gas mileage within weight class—the reason domestic cars yield poorer gas mileage is because they are, on average, heavier.

\subsection*{Example 3}

If we do not specify the statistics to be included in a table, \texttt{tabulate} reports the mean, standard deviation, and frequency. We can specify the statistics that we want to see using the \texttt{means}, \texttt{standard}, and \texttt{freq} options:
. tabulate wgtcat foreign, summarize(mpg) means

Means of Mileage (mpg)

<table>
<thead>
<tr>
<th>Car origin</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>Foreign</td>
</tr>
<tr>
<td>2530</td>
<td>2530</td>
</tr>
<tr>
<td>3300</td>
<td>3300</td>
</tr>
<tr>
<td>4070</td>
<td>4070</td>
</tr>
<tr>
<td>4840</td>
<td>4840</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Total</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>Foreign</td>
<td></td>
</tr>
<tr>
<td>2530</td>
<td>3300</td>
<td></td>
</tr>
<tr>
<td>4070</td>
<td>4840</td>
<td></td>
</tr>
</tbody>
</table>

When we specify one or more of the means, standard, and freq options, only those statistics are displayed. Thus, we could obtain a table containing just the means and standard deviations by typing means standard after the summarize(mpg) option. We can also suppress selected statistics by placing no in front of the option name. Another way of obtaining only the means and standard deviations is to add the nofreq option:

. tabulate wgtcat foreign, summarize(mpg) nofreq

Means and Standard Deviations of Mileage (mpg)

<table>
<thead>
<tr>
<th>Car origin</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>Foreign</td>
</tr>
<tr>
<td>2530</td>
<td>2530</td>
</tr>
<tr>
<td>3300</td>
<td>3300</td>
</tr>
<tr>
<td>4070</td>
<td>4070</td>
</tr>
<tr>
<td>4840</td>
<td>4840</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Total</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Domestic</td>
<td>Foreign</td>
<td></td>
</tr>
<tr>
<td>2530</td>
<td>3300</td>
<td></td>
</tr>
<tr>
<td>4070</td>
<td>4840</td>
<td></td>
</tr>
</tbody>
</table>

Description

`test` performs Wald tests of simple and composite linear hypotheses about the parameters of the most recently fit model.

`test` supports `svy` estimators (see [SVY] svy estimation), carrying out an adjusted Wald test by default in such cases. `test` can be used with `svy` estimation results, see [SVY] svy postestimation.

`testparm` provides a useful alternative to `test` that permits `varlist` rather than a list of coefficients (which is often nothing more than a list of variables), allowing the use of standard Stata notation, including ‘-’ and ‘*’, which are given the expression interpretation by `test`.

`test` and `testparm` perform Wald tests. For likelihood-ratio tests, see [R] lrtest. For Wald-type tests of nonlinear hypotheses, see [R] testnl. To display estimates for one-dimensional linear or nonlinear expressions of coefficients, see [R] lincom and [R] nlcom.

See [R] anova postestimation for additional `test` syntax allowed after `anova`.

See [MV] manova postestimation for additional `test` syntax allowed after `manova`.

Quick start

**Linear tests after single-equation models**

Joint test that the coefficients on `x1` and `x2` are equal to 0

```
test x1 x2
```

Joint test that coefficients on factor indicators `2.a` and `3.a` are equal to 0

```
test 2.a 3.a
```

Test that coefficients on indicators `2.a` and `3.a` are equal

```
test 2.a = 3.a
```

Joint test that coefficients on indicators `1.a`, `2.a`, and `3.a` are all equal

```
test (1.a=2.a) (1.a=3.a)
```

Same as above

```
test 1.a=2.a=3.a
```

Same as above, but add separate tests for each pairing

```
test 1.a=2.a=3.a, mtest
```

Same as above, but with `p`-values adjusted for multiple comparisons using Šidák’s method

```
test (1.a=2.a) (1.a=3.a), mtest(sidak)
```
Test that the sum of the coefficients for x1 and x2 is equal to 4
   test x1 + x2 = 4

Test the equality of two linear expressions involving coefficients on x1 and x2
   test 2*x1 = 3*x2

*Shorthand varlist notation*

Joint test that all coefficients on the indicators for a are equal to 0
   testparm i.a

Joint test that all coefficients on the indicators for a and b are equal to 0
   testparm i.a i.b

Joint test that all coefficients associated with the interaction of factor variables a and b are equal to 0
   testparm i.a#i.b

Joint test that the coefficients on all variables x* are equal to 0
   testparm x*

*Linear tests after multiple-equation models*

Joint test that the coefficient on x1 is equal to 0 in all equations
   test x1

Joint test that the coefficients for x1 and x2 are equal to 0 in equation y3
   test [y3]x1 [y3]x2

Test that the coefficients for x1 are equal in equations y1 and y3
   test [y1]x1=[y3]x1

Same as above
   test [y1=y3]: x1

Joint test of the equality of coefficients for x1 and x2 across equations y1 and y3
   test [y1=y3]: x1 x2

Add coefficients for x1 and x2 from equation y4 to test
   test [y1=y3=y4]: x1 x2

Test that all coefficients in the equation for y1 are equal to those in the equation for y2
   test [y1=y2]

Same as above, but only for coefficients on variables common to both equations
   test [y1=y2], common
Shorthand varlist notation

Joint test that all coefficients on the indicators for a are 0 in all equations
   testparm i.a

Joint test that all coefficients on the indicators for a are equal to each other in the first equation
   testparm i.a, equal

Same as above, but for the equation for y4
   testparm i.a, equal equation(y4)

Joint test that the coefficients on the indicators for a and b are equal to 0 in all equations
   testparm i.a i.b

Joint test that all coefficients associated with the interaction of factors a and b are 0
   testparm i.a#i.b

Syntax

Basic syntax

\texttt{test \ coeflist} \hspace{3.5cm} (Syntax 1)
\texttt{test \ exp=}exp[=...]
\hspace{3.5cm} (Syntax 2)
\texttt{test \ [eqno] \ [:: \ coeflist]} \hspace{3.5cm} (Syntax 3)
\texttt{test \ [eqno=}eqno[=...][:: \ coeflist]} \hspace{3.5cm} (Syntax 4)
\texttt{testparm \ varlist \ [\ , \ testparm\_options]} \hspace{3.5cm}

Full syntax

\texttt{test \ (spec) \ [(spec) \ ...] \ [\ , \ test\_options]} \hspace{3.5cm}
\texttt{testparm \ varlist \ [\ , \ testparm\_options]} \hspace{3.5cm}
\texttt{testparm \ options} \hspace{3.5cm}
\begin{tabular}{ll}
\texttt{equal} & hypothesize that the coefficients are equal to each other \\
\texttt{equation(eqno)} & specify equation name or number for which the hypothesis is tested \\
\texttt{nosvyadjust} & compute unadjusted Wald tests for survey results \\
\texttt{df(#)} & use $F$ distribution with # denominator degrees of freedom for the reference \
& distribution of the test statistic; for survey data, # specifies the design \
& degrees of freedom unless \texttt{nosvyadjust} is specified
\end{tabular}

\texttt{df(#)} does not appear in the dialog box.

\texttt{test\_options} \hspace{3.5cm}
\begin{tabular}{ll}
Options & Description \\
\texttt{m\_test[\ (opt)\ ]} & test each condition separately \\
\texttt{coef} & report estimated constrained coefficients \\
\texttt{accumulate} & test hypothesis jointly with previously tested hypotheses \\
\texttt{notest} & suppress the output \\
\texttt{common} & test only variables common to all the equations \\
\texttt{constant} & include the constant in coefficients to be tested \\
\texttt{nosvyadjust} & compute unadjusted Wald tests for survey results \\
\texttt{minimum} & perform test with the constant, drop terms until the test \
& becomes nonsingular, and test without the constant on the \
& remaining terms; highly technical \\
\texttt{matvlc(matname)} & save the variance–covariance matrix; programmer’s option \\
\texttt{df(#)} & use $F$ distribution with # denominator degrees of freedom for the reference \
& distribution of the test statistic; for survey data, # specifies the design \
& degrees of freedom unless \texttt{nosvyadjust} is specified
\end{tabular}

\texttt{matvlc(matname)} and \texttt{df(#)} do not appear in the dialog box.

\texttt{coeflist} and \texttt{varlist} may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.

\texttt{collect} is allowed with \texttt{test}; see [U] 11.1.10 Prefix commands.
Syntax 1 tests that coefficients are 0.
Syntax 2 tests that linear expressions are equal.
Syntax 3 tests that coefficients in eqno are 0.
Syntax 4 tests equality of coefficients between equations.

spec is one of

\[
\begin{align*}
    spec & = \text{coeflist} \\
    \text{coeflist} & = \exp = \exp [ = \exp ] \\
    & \text{[eqno]} [ : \text{coeflist}] \\
    & \text{[eqno1=eqno2 [ = \ldots ]]} [ : \text{coeflist}] \\
\end{align*}
\]

\[
\begin{align*}
    \text{coeflist} & = \text{coef} [ \text{coef} \ldots ] \\
    & \text{[eqno]coef} [ [ \text{eqno}]coef\ldots ] \\
    & \text{[eqno]} _b[\text{coef}] [ [ \text{eqno}] _b[\text{coef}]\ldots ] \\
\end{align*}
\]

\[
\begin{align*}
    \exp & = \text{a linear expression containing} \\
    & \text{coef} \\
    & _b[\text{coef}] \\
    & _b[\text{eqno}:\text{coef}] \\
    & \text{[eqno]coef} \\
    & \text{[eqno]} _b[\text{coef}] \\
\end{align*}
\]

eqno is

\[
\begin{align*}
    & \# \# \\
    & \text{name} \\
\end{align*}
\]

coeff identifies a coefficient in the model. coeff is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [U] 11.4.3 Factor variables. coeff may contain time-series operators; see [U] 11.4.4 Time-series varlists.

Distinguish between [], which are to be typed, and [], which indicate optional arguments.

Although not shown in the syntax diagram, parentheses around spec are required only with multiple specifications. Also, the diagram does not show that test may be called without arguments to redisplay the results from the last test.

anova and manova (see [R] anova and [MV] manova) allow the test syntax above plus more (see [R] anova postestimation for test after anova; see [MV] manova postestimation for test after manova).

Options for testparm

equal tests that the variables appearing in varlist, which also appear in the previously fit model, are equal to each other rather than jointly equal to zero.
equation(eqno) is relevant only for multiple-equation models, such as mvreg, mlogit, and heckman.

It specifies the equation for which the all-zero or all-equal hypothesis is tested. equation(#1) specifies that the test be conducted regarding the first equation #1. equation(price) specifies that the test concern the equation named price.

nosvyadjust is for use with svy estimation commands; see [SVY] svy estimation. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as $W/k \sim F(k, d)$ rather than as $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$, where $k =$ the dimension of the test and $d =$ the total number of sampled PSUs minus the total number of strata. When the df() option is used, it will override the default design degrees of freedom.

The following option is available with testparm but is not shown in the dialog box:

df(#) specifies that the $F$ distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. The default is to use e(df_r) degrees of freedom or the $\chi^2$ distribution if e(df_r) is missing. With survey data, # is the design degrees of freedom unless nosvyadjust is specified.

### Options for test

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtest[opt]</td>
<td>specifies that tests be performed for each condition separately. opt specifies the method for adjusting $p$-values for multiple testing. Valid values for opt are</td>
</tr>
<tr>
<td>bonferroni</td>
<td>Bonferroni’s method</td>
</tr>
<tr>
<td>holm</td>
<td>Holm’s method</td>
</tr>
<tr>
<td>sidak</td>
<td>Šidák’s method</td>
</tr>
<tr>
<td>noadjust</td>
<td>no adjustment is to be made</td>
</tr>
</tbody>
</table>

Specifying mtest without an argument is equivalent to mtest(noadjust).

coeff specifies that the constrained coefficients be displayed.

accumulate allows a hypothesis to be tested jointly with the previously tested hypotheses.

notest suppresses the output. This option is useful when you are interested only in the joint test of several hypotheses, specified in a subsequent call of test, accumulate.

common specifies that when you use the [eqno1=eqno2[=...]] form of spec, the variables common to the equations eqno1, eqno2, etc., be tested. The default action is to complain if the equations have variables not in common.

constant specifies that _cons be included in the list of coefficients to be tested when using the [eqno1=eqno2[=...]] or [eqno] forms of spec. The default is not to include _cons.

nosvyadjust is for use with svy estimation commands; see [SVY] svy estimation. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as $W/k \sim F(k, d)$ rather than as $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$, where $k =$ the dimension of the test and $d =$ the total number of sampled PSUs minus the total number of strata. When the df() option is used, it will override the default design degrees of freedom.
minimum is a highly technical option. It first performs the test with the constant added. If this test is singular, coefficients are dropped until the test becomes nonsingular. Then the test without the constant is performed with the remaining terms.

The following options are available with test but are not shown in the dialog box:

- **matvlc(matname)**, a programmer’s option, saves the variance–covariance matrix of the linear combinations involved in the suite of tests. For the test of the linear constraints \( Lb = c \), matname contains \( LVL' \), where \( V \) is the estimated variance–covariance matrix of \( b \).

- **df(#)** specifies that the \( F \) distribution with \( # \) denominator degrees of freedom be used for the reference distribution of the test statistic. The default is to use \( e(df_r) \) degrees of freedom or the \( \chi^2 \) distribution if \( e(df_r) \) is missing. With survey data, \( # \) is the design degrees of freedom unless nosvyadjust is specified.

**Remarks and examples**

Remarks are presented under the following headings:

- Introductory examples
- Special syntaxes after multiple-equation estimation
- Constrained coefficients
- Multiple testing

**Introductory examples**

- **test** performs \( F \) or \( \chi^2 \) tests of linear restrictions applied to the most recently fit model (for example, **regress** or **svy: regress** in the linear regression case; **logit**, **stcox**, **svy: logit**,... in the single-equation maximum-likelihood case; and **mlogit**, **mvreg**, **streg**, ... in the multiple-equation maximum-likelihood case). test may be used after any estimation command, although for maximum likelihood techniques, test produces a Wald test that depends only on the estimate of the covariance matrix—you may prefer to use the more computationally expensive likelihood-ratio test; see [U] 20 Estimation and postestimation commands and [R] lrtest.

There are several variations on the syntax for test. The second syntax,

- **test exp=exp[=...]**

is allowed after any form of estimation. After fitting a model of **depvar** on \( x1, x2, \) and \( x3 \), typing **test x1+x2=x3** tests the restriction that the coefficients on \( x1 \) and \( x2 \) sum to the coefficient on \( x3 \). The expressions can be arbitrarily complicated; for instance, typing **test x1+2*(x2+x3)=x2+3*x3** is the same as typing **test x1+x2=x3**.

As a convenient shorthand, test also allows you to specify equality for multiple expressions; for example, **test x1+x2 = x3+x4 = x5+x6** tests that the three specified pairwise sums of coefficients are equal.

- **test** understands that when you type \( x1 \), you are referring to the coefficient on \( x1 \). You could also more explicitly type **test _b[x1]+_b[x2]=_b[x3]**; or you could **test _coef[x1]+_coef[x2]=_coef[x3]**, or **test [#1]x1+[#1]x2=[#1]x3**, or many other things because there is more than one way to refer to an estimated coefficient; see [U] 13.5 Accessing coefficients and standard errors. The shorthand involves less typing. On the other hand, you must be more explicit after estimation of multiple-equation models because there may be more than one coefficient associated
with an independent variable. You might type, for instance, test \([#2]x1+[#2]x2= [#2]x3\) to test the constraint in equation 2 or, more readably, test \([ford]x1+ [ford]x2= [ford]x3\), meaning that Stata will test the constraint on the equation corresponding to \(ford\), which might be equation 2. \(ford\) would be an equation name after, say, \(sureg\), or, after \(mlogit\), \(ford\) would be one of the outcomes. For \(mlogit\), you could also type test \([2]x1+[2]x2=[2]x3\) — note the lack of the \# — meaning not equation 2, but the equation corresponding to the numeric outcome 2. You can even test constraints across equations: test \([ford]x1+[ford]x2= [buick]x3\).

The syntax

\[
\text{test coeflist}
\]

is available after all estimation commands and is a convenient way to test that multiple coefficients are zero following estimation. A \textit{coeflist} can simply be a list of variable names,

\[
\text{test varname [ varname ... ]}
\]

and it is most often specified that way. After you have fit a model of \textit{depvar} on \textit{x1}, \textit{x2}, and \textit{x3}, typing \text{test} \textit{x1} \textit{x3} tests that the coefficients on \textit{x1} and \textit{x3} are jointly zero. After multiple-equation estimation, this would test that the coefficients on \textit{x1} and \textit{x3} are zero in all equations that contain them. You can also be more explicit and type, for instance, \text{test} \textit{[ford]} \textit{x1} \textit{[ford]} \textit{x3} to test that the coefficients on \textit{x1} and \textit{x3} are zero in the equation for \textit{ford}.

In the multiple-equation case, there are more alternatives. You could also test that the coefficients on \textit{x1} and \textit{x3} are zero in the equation for \textit{ford} by typing \text{test} \textit{[ford]}: \textit{x1} \textit{x3}. You could test that all coefficients except the coefficient on the constant are zero in the equation for \textit{ford} by typing \text{test} \textit{[ford]}: \textit{x1} \textit{x3}. You could test that the coefficients on \textit{x1} and \textit{x3} in the equation for \textit{ford} are equal to the corresponding coefficients in the equation corresponding to \textit{buick} by typing \text{test} \textit{[ford=buick]}: \textit{x1} \textit{x3}. You could test that all the corresponding coefficients except the constant in three equations are equal by typing \text{test} \textit{[ford=buick=volvo]}.

\texttt{testparm} is much like the first syntax of \texttt{test}. Its usefulness will be demonstrated below.

The examples below use \texttt{regress}, but what is said applies equally after any single-equation estimation command (such as \texttt{logistic}). It also applies after multiple-equation estimation commands as long as references to coefficients are qualified with an equation name or number in square brackets placed before them. The convenient syntaxes for dealing with tests of many coefficients in multiple-equation models are demonstrated in \textit{Special syntaxes after multiple-equation estimation} below.

\textbf{Example 1: Testing for a single coefficient against zero}

We have 1980 census data on the 50 states recording the birth rate in each state (\textit{brate}), the median age (\textit{medage}), and the region of the country in which each state is located.

The \textit{region} variable is 1 if the state is in the Northeast, 2 if the state is in the North Central, 3 if the state is in the South, and 4 if the state is in the West. We estimate the following regression:
. use https://www.stata-press.com/data/r18/census3
(1980 Census data by state)
. regress brate medage c.medage#c.medage i.region

The $F$ statistic with 1 numerator and 44 denominator degrees of freedom is 3.47. The significance level of the test is 6.91%—we can reject the hypothesis at the 10% level but not at the 5% level.

This result from test is identical to one presented in the output from regress, which indicates that the $t$ statistic on the 3.region coefficient is 1.863 and that its significance level is 0.069. The $t$ statistic presented in the output can be used to test the hypothesis that the corresponding coefficient is zero, although it states the test in slightly different terms. The $F$ distribution with 1 numerator degree of freedom is, however, identical to the $t^2$ distribution. We note that $1.863^2 \approx 3.47$ and that the significance levels in each test agree, although one extra digit is presented by the test command.

### Technical note

After all estimation commands, including those that use the maximum likelihood method, the test that one variable is zero is identical to that reported by the command’s output. The tests are performed in the same way—using the estimated covariance matrix—and are known as Wald tests. If the estimation command reports significance levels and confidence intervals using $z$ rather than $t$ statistics, test reports results using the $\chi^2$ rather than the $F$ statistic.
Example 2: Testing the value of a single coefficient

If that were all test could do, it would be useless. We can use test, however, to perform other tests. For instance, we can test the hypothesis that the coefficient on 2.region is 21 by typing

```
. test 2.region=21
   ( 1) 2.region = 21
    F( 1, 44) = 1.99
    Prob > F = 0.1654
```

We find that we cannot reject that hypothesis, or at least we cannot reject it at any significance level below 16.5%.

Example 3: Testing the equality of two coefficients

The previous test is useful, but we could almost as easily perform it by hand using the results presented in the regression output if we were well read on our statistics. We could type

```
. display Ftail(1,44,((_coef[2.region]-21)/4.252068)^2)
   .16544873
```

So, now let's test something a bit more difficult: whether the coefficient on 2.region is the same as the coefficient on 4.region:

```
. test 2.region=4.region
   ( 1) 2.region - 4.region = 0
    F( 1, 44) = 2.84
    Prob > F = 0.0989
```

We find that we cannot reject the equality hypothesis at the 5% level, but we can at the 10% level.

Example 4

When we tested the equality of the 2.region and 4.region coefficients, Stata rearranged our algebra. When Stata displayed its interpretation of the specified test, it indicated that we were testing whether 2.region minus 4.region is zero. The rearrangement is innocuous and, in fact, allows Stata to perform much more complicated algebra, for instance,

```
   ( 1) 2.region - 3.region = 0
    F( 1, 44) = 5.06
    Prob > F = 0.0295
```

Although we requested what appeared to be a lengthy hypothesis, once Stata simplified the algebra, it realized that all we wanted to do was test whether the coefficient on 2.region is the same as the coefficient on 3.region.

Technical note

Stata's ability to simplify and test complex hypotheses is limited to linear hypotheses. If you attempt to test a nonlinear hypothesis, you will be told that it is not possible:

```
. test 2.region/3.region=2.region+3.region
   not possible with test
r(131);
```

To test a nonlinear hypothesis, see [R] testnl.
Example 5: Testing joint hypotheses

The real power of `test` is demonstrated when we test joint hypotheses. Perhaps we wish to test whether the region variables, taken as a whole, are significant by testing whether the coefficients on `2.region, 3.region,` and `4.region` are simultaneously zero. `test` allows us to specify multiple conditions to be tested, each embedded within parentheses.

```
. test (2.region=0) (3.region=0) (4.region=0)
   ( 1) 2.region = 0
   ( 2) 3.region = 0
   ( 3) 4.region = 0
   F( 3, 44) =  8.85
   Prob > F =  0.0001
```

test displays the set of conditions and reports an $F$ statistic of 8.85. `test` also reports the degrees of freedom of the test to be 3, the “dimension” of the hypothesis, and the residual degrees of freedom, 44. The significance level of the test is close to 0, so we can strongly reject the hypothesis of no difference between the regions.

An alternative method to specify simultaneous hypotheses uses the convenient shorthand of conditions with multiple equality operators.

```
. test 2.region=3.region=4.region=0
   ( 1) 2.region - 3.region = 0
   ( 2) 2.region - 4.region = 0
   ( 3) 2.region = 0
   F( 3, 44) =  8.85
   Prob > F =  0.0001
```

Technical note

Another method to test simultaneous hypotheses is to specify a `test` for each constraint and accumulate it with the previous constraints:

```
. test 2.region=0
   ( 1) 2.region = 0
   F( 1, 44) = 12.45
   Prob > F = 0.0010
.
. test 3.region=0, accumulate
   ( 1) 2.region = 0
   ( 2) 3.region = 0
   F( 2, 44) =  6.42
   Prob > F =  0.0036
.
. test 4.region=0, accumulate
   ( 1) 2.region = 0
   ( 2) 3.region = 0
   ( 3) 4.region = 0
   F( 3, 44) =  8.85
   Prob > F =  0.0001
```

We tested the hypothesis that the coefficient on `2.region` was zero by typing `test 2.region=0`. We then tested whether the coefficient on `3.region` was also zero by typing `test 3.region=0, accumulate`. The `accumulate` option told Stata that this was not the start of a new test but a continuation of a previous one. Stata responded by showing us the two equations and reporting an $F$ statistic of 6.42. The significance level associated with those two coefficients being zero is 0.36%.
When we added the last constraint test 4.region=0, accumulate, we discovered that the three region variables are significant. If all we wanted was the overall significance and we did not want to bother seeing the interim results, we could have used the notest option:

```
.test 2.region=0, notest
( 1) 2.region = 0
.test 3.region=0, accumulate notest
( 1) 2.region = 0
( 2) 3.region = 0
.test 4.region=0, accumulate
( 1) 2.region = 0
( 2) 3.region = 0
( 3) 4.region = 0
F( 3, 44) = 8.85
Prob > F = 0.0001
```

Example 6: Quickly testing coefficients against zero

Because tests that coefficients are zero are so common in applied statistics, the test command has a more convenient syntax to accommodate this case:

```
.test 2.region 3.region 4.region
( 1) 2.region = 0
( 2) 3.region = 0
( 3) 4.region = 0
F( 3, 44) = 8.85
Prob > F = 0.0001
```

Example 7: Specifying varlists

We will now show how to use testparm. In its first syntax, test accepts a list of variable names but not a varlist.

```
.test i(2/4).region
i not found
r(111);
```

In the varlist, i(2/4).region means all the level variables from 2.region through 4.region, yet we received an error. test does not actually understand varlists, but testparm does. In fact, it understands only varlists.

```
.testparm i(2/4).region
( 1) 2.region = 0
( 2) 3.region = 0
( 3) 4.region = 0
F( 3, 44) = 8.85
Prob > F = 0.0001
```

Another way to test all the region variables is to type testparm i.region.

That testparm accepts varlists has other advantages that do not involve factor variables. Suppose that we have a dataset that has dummy variables reg2, reg3, and reg4, rather than the categorical variable region.
. use https://www.stata-press.com/data/r18/census4
(Census data on birthrate, median age)
. regress brate medage c.medage#c.medage reg2 reg3 reg4
(output omitted)
. test reg2-reg4
   - not found
   r(111);

In a varlist, reg2-reg4 means variables reg2 and reg4 and all the variables between, yet we received an error. test is confused because the - has two meanings: it means subtraction in an expression and “through” in a varlist. Similarly, ‘*’ means “any set of characters” in a varlist and multiplication in an expression. testparm avoids this confusion—it allows only a varlist.

. testparm reg2-reg4
   ( 1) reg2 = 0
   ( 2) reg3 = 0
   ( 3) reg4 = 0
   F( 3, 44) = 8.85
   Prob > F = 0.0001

   testparm has another advantage. We have five variables in our dataset that start with the characters reg: region, reg1, reg2, reg3, and reg4. reg* thus means those five variables:

   . describe reg*
   Variable name   Storage type   Display format   Value label   Variable label
   region          byte       %8.0g   region          Census region
   reg1            byte       %9.0g   Region: NE
   reg2            byte       %9.0g   Region: N Cntrl
   reg3            byte       %9.0g   Region: South
   reg4            byte       %9.0g   Region: West

   We cannot type test reg* because, in an expression, ‘*’ means multiplication, but here is what would happen if we attempted to test all the variables that begin with reg:

   . test region reg1 reg2 reg3 reg4
      region not found
      r(111);

   The variable region was not included in our model, so it was not found. However, with testparm,

   . testparm reg*
      ( 1) reg2 = 0
      ( 2) reg3 = 0
      ( 3) reg4 = 0
      F( 3, 44) = 8.85
      Prob > F = 0.0001

   That is, testparm took reg* to mean all variables that start with reg that were in our model.

Technical note

   Actually, reg* means what it always does—all variables in our dataset that begin with reg—in this case, region reg1 reg2 reg3 reg4. testparm just ignores any variables you specify that are not in the model.
Example 8: Replaying the previous test

We just used `test` (testparm, actually, but it does not matter) to test the hypothesis that `reg2`, `reg3`, and `reg4` are jointly zero. We can review the results of our last test by typing `test` without arguments:

```
. test
   ( 1) reg2 = 0
   ( 2) reg3 = 0
   ( 3) reg4 = 0
   F( 3, 44) = 8.85
   Prob > F = 0.0001
```

Technical note

`test` does not care how we build joint hypotheses; we may freely mix different forms of syntax. (We can even start with `testparm`, but we cannot use it thereafter because it does not have an `accumulate` option.)

Say that we type `test reg2 reg3 reg4` to test that the coefficients on our region dummies are jointly zero. We could then add a fourth constraint, say, that `medage = 100`, by typing `test medage=100`, accumulate. Or, if we had introduced the `medage` constraint first (our first `test` command had been `test medage=100`), we could then add the region dummy test by typing `test reg2 reg3 reg4, accumulate` or `test (reg2=0) (reg3=0) (reg4=0), accumulate`.

Remember that all previous tests are cleared when we do not specify the `accumulate` option. No matter what tests we performed in the past, if we type `test medage c.medage#c.medage`, omitting the `accumulate` option, we would test that `medage` and `c.medage#c.medage` are jointly zero.

Example 9: Testing the equality of multiple coefficients

Let's return to our `census3.dta` dataset and test the hypothesis that all the included regions have the same coefficient—that the Northeast is significantly different from the rest of the nation:

```
. use https://www.stata-press.com/data/r18/census3
(1980 Census data by state)
. regress brate medage c.medage#c.medage i.region
(output omitted)
. test 2.region=3.region=4.region
   ( 1) 2.region - 3.region = 0
   ( 2) 2.region - 4.region = 0
   F( 2, 44) = 8.23
   Prob > F = 0.0009
```

We find that they are not all the same. The syntax `2.region=3.region=4.region` with multiple `=` operators is just a convenient shorthand for typing that the first expression equals the second expression and that the first expression equals the third expression.

```
. test (2.region=3.region) (2.region=4.region)
```

We performed the test for equality of the three regions by imposing two constraints: region 2 has the same coefficient as region 3, and region 2 has the same coefficient as region 4. Alternatively, we could have tested that the coefficients on regions 2 and 3 are the same and that the coefficients on regions 3 and 4 are the same. We would obtain the same results in either case.

To test for equality of the three regions, we might, likely by mistake, type equality constraints for all pairs of regions:
Equality of regions 2 and 3 and of regions 2 and 4, however, implies equality of regions 3 and 4. **test** recognized that the last constraint is implied by the other constraints and hence dropped it.

---

### Example 10

The test for the equality of the regions is also possible with the **testparm** command. When we include the equal option, **testparm** tests that the coefficients of all the variables specified are equal:

```stata
.testparm i(2/4).region, equal
( 1) - 2.region + 3.region = 0
( 2) - 2.region + 4.region = 0
F( 2, 44) = 8.23
Prob > F = 0.0009
```

We can also obtain the equality test by accumulating single equality tests.

```stata
.test 2.region=3.region, notest
( 1) 2.region - 3.region = 0
.test 2.region=4.region, accum
( 1) 2.region - 3.region = 0
( 2) 2.region - 4.region = 0
F( 2, 44) = 8.23
Prob > F = 0.0009
```

---

### Technical note

Generally, Stata uses `=` for assignment, as in `gen newvar = exp`, and `==` as the operator for testing equality in expressions. For your convenience, **test** allows both `=` and `==` to be used.

---

If we specify a set of inconsistent constraints, **test** will tell us by dropping the constraint or constraints that led to the inconsistency. For instance, let’s **test** that the coefficients on region 2 and region 4 are the same, add the test that the coefficient on region 2 is 20, and finally add the test that the coefficient on region 4 is 21:

```stata
.test (2.region=4.region) (2.region=20) (4.region=21)
( 1) 2.region - 4.region = 0
( 2) 2.region = 20
( 3) 4.region = 21
Constraint 2 dropped
F( 2, 44) = 1.82
Prob > F = 0.1737
```

test informed us that it was dropping constraint 2. All three equations cannot be simultaneously true, so **test** drops whatever it takes to get back to something that makes sense.
Special syntaxes after multiple-equation estimation

Everything said above about tests after single-equation estimation applies to tests after multiple-equation estimation, as long as you remember to specify the equation name. To demonstrate, let’s estimate a seemingly unrelated regression by using `sureg`; see [R] `sureg`.

```stata
use https://www.stata-press.com/data/r18/auto
(s1978 automobile data)
sureg (price foreign mpg displ) (weight foreign length)
```

Seemingly unrelated regression

To test the significance of `foreign` in the `price` equation, we could type

```stata
.test [price]foreign
( 1) [price]foreign = 0
   chi2( 1) = 19.89
   Prob > chi2 = 0.0000
```

which is the same result reported by `sureg`: $4.46^2 \approx 19.89$. To test `foreign` in both equations, we could type

```stata
.test [price]foreign [weight]foreign
( 1) [price]foreign = 0
( 2) [weight]foreign = 0
   chi2( 2) = 31.61
   Prob > chi2 = 0.0000
```
or

```stata
.test foreign
( 1) [price]foreign = 0
( 2) [weight]foreign = 0
   chi2( 2) = 31.61
   Prob > chi2 = 0.0000
```

This last syntax—typing the variable name by itself—tests the coefficients in all equations in which they appear. The variable `length` appears in only the `weight` equation, so typing
yields the same result as typing \texttt{test [weight]length}. We may also specify a linear expression rather than a list of coefficients:

\begin{verbatim}
    . test mpg=displ
    ( 1) \{price\}mpg - \{price\}displacement = 0
        chisq( 1) =  4.85
        Prob > chisq = 0.0277
\end{verbatim}

or

\begin{verbatim}
    . test \{price\}mpg = \{price\}displ
    ( 1) \{price\}mpg - \{price\}displacement = 0
        chisq( 1) =  4.85
        Prob > chisq = 0.0277
\end{verbatim}

A variation on this syntax can be used to test cross-equation constraints:

\begin{verbatim}
    . test \{price\}foreign = \{weight\}foreign
    ( 1) \{price\}foreign - \{weight\}foreign = 0
        chisq( 1) = 23.07
        Prob > chisq = 0.0000
\end{verbatim}

Typing an equation name in square brackets by itself tests all the coefficients except the intercept in that equation:

\begin{verbatim}
    . test \{price\}
    ( 1) \{price\}foreign = 0
    ( 2) \{price\}mpg = 0
    ( 3) \{price\}displacement = 0
        chisq( 3) = 49.64
        Prob > chisq = 0.0000
\end{verbatim}

Typing an equation name in square brackets, a colon, and a list of variable names tests those variables in the specified equation:

\begin{verbatim}
    . test \{price\}: foreign displ
    ( 1) \{price\}foreign = 0
    ( 2) \{price\}displacement = 0
        chisq( 2) = 25.19
        Prob > chisq = 0.0000
\end{verbatim}

\texttt{test [eqname\_1=eqname\_2]} tests that all the coefficients in the two equations are equal. We cannot use that syntax here because there are different variables in the model:

\begin{verbatim}
    . test \{price\}=\{weight\}
    variables differ between equations
\end{verbatim}

(r(111));

The \texttt{common} option specifies a test of the equality coefficients common to the equations \texttt{price} and \texttt{weight},

\begin{verbatim}
    . test \{price\}=\{weight\}
    \texttt{common} option
\end{verbatim}

(r(111));
By default, `test` does not include the constant, the coefficient of the constant variable `_cons`, in the test. The `cons` option specifies that the constant be included.

```
. test [price=weight], common cons
  ( 1) [price]foreign - [weight]foreign = 0
   chi2( 1) = 23.07
   Prob > chi2 = 0.0000
```

We can also use a modification of this syntax with the model if we also type a colon and the names of the variables we want to test:

```
. test [price=weight]: foreign
  ( 1) [price]foreign - [weight]foreign = 0
   chi2( 1) = 23.07
   Prob > chi2 = 0.0000
```

We have only one variable in common between the two equations, but if there had been more, we could have listed them.

Finally, a simultaneous test of multiple constraints may be specified just as after single-equation estimation.

```
. test ([price]: foreign) ([weight]: foreign)
  ( 1) [price]foreign = 0
  ( 2) [weight]foreign = 0
   chi2( 2) = 31.61
   Prob > chi2 = 0.0000
```

test can also test for equality of coefficients across more than two equations. For instance, `test [eq1=eq2=eq3]` specifies a test that the coefficients in the three equations `eq1`, `eq2`, and `eq3` are equal. This requires that the same variables be included in the three equations. If some variables are entered only in some of the equations, you can type `test [eq1=eq2=eq3]`, common to test that the coefficients of the variables common to all three equations are equal. Alternatively, you can explicitly list the variables for which equality of coefficients across the equations is to be tested. For instance, `test [eq1=eq2=eq3]: time money` tests that the coefficients of the variables `time` and `money` do not differ between the equations.

Technical note

`test [eq1=eq2=eq3], common` tests the equality of the coefficients common to all equations, but it does not test the equality of all common coefficients. Consider the case where

```
eq1 contains the variables var1 var2 var3
eq2 contains the variables var1 var2 var4
eq3 contains the variables var1 var3 var4
```

Obviously, only `var1` is common to all three equations. Thus `test [eq1=eq2=eq3], common` tests that the coefficients of `var1` do not vary across the equations, so it is equivalent to `test [eq1=eq2=eq3] : var1`. To perform a test of the coefficients of variables common to two equations, you could explicitly list the constraints to be tested,

```
. test ([eq1=eq2=eq3]:var1) ([eq1=eq2]:var2) ([eq1=eq3]:var3) ([eq2=eq3]:var4)
```
or use `test` with the `accumulate` option, and maybe also with the `notest` option, to form the appropriate joint hypothesis:

```
. test [eq1=eq2], common notest
. test [eq1=eq3], common accumulate notest
. test [eq2=eq3], common accumulate
```

## Constrained coefficients

If the test indicates that the data do not allow you to conclude that the constraints are not satisfied, you may want to inspect the constrained coefficients. The `coef` option specified that the constrained results, estimated by GLS, are shown.

```
. test [price=weight], common coef
( 1) [price]foreign - [weight]foreign = 0
    ch2( 1) = 23.07
    Prob > ch2 = 0.0000
```

### Constrained coefficients

|                  | Coefficient | Std. err. | z    | P>|z|  | [95% conf. interval] |
|------------------|-------------|-----------|------|-----|---------------------|
| price            |             |           |      |     |                     |
| foreign          | -216.4015   | 74.06083  | -2.92| 0.003| -361.558 -71.2449   |
| mpg              | -121.5717   | 58.36972  | -2.08| 0.037| -235.9742 -7.169116 |
| displacement     | 7.632566    | 3.681114  | 2.07 | 0.038| .4177148 14.84742  |
| _cons            | 7312.856    | 1834.034  | 3.99 | 0.000| 3718.215 10907.5   |
| weight           |             |           |      |     |                     |
| foreign          | -216.4015   | 74.06083  | -2.92| 0.003| -361.558 -71.2449   |
| length           | 30.34875    | 1.534815  | 19.77| 0.000| 27.34057 33.35693  |
| _cons            | -2619.719   | 302.6632  | -8.66| 0.000| -3212.928 -2026.51 |

The constrained coefficient of `foreign` is $-216.40$ with standard error 74.06 in equations `price` and `weight`. The other coefficients and their standard errors are affected by imposing the equality constraint of the two coefficients of `foreign` because the unconstrained estimates of these two coefficients were correlated with the estimates of the other coefficients.

### Technical note

The two-step constrained coefficients $b_c$ displayed by `test, coef` are asymptotically equivalent to the one-stage constrained estimates that are computed by specifying the constraints during estimation using the `constraint()` option of estimation commands (Gouriéroux and Monfort 1995, chap. 10). Generally, one-step constrained estimates have better small-sample properties. For inspection and interpretation, however, two-step constrained estimates are a convenient alternative. Moreover, some estimation commands (for example, `stcox`, many `xt` estimators) do not have a `constraint()` option.
Multiple testing

When performing the test of a joint hypothesis, you might want to inspect the underlying 1-degree-of-freedom hypotheses. Which constraint “is to blame”? `test` displays the univariate as well as the simultaneous test if the `mtest` option is specified. For example,

```
. test [price=weight], common cons mtest
  ( 1) [price]foreign - [weight]foreign = 0
  ( 2) [price]_cons - [weight]_cons = 0

     | chi2    df  p > chi2
  -------------  -------  -------
(1)        23.07 1.0000
(2)        11.17 1.0000*
All       51.23 2.0000

* Unadjusted p-values
```

Both coefficients seem to contribute to the highly significant result. The 1-degree-of-freedom test shown here is identical to those if `test` had been invoked to test just this simple hypotheses. There is, of course, a real risk in inspecting these simple hypotheses. Especially in high-dimensional hypotheses, you may easily find one hypothesis that happens to be significant. Multiple testing procedures are designed to provide some safeguard against this risk. $p$-values of the univariate hypotheses are modified so that the probability of falsely rejecting one of the null hypotheses is bounded. `test` provides the methods based on Bonferroni, Šidák, and Holm.

```
. test [price=weight], common cons mtest(b)
  ( 1) [price]foreign - [weight]foreign = 0
  ( 2) [price]_cons - [weight]_cons = 0

     | chi2    df  p > chi2
  -------------  -------  -------
(1)        23.07 1.0000*
(2)        11.17 1.0000*
All       51.23 2.0000

* Bonferroni-adjusted p-values
```

Stored results

test and testparm store the following in `r()`:

Scalars

- `r(p)`: two-sided $p$-value
- `r(F)`: $F$ statistic
- `r(df)`: test constraints degrees of freedom
- `r(df_r)`: residual degrees of freedom
- `r(chi2)`: $\chi^2$
- `r(ss)`: sum of squares (test)
- `r(rss)`: residual sum of squares
- `r(df_r)`: 1 if constraints were dropped, 0 otherwise

Macros

- `r(mtmeth)`: method of adjustment for multiple testing
- `r(mtest)`: multiple test results

$r(ss)$ and $r(rss)$ are defined only when `test` is used for testing effects after `anova`. 
Methods and formulas

**test** and **testparm** perform Wald tests. Let the estimated coefficient vector be \( \mathbf{b} \) and the estimated variance–covariance matrix be \( \mathbf{V} \). Let \( \mathbf{Rb} = \mathbf{r} \) denote the set of \( q \) linear hypotheses to be tested jointly.

The Wald test statistic is (Judge et al. 1985, 20–28)

\[
W = (\mathbf{Rb} - \mathbf{r})' (\mathbf{RVR}')^{-1} (\mathbf{Rb} - \mathbf{r})
\]

If the estimation command reports its significance levels using \( Z \) statistics, a \( \chi^2 \) distribution with \( q \) degrees of freedom,

\[
W \sim \chi^2_q
\]

is used for computation of the significance level of the hypothesis test.

If the estimation command reports its significance levels using \( t \) statistics with \( d \) degrees of freedom, an \( F \) statistic,

\[
F = \frac{1}{q} W
\]

is computed, and an \( F \) distribution with \( q \) numerator degrees of freedom and \( d \) denominator degrees of freedom computes the significance level of the hypothesis test.

The two-step constrained estimates \( \mathbf{b}_c \) displayed by **test** with the **coef** option are the GLS estimates of the unconstrained estimates \( \mathbf{b} \) subject to the specified constraints \( Rb = \mathbf{c} \) (Gouri´eroux and Monfort 1995, chap. 10),

\[
\mathbf{b}_c = \mathbf{b} - \mathbf{VR}'(\mathbf{RVR}')^{-1}(\mathbf{Rb} - \mathbf{r})
\]

with variance–covariance matrix

\[
\mathbf{V}_c = \mathbf{V} - \mathbf{VR}'(\mathbf{RVR}')^{-1}\mathbf{RV}
\]

If **test** displays a Wald test for joint (simultaneous) hypotheses, it can also display all 1-degree-of-freedom tests, with \( p \)-values adjusted for multiple testing. Let \( p_1, p_2, \ldots, p_k \) be the unadjusted \( p \)-values of these 1-degree-of-freedom tests. The Bonferroni-adjusted \( p \)-values are defined as \( p_i^b = \min(1, kp_i) \). The Šidák-adjusted \( p \)-values are \( p_i^s = 1 - (1 - p_i)^k \). Holm’s method for adjusting \( p \)-values is defined as \( p_i^h = \min(1, k_ip_i) \), where \( k_i \) is the number of \( p \)-values at least as large as \( p_i \). Note that \( p_i^h < p_i^b \), reflecting that Holm’s method is strictly less conservative than the widely used Bonferroni method.

If **test** is used after a **svy** command, it carries out an adjusted Wald test—this adjustment should not be confused with the adjustment for multiple testing. Both adjustments may actually be combined. Specifically, the survey adjustment uses an approximate \( F \) statistic \((d-k+1)W/(kd)\), where \( W \) is the Wald test statistic, \( k \) is the dimension of the hypothesis test, and \( d = \) the total number of sampled PSUs minus the total number of strata. Under the null hypothesis, \((d-k+1)F/(kd) \sim F(k, d-k+1)\), where \( F(k, d-k+1) \) is an \( F \) distribution with \( k \) numerator degrees of freedom and \( d-k+1 \) denominator degrees of freedom. If **nosvyadjust** is specified, the \( p \)-value is computed using \( W/k \sim F(k, d) \).

See Korn and Graubard (1990) for a detailed description of the Bonferroni adjustment technique and for a discussion of the relative merits of it and of the adjusted and unadjusted Wald tests.
Acknowledgment

The `svy` adjustment code was adopted from another command developed in collaboration with John L. Eltinge of the United States Census Bureau.

testnl — Test nonlinear hypotheses after estimation

Description

testnl tests (linear or nonlinear) hypotheses about the estimated parameters from the most recently fit model.

testnl produces Wald-type tests of smooth nonlinear (or linear) hypotheses about the estimated parameters from the most recently fit model. The \( p \)-values are based on the delta method, an approximation appropriate in large samples.

testnl can be used with \texttt{svy} estimation results; see [SVY] \texttt{svy postestimation}.

The format \((\texttt{exp}_1=\texttt{exp}_2=\texttt{exp}_3, \ldots)\) for a simultaneous-equality hypothesis is just a convenient shorthand for a list \((\texttt{exp}_1=\texttt{exp}_2) (\texttt{exp}_1=\texttt{exp}_3), \text{ etc.}\)

testnl may also be used to test linear hypotheses. \texttt{test} is faster if you want to test only linear hypotheses; see [R] \texttt{test}. testnl is the only option for testing linear and nonlinear hypotheses simultaneously.

Quick start

After single-equation models

Test that the product of the coefficients for \(x_1\) and \(x_2\) is equal to 4
\[
\text{testnl } _b[x_1]*_b[x_2] = 4
\]

Test that the ratio of the indicators for the factor variable \(a = 2\) and \(a = 3\) is 1
\[
\text{testnl } _b[2.a]/_b[3.a] = 1
\]

Test that an expression involving continuous factor variable syntax is equal to 16
\[
\text{testnl } -_b[x_1]/(2*_b[c.x1#c.x1]) = 16
\]

Test the equality of two expressions
\[
\text{testnl } _b[x_1]*_b[x_2] = _b[x_1]*_b[x_3]
\]

Joint test that two products are both equal to 2
\[
\text{testnl } (_b[x_1]*_b[x_2] = 2) (_b[x_1]*_b[x_3] = 2)
\]

Same as above
\[
\text{testnl } _b[x_1]*_b[x_2] = _b[x_1]*_b[x_3] = 2
\]

Same as above, but add separate tests for each expression
\[
\text{testnl } _b[x_1]*_b[x_2] = _b[x_1]*_b[x_3] = 2, \texttt{mtest}
\]

Same as above, but adjust \( p \)-values for multiple comparisons using Holm’s method
\[
\text{testnl } _b[x_1]*_b[x_2] = _b[x_1]*_b[x_3] = 2, \texttt{mtest(holm)}
\]
Test a linear hypothesis and a nonlinear hypothesis together

\[ \text{testnl } (_{b}[x1] = _{b}[x2]) (_{b}[x2]^2 = _{b}[x3]) \]

After multiple-equation models

Test that the product of the coefficients for \( x1 \) and \( x2 \) in the equation for \( y1 \) is equal to 1

\[ \text{testnl } _{b}[y1:x1]*_{b}[y1:x2] = 1 \]

Test that the product of the coefficients for \( x1 \) and \( x2 \) in the equation for \( y2 \) is equal to 1

\[ \text{testnl } _{b}[y2:x1]*_{b}[y2:x2] = 1 \]

Test the equality of expressions involving coefficients from the equations for \( y1 \) and \( y4 \)

\[ \text{testnl } _{b}[y1:x1]*_{b}[y1:x2] = _{b}[y4:x1]*_{b}[y4:x2] \]
Syntax

\[ \text{testnl } \exp = \exp \ [ = \exp \ldots ] \ [ , \text{options} ] \]

\[ \text{testnl} (\exp = \exp \ [ = \exp \ldots ] ) \ [ (\exp = \exp \ [ = \exp \ldots ] \ldots ) \ [ , \text{options} ] \]

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtest[(opt)]</td>
<td>test each condition separately</td>

<td>carry out the Wald test as $W/k \sim F(k,d)$; use with svy estimation commands when the df() option is also specified</td>
</tr>
</tbody>
</table>

collect is allowed; see [U] 11.1.10 Prefix commands.
df(#) and nosvyadjust do not appear in the dialog box.

The second syntax means that if more than one expression is specified, each must be surrounded by parentheses.

\( \exp \) is a possibly nonlinear expression containing

\[ _b[\text{coef}] \]
\[ _b[\text{eqno}:\text{coef}] \]
\[ [\text{eqno}] \text{coef} \]
\[ [\text{eqno}]_b[\text{coef}] \]

\( \text{eqno} \) is

\[ ## \]
\[ \text{name} \]

\( \text{coef} \) identifies a coefficient in the model. \( \text{coef} \) is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [U] 11.4.3 Factor variables. \( \text{coef} \) may contain time-series operators; see [U] 11.4.4 Time-series varlists.

Distinguish between [], which are to be typed, and [ ], which indicate optional arguments.

Options

mtest[(opt)] specifies that tests be performed for each condition separately. \( \text{opt} \) specifies the method for adjusting \( p \)-values for multiple testing. Valid values for \( \text{opt} \) are

- bonferroni Bonferroni’s method
- holm Holm’s method
- sidak Šidák’s method
- noadjust no adjustment is to be made

Specifying mtest without an argument is equivalent to specifying mtest(noadjust).
iterate(#) specifies the maximum number of iterations used to find the optimal step size in the calculation of numerical derivatives of the test expressions. By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.

The following options are available with testnl but are not shown in the dialog box:
df(#) specifies that the $F$ distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. With survey data, # is the design degrees of freedom unless nosvyadjust is specified.
nosvyadjust is for use with svy estimation commands when the df() option is also specified; see [SVY] svy estimation. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as $W/k \sim F(k, d)$ rather than as $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$, where $k$ = the dimension of the test and $d$ = the design degrees of freedom specified in the df() option.

Remarks and examples

Remarks are presented under the following headings:

Introduction
Using testnl to perform linear tests
Specifying constraints
Dropped constraints
Multiple constraints
Manipulability

Introduction

Example 1

We have just estimated the parameters of an earnings model on cross-sectional time-series data using one of Stata’s more sophisticated estimators:

```
. use https://www.stata-press.com/data/r18/earnings
   (NLS women 14-24 in 1968)
. xtgee ln_w grade age c.age#c.age, corr(exchangeable) nolog
```

```
GEE population-averaged model                 Number of obs  =  1,326
Group variable: idcode                       Number of groups =   269
Family: Gaussian                             Obs per group:
Link: Identity                              min =       1
Correlation: exchangeable                   avg =     4.9
                                              max =      9
Wald chi2(3) =  327.33
Scale parameter =  .0976738                  Prob > chi2    =  0.0000

         ln_wage | Coefficient Std. err.      z    P>|z|     [95% conf. interval]
-------------+--------------------------------------
       grade  | .0749686   .0066111   11.34  0.000     .062011   .0879261
       age    | .1080806   .0235861    4.58  0.000     .0618526   .1543086

         _cons | -.8788933   .2830899   -3.10  0.002    -1.433739  -.3240473
```

An implication of this model is that peak earnings occur at age \( \frac{-b[\text{age}]}{2 \times b[\text{age} \times \text{age}]} \), which here is equal to 33.2. Say that we have a theory that peak earnings should occur at age \( 16 + \frac{1}{b[\text{grade}]} \).

\[
.\text{testnl } \frac{-b[\text{age}]}{2 \times b[\text{age} \times \text{age}]} = 16 + \frac{1}{b[\text{grade}]}
\]

(1) \( \frac{-b[\text{age}]}{2 \times b[\text{age} \times \text{age}]} = 16 + \frac{1}{b[\text{grade}]} \)

\[
\text{chi2}(1) = 1.71
\]

\[
\text{Prob > chi2} = 0.1914
\]

These data do not reject our theory.

**Using testnl to perform linear tests**

`testnl` may be used to test linear constraints, but `test` is faster; see [R] `test`. You could type

\[
.\text{testnl } _b[x4] = _b[x1]
\]

but it would take less computer time if you typed

\[
.\text{test } _b[x4] = _b[x1]
\]

**Specifying constraints**

The constraints to be tested can be formulated in many different ways. You could type

\[
.\text{testnl } _b[\text{mpg}] \times _b[\text{weight}] = 1
\]

or

\[
.\text{testnl } _b[\text{mpg}] = \frac{1}{_b[\text{weight}]}
\]

or you could express the constraint any other way you wished. (To say that `testnl` allows constraints to be specified in different ways does not mean that the test itself does not depend on the formulation. This point is briefly discussed later.) In formulating the constraints, you must, however, exercise one caution: users of `test` often refer to the coefficient on a variable by specifying the variable name. For example,

\[
.\text{test mpg} = 0
\]

More formally, they should type

\[
.\text{test } _b[\text{mpg}] = 0
\]

but `test` allows the `_b[ ]` surrounding the variable name to be omitted. `testnl` does not allow this shorthand. Typing

\[
.\text{testnl} \text{ mpg=0}
\]

specifies the constraint that the value of variable `mpg` in the first observation is zero. If you make this mistake, sometimes `testnl` will catch it:

\[
.\text{testnl mpg=0}
\]

`equation (1) contains reference to X rather than _b[X]`

`r(198);`
In other cases, `testnl` may not catch the mistake; then, the constraint will be dropped because it does not make sense:

```
  . testnl mpg=0
      Constraint (1) dropped
```

(There are reasons other than this for constraints being dropped.) The worst case, however, is

```
  . testnl _b[weight]*mpg = 1
```

when what you mean is not that `_b[weight]` equals the reciprocal of the value of `mpg` in the first observation, but rather that

```
  . testnl _b[weight]*_b[mpg] = 1
```

Sometimes, this mistake will be caught by the “contains reference to X rather than `_b[X]`” error, and sometimes it will not. Be careful.

`testnl`, like `test`, can be used after any Stata estimation command, including the survey estimators. When you use it after a multiple-equation command, such as `mlogit` or `heckman`, you refer to coefficients by using Stata’s standard syntax: `[eqname]_b[varname]`.

Stata’s single-equation estimation output looks like this:

<table>
<thead>
<tr>
<th></th>
<th>Coef</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>weight</td>
<td>12.27</td>
<td>...</td>
</tr>
<tr>
<td>mpg</td>
<td>3.21</td>
<td>...</td>
</tr>
</tbody>
</table>

Stata’s multiple-equation output looks like this:

<table>
<thead>
<tr>
<th></th>
<th>Coef</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat1</td>
<td></td>
<td>...</td>
</tr>
<tr>
<td>weight</td>
<td>12.27</td>
<td>...</td>
</tr>
<tr>
<td>mpg</td>
<td>3.21</td>
<td>...</td>
</tr>
<tr>
<td>8</td>
<td></td>
<td>...</td>
</tr>
<tr>
<td>weight</td>
<td>5.83</td>
<td>...</td>
</tr>
<tr>
<td>mpg</td>
<td>7.43</td>
<td>...</td>
</tr>
</tbody>
</table>

**Dropped constraints**

`testnl` automatically drops constraints when

- They are nonbinding, for example, `_b[mpg]=_b[mpg]`. More subtle cases include
  
  
  \[
  _b[mpg]*_b[weight] = 4 \\
  _b[weight] = 2 \\
  _b[mpg] = 2
  \]

  In this example, the third constraint is nonbinding because it is implied by the first two.

- They are contradictory, for example, `_b[mpg]=2` and `_b[mpg]=3`. More subtle cases include

  \[
  _b[mpg]*_b[weight] = 4 \\
  _b[weight] = 2 \\
  _b[mpg] = 3
  \]

  The third constraint contradicts the first two.
Multiple constraints

Example 2

We illustrate the simultaneous test of a series of constraints using simulated data on labor-market promotion in a given year. We fit a probit model with separate effects for education, experience, and experience-squared for men and women.

```
. use https://www.stata-press.com/data/r18/promotion
(Simulated data on promotions)
. probit promo male male#c.(yedu yexp yexp2), nolog
```

Probit regression

```
Number of obs = 775
LR chi2(7) = 424.42
Prob > chi2 = 0.0000
Log likelihood = -245.42768 Pseudo R2 = 0.4637
```

| promo | Coefficient | Std. err. | z | P>|z| | 95% conf. interval |
|-------|-------------|-----------|---|------|------------------|
| male  | .6489974    | .203739   | 3.19 | 0.001 | .2496763 - 1.048318 |
| male#c.yedu Female | .9730237    | .1056136  | 9.21 | 0.000 | .7660248 - 1.180023 |
| Male   | 1.390517    | .1527288  | 9.10 | 0.000 | 1.091174 - 1.68986 |
| male#c.yexp Female | .4559544    | .0901169  | 5.06 | 0.000 | .2793285 - 0.6325803 |
| Male   | 1.422539    | .1544255  | 9.21 | 0.000 | 1.11987 - 1.725207 |
| male#c.yexp2 Female | -.1027149   | .0573059  | -1.79 | 0.073 | -.2150325 - .0096026 |
| Male   | -.3749457   | .1160113  | -3.23 | 0.001 | -.6023236 - .1475677 |
| _cons | .9872018    | .1148215  | 8.60 | 0.000 | .7621559 - 1.212248 |

Note: 1 failure and 2 successes completely determined.

The effects of human capital seem to differ between men and women. A formal test confirms this.

```
. test (yedu#0.male = yedu#1.male) (yexp#0.male = yexp#1.male)
> (yexp2#0.male = yexp2#1.male)
( 1) [promo]0b.male#c.yedu - [promo]1.male#c.yedu = 0
( 2) [promo]0b.male#c.yexp - [promo]1.male#c.yexp = 0
( 3) [promo]0b.male#c.yexp2 - [promo]1.male#c.yexp2 = 0
    chi2( 3) = 35.43
    Prob > chi2 = 0.0000
```

How do we interpret this gender difference? It has repeatedly been stressed (see, for example, Long [1997, 47–50]; Allison [1999]) that comparison of groups in binary response models, and similarly in other latent-variable models, is hampered by an identification problem: with $\beta$ the regression coefficients for the latent variable and $\sigma$ the standard deviation of the latent residual, only the $\beta/\sigma$ are identified. In fact, in terms of the latent regression, the probit coefficients should be interpreted as $\beta/\sigma$, not as the $\beta$. If we cannot claim convincingly that the residual standard deviation $\sigma$ does not vary between the sexes, equality of the regression coefficients $\beta$ implies that the coefficients of the probit model for men and women are proportional but not necessarily equal. This is a nonlinear hypothesis in terms of the probit coefficients, not a linear one.
. testnl _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
  > = _b[yexp2#1.male]/_b[yexp2#0.male]
  (1)  _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
  (2)  _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]

  chi2(2) = 9.21
  Prob > chi2 = 0.0100

We conclude that we find fairly strong evidence against the proportionality of the coefficients, and hence we have to conclude that success in the labor market is produced in different ways by men and women. (But remember, these were simulated data.)

Example 3

The syntax for specifying the equality of multiple expressions is just a convenient shorthand for specifying a series of constraints, namely, that the first expression equals the second expression, the first expression also equals the third expression, etc. The Wald test performed and the output of `testnl` are the same whether we use the shorthand or we specify the series of constraints.

. testnl (_b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male])
  > (_b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male])

  chi2(2) = 9.21
  Prob > chi2 = 0.0100

Having established differences between men and women, we would like to do multiple testing between the ratios. Because we did not specify hypotheses in advance, we prefer to adjust the $p$-values of tests using, here, Bonferroni’s method.

. testnl _b[yedu#1.male]/_b[yedu#0.male] =
  > _b[yexp#1.male]/_b[yexp#0.male] =
  > _b[yexp2#1.male]/_b[yexp2#0.male], mtest(b)

* Bonferroni-adjusted $p$-values

Manipulability

Although `testnl` allows you to specify constraints in different ways that are mathematically equivalent, as noted above, this does not mean that the tests are the same. This difference is known as the manipulability of the Wald test for nonlinear hypotheses; also see [R] boxcox. The test might even be significant for one formulation but not significant for another formulation that is mathematically equivalent.
equivalent. Trying out different specifications to find a formulation with the desired \( p \)-value is totally inappropriate, though it may actually be fun to try. There is no variance under representation because the nonlinear Wald test is actually a standard Wald test for a linearization of the constraint, which depends on the particular specification. We note that the likelihood-ratio test is not manipulable in this sense.

From a statistical point of view, it is best to choose a specification of the constraints that is as linear as possible. Doing so usually improves the accuracy of the approximation of the null-distribution of the test by a \( \chi^2 \) or an \( F \) distribution. The example above used the nonlinear Wald test to test whether the coefficients of human capital variables for men were proportional to those of women. A specification of proportionality of coefficients in terms of ratios of coefficients is fairly nonlinear if the coefficients in the denominator are close to 0. A more linear version of the test results from a bilinear formulation. Thus, instead of

\[
\text{testnl } \frac{\_b[yedu#1.male]}{\_b[yedu#0.male]} = \frac{\_b[yexp#1.male]}{\_b[yexp#0.male]}
\]

\begin{align*}
\text{chi2}(1) &= 6.89 \\
\text{Prob} > \text{chi2} &= 0.0087
\end{align*}

perhaps

\[
\text{testnl } \frac{\_b[yedu#1.male]}{\_b[yedu#0.male]} = \frac{\_b[yexp#0.male]}{\_b[yedu#1.male]}
\]

\begin{align*}
\text{chi2}(1) &= 13.95 \\
\text{Prob} > \text{chi2} &= 0.0002
\end{align*}

is better, and in fact it has been suggested that the latter version of the test is more reliable. This assertion is confirmed by performing simulations and is in line with theoretical results of Phillips and Park (1988). There is strong evidence against the proportionality of human capital effects between men and women, implying for this example that differences in the residual variances between the sexes can be ruled out as the explanation of the sex differences in the analysis of labor market participation.

### Stored results

testnl stores the following in \( r() \):

**Scalars**

- \( r(df) \) degrees of freedom
- \( r(df_r) \) residual degrees of freedom
- \( r(chi2) \) \( \chi^2 \)
- \( r(p) \) \( p \)-value for Wald test
- \( r(F) \) \( F \) statistic

**Macros**

- \( r(mtmeth) \) method specified in mtest()

**Matrices**

- \( r(G) \) derivatives of \( R(b) \) with respect to \( b \); see Methods and formulas below
- \( r(R) \) \( R(b) - q \); see Methods and formulas below
- \( r(mtest) \) multiple test results

### Methods and formulas

After fitting a model, define \( b \) as the resulting \( 1 \times k \) parameter vector and \( V \) as the \( k \times k \) covariance matrix. The (linear or nonlinear) hypothesis is given by \( R(b) = q \), where \( R \) is a function returning a \( j \times 1 \) vector. The Wald test formula is (Greene 2018, 512–513)
\[ W = \left\{ R(b) - q \right\}' \left( GVG' \right)^{-1} \left\{ R(b) - q \right\} \]

where \( G \) is the derivative matrix of \( R(b) \) with respect to \( b \). \( W \) is distributed as \( \chi^2 \) if \( V \) is an asymptotic covariance matrix. \( F = W / j \) is distributed as \( F \) for linear regression.

The adjustment methods for multiple testing are described in \([R] \text{ test}\). The adjustment for survey design effects is described in \([SVY] \text{ svy postestimation}\).

**tetrachoric** — Tetrachoric correlations for binary variables

**Description**

`tetrachoric` computes estimates of the tetrachoric correlation coefficients of the binary variables in `varlist`. All of these variables should be 0, 1, or missing values.

Tetrachoric correlations assume a latent bivariate normal distribution \((X_1, X_2)\) for each pair of variables \((v_1, v_2)\), with a threshold model for the manifest variables, \(v_i = 1\) if and only if \(X_i > 0\). The means and variances of the latent variables are not identified, but the correlation, \(r\), of \(X_1\) and \(X_2\) can be estimated from the joint distribution of \(v_1\) and \(v_2\) and is called the tetrachoric correlation coefficient.

`tetrachoric` computes pairwise estimates of the tetrachoric correlations by the (iterative) maximum likelihood estimator obtained from bivariate probit without explanatory variables (see [R] `biprobit`) by using the Edwards and Edwards (1984) noniterative estimator as the initial value.

The pairwise correlation matrix is returned as \(r(\text{Rho})\) and can be used to perform a factor analysis or a principal component analysis of binary variables by using the `factormat` or `pcamat` commands; see [MV] `factor` and [MV] `pca`.

**Quick start**

Tetrachoric correlation of \(v1\) and \(v2\) with standard error and test of independence

```
tetrachoric v1 v2
```

Matrix of pairwise tetrachoric correlations for \(v1\), \(v2\), and \(v3\)

```
tetrachoric v1 v2 v3
```

Add standard errors and \(p\)-values

```
tetrachoric v1 v2 v3, stats(rho se p)
```

Same as above, but adjust \(p\)-values for multiple comparisons using Bonferroni’s method

```
tetrachoric v1 v2 v3, stats(rho se p) bonferroni
```

Add star to correlations significant at the 5% level

```
tetrachoric v1 v2 v3, star(.05)
```

Use all available data for each pair of variables and report number of observations used

```
tetrachoric v1 v2 v3, pw stats(rho obs)
```

Adjust correlation matrix to be positive semidefinite

```
tetrachoric v1 v2 v3, posdef
```

by and collect are allowed; see [U] 11.1.10 Prefix commands.
fweights are allowed; see [U] 11.1.6 weight.

Options

stats(statlist) specifies the statistics to be displayed in the matrix of output. stats(rho) is the default. Up to four statistics may be specified. stats(rho se p obs) would display the tetrachoric correlation coefficient, its standard error, the significance level, and the number of observations. If varlist contains only two variables, all statistics are shown in tabular form. stats(), print(), and star() have no effect unless the matrix option is also specified.

edwards specifies that the noniterative Edwards and Edwards estimator be used. The default is the maximum likelihood estimator. If you analyze many binary variables, you may want to use the fast noniterative estimator proposed by Edwards and Edwards (1984). However, if you have skewed variables, the approximation does not perform well.
print(#) specifies the maximum significance level of correlation coefficients to be printed. Correlation coefficients with larger significance levels are left blank in the matrix. Typing tetrachoric ..., print(.10) would list only those correlation coefficients that are significant at the 10% level or lower.

star(#) specifies the maximum significance level of correlation coefficients to be marked with a star. Typing tetrachoric ..., star(.05) would “star” all correlation coefficients significant at the 5% level or lower.

bonferroni makes the Bonferroni adjustment to calculated significance levels. This option affects printed significance levels and the print() and star() options. Thus, tetrachoric ..., print(.05) bonferroni prints coefficients with Bonferroni-adjusted significance levels of 0.05 or less.

sidak makes the Šidák adjustment to calculated significance levels. This option affects printed significance levels and the print() and star() options. Thus, tetrachoric ..., print(.05) sidak prints coefficients with Šidák-adjusted significance levels of 0.05 or less.

pw specifies that the tetrachoric correlation be calculated by using all available data. By default, tetrachoric uses casewise deletion, where observations are ignored if any of the specified variables in varlist are missing.

zeroadjust specifies that when one of the cells has a zero count, a frequency adjustment be applied in such a way as to increase the zero to one-half and maintain row and column totals.

matrix forces tetrachoric to display the statistics as a matrix, even if varlist contains only two variables. matrix is implied if more than two variables are specified.

notable suppresses the output.

posef modifies the correlation matrix so that it is positive semidefinite, that is, a proper correlation matrix. The modified result is the correlation matrix associated with the least-squares approximation of the tetrachoric correlation matrix by a positive-semidefinite matrix. If the correlation matrix is modified, the standard errors and significance levels are not displayed and are returned in r().

Remarks and examples

Remarks are presented under the following headings:

Association in 2-by-2 tables
Factor analysis of dichotomous variables
Tetrachoric correlations with simulated data

Association in 2-by-2 tables

Although a wide variety of measures of association in cross tabulations have been proposed, such measures are essentially equivalent (monotonically related) in the special case of 2 × 2 tables—there is only 1 degree of freedom for nonindependence. Still, some measures have more desirable properties than others. Here we compare two measures: the standard Pearson correlation coefficient and the tetrachoric correlation coefficient. Given asymmetric row or column margins, Pearson correlations are limited to a range smaller than −1 to 1, although tetrachoric correlations can still span the range from −1 to 1. To illustrate, consider the following set of tables for two binary variables, X and Z:
3064 tetrachoric — Tetrachoric correlations for binary variables

<table>
<thead>
<tr>
<th>Z = 0</th>
<th>Z = 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>X = 0</td>
<td>20 − a</td>
</tr>
<tr>
<td>X = 1</td>
<td>a</td>
</tr>
<tr>
<td></td>
<td>20</td>
</tr>
</tbody>
</table>

For \( a \) equal to 0, 1, 2, 5, 8, 9, and 10, the Pearson and tetrachoric correlations for the above table are

<table>
<thead>
<tr>
<th>( a )</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>5</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pearson</td>
<td>0.577</td>
<td>0.462</td>
<td>0.346</td>
<td>0</td>
<td>−0.346</td>
<td>−0.462</td>
<td>−0.577</td>
</tr>
<tr>
<td>Tetrachoric</td>
<td>1.000</td>
<td>0.792</td>
<td>0.607</td>
<td>0</td>
<td>−0.607</td>
<td>−0.792</td>
<td>−1.000</td>
</tr>
</tbody>
</table>

The restricted range for the Pearson correlation is especially unfortunate when you try to analyze the association between binary variables by using models developed for continuous data, such as factor analysis and principal component analysis.

The tetrachoric correlation of two variables \((Y_1, Y_2)\) can be thought of as the Pearson correlation of two latent bivariate normal distributed variables \((Y_{1*}, Y_{2*})\) with threshold measurement models \(Y_i = (Y_{i*} > c_i)\) for unknown cutpoints \(c_i\). Or equivalently, \(Y_i = (Y_{i**} > 0)\) where the latent bivariate normal \((Y_{1**}, Y_{2**})\) are shifted versions of \((Y_{1*}, Y_{2*})\) so that the cutpoints are zero. Obviously, you must judge whether assuming underlying latent variables is meaningful for the data. If this assumption is justified, tetrachoric correlations have two advantages. First, you have an intuitive understanding of the size of correlations that are substantively interesting in your field of research, and this intuition is based on correlations that range from −1 to 1. Second, because the tetrachoric correlation for binary variables estimates the Pearson correlation of the latent continuous variables (assumed multivariate normal distributed), you can use the tetrachoric correlations to analyze multivariate relationships between the dichotomous variables. When doing so, remember that you must interpret the model in terms of the underlying continuous variables.

> Example 1

To illustrate tetrachoric correlations, we examine three binary variables from the `familyvalues` dataset (described in example 2).

```
. use https://www.stata-press.com/data/r18/familyvalues
(Attitudes on gender, relationships and family)
. tabulate RS075 RS076
    Fam att: RS075 RS076
    Fam att: trad
    women in charge bad      0   1   Total
    0 | 1,564 979    2,543
    1 |  119 632    751
    Total | 1,683 1,611   3,294
. correlate RS074 RS075 RS076
    (obs=3,291)
```

<table>
<thead>
<tr>
<th></th>
<th>RS074</th>
<th>RS075</th>
<th>RS076</th>
</tr>
</thead>
<tbody>
<tr>
<td>RS074</td>
<td>1.000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>RS075</td>
<td>0.0396</td>
<td>1.000</td>
<td></td>
</tr>
<tr>
<td>RS076</td>
<td>0.1595</td>
<td>0.3830</td>
<td>1.000</td>
</tr>
</tbody>
</table>
As usual, the tetrachoric correlation coefficients are larger (in absolute value) and more dispersed than the Pearson correlations.

Factor analysis of dichotomous variables

Example 2

Factor analysis is a popular model for measuring latent continuous traits. The standard estimators are appropriate only for continuous unimodal data. Because of the skewness implied by Bernoulli-distributed variables (especially when the probability is distributed unevenly), a factor analysis of a Pearson correlation matrix can be rather misleading when used in this context. A factor analysis of a matrix of tetrachoric correlations is more appropriate under these conditions (Uebersax 2000). We illustrate this with data on gender, relationship, and family attitudes of spouses using the Households in The Netherlands survey 1995 (Weesie et al. 1995). For attitude variables, it seems reasonable to assume that agreement or disagreement is just a coarse measurement of more nuanced underlying attitudes.
To demonstrate, we examine a few of the variables from the `familyvalues` dataset.

```
use https://www.stata-press.com/data/r18/familyvalues
(Attitudes on gender, relationships and family)
describe RS056-RS063
```

<table>
<thead>

| RS063    | 1.0000|       |       |       |       |       |       |       |
Skewness in these data is relatively modest. For comparison, here are the tetrachoric correlations:

```
   . tetrachoric RS056-RS063
    (obs=3,221)
   RS056 RS057 RS058 RS059 RS060 RS061 RS062
RS056  1.0000
RS057  0.2114  1.0000
RS058  0.3716  0.0416  1.0000
RS059  0.2887  0.0158  0.4007  1.0000
RS060 -0.1620 -0.0856 -0.0688  0.0208  1.0000
RS061 -0.1905  0.1011 -0.2382 -0.3664  0.1200  1.0000
RS062  0.3135  0.0452  0.3563  0.6109 -0.1267 -0.4845  1.0000
RS063  0.3187  0.2278  0.1677  0.1467  0.0286 -0.0388  0.1538
RS063  1.0000
```

Again, we see that the tetrachoric correlations are generally larger in absolute value than the Pearson correlations. The bivariate probit and Edwards and Edwards estimators (the `edwards` option) implemented in `tetrachoric` may return a correlation matrix that is not positive semidefinite—a mathematical property of any real correlation matrix. Positive definiteness is required by commands for analyses of correlation matrices, such as `factormat` and `pcamat`; see [MV] `factor` and [MV] `pca`. The `posdef` option of `tetrachoric` tests for positive definiteness and projects the estimated correlation matrix to a positive-semidefinite matrix if needed.

```
   . tetrachoric RS056-RS063, notable posdef
   . matrix C = r(Rho)
```

This time, we suppressed the display of the correlations with the `notable` option and requested that the correlation matrix be positive semidefinite with the `posdef` option. Had the correlation matrix not been positive definite, `tetrachoric` would have displayed a warning message and then adjusted the matrix to be positive semidefinite. We placed the resulting tetrachoric correlation matrix into a matrix, C, so that we can perform a factor analysis upon it.

`tetrachoric` with the `posdef` option asserted that C was positive definite because no warning message was displayed. We can verify this by using a familiar characterization of symmetric positive-definite matrices: all eigenvalues are real and positive.

```
   . matrix symeigen eigenvectors eigenvalues = C
   . matrix list eigenvalues
   eigenvalues[1,8]
     e1   e2   e3   e4   e5   e6   e7
     r1 2.5974789 1.3544664 1.0532476 .77980391 .73462018 .57984565 .54754512
     e8
     r1 .35299228
```

We can proceed with a factor analysis on the matrix C. We use `factormat` and select iterated principal factors as the estimation method; see [MV] `factor`.
Example 3

We noted in example 2 that the matrix of estimates of the tetrachoric correlation coefficients need not be positive definite. Here is an example:

```stata
use https://www.stata-press.com/data/r18/familyvalues
(Attitudes on gender, relationships and family)
tetrachoric RS056-RS063 in 1/20, posdef
```

matrix with tetrachoric correlations is not positive semidefinite;  
   it has 2 negative eigenvalues  
maxdiff(corr,adj-corr) = 0.2346  
(adj-corr: tetrachoric correlations adjusted to be positive semidefinite)
The estimated tetrachoric correlation matrix is rank-2 deficient. With this C2 matrix, we can only use models of correlation that allow for singular cases.

### Tetrachoric correlations with simulated data

#### Example 4

We use `drawnorm` (see \([D]\) `drawnorm`) to generate a sample of 1,000 observations from a bivariate normal distribution with means $-1$ and 1, unit variances, and correlation 0.4.

```stata
. clear
. set seed 11000
. matrix m = (1, -1)
. matrix V = (1, 0.4 \ 0.4, 1)
. drawnorm c1 c2, n(1000) means(m) cov(V)
   (obs 1,000)
```

Now, consider the measurement model assumed by the tetrachoric correlations. We observe only whether $c_1$ and $c_2$ are greater than zero,

```stata
. generate d1 = (c1 > 0)
. generate d2 = (c2 > 0)
. tabulate d1 d2
```

<table>
<thead>
<tr>
<th>d1</th>
<th>d2</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>141</td>
<td>6</td>
</tr>
<tr>
<td>1</td>
<td>706</td>
<td>147</td>
</tr>
<tr>
<td></td>
<td>847</td>
<td>153</td>
</tr>
</tbody>
</table>

We want to estimate the correlation of $c_1$ and $c_2$ from the binary variables $d_1$ and $d_2$. Pearson’s correlation of the binary variables $d_1$ and $d_2$ is 0.129—a seriously biased estimate of the underlying correlation $\rho = 0.4$. 
The tetrachoric correlation coefficient of \( d_1 \) and \( d_2 \) estimates the Pearson correlation of the latent continuous variables, \( c_1 \) and \( c_2 \).

The estimate of the tetrachoric correlation of \( d_1 \) and \( d_2 \), 0.3875, is much closer to the underlying correlation, 0.4, between \( c_1 \) and \( c_2 \).

**Stored results**

`tetrachoric` stores the following in `r()`:

Scalars
- `r(rho)`: tetrachoric correlation coefficient between variables 1 and 2
- `r(N)`: number of observations
- `r(nneg)`: number of negative eigenvalues (posdef only)
- `r(se_rho)`: standard error of `r(rho)`
- `r(p)`: p-value for two-sided Fisher’s exact test (for the first two variables)

Macros
- `r(method)`: estimator used

Matrices
- `r(Rho)`: tetrachoric correlation matrix
- `r(Se_Rho)`: standard errors of `r(Rho)`
- `r(Nobs)`: number of observations used in computing correlation
- `r(P)`: matrix of p-values for two-sided Fisher’s exact test

**Methods and formulas**

`tetrachoric` provides two estimators for the tetrachoric correlation \( \rho \) of two binary variables with the frequencies \( n_{ij}, i, j = 0, 1 \). `tetrachoric` defaults to the slower (iterative) maximum likelihood estimator obtained from bivariate probit without explanatory variables (see [R] biprobit) by using the Edwards and Edwards noniterative estimator as the initial value. A fast (noniterative) estimator is also available by specifying the `edwards` option (Edwards and Edwards 1984; Digby 1983)

\[
\hat{\rho} = \frac{\alpha - 1}{\alpha + 1}
\]
where

$$\alpha = \left( \frac{n_{00}n_{11}}{n_{01}n_{10}} \right)^{\pi/4} \left( \pi = 3.14\ldots \right)$$

if all \( n_{ij} > 0 \). If \( n_{00} = 0 \) or \( n_{11} = 0 \), \( \hat{\rho} = -1 \); if \( n_{01} = 0 \) or \( n_{10} = 0 \), \( \hat{\rho} = 1 \).

The asymptotic variance of the Edwards and Edwards estimator of the tetrachoric correlation is easily obtained by the delta method,

$$\text{avvar}(\hat{\rho}) = \left\{ \frac{\pi \alpha}{2(1 + \alpha)^2} \right\}^2 \left( \frac{1}{n_{00}} + \frac{1}{n_{01}} + \frac{1}{n_{10}} + \frac{1}{n_{11}} \right)$$

provided all \( n_{ij} > 0 \), otherwise it is left undefined (missing). The Edwards and Edwards estimator is fast, but may be inaccurate if the margins are very skewed.

tetrachoric reports exact \( p \)-values for statistical independence, computed by the \texttt{exact} option of \texttt{[R] tabulate twoway}.

tnbreg estimates the parameters of a truncated negative binomial model by maximum likelihood. The dependent variable depvar is regressed on indepvars, where depvar is a positive count variable whose values are all above the truncation point.

Quick start

Truncated negative binomial regression of y on x with truncation at 0
  tnbreg y x

Report incidence-rate ratios
  tnbreg y x, irr

Add categorical variable a using factor variable syntax
  tnbreg y x i.a

Same as above, but specify a constant truncation point of 2
  tnbreg y x i.a, ll(2)

With exposure variable exp
  tnbreg y x i.a, exposure(exp)

Same as above, but specifying a variable truncation point stored in variable min
  tnbreg y x i.a, exposure(exp) ll(min)

With cluster–robust standard errors clustering by the levels of cvar
  tnbreg y x i.a, exposure(exp) ll(min) vce(cluster cvar)
Syntax

```
tnbreg depvar [ indepvars ] [ if ] [ in ] [ weight ] [ , options ]
```

**options**

**SE/Robust**

- `vce(vcetype)`
  - `vcetype` may be `oim`, `robust`, `cluster clustvar`, `opg`, `bootstrap`, or `jackknife`

**Reporting**

- `level(#)`
  - set confidence level; default is `level(95)`
- `nolrtest`
  - suppress likelihood-ratio test
- `irr`
  - report incidence-rate ratios
- `nocnsreport`
  - do not display constraints
- `display_options`
  - control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

**Maximization**

- `maximize_options`
  - control the maximization process; seldom used
- `collinear`
  - keep collinear variables
- `coeflegend`
  - display legend instead of statistics

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.
`depvar` and `indepvars` may contain time-series operators; see [U] 11.4.4 Time-series varlists.
`bayes, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: tnbreg.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
`vce()` and weights are not allowed with the svy prefix; see [SVY] svy.
`fweights, iweights, and pweights` are allowed; see [U] 11.1.6 weight.
collinear and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

---

**Options**

- `noconstant`: see [R] Estimation options.
- `ll(# | varname)` specifies the truncation point, which is a nonnegative integer. The default is zero truncation, `ll(0)`. 
dispersion(mean | constant) specifies the parameterization of the model. dispersion(mean), the default, yields a model with dispersion equal to \(1 + \alpha \exp(x_j \beta + \text{offset}_j)\); that is, the dispersion is a function of the expected mean: \(\exp(x_j \beta + \text{offset}_j)\). dispersion(constant) has dispersion equal to \(1 + \delta\); that is, it is a constant for all observations.

dispersion(mean), the default, yields a model with dispersion equal to \(1 + \alpha \exp(x_j \beta + \text{offset}_j)\); that is, the dispersion is a function of the expected mean: \(\exp(x_j \beta + \text{offset}_j)\). dispersion(constant) has dispersion equal to \(1 + \delta\); that is, it is a constant for all observations.

exposure(varname), offset(varname), constraints(constraints); see [R] Estimation options.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

level(#); see [R] Estimation options.

nolrtest suppresses fitting the Poisson model. Without this option, a comparison Poisson model is fit, and the likelihood is used in a likelihood-ratio test of the null hypothesis that the dispersion parameter is zero.

irr reports estimated coefficients transformed to incidence-rate ratios, that is, \(e^\beta_i\), rather than \(\beta_i\). Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. irr may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following options are available with tnbreg but are not shown in the dialog box:

collinear, coeflegend; see [R] Estimation options.

Remarks and examples

Grogger and Carson (1991) showed that overdispersion causes inconsistent estimation of the mean in the truncated Poisson model. To solve this problem, they proposed using the truncated negative binomial model as an alternative. If data are truncated but do not exhibit overdispersion, the truncated Poisson model is more appropriate; see [R] tpoisson. For an introduction to negative binomial regression, see Cameron and Trivedi (2005, 2022) and Long and Freese (2014). For an introduction to truncated negative binomial models, see Cameron and Trivedi (2013) and Long (1997, chap. 8).
tnbreg fits the mean-dispersion and the constant-dispersion parameterizations of truncated negative binomial models. These parameterizations extend those implemented in nbreg; see [R] nbreg.

Example 1

We illustrate the truncated negative binomial model using the 1997 MedPar dataset (Hilbe 1999). The data are from 1,495 patients in Arizona who were assigned to a diagnostic-related group (DRG) of patients having a ventilator. Length of stay (los), the dependent variable, is a positive integer; it cannot have zero values. The data are truncated because there are no observations on individuals who stayed for zero days.

The objective of this example is to determine whether the length of stay was related to the binary variables: died, hmo, type1, type2, and type3.

The died variable was recorded as a 0 unless the patient died, in which case, it was recorded as a 1. The other variables also adopted this encoding. The hmo variable was set to 1 if the patient belonged to a health maintenance organization (HMO).

The type1–type3 variables indicated the type of admission used for the patient. The type1 variable indicated an emergency admit. The type2 variable indicated an urgent admit—that is, the first available bed. The type3 variable indicated an elective admission. Because type1–type3 were mutually exclusive, only two of the three could be used in the truncated negative binomial regression shown below.

```
. use https://www.stata-press.com/data/r18/medpar
(Arizona ventilator data)
. tnbreg los died hmo type2-type3, vce(cluster provnum) nolog
```

| los | coefficient | std. err. | z | P>|z| | [95% conf. interval] |
|-----|-------------|-----------|---|-------|----------------------|
| died | -.2521884 | .061533 | -4.10 | 0.000 | -0.3727908 to -0.1315859 |
| hmo | -.0754173 | .0533132 | -1.41 | 0.157 | -.1799091 to .0290746 |
| type2 | .2685095 | .0666474 | 4.03 | 0.000 | .137883 to .3991359 |
| type3 | .7668101 | .2183505 | 3.51 | 0.000 | .338851 to 1.194769 |
| _cons | 2.224028 | .034727 | 64.04 | 0.000 | 2.155964 to 2.292091 |

Because observations within the same hospital (provnum) are likely to be correlated, we specified the vce(cluster provnum) option. The results show that whether the patient died in the hospital and the type of admission have significant effects on the patient’s length of stay.

Example 2

To illustrate truncated negative binomial regression with more complex data than the previous example, similar data were created from 100 hospitals. Each hospital had its own way of tracking patient data. In particular, hospitals only recorded data from patients with a minimum length of stay, denoted by the variable minstay.
Definitions for minimum length of stay varied among hospitals, typically, from 5 to 18 days. The objective of this example is the same as before: to determine whether the length of stay, recorded in `los`, was related to the binary variables: `died`, `hmo`, `type1`, `type2`, and `type3`.

The binary variables encode the same information as in example 1 above. The `minstay` variable was used to allow for varying truncation points.

```
use https://www.stata-press.com/data/r18/medproviders
tnbreg los died hmo type2-type3, ll(minstay) vce(cluster hospital) nolog
```

```
Truncated negative binomial regression
Number of obs = 2,144
Truncation points: minstay Wald chi2(4) = 15.22
Dispersion: mean Prob > chi2 = 0.0043
Log pseudolikelihood = -7864.0928 Pseudo R2 = 0.0007
(Std. err. adjusted for 100 clusters in hospital)

| los       | Coefficient | std. err. | z     | P>|z|   | [95% conf. interval] |

alpha .3691649 .0305923 .313821 .4342688
```

In this analysis, two variables have a statistically significant relationship with length of stay. On average, patients who died in the hospital had longer lengths of stay ($p = 0.01$). Because the coefficient for HMO is negative, that is, $b_{HMO} = -0.073$, on average, patients who were insured by an HMO had shorter lengths of stay ($p = 0.047$). The type of admission was not statistically significant ($p > 0.05$).
tnbreg stores the following in e():

Scalars
- \( e(N) \): number of observations

- \( e(wtype) \): weight type
- \( e(wexp) \): weight expression
- \( e(title) \): title in estimation output
- \( e(clustvar) \): name of cluster variable
- \( e(offset) \): linear offset variable
- \( e(chi2type) \): Wald or LR: type of model \( \chi^2 \) test
- \( e(chi2\_ct) \): Wald or LR: type of model \( \chi^2 \) test corresponding to \( e(chi2\_c) \)
- \( e(dispers) \): mean or constant
- \( e(vce) \): \texttt{vce}\texttt{(}\texttt{)} specified in \( vce() \)
- \( e(vcetype) \): title used to label Std. err.
- \( e(opt) \): type of optimization
- \( e(which) \): max or min: whether optimizer is to perform maximization or minimization
- \( e(ml\_method) \): type of \texttt{ml} method
- \( e(user) \): name of likelihood-evaluator program
- \( e(technique) \): maximization technique
- \( e(properties) \): \texttt{b V}
- \( e(predict) \): program used to implement \texttt{predict}
- \( e(asbalanced) \): factor variables \texttt{fvset} as \texttt{asbalanced}
- \( e(asobserved) \): factor variables \texttt{fvset} as \texttt{asobserved}

Matrices
- \( e(b) \): coefficient vector
- \( e(Cns) \): constraints matrix
- \( e(ilog) \): iteration log (up to 20 iterations)
- \( e(gradient) \): gradient vector
- \( e(V) \): variance–covariance matrix of the estimators
- \( e(V_{modelbased}) \): model-based variance

Functions
- \( e(sample) \): marks estimation sample
In addition to the above, the following is stored in `r()`:

Matrices

$r(table)$ matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals.

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

**Methods and formulas**

Methods and formulas are presented under the following headings:

- **Mean-dispersion model**
- **Constant-dispersion model**

**Mean-dispersion model**

A negative binomial distribution can be regarded as a gamma mixture of Poisson random variables. The number of times an event occurs, $y_j$, is distributed as $\text{Poisson}(\nu_j \mu_j)$. That is, its conditional likelihood is

$$f(y_j \mid \nu_j) = \frac{(\nu_j \mu_j)^{y_j} e^{-\nu_j \mu_j}}{\Gamma(y_j + 1)}$$

where $\mu_j = \exp(x_j \beta + \text{offset}_j)$ and $\nu_j$ is an unobserved parameter with a Gamma$(1/\alpha, \alpha)$ density:

$$g(\nu) = \frac{\nu^{(1-\alpha)/\alpha} e^{-\nu/\alpha}}{\alpha^{1/\alpha} \Gamma(1/\alpha)}$$

This gamma distribution has a mean of 1 and a variance of $\alpha$, where $\alpha$ is our ancillary parameter.

The unconditional likelihood for the $j$th observation is therefore

$$f(y_j) = \int_0^\infty f(y_j \mid \nu) g(\nu) d\nu = \frac{\Gamma(m + y_j)}{\Gamma(y_j + 1) \Gamma(m)} p_j^m (1 - p_j)^{y_j}$$

where $p_j = 1/(1 + \alpha \mu_j)$ and $m = 1/\alpha$. Solutions for $\alpha$ are handled by searching for $\ln \alpha$ because $\alpha$ must be greater than zero. The conditional probability of observing $y_j$ events given that $y_j$ is greater than the truncation point $\tau_j$ is

$$\Pr(Y = y_j \mid y_j > \tau_j, x_j) = \frac{f(y_j)}{\Pr(Y > \tau_j \mid x_j)}$$

The log likelihood (with weights $w_j$ and offsets) is given by

$$\ln L = \sum_{j=1}^n w_j \left[ \ln \{\Gamma(m + y_j)\} - \ln \{\Gamma(y_j + 1)\} - \ln \{\Pr(Y > \tau_j \mid p_j, m)\} \right] + m \ln(p_j) + y_j \ln(1 - p_j) - \ln \{\Pr(Y > \tau_j \mid p_j, m)\}$$
Constant-dispersion model

The constant-dispersion model assumes that \( y_j \) is conditionally distributed as Poisson\( (\mu^*_j) \), where \( \mu^*_j \sim \text{Gamma}(\mu_j/\delta,\delta) \) for some dispersion parameter \( \delta \) [by contrast, the mean-dispersion model assumes that \( \mu^*_j \sim \text{Gamma}(1/\alpha, \alpha \mu_j) \)]. The log likelihood is given by

\[
m_j = \mu_j / \delta \quad p = 1/(1 + \delta)
\]

\[
\ln L = \sum_{j=1}^{n} w_j \left[ \ln\{\Gamma(m_j + y_j)\} - \ln\{\Gamma(y_j + 1)\} - \ln\{\Gamma(m_j)\} + m_j \ln(p) + y_j \ln(1 - p) - \ln\{\text{Pr}(Y > \tau_j | p, m_j)\} \right]
\]

with everything else defined as shown above in the calculations for the mean-dispersion model.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] _robust}, particularly Maximum likelihood estimators and Methods and formulas.

\texttt{tnbreg} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] Variance estimation}.

</tbody>
</table>

*`forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.*
predict

Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
predict [type] stub* [if] [in], scores
```

<table>

</tbody>
</table>

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Options for predict

- `n`, the default, calculates the predicted number of events, which is \( \exp(x_j \beta) \) if neither `offset()` nor `exposure()` was specified when the model was fit; \( \exp(x_j \beta + \text{offset}_j) \) if `offset()` was specified; or \( \exp(x_j \beta) \times \text{exposure}_j \) if `exposure()` was specified.

- `ir` calculates the incidence rate \( \exp(x_j \beta) \), which is the predicted number of events when exposure is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

- `cm` calculates the conditional mean,

\[
E(y_j \mid y_j > \tau_j) = \frac{E(y_j, y_j > \tau_j)}{Pr(y_j > \tau_j)}
\]

where \( \tau_j \) is the truncation point found in `e(llopt)`. 
pr(n) calculates the probability \( \Pr(y_j = n) \), where \( n \) is a nonnegative integer that may be specified as a number or a variable.

\( \Pr(a \leq y_j \leq b) \) calculates the probability \( \Pr(a \leq y_j \leq b) \), where \( a \) and \( b \) are nonnegative integers that may be specified as numbers or variables;

\( b \) missing \( (b \geq .) \) means \( +\infty \);

\( \Pr(20, .) \) calculates \( \Pr(y_j \geq 20) \);

\( \Pr(20, b) \) calculates \( \Pr(y_j \geq 20) \) in observations for which \( b \geq . \) and calculates \( \Pr(20 \leq y_j \leq b) \) elsewhere.

\( \Pr(., b) \) produces a syntax error. A missing value in an observation of the variable \( a \) causes a missing value in that observation for \( \Pr(a, b) \).

cpr(n) calculates the conditional probability \( \Pr(y_j = n \mid y_j > \tau_j) \), where \( \tau_j \) is the truncation point found in \texttt{e(llopt)}. \( n \) is an integer greater than the truncation point that may be specified as a number or a variable.

cpr(a, b) calculates the conditional probability \( \Pr(a \leq y_j \leq b \mid y_j > \tau_j) \), where \( \tau_j \) is the truncation point found in \texttt{e(llopt)}. The syntax for this option is analogous to that used for \( \Pr(a, b) \) except that \( a \) must be greater than the truncation point.

xb calculates the linear prediction, which is \( x_j \beta \) if neither \texttt{offset()} nor \texttt{exposure()} was specified when the model was fit; \( x_j \beta + \text{offset}_j \) if \texttt{offset()} was specified; or \( x_j \beta + \ln(\text{exposure}_j) \) if \texttt{exposure()} was specified; see \texttt{nooffset} below.

stdp calculates the standard error of the linear prediction.

\texttt{nooffset} is relevant only if you specified \texttt{offset()} or \texttt{exposure()} when you fit the model. It modifies the calculations made by \texttt{predict} so that they ignore the offset or exposure variable; the linear prediction is treated as \( x_j \beta \) rather than as \( x_j \beta + \text{offset}_j \) or \( x_j \beta + \ln(\text{exposure}_j) \). Specifying \texttt{predict ...}, \texttt{nooffset} is equivalent to specifying \texttt{predict ...}, ir.

tscores calculates equation-level score variables.

The first new variable will contain \( \partial \ln L / \partial (x_j \beta) \).

The second new variable will contain \( \partial \ln L / \partial (\ln \alpha) \) for \texttt{dispersion(mean)}.

The second new variable will contain \( \partial \ln L / \partial (\ln \delta) \) for \texttt{dispersion(constant)}.  

margins

Description for margins

margins estimates margins of response for numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, and linear predictions.

Menu for margins

Statistics not allowed with margins are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] margins.

Methods and formulas

In the following formulas, we use the same notation as in [R] tnbreg.

Methods and formulas are presented under the following headings:

- Mean-dispersion model
- Constant-dispersion model
Mean-dispersion model

The equation-level scores are given by

\[
\text{score}(x_\beta)_j = p_j(y_j - \mu_j) - p_j^{(m+1)} \frac{\mu_j}{\Pr(Y > \tau_j | p_j, m)}
\]

\[
\text{score}(\omega)_j = -m \left\{ \frac{\alpha(\mu_j - y_j)}{1 + \alpha \mu_j} - \ln(1 + \alpha \mu_j) + \psi(y_j + m) - \psi(m) \right\}
\]

\[
- \frac{p_j^m}{\Pr(Y > \tau_j | p_j, m)} \{m \ln(p_j) + \mu_j p_j\}
\]

where \(\omega_j = \ln \alpha_j\), \(\psi(z)\) is the digamma function, and \(\tau_j\) is the truncation point found in \(\text{e(1lopt)}\).

Constant-dispersion model

The equation-level scores are given by

\[
\text{score}(x_\beta)_j = m_j \left\{ \psi(y_j + m_j) - \psi(m_j) + \ln(p) + \frac{p_j^{m_j} \ln(p)}{\Pr(Y > \tau_j | p, m_j)} \right\}
\]

\[
\text{score}(\omega)_j = y_j - (y_j + m_j)(1 - p) - \text{score}(x_\beta)_j - \frac{\mu_j p}{\Pr(Y > \tau_j | p, m_j)}
\]

where \(\omega_j = \ln \delta_j\) and \(\tau_j\) is the truncation point found in \(\text{e(1lopt)}\).

[U] 20 Estimation and postestimation commands
tobit — Tobit regression

Description

tobit fits models for continuous responses where the outcome variable is censored. Censoring limits may be fixed for all observations or vary across observations.

Quick start

Tobit regression of y on x1 and x2, specifying that y is censored at the minimum of y

tobit y x1 x2, ll

Same as above, but where the lower-censoring limit is zero

tobit y x1 x2, ll(0)

Same as above, but specify the lower- and upper-censoring limits

tobit y x1 x2, ll(17) ul(34)

Same as above, but where lower and upper are variables containing the censoring limits

tobit y x1 x2, ll(lower) ul(upper)

Menu

Statistics > Linear models and related > Censored regression > Tobit regression
Syntax

\[
\texttt{tobit } \textit{depvar} \ [\textit{indepvars}] \ [\textit{if}] \ [\textit{in}] \ [\textit{weight}] \ [, \textit{options}] \]

\begin{tabular}{l l}
| \textit{options} & \textit{Description} \\
|-----------------|-----------------|
| \texttt{noconstant} & suppress constant term \\
| \texttt{ll \{varname | \#\}} & left-censoring variable or limit \\
| \texttt{ul \{varname | \#\}} & right-censoring variable or limit \\
| \texttt{offset \{varname\}} & include \textit{varname} in model with coefficient constrained to 1 \\
| \texttt{constraints(\{constraints\)}} & apply specified linear constraints \\
| \texttt{vce(vctype)} & \textit{vctype} may be \texttt{oim, opg, robust, cluster clustvar, bootstrap}, or \texttt{jackknife} \\
| \texttt{level(\#)} & set confidence level; default is \texttt{level(95)} \\
| \texttt{nocnsreport} & do not display constraints \\
| \texttt{display_options} & control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling \\
| \texttt{maximize_options} & control the maximization process; seldom used \\
| \texttt{collinear} & keep collinear variables \\
| \texttt{coeflegend} & display legend instead of statistics \\
\end{tabular}

\textit{indeps} may contain factor variables; see \cite{U11.4.3 Factor variables}.
\textit{depvar} and \textit{indepvars} may contain time-series operators; see \cite{U11.4.4 Time-series varlists}.
\textit{bayes}, \textit{bootstrap}, \textit{by}, \textit{collect}, \textit{fmm}, \textit{fp}, \textit{jackknife}, \textit{nestreg}, \textit{rolling}, \textit{statsby}, \textit{stepwise}, and \textit{svy} are allowed; see \cite{U11.1.10 Prefix commands}. For more details, see \cite{BAYES} \textit{bayes: tobit} and \cite{FMM} \textit{fmm: tobit}.

Weights are not allowed with the \textit{bootstrap} prefix; see \cite{R bootstrap}.
\textit{aweights} are not allowed with the \textit{jackknife} prefix; see \cite{R jackknife}.
\texttt{vce()} and weights are not allowed with the \textit{svy} prefix; see \cite{SVY} \textit{svy}.
\textit{aweights}, \textit{fweights}, \textit{iweights}, and \textit{pweights} are allowed; see \cite{U11.1.6 weight}.
\textit{collinear} and \textit{coeflegend} do not appear in the dialog box.

See \cite{U20 Estimation and postestimation commands} for more capabilities of estimation commands.

Options

\texttt{noconstant}; see \cite{R Estimation options}.

\texttt{ll \{varname | \#\}} and \texttt{ul \{varname | \#\}} indicate the lower and upper limits for censoring, respectively. Observations with \textit{depvar} \leq \texttt{ll()} are left-censored; observations with \textit{depvar} \geq \texttt{ul()} are right-censored; and remaining observations are not censored. You do not have to specify the censoring values. If you specify \texttt{ll}, the lower limit is the minimum of \textit{depvar}. If you specify \texttt{ul}, the upper limit is the maximum of \textit{depvar}. 
offset(varname), constraints(constraints); see [R] Estimation options.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

level(#), nocnsreport; see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

The following options are available with tobit but are not shown in the dialog box:
collinear, coeflegend; see [R] Estimation options.

Remarks and examples

tobit fits a linear regression model for a censored continuous outcome. Censoring occurs when the dependent variable is observed only within a certain range of values. When it is not, we know only that it is either above (right-censoring) or below (left-censoring) the censoring value. Censoring differs from truncation. When the data are truncated, we do not observe either the dependent variable or the covariates; see [R] truncreg.

Censoring may result from study design or may be a result of how the outcome is measured. Right-censoring of data may occur, for example, in income surveys that top code the highest income category. Any respondent that earns the censoring limit or more reports only the value at the limit, and we do not know the respondent’s true income. Left-censoring arises naturally when measurements are obtained from an instrument or a laboratory procedure that has a limit of detection. If we observe a value at the measurement limit, we know the true value is at the limit or below it. tobit allows the censoring limits to be the same for all observations or to vary from observation to observation.

Tobin (1958) originally conceived the tobit model as one of consumption of consumer durables where purchases were left-censored at zero. Contemporary literature treats this and similar cases as a corner solution model. See Wooldridge (2020, sec. 17.2), Long (1997, 196–210), and Maddala and Lahiri (2006, 333–336) for an introduction to the tobit model. Wooldridge (2010, chap. 17 and 19) provides an advanced treatment of censored regression models. Cameron and Trivedi (2022, chap. 19) discuss the tobit model using Stata examples.

The tobit model can be written as the latent regression model $y = x\beta + \epsilon$ with a continuous outcome that is either observed or unobserved. Following Cong (2000), the observed outcome for observation $i$ is defined as
\[ y_i^* = \begin{cases} 
 y_i & \text{if } a < y_i < b \\
 a & \text{if } y_i \leq a \\
 b & \text{if } y_i \geq b 
\end{cases} \]

where \( a \) is the lower-censoring limit and \( b \) is the upper-censoring limit. The tobit model assumes that the error term is normally distributed: \( \epsilon \sim N(0, \sigma^2 I) \). Depending on the problem at hand, the quantity of interest in a tobit model may be the censored outcome, \( y_i^* \), or the uncensored outcome, \( y_i \). In the measurement instrument scenario above, we may wish to predict the values that fall below the measurement threshold. By contrast, in the consumption of consumer durables scenario above, the latent variable is an artificial construct and the variable of interest is the observed consumer expenditure.

> **Example 1: Constant-censoring limit**

University administrators want to know the relationship between high school grade point average (GPA) and students’ performance in college. `gpa.dta` contains fictional data on a cohort of 4,000 college students. College GPA (`gpa2`) and high school GPA (`hsgpa`) are measured on a continuous scale between zero and four. The outcome of interest is the student’s college GPA. But, for reasons of confidentiality, GPAs below 2.0 are reported as 2.0. In other words, the outcome is censored on the left.

We believe that GPA is also a function of the logarithm of income of the student’s parents (`pincome`) and whether or not the student participated in a study-skills program while in college (`program`).

```stata
use https://www.stata-press.com/data/r18/gpa (High school GPA and performance in college)
tobit gpa2 hsgpa pincome program, ll
```

Refining starting values:

| Grid node 0: | Log likelihood = -2551.3989 |

Fitting full model:

| Iteration 0: | Log likelihood = -2551.3989 |
| Iteration 1: | Log likelihood = -2065.4023 |
| Iteration 2: | Log likelihood = -2015.8135 |
| Iteration 3: | Log likelihood = -2015.1281 |
| Iteration 4: | Log likelihood = -2015.1258 |
| Iteration 5: | Log likelihood = -2015.1258 |

Tobit regression

| Coefficient | Std. err. | t | P>|t| | [95% conf. interval] |
|-------------|-----------|---|--------|-------------------|
| hsgpa       | .6586311  | .0128699 | 51.18 | .000 | .633399 - .6838632 |
| pincome     | .3159297  | .0074568 | 42.37 | .000 | .3013103 - .3305491 |
| program     | .5554416  | .0147468 | 37.67 | .000 | .5265297 - .5843535 |
| _cons       | -.8902578 | .0478484 | -18.61 | .000 | -.9840673 - -.7964482 |

| var(e.gpa2) | .161703 | .0044004 | .1533019 | .1705645 |
```

tobit reports the coefficients for the latent regression model. Thus, we can interpret the coefficients just as we would the coefficients from OLS. For example, participation in a study-skills program increases the expected uncensored GPA by 0.56 points.
Example 2: Tobit model for a corner solution

Suppose that we are interested in the number of hours married women spend working for wages, and we treat observations recording zero hours as observed, per the corner-solution approach discussed in Wooldridge (2010, chap. 16). We use the labor supply data extracted by Mroz (1987) from the 1975 PSID for 753 married women. The variable `whrs75` records the annual number of hours worked. Forty-three percent of the surveyed women worked zero hours, and the remaining women worked on average 1,303 hours a year.

We regress hours worked on household income excluding wife’s income (`nwinc`), years of schooling (`wedyrs`), years of labor market experience (`wexper`) and its square, age (`wifeage`), an indicator for the presence of children under 6 years of age at home (`k16`), and an indicator for the presence of children from 6 to 18 years old at home (`k618`).

```
. use https://www.stata-press.com/data/r18/mroz87
(1975 PSID data from Mroz, 1987)
. tobit whrs75 nwinc wedyrs wexper c.wexper#c.wexper wifeage k16 k618, ll(0)
```

Refining starting values:
Grid node 0:  Log likelihood = -3961.1577

Fitting full model:
Iteration 0:  Log likelihood = -3961.1577
Iteration 1:  Log likelihood = -3836.8928
Iteration 2:  Log likelihood = -3819.2637

Unlike in example 1, we are interested in the marginal effect of the covariates on the observed outcome. We can use `margins` to estimate, for example, the average marginal effect of years of education on the expected value of the actual hours worked.
The average marginal effect of years of education on the actual hours worked is 47.47. See [R] tobit postestimation for more examples using margins.

James Tobin (1918–2002) was an American economist who after education and research at Harvard moved to Yale, where he was on the faculty from 1950 to 1988. He made many outstanding contributions to economics and was awarded the Nobel Prize in 1981 “for his analysis of financial markets and their relations to expenditure decisions, employment, production and prices”. He trained in the U.S. Navy with the writer, Herman Wouk, who later fashioned a character after Tobin in the novel The Caine Mutiny (1951): “A mandarin-like midshipman named Tobit, with a domed forehead, measured quiet speech, and a mind like a sponge, was ahead of the field by a spacious percentage.”

Stored results

tobit stores the following in e():

Scalars

- e(N) number of observations
- e(N_unc) number of uncensored observations
- e(N_lc) number of left-censored observations
- e(N_rc) number of right-censored observations
- e(k) number of parameters
- e(k_eq) number of equations in e(b)
- e(k_aux) number of auxiliary parameters
- e(k_dv) number of dependent variables
- e(df_m) model degrees of freedom
- e(df_r) residual degrees of freedom
- e(r2_p) pseudo-$R^2$
- e(ll) log likelihood
- e(ll_0) log likelihood, constant-only model
- e(N_clust) number of clusters
- e(chi2) $\chi^2$ statistic
- e(F) $F$ statistic
- e(p) $p$-value for model test
- e(rank) rank of e(V)
- e(ic) number of iterations
- e(rc) return code
- e(converged) 1 if converged, 0 otherwise
Macros
  - `e(cmd)`  `tobit`
  - `e(cmdline)`  command as typed
  - `e(depvar)`  name of dependent variable
  - `e(llopt)`  minimum of `depvar` or contents of `ll()`
  - `e(ulopt)`  maximum of `depvar` or contents of `ul()`
  - `e(wtype)`  weight type
  - `e(wexp)`  weight expression
  - `e(covariates)`  list of covariates
  - `e(title)`  title in estimation output
  - `e(clustvar)`  name of cluster variable
  - `e(offset)`  linear offset variable
  - `e(chi2type)`  type of model $\chi^2$ test
  - `e(vce)`  `vcetype` specified in `vce()`
  - `e(vcetype)`  title used to label Std. err.
  - `e(opt)`  type of optimization
  - `e(which)`  `max` or `min`; whether optimizer is to perform maximization or minimization
  - `e(method)`  estimation method: `ml`
  - `e(ml_method)`  type of `ml` method
  - `e(user)`  name of likelihood-evaluator program
  - `e(technique)`  maximization technique
  - `e(properties)`  `b V`
  - `e(predict)`  program used to implement `predict`
  - `e(marginsok)`  predictions allowed by `margins`
  - `e(asbalanced)`  factor variables `fvset` as `asbalanced`
  - `e(asobserved)`  factor variables `fvset` as `asobserved`

Matrices
  - `e(b)`  coefficient vector
  - `e(Cns)`  constraints matrix
  - `e(ilog)`  iteration log (up to 20 iterations)
  - `e(gradient)`  gradient vector
  - `e(V)`  variance–covariance matrix of the estimators
  - `e(V_modelbased)`  model-based variance

Functions
  - `e(sample)`  marks estimation sample

In addition to the above, the following is stored in `r()`:

Matrices
  - `r(table)`  matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

Methods and formulas

See Methods and formulas in [R] `intreg`.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly Maximum likelihood estimators and Methods and formulas.

`tobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

<td>E(y_j</td>
</tr>
<tr>
<td>ystar(a,b)</td>
<td>E(y^<em>_j), y^</em>_j = max{a, min(y_j, b)}</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

stdf is not allowed with `svy` estimation results.

where a and b may be numbers or variables; a missing (a ≥ .) means −∞, and b missing (b ≥ .) means +∞; see [U] 12.2.1 Missing values.

Options for predict

```
Main
```

xb, the default, calculates the linear prediction.

stdp calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

stdf calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by stdf are always larger than those produced by stdp; see Methods and formulas in [R] regress postestimation.
\( pr(a,b) \) calculates \( Pr(a < x_j \beta + \epsilon_j < b) \), the probability that \( y_j | x_j \) would be observed in the interval \((a, b)\).

\( a \) and \( b \) may be specified as numbers or variable names; \( lb \) and \( ub \) are variable names; \( pr(20, 30) \) calculates \( Pr(20 < x_j \beta + \epsilon_j < 30) \); \( pr(lb, ub) \) calculates \( Pr(lb < x_j \beta + \epsilon_j < ub) \); and \( pr(20, ub) \) calculates \( Pr(20 < x_j \beta + \epsilon_j < ub) \).

\( a \) missing (\( a \geq . \)) means \(-\infty\); \( pr(. , 30) \) calculates \( Pr(-\infty < x_j \beta + \epsilon_j < 30) \); \( pr(lb, 30) \) calculates \( Pr(-\infty < x_j \beta + \epsilon_j < 30) \) in observations for which \( lb \geq . \) and calculates \( Pr(lb < x_j \beta + \epsilon_j < 30) \) elsewhere.

\( b \) missing (\( b \geq . \)) means \(+\infty\); \( pr(20, .) \) calculates \( Pr(+\infty > x_j \beta + \epsilon_j > 20) \); \( pr(20, ub) \) calculates \( Pr(+\infty > x_j \beta + \epsilon_j > 20) \) in observations for which \( ub \geq . \) and calculates \( Pr(20 < x_j \beta + \epsilon_j < ub) \) elsewhere.

\( e(a, b) \) calculates \( E(x_j \beta + \epsilon_j \mid a < x_j \beta + \epsilon_j < b) \), the expected value of \( y_j | x_j \) conditional on \( y_j | x_j \) being in the interval \((a, b)\), meaning that \( y_j | x_j \) is truncated.

\( a \) and \( b \) are specified as they are for \( pr() \).

\( ystar(a, b) \) calculates \( E(y^*_j) \), where \( y^*_j = a \) if \( x_j \beta + \epsilon_j \leq a \), \( y^*_j = b \) if \( x_j \beta + \epsilon_j \geq b \), and \( y^*_j = x_j \beta + \epsilon_j \) otherwise, meaning that \( y^*_j \) is censored. \( a \) and \( b \) are specified as they are for \( pr() \).

\texttt{nooffset} is relevant only if you specified \texttt{offset(varname)}. It modifies the calculations made by \texttt{predict} so that they ignore the offset variable; the linear prediction is treated as \( x_j \beta \) rather than as \( x_j \beta + \text{offset}_j \).

\texttt{scores} calculates equation-level score variables.

The first new variable will contain \( \partial \ln L / \partial (x_j \beta) \).

The second new variable will contain \( \partial \ln L / \partial \sigma \).
margins

Description for margins

margins estimates margins of response for linear predictions, probabilities, and expected values.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xb</td>
<td>linear prediction; the default</td>
</tr>
<tr>
<td>pr(a,b)</td>
<td>Pr(a &lt; y_j &lt; b)</td>
</tr>
<tr>
<td>e(a,b)</td>
<td>E(y_j</td>
</tr>
<tr>
<td>ystar(a,b)</td>
<td>E(y_j^<em>), y_j^</em> = max{a, min(y_j,b)}</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
<tr>
<td>stdf</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

Remarks and examples

Example 1: Marginal predictions

In example 2 of [R] tobit, we fit a tobit model of annual number of hours that married women spend working and then obtained estimated average marginal effect of 47.47 for years of education on observed hours worked.

```
. use https://www.stata-press.com/data/r18/mroz87
(1975 PSID data from Mroz, 1987)
. tobit whrs75 nwinc wedyrs wexper c.wexper#c.wexper wifeage kl6 k618, ll(0)
(output omitted)
. margins, dydx(wedyrs) predict(ystar(0,.))
(output omitted)
```

However, we may not want this overall effect. To obtain marginal effects for specific alternative scenarios, we use margins with the at() option. For example, continuing with example 2 of [R] tobit to estimate the means of the marginal effects on the expected value of the censored outcome conditional on education ranging from 8 years to 17 years, we type
Average marginal effects

Model VCE: OIM
Expression: E(whrs75*|whrs75>0), predict(ystar(0,.))
dy/dx wrt: wedyrs
1._at: wedyrs = 8
2._at: wedyrs = 9
3._at: wedyrs = 10
4._at: wedyrs = 11
5._at: wedyrs = 12
6._at: wedyrs = 13
7._at: wedyrs = 14
8._at: wedyrs = 15
9._at: wedyrs = 16
10._at: wedyrs = 17

| dy/dx | std. err. | z  | P>|z| | [95% conf. interval] |
|-------|-----------|----|------|----------------------|
| _at   |           |    |      |                      |
| 1     | 39.58775  | 8.432006 | 4.69 | 0.000 | 23.06132  | 56.11418 |
| 2     | 41.4497   | 9.421414 | 4.40 | 0.000 | 22.98407  | 59.91533 |
| 3     | 43.30531  | 10.41233 | 4.16 | 0.000 | 22.89752  | 63.71309 |
| 4     | 45.14859  | 11.39804 | 3.96 | 0.000 | 22.80885  | 67.48833 |
| 5     | 46.97371  | 12.37208 | 3.80 | 0.000 | 22.72489  | 71.22254 |
| 6     | 48.77504  | 13.32825 | 3.66 | 0.000 | 22.65216  | 74.89793 |
| 7     | 50.54717  | 14.26071 | 3.54 | 0.000 | 22.5967   | 78.49765 |
| 8     | 52.28499  | 15.16403 | 3.45 | 0.001 | 22.56403  | 82.00594 |
| 9     | 53.98369  | 16.03324 | 3.37 | 0.001 | 22.55912  | 85.40827 |
| 10    | 55.63887  | 16.8639  | 3.30 | 0.001 | 22.58624  | 88.6915  |

The estimated mean of the marginal effects is about 39.59 hours for 8 years of schooling, about 41.45 hours for 9 years of schooling, and so on.

[R] tobit — Tobit regression
[U] 20 Estimation and postestimation commands
total produces estimates of totals, along with standard errors.

Quick start

Total of continuous variable v1

```
total v1
```

Same as above, but restrict estimation to observations where \texttt{catvar} = 1

```
total v1 if catvar==1
```

Same as above, but using \texttt{svyset} data

```
svy, subpop(if catvar==1): total v1
```

Total of v1 for each level of \texttt{catvar}

```
total v1, over(catvar)
```

With jackknife standard errors

```
total v1, vce(jackknife)
```

Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Totals
### Syntax

```
total varlist [if] [in] [weight] [ , options ]
```

**options**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**varlist** may contain factor variables; see [U] 11.4.3 Factor variables.

*bootstrap, collect, jackknife, mi estimate, rolling, statsby, and svy* are allowed; see [U] 11.1.10 Prefix commands.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the *mi estimate* prefix.

Weights are not allowed with the *bootstrap* prefix; see [R] bootstrap.

`vce()` and weights are not allowed with the *svy* prefix; see [SVY] svy.

`fweights, iweights, and pweights` are allowed; see [U] 11.1.6 weight.

`coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

### Options

**If/in/over**

`over(varlist_o)` specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in varlist_o. Only numeric, nonnegative, integer-valued variables are allowed in over(varlist_o).

**SE/Cluster**

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (analytic), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

`vce(analytic)`, the default, uses the analytically derived variance estimator associated with the sample total.

**Reporting**

`level(#)`; see [R] Estimation options.

`noheader` prevents the table header from being displayed.
display_options: noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), and nolstretch; see [R] Estimation options.

The following option is available with total but is not shown in the dialog box: coeflegend; see [R] Estimation options.

Remarks and examples

Example 1

Suppose that we collected data on incidence of heart attacks. The variable heartatk indicates whether a person ever had a heart attack (1 means yes; 0 means no). We can then estimate the total number of persons who have had heart attacks for each sex in the population represented by the data we collected.

```
. use https://www.stata-press.com/data/r18/total
  (Fictional incidence of heart-attack data)
. total heartatk [pw=swgt], over(sex)
```

```
Total estimation Number of obs = 4,946

</table>
```

Stored results

total stores the following in e():

Scalars

- `e(N)`: number of observations
- `e(N_over)`: number of subpopulations
- `e(N_clust)`: number of clusters
- `e(k_eq)`: number of equations in `e(b)`
- `e(df_r)`: sample degrees of freedom
- `e(rank)`: rank of `e(V)`

Macros

- `e(cmd)`: total
- `e(cmdline)`: command as typed
- `e(varlist)`: `varlist`
- `e(wtype)`: weight type
- `e(wexp)`: weight expression
- `e(title)`: title in estimation output
- `e(clustvar)`: name of cluster variable
- `e(over)`: `varlist` from `over()`
- `e(vce)`: `vcetype` specified in `vce()`
- `e(vcetype)`: title used to label Std. err.
- `e(properties)`: `b V`
- `e(estat_cmd)`: program used to implement estat
- `e(marginsnotok)`: predictions disallowed by margins
**Matrices**
- `e(b)` vector of total estimates
- `e(V)` (co)variance estimates
- `e(N)` vector of numbers of nonmissing observations
- `e(error)` error code corresponding to `e(b)`

**Functions**
- `e(sample)` marks estimation sample

In addition to the above, the following is stored in `r()`:

**Matrices**
- `r(table)` matrix containing the coefficients with their standard errors, test statistics, p-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

**Methods and formulas**

Methods and formulas are presented under the following headings:
- The total estimator
- Survey data
- The survey total estimator
- The poststratified total estimator
- Subpopulation estimation

**The total estimator**

Let \( y \) denote the variable on which to calculate the total and \( y_j, j = 1, \ldots, n \), denote an individual observation on \( y \). Let \( w_j \) be the frequency weight (or `iweight` or `pweight`), and if no weight is specified, define \( w_j = 1 \) for all \( j \). The sum of the weights is an estimate of the population size:

\[
\hat{N} = \sum_{j=1}^{n} w_j
\]

If the population values of \( y \) are denoted by \( Y_j, j = 1, \ldots, N \), the associated population total is

\[
Y = \sum_{j=1}^{N} Y_j = N\bar{y}
\]

where \( \bar{y} \) is the population mean. The total is estimated as

\[
\hat{Y} = \hat{N}\bar{y}
\]

The variance estimator for the total is

\[
\hat{V}(\hat{Y}) = \hat{N}^2\hat{V}(\bar{y})
\]

where \( \hat{V}(\bar{y}) \) is the variance estimator for the mean; see [R] mean. The standard error of the total is the square root of the variance.

If \( x, x_j, \bar{x} \), and \( \hat{X} \) are similarly defined for another variable (observed jointly with \( y \)), the covariance estimator between \( \hat{X} \) and \( \hat{Y} \) is

\[
\hat{\text{Cov}}(\hat{X}, \hat{Y}) = \hat{N}^2\hat{\text{Cov}}(\bar{x}, \bar{y})
\]

where \( \hat{\text{Cov}}(\bar{x}, \bar{y}) \) is the covariance estimator between two means; see [R] mean.
Survey data

See [SVY] Variance estimation and [SVY] Poststratification for discussions that provide background information for the following formulas.

The survey total estimator

Let $Y_j$ be a survey item for the $j$th individual in the population, where $j = 1, \ldots, M$ and $M$ is the size of the population. The associated population total for the item of interest is

$$Y = \sum_{j=1}^{M} Y_j$$

Let $y_j$ be the survey item for the $j$th sampled individual from the population, where $j = 1, \ldots, m$ and $m$ is the number of observations in the sample.

The estimator $\hat{Y}$ for the population total $Y$ is

$$\hat{Y} = \sum_{j=1}^{m} w_j y_j$$

where $w_j$ is a sampling weight. The estimator for the number of individuals in the population is

$$\hat{M} = \sum_{j=1}^{m} w_j$$

The score variable for the total estimator is the variable itself,

$$z_j(\hat{Y}) = y_j$$

The poststratified total estimator

Let $P_k$ denote the set of sampled observations that belong to poststratum $k$, and define $I_{Pk}(j)$ to indicate if the $j$th observation is a member of poststratum $k$, where $k = 1, \ldots, L_P$ and $L_P$ is the number of poststrata. Also, let $M_k$ denote the population size for poststratum $k$. $P_k$ and $M_k$ are identified by specifying the poststrata() and postweight() options on svyset; see [SVY] svyset.

The estimator for the poststratified total is

$$\hat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \sum_{j=1}^{m} I_{Pk}(j) w_j y_j$$

where

$$\hat{M}_k = \sum_{j=1}^{m} I_{Pk}(j) w_j$$

The score variable for the poststratified total is

$$z_j(\hat{Y}^P) = \sum_{k=1}^{L_P} I_{Pk}(j) \frac{M_k}{\hat{M}_k} \left( y_j - \frac{\hat{Y}_k}{\hat{M}_k} \right)$$
Subpopulation estimation

Let $S$ denote the set of sampled observations that belong to the subpopulation of interest, and define $I_S(j)$ to indicate if the $j$th observation falls within the subpopulation.

The estimator for the subpopulation total is

$$\hat{Y}^S = \sum_{j=1}^{m} I_S(j) w_j y_j$$

and its score variable is

$$z_j(\hat{Y}^S) = I_S(j) y_j$$

The estimator for the poststratified subpopulation total is

$$\hat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{M} \hat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{M} \sum_{j=1}^{m} I_{P_k}(j) I_S(j) w_j y_j$$

and its score variable is

$$z_j(\hat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{M} \left\{ I_S(j) y_j - \frac{\hat{Y}_k^S}{M_k} \right\}$$

Remarks and examples

Example 1

Continuing with our data on incidence of heart attacks from `example 1` in [R] `total`, we want to test whether there are twice as many heart attacks among men than women in the population.

```stata
use https://www.stata-press.com/data/r18/total
(output omitted)
.total heartatk [pw=swgt], over(sex)
(test heartatk@1.sex = 2 * heartatk@2.sex
( 1)  c.heartatk@1bn.sex - 2*c.heartatk@2.sex = 0
    F(  1,  4945) =  1.25
    Prob > F =  0.2643
```

Thus we do not reject our hypothesis that the total number of heart attacks for men is twice that for women in the population.

[U] 20 Estimation and postestimation commands
tpoisson fits a truncated Poisson regression model when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. Truncated Poisson models are appropriate when neither the dependent variable nor the covariates are observed in the truncated part of the distribution. By default, tpoisson assumes left-truncation occurs at zero, but truncation may be specified at other fixed points or at values that vary across observations.

**Quick start**

Truncated Poisson regression of y on x1 and x2 with left-truncation at 0  
\[ \text{tpoisson} \ y \ x1 \ x2 \]

Add categorical variable a using factor-variable syntax  
\[ \text{tpoisson} \ y \ x1 \ x2 \ i.a \]

Same as above, but report incidence-rate ratios and use a constant truncation point of 4  
\[ \text{tpoisson} \ y \ x1 \ x2 \ i.a, \text{irr} \ ll(4) \]

With offset variable lnexp  
\[ \text{tpoisson} \ y \ x1 \ x2 \ i.a, \text{offset(lnexp)} \]

Same as above, but with a variable truncation point stored in variable min  
\[ \text{tpoisson} \ y \ x1 \ x2 \ i.a, \text{offset(lnexp)} \ ll(min) \]

With variable left- and right-truncation points  
\[ \text{tpoisson} \ y \ x1 \ x2, \text{ll(min)} \ ul(max) \]

With variable right-truncation points  
\[ \text{tpoisson} \ y \ x1 \ x2, \text{ul(max)} \]

Constrain the coefficients for 2.a and 3.a to equality  
\[ \text{constraint} \ \text{define} \ 1 \ 2.a = 3.a \]
\[ \text{tpoisson} \ y \ x1 \ x2 \ i.a, \text{constraints}(1) \]
Syntax

tpoisson  depvar  [indepvars]  [if]  [in]  [weight]  [,  options]

options     Description

Model

noconstant suppress constant term
ll(#  |  varname) lower limit for truncation; default is 11(0) when neither
     ll() nor ul() is specified
ul(#  |  varname) upper limit for truncation
exposure(varname_e) include ln(varname_e) in model with coefficient constrained to 1
offset(varname_o) include varname_o in model with coefficient constrained to 1
constraints(constraints) apply specified linear constraints

SE/Robust

vce(vcetype) vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife

Reporting

level(#) set confidence level; default is level(95)
irr report incidence-rate ratios
noconsreport do not display constraints
display_options control columns and column formats, row spacing, line width,
     display of omitted variables and base and empty cells, and
     factor-variable labeling

Maximization

maximize_options control the maximization process; seldom used

collinear keep collinear variables
coefflegend display legend instead of statistics

Options

Model

noconstant; see [R] Estimation options.

ll(# | varname) and ul(# | varname) specify the lower and upper limits for truncation, respectively.
You may specify nonnegative integer values for one or both.
When neither ll() nor ul() is specified, the default is zero truncation, 11(0), equivalent to
left-truncation at zero.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweight(), iweight(), and pweight() are allowed; see [U] 11.1.6 weight.
collinear and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
tpoisson — Truncated Poisson regression

exposure(varname_e), offset(varname_o), constraints(constraints); see [R] Estimation options.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

Reporting

level(#) ; see [R] Estimation options.

irr reports estimated coefficients transformed to incidence-rate ratios, that is, \( e^{\beta_i} \) rather than \( \beta_i \). Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. irr may be specified at estimation or when replaying previously estimated results.

cnsreport; see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), lrtolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following options are available with tpoisson but are not shown in the dialog box: collinear, coeflegend; see [R] Estimation options.

Remarks and examples

tpoisson fits a truncated Poisson regression model by maximum likelihood estimation when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. If the dependent variable is not truncated, standard Poisson regression may be more appropriate; see [R] poisson.

When the data are truncated, we do not observe either the dependent variable or the covariates. For example, consider a study about the number of days that individuals with hyperglycemia are hospitalized after presenting to the hospital. If we select our sample only from admission records, then the sample is truncated at zero because we have data only on individuals who stayed at least one day. Now assume that we are relying on billing data and that hospitals may submit either a final bill when a patient is discharged or an interim bill every 30 days. In this case, we have no information about patients who are hospitalized fewer than 1 day or more than 30 days. Our data are left-truncated at 0 and right-truncated at 30.

A related phenomenon is censoring. For censored observations, we observe complete covariate information but only a censored value of the dependent variable. Different research designs can give rise to censored data or truncated data. See [R] cpoisson for information about censored Poisson regression.
Truncated Poisson regression was first proposed by Grogger and Carson (1991). For an introduction to Poisson regression, see Cameron and Trivedi (2005, 2022) and Long and Freese (2014). For an introduction to truncated Poisson models, see Cameron and Trivedi (2013) and Long (1997, chap. 8).

Example 1: Left-truncation at zero

Consider the Simonoff (2003) dataset of running shoes for a sample of runners who registered an online running log. A running-shoe marketing executive is interested in knowing how the number of pairs of running shoes purchased relates to other factors such as gender, marital status, age, education, income, typical number of runs per week, average miles run per week, and the preferred type of running. These data are naturally truncated at zero. A truncated Poisson model is fit to the number of pairs of shoes owned on runs per week, miles run per week, gender, age, and marital status.

No options are needed because zero truncation is the default for tpoisson.

```
. use https://www.stata-press.com/data/r18/runshoes  
(Running shoes)
. tpoisson shoes rpweek mpweek male age married
```

```
Truncated Poisson regression

</tbody>
</table>

Using the zero-truncated Poisson regression with these data, only the coefficient on average miles per week is statistically significant at the 5% level.

Example 2: Left-truncation with a fixed-truncation point

Semiconductor manufacturing requires that silicon wafers be coated with a layer of metal oxide. The depth of this layer is strictly controlled. In this example, a critical oxide layer is designed for 300 ± 20 angstroms (Å).

After the oxide layer is coated onto a wafer, the wafer enters a photolithography step in which the lines representing the electrical connections are printed on the oxide and later etched and filled with metal. The widths of these lines are measured. In this example, they are controlled to 90 ± 5 micrometers (µm).

After these and other steps, each wafer is electrically tested at probe. If too many failures are discovered, the wafer is rejected and sent for engineering analysis. In this example, the maximum number of probe failures tolerated for this product is 10.
A major failure at probe has been encountered—88 wafers had more than 10 failures each. The 88 wafers that failed were tested using 4 probe machines. The engineer suspects that the failures were a result of faulty probe machines, poor depth control, or poor line widths. The line widths and depths in these data are the actual measurement minus its specification target, 300 Å for the oxide depths and 90 µm for the line widths.

The following table tabulates the average failure rate for each probe using Stata’s `mean` command; see [R] `mean`.

```
use https://www.stata-press.com/data/r18/probe
(Silicon wafers)
.mean failures, over(probe)
```

<table>
<thead>
<tr>
<th>Mean estimation</th>
<th>Number of obs = 88</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mean</td>
<td>Std. err.</td>
</tr>
<tr>
<td>c.failures@probe</td>

</tr>
<tr>
<td>3</td>
<td>16.47059</td>
</tr>
<tr>
<td>4</td>
<td>23.09677</td>
</tr>
</tbody>
</table>

The 95% confidence intervals in this table suggest that there are about 5–11 additional failures per wafer on probe 4. These are unadjusted for varying line widths and oxide depths. Possibly, probe 4 received the wafers with larger line widths or extreme oxide depths.

Truncated Poisson regression more clearly identifies the root causes for the increased failures by estimating the differences between probes adjusted for the line widths and oxide depths. It also allows us to determine whether the deviations from specifications in line widths or oxide depths might be contributing to the problem.

```
.tpoisson failures i.probe depth width, ll(10) nolog
```

Truncated Poisson regression  Number of obs = 88
Limits: lower = 10 LR chi2(5) = 73.70
upper = +inf Prob > chi2 = 0.0000
Log likelihood = -239.35746 Pseudo R2 = 0.1334

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The coefficients listed for the probes are testing the null hypothesis: $H_0: \text{probe}_i = \text{probe}_1$, where $i$ equals 2, 3, and 4. Because the only coefficient that is statistically significant is the one for testing $H_0: \text{probe}_4 = \text{probe}_1$, $p < 0.001$, and because the $p$-values for the other probes are not statistically significant, that is, $p \geq 0.275$, the implication is that there is a difference between probe 4 and the other machines. Because the coefficient for this test is positive, 0.425, the conclusion is that the average failure rate for probe 4, after adjusting for line widths and oxide depths, is higher than the other probes. Possibly, probe 4 needs calibration or the head used with this machine is defective.

Line-width control is statistically significant, $p = 0.034$, but variation in oxide depths is not causing the increased failure rate. The engineer concluded that the sudden increase in failures is the result of
two problems. First, probe 4 is malfunctioning, and second, there is a possible lithography or etching problem.

Stored results

`tpoisson` stores the following in `e()`:

Scalars
- `e(N)` number of observations
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(r2_p)` pseudo-$R^2$
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(N_clust)` number of clusters
- `e(chi2)` $\chi^2$
- `e(p)` $p$-value for model test
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

Macros
- `e(cmd)` `tpoisson`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(llopt)` contents of `ll()`, or 0 if neither `ll()` nor `ul()` is specified
- `e(ulopt)` contents of `ul()`, if specified
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset)` linear offset variable
- `e(chi2type)` Wald or LR; type of model $\chi^2$ test
- `e(vce)` `vcetype` specified in `vce()`
- `e(vcetitle)` title used to label Std. err.
- `e(opt)` type of optimization
- `e(which)` `max` or `min`; whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of `ml` method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` `b V`
- `e(predict)` program used to implement `predict`
- `e(asbalanced)` factor variables `fvset` as `asbalanced`
- `e(asobserved)` factor variables `fvset` as `asobserved`

Matrices
- `e(b)` coefficient vector
- `e(Cns)` constraints matrix
- `e(ilog)` iteration log (up to 20 iterations)
- `e(gradient)` gradient vector
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance

Functions
- `e(sample)` marks estimation sample
In addition to the above, the following is stored in \( r() \):

Matrices
\[
\mat{table}
\]
matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in \( r() \) are updated when the command is replayed and will be replaced when any \( r \)-class command is run after the estimation command.

**Methods and formulas**

For a nonnegative count outcome \( Y \) with left-truncation point \( ll_j \) and right-truncation point \( ul_j \), we can write the truncated Poisson model as

\[
f(y_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | \xi_j)}
\]

where

\[
\xi_j = \mathbf{x}_j \beta + \text{offset}_j
\]

\[
\lambda_j = \exp(\xi_j)
\]

and \( \mathbf{x}_j \) is a vector of observed covariates. The conditional probability of observing \( y_j \) events, therefore given by \( ll_j < y_j < ul_j \), is

\[
\Pr(Y = y_j | ll_j < y_j < ul_j, \mathbf{x}_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | \mathbf{x}_j)}
\]

The log likelihood is given by

\[
\ln L = \sum_{j=1}^{n} w_j [-\lambda_j + \xi_j y_j - \ln(y_j!) - \ln \{ \Pr(ll_j < Y < ul_j | \xi_j) \}]
\]

If no weights are specified, \( w_j = 1 \).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] _robust}, particularly \texttt{Maximum likelihood estimators} and \texttt{Methods and formulas}.

\texttt{tpoisson} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] Variance estimation}.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

n, the default, calculates the predicted number of events, which is $\exp(x_j\beta)$ if neither offset() nor exposure() was specified when the model was fit; $\exp(x_j\beta + \text{offset})$ if offset() was specified; or $\exp(x_j\beta) \times \text{exposure}$ if exposure() was specified.

ir calculates the incidence rate $\exp(x_j\beta)$, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the n and the nooffset options.

cm calculates the conditional mean,

$$E(y_j | ll_j < y_j < ul_j) = \frac{E(y_j, ll_j < y_j < ul_j)}{Pr(ll_j < y_j < ul_j)}$$

where $ll_j$ is the left-truncation point specified at estimation and $ul_j$ is the right-truncation point specified at estimation.
\( \text{pr}(n) \) calculates the probability \( \Pr(y_j = n) \), where \( n \) is a nonnegative integer that may be specified as a number or a variable.

\( \text{pr}(a, b) \) calculates the probability \( \Pr(a \leq y_j \leq b) \), where \( a \) and \( b \) are nonnegative integers that may be specified as numbers or variables;

- \( b \) missing (\( b \geq . \)) means \(+\infty\);
- \( \text{pr}(20, .) \) calculates \( \Pr(y_j \geq 20) \);
- \( \text{pr}(20, b) \) calculates \( \Pr(y_j \geq 20) \) in observations for which \( b \geq . \) and calculates \( \Pr(20 \leq y_j \leq b) \) elsewhere.

\( \text{pr}(., b) \) produces a syntax error. A missing value in an observation of the variable \( a \) causes a missing value in that observation for \( \text{pr}(a, b) \).

\( \text{cpr}(n) \) calculates the conditional probability \( \Pr(y_j = n \mid ll_j < y_j < ul_j) \), where \( n \) is a nonnegative integer that may be specified as a number or a variable. \( ll_j \) and \( ul_j \) are as defined in \( cm \).

\( \text{cpr}(a, b) \) calculates the conditional probability \( \Pr(a \leq y_j \leq b \mid ll_j < y_j < ul_j) \), where \( a \) and \( b \) are as defined in \( \text{pr}(a, b) \) with the additional restrictions that \( a > ll_j \) and \( b < ul_j \). \( ll_j \) and \( ul_j \) are as defined in \( cm \).

\( \text{xb} \) calculates the linear prediction, which is \( x_j \beta \) if neither \( \text{offset()} \) nor \( \text{exposure()} \) was specified when the model was fit; \( x_j \beta + \text{offset}_j \) if \( \text{offset()} \) was specified; or \( x_j \beta + \ln(\text{exposure}_j) \) if \( \text{exposure()} \) was specified; see \( \text{nooffset} \) below.

\( \text{stdp} \) calculates the standard error of the linear prediction.

\( \text{score} \) calculates the equation-level score, \( \partial \ln L / \partial(x_j \beta) \).

\( \text{nooffset} \) is relevant only if you specified \( \text{offset()} \) or \( \text{exposure()} \) when you fit the model. It modifies the calculations made by \( \text{predict} \) so that they ignore the offset or exposure variable; the linear prediction is treated as \( x_j \beta \) rather than as \( x_j \beta + \text{offset}_j \) or \( x_j \beta + \ln(\text{exposure}_j) \). Specifying \( \text{predict...}, \text{nooffset} \) is equivalent to specifying \( \text{predict...}, \text{ir} \).
margins

Description for margins

margins estimates margins of response for numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, and linear predictions.

Statistics not allowed with margins are functions of stochastic quantities other than $e(b)$.

For the full syntax, see [R] margins.

Remarks and examples

Example 1: Obtaining margins of the conditional mean

In example 1 of [R] tpoisson, a truncated Poisson model is fit to the number of pairs of shoes owned on runs per week, miles run per week, gender, age, and marital status. We continue that example to determine the effect of miles run per week on the average number of pairs of shoes owned.

After reading in the data, we use summarize to obtain the 25th, 50th, and 75th percentiles for miles run per week.
We fit the model from example 1 of [R] tpoisson again. We next specify these values for the percentiles to margins to estimate the conditional mean of the number of pairs of shoes at different quantiles of miles run per week. To do this, we use the at() option of margins.

```
. quietly tpoisson shoes rpweek mpweek male age married
. margins, at(mpweek=(12.5 27.5 32.5)) predict(cm)
```

```
Predictive margins Number of obs = 60
Model VCE: OIM
Expression: Conditional mean of n > ll(0), predict(cm)
1._at: mpweek = 12.5
2._at: mpweek = 27.5
3._at: mpweek = 32.5

| _at | Delta-method | Margin std. err. | z | P>|z| | [95% conf. interval] |
|-----|---------------|------------------|---|-------|-------------------|
| 1   | 1.942149      | 0.2111564        | 9.20| 0.000 | 1.52829          | 2.356008          |
| 2   | 2.376253      | 0.1714522        | 13.86| 0.000 | 2.040213         | 2.712293          |
| 3   | 2.564339      | 0.1948129        | 13.16| 0.000 | 2.182513         | 2.946165          |
```

We see that people who run 12.5 miles per week are expected to own 1.94 pairs of shoes. The expected number of pairs of shoes owned increases as the average miles per week increases. We expect people who run 27.5 miles per week have 2.38 pairs of shoes and those who run 32.5 miles per week have 2.56 pairs of shoes.

### Methods and formulas

Continuing from *Methods and formulas* in [R] tpoisson, the equation-level score is given by

\[
score(x_\beta)_j = y_j - \lambda_j - \frac{\{\exp(-\lambda_j)\lambda_j^{ll_j}/ll_j! - \exp(-\lambda_j)\lambda_j^{(ul_j-1)}/(ul_j - 1)!\}\lambda_j}{\Pr(ll_j < Y < ul_j | \xi_j)}
\]

[U] 20 Estimation and postestimation commands
**translate — Print and translate logs**

### Description

print prints log, SMCL, and text files. translate translates log and SMCL files from one format to another, the other typically being suitable for printing. `translate` can also translate SMCL logs to plain text.

### Quick start

Translate SMCL-format log `mylog.smcl` to a text log file `mylog.log`

```bash
translate mylog.smcl mylog.log
```

Same as above, but translate `mylog.smcl` to PostScript file `mylog.ps`

```bash
translate mylog.smcl mylog.ps
```

Send output from the Results window to new `mylog.txt` when no log was started

```bash
translate @Results mylog.txt
```
Syntax

Print log and SMCL files

\texttt{print filename[, like(ext) name(windowname) override\_options]}

Translate log files to SMCL files and vice versa

\texttt{translate filename\_in filename\_out[, translator(tname) name(windowname) override\_options replace]}

View translator parameter settings

\texttt{translator query [tname]}

Change translator parameter settings

\texttt{translator set [tname setopt setval]}

Return translator parameter settings to default values

\texttt{translator reset tname}

List current mappings from one extension to another

\texttt{transmap query [.ext]}

Specify that files with one extension be treated the same as files with another extension

\texttt{transmap define .ext\_new .ext\_old}

\texttt{filename} in \texttt{print}, in addition to being a filename to be printed, may be specified as @Results to mean the Results window and @Viewer to mean the Viewer window.

\texttt{filename\_in} in \texttt{translate} may be specified just as \texttt{filename} in \texttt{print}.

\texttt{tname} in \texttt{translator} specifies the name of a translator; see the \texttt{translator()} option under \texttt{Options for translate}.

Options for print

\texttt{like(ext)} specifies how the file should be translated to a form suitable for printing. The default is to determine the translation method from the extension of \texttt{filename}. Thus, \texttt{mylog.smcl} is translated according to the rule for translating \texttt{smcl} files, \texttt{myfile.txt} is translated according to the rule for translating \texttt{txt} files, and so on. (These rules are, in fact, translate’s \texttt{smcl2prn} and \texttt{txt2prn} translators, but put that aside for the moment.)

Rules for the following extensions are predefined:

\begin{itemize}
  \item [.txt] assume input file contains plain text
  \item [.log] assume input file contains Stata log text
  \item [.smcl] assume input file contains SMCL
\end{itemize}
To print a file that has an extension different from those listed above, you can define a new extension, but you do not have to do that. Assume that you wish to print the file `read.me`, which you know to contain plain text. If you were just to type `print read.me`, you would be told that Stata cannot translate `.me` files. (You would actually be told that the translator for `me2prn` was not found.) You could type `print read.me, like(txt)` to tell `print` to print `read.me` like a `.txt` file.

On the other hand, you could type

```
  . transmap define .me .txt
```

to tell Stata that `.me` files are always to be treated like `.txt` files. If you did that, Stata would remember the new rule, even in future sessions.

When you specify the `like()` option, you override the recorded rules. So, if you were to type `print mylog.smcl, like(txt)`, the file would be printed as plain text (meaning that all the SMCL commands would show).

`name(windowname)` specifies which window to print when printing a Viewer. The default is for Stata to print the topmost Viewer [Unix(GUI) users: See the third technical note in Printing files, Unix]. The `name()` option is ignored when printing the Results window.

The window name is located inside the parentheses in the window title. For example, if the title for a Viewer window is `Viewer (#1) [help print]`, the name for the window is `#1`.

`override_options` refer to `translate`'s options for overriding default values. `print` uses `translate` to translate the file into a format suitable for sending to the printer, and thus `translate`'s `override_options` may also be used with `print`. The settings available vary between each translator (for example, `smcl2ps` will have different settings than `smcl2txt`) and may also differ across operating systems (for example, Windows may have different printing options than macOS). To find out what you can override when printing `.smcl` files, type

```
  . translator query smcl2prn
  (output omitted)
```

In the omitted output, you might learn that there is an `rmargin #` tunable value, which specifies the right margin in inches. You could specify the `override_option rmargin(#)` to temporarily override the default value, or you could type `translator set smcl2prn rmargin #` beforehand to permanently reset the value.

Alternatively, on some computers with some translators, you might discover that nothing can be set.
Options for translate

`translator(tname)` specifies the name of the translator to be used to translate the file. The available translators are

<table>
<thead>
<tr>
<th><code>tname</code></th>

</tr>
<tr>
<td><code>smcl2log</code></td>
<td>SMCL</td>
<td>Stata text log</td>
</tr>
<tr>
<td><code>Results2txt</code></td>
<td>Results window</td>
<td>generic text file</td>
</tr>
<tr>
<td><code>Viewer2txt</code></td>
<td>Viewer window</td>
<td>generic text file</td>
</tr>
<tr>
<td><code>smcl2pdf</code></td>
<td>SMCL</td>
<td>PDF</td>
</tr>
<tr>
<td><code>log2pdf</code></td>
<td>Stata text log</td>
<td>PDF</td>
</tr>
<tr>
<td><code>txt2pdf</code></td>
<td>generic text log</td>
<td>PDF</td>
</tr>
<tr>
<td><code>Results2pdf</code></td>
<td>Results window</td>
<td>PDF</td>
</tr>
<tr>
<td><code>Viewer2pdf</code></td>
<td>Viewer window</td>
<td>PDF</td>
</tr>
</tbody>
</table>

If `translator()` is not specified, `translate` determines which translator to use from extensions of the filenames specified. Typing `translate myfile.smcl myfile.ps` would use the `smcl2ps` translator. Typing `translate myfile.smcl myfile.ps, translate(smcl2prn)` would override the default and use the `smcl2prn` translator.

Actually, when you type `translate a.b c.d`, `translate` looks up `.b` in the `transmap` extension-synonym table. If `.b` is not found, the translator `b2d` is used. If `.b` is found in the table, the mapped extension is used (call it `b'`), and then the translator `b'2d` is used. For example,

<table>
<thead>
<tr>
<th>Command</th>
<th>Translator used</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>. translate myfile.smcl myfile.ps</code></td>
<td><code>smcl2ps</code></td>
</tr>
<tr>
<td><code>. translate myfile.odd myfile.ps</code></td>
<td><code>odd2ps</code>, which does not exist, so error</td>
</tr>
<tr>
<td><code>. transmap define .odd .txt</code></td>
<td></td>
</tr>
<tr>
<td><code>. translate myfile.odd myfile.ps</code></td>
<td><code>txt2ps</code></td>
</tr>
</tbody>
</table>

You can list the mappings that `translate` uses by typing `transmap query`.

`name(windowname)` specifies which window to translate when translating a Viewer. The default is for Stata to translate the topmost Viewer. The `name()` option is ignored when translating the Results window.

The window name is located inside the parentheses in the window title. For example, if the title for a Viewer window is `Viewer (#1) [help print]`, the name for the window is `#1`. 
override_options override any of the default options of the specified or implied translator. To find out what you can override for, say, log2ps, type

```
    . translator query log2ps
```

In the omitted output, you might learn that there is an rmargin # tunable value, which, for log2ps, specifies the right margin in inches. You could specify the `override_option rmargin(#)` to temporarily override the default value or type `translator set log2ps rmargin #` beforehand to permanently reset the value.

replace specifies that filename_out be replaced if it already exists.

**Remarks and examples**

Remarks are presented under the following headings:

- **Overview**
- **Printing files**
- **Printing files, Mac and Windows**
- **Printing files, Unix**
- **Translating files from one format to another**

**Overview**

`print` prints log, SMCL, and text files. Although there is considerable flexibility in how `print` (and `translate`, which `print` uses) can be set to work, they have already been set up and should just work:

```
    . print mylog.smcl
    . print mylog.log
```

Unix users may discover that they need to do a bit of setup before `print` works; see *Printing files, Unix* below. International Unix users may also wish to modify the default paper size. All users can tailor `print` and `translate` to their needs.

`print` may also be used to print the current contents of the Results window or the Viewer. For instance, the current contents of the Results window could be printed by typing

```
    . print @Results
```

`translate` translates log and SMCL files from one format to another, the other typically being suitable for printing. `translate` can also translate SMCL logs (logs created by typing, say, log using mylog) to plain text:

```
    . translate mylog.smcl mylog.log
```

You can use `translate` to recover a log when you have forgotten to start one. You may type

```
    . translate @Results mylog.txt
```

to capture as plain text what is currently shown in the Results window.

This entry provides a general overview of `print` and `translate` and covers in detail the printing and translation of text (nongraphic) files.

`translator query`, `translator set`, and `translator reset` show, change, and restore the default values of the settings for each translator.

`transmap define` and `transmap query` create and show mappings from one file extension to another for use with `print` and `translate`. 
For example, `print myfile.txt` knows to use a translator appropriate for printing text files because of the `.txt` extension. However, it does not know what to do with `.xyz` files. If you have `.xyz` files and always wish to treat them as `.txt` files, you can type `transmap define .xyz .txt`.

### Printing files

Printing should be easy; just type

```
    . print mylog.smcl
    . print mylog.log
```

You can use `print` to print SMCL files, plain text files, and even the contents of the Results and Viewer windows:

```
    . print @Results
    . print @Viewer
    . print @Viewer, name(#2)
```

For information about printing and translating graph files, see `[G-2] graph print` and see `[G-2] graph export`.

### Printing files, Mac and Windows

When you type `print`, you are using the same facility that you would be using if you had selected `Print` from the `File` menu. If you try to print a file that Stata does not know about, Stata will complain:

```
    . print read.me
    translator me2prn not found
    r(111);
```

Then, you could type

```
    . print read.me, like(txt)
```

to indicate that you wanted `read.me` sent to the printer in the same fashion as if the file were named `readme.txt`, or you could type

```
    . transmap define .me .txt
    . print read.me
```

Here you are telling Stata once and for all that you want files ending in `.me` to be treated in the same way as files ending in `.txt`. Stata will remember this mapping, even across sessions. To clear the `.me` mapping, type

```
    . transmap define .me
```

To see all the mappings, type

```
    . transmap query
```

To print to a file, use the `translate` command, not `print`:

```
    . translate mylog.smcl mylog.prn
```

`translate` prints to a file by using the Windows print driver when the new filename ends in `.prn`. Under Mac, the `.prn` translators are the same as the `.pdf` translators. We suggest that you simply use the `.pdf` file extension when printing to a file.
Printing files, Unix

Stata assumes that you have a PostScript printer attached to your Unix computer and that the Unix command `lpr(1)` can be used to send PostScript files to it, but you can change this. On your Unix system, typing

```
mycomputer$ lpr < filename
```

may not be sufficient to print PostScript files. For instance, perhaps on your system you would need to type

```
mycomputer$ lpr -Plexmark < filename
```

or

```
mycomputer$ lpr -Plexmark filename
```

or something else. To set the print command to be `lpr -Plexmark filename` and to state that the printer expects to receive PostScript files, type

```
.printer define prn ps "lpr -Plexmark @"
```

To set the print command to `lpr -Plexmark < filename` and to state that the printer expects to receive plain text files, type

```
.printer define prn txt "lpr -Plexmark < @"
```

That is, just type the command necessary to send files to your printer and include an `@` sign where the filename should be substituted. Two file formats are available: `ps` and `txt`. The default setting, as shipped from the factory, is

```
.printer define prn ps "lpr < @"
```

We will return to the `printer` command in the technical note that follows because it has some other capabilities you should know about.

In any case, after you redefine the default printer, the following should just work:

```
.print mylog.smcl
.print mylog.log
```

If you try to print a file that Stata does not know about, it will complain:

```
.print read.me
translator me2prn not found
r(111);
```

Here you could type

```
.print read.me, like(txt)
```

to indicate that you wanted `read.me` sent to the printer in the same fashion as if the file were named `readme.txt`, or you could type
Here you are telling Stata once and for all that you want files ending in .me to be treated in the same way as files ending in .txt. Stata will remember this setting for .me, even across sessions.

If you want to clear the .me setting, type

```
.transmap define .me
```

If you want to see all your settings, type

```
.transmap query
```

**Technical note**

If the text you wish to print contains Unicode characters, those characters may not appear correctly in PostScript files because the PostScript fonts do not support Unicode. Stata will map as many characters as possible to characters supported by Unicode but will print a question mark (?) for any unsupported character. We recommend that you export the text to a PDF file, which has fonts with better support for Unicode characters.

**Technical note**

The syntax of the `printer` command is

```
printer define printername [ { ps | txt } "Unix command with @" ]
printer query [ printername ]
```

You may define multiple printers. By default, `print` uses the printer named `prn`, but `print` has the syntax

```
print filename [ , like( ext ) printer( printername ) override_options ]
```

so, if you define multiple printers, you may route your output to them.

For instance, if you have a second printer on your system, you might type

```
.printer define lexmark ps "lpr -Plexmark < @"
```

After doing that, you could type

```
.print print myfile.smcl, printer(lexmark)
```

Any printers that you set will be remembered even across sessions. You can delete printers:

```
.printer define lexmark
```

You can list all the defined printers by typing `printer query`, and you can list the definition of a particular printer, say, `prn`, by typing `printer query prn`.

The default printer `prn` we have predefined for you is

```
.printer define prn ps "lpr < @"
```

meaning that we assume that it is a PostScript printer and that the Unix command `lpr(1)`, without options, is sufficient to cause files to print. Feel free to change the default definition. If you change it, the change will be remembered across sessions.
Technical note

Unix (GUI) users should note that X-Windows does not have the concept of a window z-order, which prevents Stata from determining which window is the topmost window. Instead, Stata determines which window is topmost based on which window has the focus. However, some window managers will set the focus to a window without bringing the window to the top. What Stata considers the topmost window may not appear topmost visually. For this reason, you should always use the name() option to ensure that the correct window is printed.

Technical note

When you select the Results window to print from the Print menu or toolbar button, the result is the same as if you were to issue the print command. When you select a Viewer window to print from the Print menu or toolbar button, the result is the same as if you were to issue the print command with a name() option.

The translation to PostScript format is done by translate and, in particular, is performed by the translators smcl2ps, log2ps, and txt2ps. There are many tunable parameters in each of these translators. You can display the current values of these tunable parameters for, say, smcl2ps by typing

```
.translate query smcl2ps
(output omitted)
```

and you can set any of the tunable parameters (for instance, setting smcl2ps’s rmargin value to 1) by typing

```
.translate set smcl2ps rmargin 1
(output omitted)
```

Any settings you make will be remembered across sessions. You can reset smcl2ps to be as it was when Stata was shipped by typing

```
.translate reset smcl2ps
```

Translating files from one format to another

If you have a SMCL log, which you might have created by previously typing log using mylog, you can translate it to an text log by typing

```
.translate myfile.smcl myfile.log
```

and you can translate it to a PostScript file by typing

```
.translate myfile.smcl myfile.ps
```

translate translates files from one format to another, and, in fact, print uses translate to produce a file suitable for sending to the printer.

When you type

```
.translate a,b c,d
```

translate looks for the predefined translator b2d and uses that to perform the translation. If there is a transmap synonym for b, however, the mapped value b' is used: b'2d.
Only certain translators exist, and they are listed under the description of the `translate()` option in the `Options for translate` above, or you can type `.` translate query

for a complete (and perhaps more up-to-date) list.

Anyway, `translate` forms the name $b2d$ or $b'2d$, and if the translator does not exist, `translate` issues an error message. With the `translator()` option, you can specify exactly which translator to use, and then it does not matter how your files are named.

The only other thing to know is that some translators have tunable parameters that affect how they perform their translation. You can type `.` translator query `translator_name`

to find out what those parameters are. Some translators have no tunable parameters, and some have many:

```
. translator query smcl2ps
```

</table>

You can temporarily override any setting by specifying the `setopt(setval)` option on the `translate` (or `print`) command. For instance, you can type `.` translate ... ... cmdnumber(off)

or you can reset the value permanently by typing `.` translator set smcl2ps setopt setval

For instance,

```
. translator set smcl2ps cmdnumber off
```

If you reset a value, Stata will remember the change, even in future sessions.
Mac and Windows users: The smcl2ps (and the other *2ps translators) are not used by print, even when you have a PostScript printer attached to your computer. Instead, the Mac or Windows print driver is used. Resetting smcl2ps values will not affect printing; instead, you change the defaults in the Printers Control Panel in Windows and by selecting Page Setup... from the File menu in Mac. You can, however, translate files yourself using the smcl2ps translator and the other *2ps translators.

Technical note: Using PDF translators (Windows and Unix)

When using translate to translate a log, SMCL, or text file or a Stata graph into a PDF file, some characters may not display correctly in the resulting PDF file. This happens when translating content that contains Unicode characters from different languages; one font may not be adequate to display every character used. If an appropriate font is not available for a character, that character will not display correctly in the resulting PDF file.

Specific fonts can be used to build a font chain. Those fonts are specified using fontname and are separated by commas. The most preferred font should be listed first, followed by the less preferred fonts. A maximum of 16 fonts can be specified. Stata will inspect each character in the original content, and if a glyph for the corresponding character is not available in the default font, then each font in the font chain will be checked until a font is found to display that character.

You can set fonts in the font chain by specifying addfonts for each PDF translator as follows:

```
. translator set tname addfonts fontname
```

Here tname is the name of a PDF translator, which can be smcl2pdf, log2pdf, txt2pdf, Results2pdf, Viewer2pdf, or Graph2pdf. See the translator() option under Options for translate.

Stata has the ability to select a font automatically if the default font and the fonts in the font chain do not contain a glyph for the character. Automatic font selection can be controlled using the following:

```
. translator set tname autofont on | off
```

By default, autofont is on. Unix (console) users will need to set the font directories so the fonts can be found.

PDF files accept Base 14 fonts, Type 1 fonts (.pfa or .pfb), TrueType fonts (.ttf or .ttc), and OpenType fonts (.otf). If fontname refers to a TrueType font, an OpenType font, or a Type 1 font, the corresponding TrueType, OpenType, or Type 1 font file will be searched for within the default font directory. Unix (console) users can type

```
. translator set tname fontdir fontdirectory
```

to set the default font directory. fontdirectory can contain multiple font directories separated by semicolons. If the specified TrueType, OpenType, or Type 1 font cannot be found under the current font directory, an error message will be issued.

Stored results

```
transmap query .ext stores in macro r(suffix) the mapped extension (without the leading period) or stores ext if the ext is not mapped.

translator query translatortname stores setval in macro r(setopt) for every setopt, setval pair.
```
printer query *printername* (Unix only) stores in macro *r(suffix)* the “filetype” of the input that the printer expects (currently “ps” or “txt”) and, in macro *r(command)*, the command to send output to the printer.

truncreg — Truncated regression

Description

truncreg fits a regression model of depvar on indepvars from a sample drawn from a restricted part of the population. Under the normality assumption for the whole population, the error terms in the truncated regression model have a truncated normal distribution, which is a normal distribution that has been scaled upward so that the distribution integrates to one over the restricted range.

Quick start

Truncated regression of y on x1 and x2 truncated below 16
  truncreg y x1 x2, ll(16)

Specify that y is truncated above 35
  truncreg y x1 x2, ul(35)

With y truncated below 17 and above 35
  truncreg y x1 x2, ll(17) ul(35)

Specify a lower truncation point that varies across observations using the variable trunc
  truncreg y x1 x2, ll(trunc)

Same as above, but with bootstrap standard errors using 200 replications
  truncreg y x1 x2, ll(trunc) vce(bootstrap, reps(200))

See last estimates with legend of coefficient names instead of statistics
  truncreg, coeflegend

**Options**

- `indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.
- `depvar` and `indepvars` may contain time-series operators; see [U] 11.4.4 Time-series varlists.
- bayes, bootstrap, by, collect, fmm, fp, jackknife, mi estimate, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: truncreg and [FMM] fmm: truncreg.
- vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
- Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
-aweights are not allowed with the jackknife prefix; see [R] jackknife.
- vce(), lrmodel, and weights are not allowed with the svy prefix; see [SVY] svy.
- aweights, fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight. collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

**Options**

- `noconstant;` see [R] Estimation options.
- `ll(varname | #)` and `ul(varname | #)` indicate the lower and upper limits for truncation, respectively. You may specify one or both. Observations with `depvar ≤ ll()` are left-truncated, observations with `depvar ≥ ul()` are right-truncated, and the remaining observations are not truncated. See [R] tobit for a more detailed description.
offset(varname), constraints(constraints); see [R] Estimation options.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

level(#), lrmodel, nocnsreport; see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used, but you may use the ltolerance(#) option to relax the convergence criterion; the default is 1e-6 during specification searches.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following options are available with truncreg but are not shown in the dialog box: collinear, coeflegend; see [R] Estimation options.

Remarks and examples

Truncated regression fits a model of a dependent variable on independent variables from a restricted part of a population. Truncation is essentially a characteristic of the distribution from which the sample data are drawn. If \( x \) has a normal distribution with mean \( \mu \) and standard deviation \( \sigma \), the density of the truncated normal distribution is

\[
 f(x | a < x < b) = \frac{f(x)}{\Phi \left( \frac{b-\mu}{\sigma} \right) - \Phi \left( \frac{a-\mu}{\sigma} \right)}
\]

\[
= \frac{1}{\sigma \phi \left( \frac{x-\mu}{\sigma} \right)} \frac{\phi \left( \frac{b-\mu}{\sigma} \right)}{\Phi \left( \frac{b-\mu}{\sigma} \right) - \Phi \left( \frac{a-\mu}{\sigma} \right)}
\]

where \( \phi \) and \( \Phi \) are the density and distribution functions of the standard normal distribution.

Compared with the mean of the untruncated variable, the mean of the truncated variable is greater if the truncation is from below, and the mean of the truncated variable is smaller if the truncation is from above. Moreover, truncation reduces the variance compared with the variance in the untruncated distribution.
Example 1

We will demonstrate `truncreg` with part of the Mroz dataset distributed with Berndt (1996). This dataset contains 753 observations on women’s labor supply. Our subsample is of 250 observations, with 150 market laborers and 100 nonmarket laborers.

```stata
use https://www.stata-press.com/data/r18/laborsub
```

Contains data from `https://www.stata-press.com/data/r18/laborsub.dta`

```

Technical note

Whether truncated regression is more appropriate than the ordinary least-squares estimation depends on the purpose of that estimation. If we are interested in the mean of wife’s working hours conditional on the subsample of market laborers, least-squares estimation is appropriate. However if we are interested in the mean of wife’s working hours regardless of market or nonmarket labor status, least-squares estimates could be seriously misleading.

Truncation and censoring are different concepts. A sample has been censored if no observations have been systematically excluded but some of the information contained in them has been suppressed. In a truncated distribution, only the part of the distribution above (or below, or between) the truncation points is relevant to our computations. We need to scale it up by the probability that an observation falls in the range that interests us to make the distribution integrate to one. The censored distribution used by tobit, however, is a mixture of discrete and continuous distributions. Instead of rescaling over the observable range, we simply assign the full probability from the censored regions to the censoring points. The truncated regression model is sometimes less well behaved than the tobit model.
Davidson and MacKinnon (1993) provide an example where truncation results in more inconsistency than censoring.

**Stored results**

`truncreg` stores the following in `e()`:

### Scalars

- `e(N)`: number of observations
- `e(N_bf)`: number of observations before truncation
- `e(chi2)`: model $\chi^2$
- `e(k_eq)`: number of equations in `e(b)`
- `e(k_eq_model)`: number of equations in overall model test
- `e(k_aux)`: number of auxiliary parameters
- `e(df_m)`: model degrees of freedom
- `e(ll)`: log likelihood
- `e(ll_0)`: log likelihood, constant-only model
- `e(N_clust)`: number of clusters
- `e(sigma)`: estimate of sigma
- `e(p)`: $p$-value for model test
- `e(rank)`: rank of `e(V)`
- `e(rc)`: return code
- `e(converged)`: 1 if converged, 0 otherwise

### Macros

- `e(cmd)` = `truncreg`
- `e(cmdline)` = command as typed
- `e(llopt)` = contents of `ll()`, if specified
- `e(ulopt)` = contents of `ul()`, if specified
- `e(depvar)` = name of dependent variable
- `e(wtype)` = weight type
- `e(wexp)` = weight expression
- `e(title)` = title in estimation output
- `e(clustvar)` = name of cluster variable
- `e(offset1)` = offset
- `e(chi2type)` = Wald or LR; type of model $\chi^2$ test
- `e(vce)` = `vcetype` specified in `vce()`
- `e(vcetype)` = title used to label Std. err.
- `e(opt)` = type of optimization
- `e(which)` = `max` or `min`; whether optimizer is to perform maximization or minimization
- `e(ml_method)` = type of `ml` method
- `e(user)` = name of likelihood-evaluator program
- `e(technique)` = maximization technique
- `e(properties)` = `b V`
- `e(predict)` = program used to implement `predict`
- `e(marginsok)` = predictions allowed by `margins`
- `e(asbalanced)` = factor variables `fvset` as `asbalanced`
- `e(asobserved)` = factor variables `fvset` as `asobserved`

### Matrices

- `e(b)` = coefficient vector
- `e(Cns)` = constraints matrix
- `e(ilog)` = iteration log (up to 20 iterations)
- `e(gradient)` = gradient vector
- `e(V)` = variance–covariance matrix of the estimators
- `e(V_modelbased)` = model-based variance
- `e(means)` = means of independent variables
- `e(dummy)` = indicator for dummy variables

### Functions

- `e(sample)` = marks estimation sample
In addition to the above, the following is stored in \( r() \):

Matrices

\[
\begin{align*}
\text{r(table)} & \quad \text{matrix containing the coefficients with their standard errors, test statistics, } p\text{-values,} \\
\text{and confidence intervals}
\end{align*}
\]

Note that results stored in \( r() \) are updated when the command is replayed and will be replaced when any \( r\)-class command is run after the estimation command.

### Methods and formulas

Greene (2018, 918–924) and Davidson and MacKinnon (1993, 534–537) provide introductions to the truncated regression model.

Let \( y = X\beta + \epsilon \) be the model. \( y \) represents continuous outcomes either observed or not observed. Our model assumes that \( \epsilon \sim N(0, \sigma^2 I) \).

Let \( a \) be the lower limit and \( b \) be the upper limit. The log likelihood is

\[
\ln L = -\frac{n}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \sum_{j=1}^{n} (y_j - x_j\beta)^2 - \sum_{j=1}^{n} \log \left\{ \Phi \left( \frac{b - x_j\beta}{\sigma} \right) - \Phi \left( \frac{a - x_j\beta}{\sigma} \right) \right\}
\]

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \( vce(\text{robust}) \) and \( vce(\text{cluster clustvar}) \), respectively. See \[P\] \_robust, particularly \textit{Maximum likelihood estimators} and \textit{Methods and formulas}.

\texttt{truncreg} also supports estimation with survey data. For details on VCEs with survey data, see \[SVY\] \textit{Variance estimation}.

predict

Description for predict

predict creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [ , statistic nooffset ]
```

```
predict [type] stub* [if] [in] , scores
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xb</td>
<td>linear prediction; the default</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the prediction</td>
</tr>
<tr>
<td>stdf</td>
<td>standard error of the forecast</td>
</tr>
<tr>
<td>pr(a,b)</td>
<td>Pr(a &lt; y_j &lt; b)</td>
</tr>
<tr>
<td>e(a,b)</td>
<td>E(y_j</td>
</tr>
<tr>
<td>ystar(a,b)</td>
<td>E(y_j^<em>, y_j^</em> = max{a, min(y_j, b)})</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where a and b may be numbers or variables; a missing (a ≥ .) means –∞, and b missing (b ≥ .) means +∞; see [U] 12.2.1 Missing values.

Options for predict

- `xb`, the default, calculates the linear prediction.
- `stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation’s covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.
- `stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see `Methods and formulas` in [R] `regress postestimation`.
- `pr(a,b)` calculates Pr(a < xjb + u_j < b), the probability that y_j|x_j would be observed in the interval (a, b).
\(a\) and \(b\) may be specified as numbers or variable names; \(lb\) and \(ub\) are variable names; 
\(pr(20,30)\) calculates \(Pr(20 < x_j b + u_j < 30)\); 
\(pr(lb,ub)\) calculates \(Pr(lb < x_j b + u_j < ub)\); and 
\(pr(20,ub)\) calculates \(Pr(20 < x_j b + u_j < ub)\).

\(a\) missing \((a \geq .)\) means \(-\infty\); \(pr(.,30)\) calculates \(Pr(-\infty < x_j b + u_j < 30)\); 
\(pr(lb,30)\) calculates \(Pr(lb < x_j b + u_j < 30)\) in observations for which \(lb \geq .\) and calculates \(Pr(lb < x_j b + u_j < 30)\) elsewhere.

\(b\) missing \((b \geq .)\) means \(+\infty\); \(pr(20,.)\) calculates \(Pr(+\infty > x_j b + u_j > 20)\); 
\(pr(20,ub)\) calculates \(Pr(+\infty > x_j b + u_j > 20)\) in observations for which \(ub \geq .\) and calculates \(Pr(20 < x_j b + u_j < ub)\) elsewhere.

\(e(a,b)\) calculates \(E(x_j b + u_j \mid a < x_j b + u_j < b)\), the expected value of \(y_j \mid x_j\) conditional on \(y_j \mid x_j\) being in the interval \((a,b)\), meaning that \(y_j \mid x_j\) is truncated. 
\(a\) and \(b\) are specified as they are for \(pr()\).

\(ystar(a,b)\) calculates \(E(y_j^* )\), where \(y_j^* = a\) if \(x_j b + u_j \leq a\), \(y_j^* = b\) if \(x_j b + u_j \geq b\), and \(y_j^* = x_j b + u_j\) otherwise, meaning that \(y_j^* \) is censored. \(a\) and \(b\) are specified as they are for \(pr()\).

\(nooffset\) is relevant only if you specified \(offset(varname)\). It modifies the calculations made by \(predict\) so that they ignore the offset variable; the linear prediction is treated as \(x_j b\) rather than as \(x_j b + offset_j\).

\(scores\) calculates equation-level score variables.

The first new variable will contain \(\partial \ln L / \partial (x_j \beta)\). 
The second new variable will contain \(\partial \ln L / \partial \sigma\).
margins

Description for margins

margins estimates margins of response for linear predictions, probabilities, and expected values.

Menu for margins

Statistics > Postestimation

Syntax for margins

```
margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [ predict(statistic ...) ... ] [ options ]
```

<table>
<thead>
<tr>

[R] truncreg — Truncated regression

[U] 20 Estimation and postestimation commands
Description

ttest performs $t$ tests on the equality of means. The test can be performed for one sample against a hypothesized population mean. Two-sample tests can be conducted for paired and unpaired data. The assumption of equal variances can be optionally relaxed in the unpaired two-sample case.

ttesti is the immediate form of ttest; see [U] 19 Immediate commands.

Quick start

Test that the mean of v1 is equal between two groups defined by catvar

ttest v1, by(catvar)

Same as above, but assume unequal variances

ttest v1, by(catvar) unequal

Paired $t$ test of v2 and v3

ttest v2 == v3

Same as above, but with unpaired data and conduct test separately for each level of catvar

by catvar: ttest v2 == v3, unpaired

Test that the mean of v4 is 3 at the 90% confidence level

ttest v4 == 3, level(90)

Test $\mu_1 = \mu_2$ if $\bar{x}_1 = 3.2$, $sd_1 = 0.1$, $\bar{x}_2 = 3.4$, and $sd_2 = 0.15$ with $n_1 = n_2 = 12$

ttesti 12 3.2 .1 12 3.4 .15

by and \texttt{collect} are allowed with \texttt{ttest} and \texttt{ttesti}; see [U] 11.1.10 \textit{Prefix commands}. 
Options

by(\textit{groupvar}) specifies the \textit{groupvar} that defines the two groups that \texttt{ttest} will use to test the hypothesis that their means are equal. Specifying \texttt{by(\textit{groupvar})} implies an unpaired (two sample) \textit{t} test. Do not confuse the \texttt{by()} option with the \texttt{by} prefix; you can specify both.

\texttt{reverse} reverses the order of the mean difference between groups defined in \texttt{by()}. By default, the mean of the group corresponding to the largest value in the variable in \texttt{by()} is subtracted from the mean of the group with the smallest value in \texttt{by()}. \texttt{reverse} reverses this behavior and the order in which variables appear on the table.

\texttt{unpaired} specifies that the data be treated as unpaired. The \texttt{unpaired} option is used when the two sets of values to be compared are in different variables.

\texttt{unequal} specifies that the unpaired data not be assumed to have equal variances.

\texttt{welch} specifies that the approximate degrees of freedom for the test be obtained from Welch’s formula (1947) rather than from Satterthwaite’s approximation formula (1946), which is the default when \texttt{unequal} is specified. Specifying \texttt{welch} implies \texttt{unequal}.

\texttt{level(#)} specifies the confidence level, as a percentage, for confidence intervals. The default is \texttt{level(95)} or as set by \texttt{set level}; see [U] 20.8 Specifying the width of confidence intervals.

Remarks and examples

Remarks are presented under the following headings:

\begin{itemize}
  \item \texttt{One-sample \textit{t} test}
  \item \texttt{Two-sample \textit{t} test}
  \item \texttt{Paired \textit{t} test}
  \item \texttt{Two-sample \textit{t} test compared with one-way ANOVA}
  \item \texttt{Immediate form}
  \item \texttt{Video examples}
\end{itemize}

One-sample \textit{t} test

\begin{itemize}
  \item \texttt{Example 1}
\end{itemize}

In the first form, \texttt{ttest} tests whether the mean of the sample is equal to a known constant under the assumption of unknown variance. Assume that we have a sample of 74 automobiles. We know each automobile’s average mileage rating and wish to test whether the overall average for the sample is 20 miles per gallon.
. use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
. ttest mpg==20

One-sample $t$ test

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>.6725511</td>
<td>5.785503</td>
<td>19.9569  22.63769</td>
</tr>
</tbody>
</table>

mean = mean(mpg)  
$ t = 1.9289$  
H0: mean = 20  
Degrees of freedom = 73  
Ha: mean < 20  
Ha: mean != 20  
Ha: mean > 20  
$ Pr(T < t) = 0.9712$  
$ Pr(|T| > |t|) = 0.0576$  
$ Pr(T > t) = 0.0288$  
The test indicates that the underlying mean is not 20 with a significance level of 5.8%.

Two-sample $t$ test

Example 2: Two-sample $t$ test using groups

We are testing the effectiveness of a new fuel additive. We run an experiment in which 12 cars are given the fuel treatment and 12 cars are not. The results of the experiment are as follows:

<table>
<thead>
<tr>
<th>treated</th>
<th>mpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
</tr>
<tr>
<td>0</td>
<td>23</td>
</tr>
<tr>
<td>0</td>
<td>21</td>
</tr>
<tr>
<td>0</td>
<td>25</td>
</tr>
<tr>
<td>0</td>
<td>18</td>
</tr>
<tr>
<td>0</td>
<td>17</td>
</tr>
<tr>
<td>0</td>
<td>18</td>
</tr>
<tr>
<td>0</td>
<td>24</td>
</tr>
<tr>
<td>0</td>
<td>20</td>
</tr>
<tr>
<td>0</td>
<td>24</td>
</tr>
<tr>
<td>0</td>
<td>23</td>
</tr>
<tr>
<td>0</td>
<td>19</td>
</tr>
<tr>
<td>1</td>
<td>24</td>
</tr>
<tr>
<td>1</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
</tr>
<tr>
<td>1</td>
<td>22</td>
</tr>
<tr>
<td>1</td>
<td>23</td>
</tr>
<tr>
<td>1</td>
<td>18</td>
</tr>
<tr>
<td>1</td>
<td>17</td>
</tr>
<tr>
<td>1</td>
<td>28</td>
</tr>
<tr>
<td>1</td>
<td>24</td>
</tr>
<tr>
<td>1</td>
<td>27</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
</tr>
<tr>
<td>1</td>
<td>23</td>
</tr>
</tbody>
</table>

The treated variable is coded as 1 if the car received the fuel treatment and 0 otherwise.
We can test the equality of means of the treated and untreated group by typing

```stata
. use https://www.stata-press.com/data/r18/fuel3
. ttest mpg, by(treated)
```

* Two-sample t test with equal variances

<table>
<thead>
<tr>
<th>Group</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>12</td>
<td>21</td>
<td>.7881701</td>
<td>2.730301</td>
<td>22.73475</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>22.75</td>
<td>.9384465</td>
<td>3.250874</td>
<td>24.81551</td>
</tr>
<tr>
<td>Combined</td>
<td>24</td>
<td>21.875</td>
<td>.6264476</td>
<td>3.068954</td>
<td>23.17091</td>
</tr>
<tr>
<td>diff</td>
<td>24</td>
<td>-1.75</td>
<td>1.225518</td>
<td>-4.291568</td>
<td>.7915684</td>
</tr>
</tbody>
</table>

\[
diff = \text{mean}(0) - \text{mean}(1) \quad t = -1.4280
\]

H0: diff = 0  
Ha: diff < 0  
Ha: diff ≠ 0  
Ha: diff > 0  
Pr(T < t) = 0.0837  
Pr(|T| > |t|) = 0.1673  
Pr(T > t) = 0.9163

We do not find a statistically significant difference in the means.

If we were not willing to assume that the variances were equal and wanted to use Welch’s formula, we could type

```stata
. ttest mpg, by(treated) welch
```

* Two-sample t test with unequal variances

<table>
<thead>
<tr>
<th>Group</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>12</td>
<td>21</td>
<td>.7881701</td>
<td>2.730301</td>
<td>22.73475</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>22.75</td>
<td>.9384465</td>
<td>3.250874</td>
<td>24.81551</td>
</tr>
<tr>
<td>Combined</td>
<td>24</td>
<td>21.875</td>
<td>.6264476</td>
<td>3.068954</td>
<td>23.17091</td>
</tr>
<tr>
<td>diff</td>
<td>24</td>
<td>-1.75</td>
<td>1.225518</td>
<td>-4.28369</td>
<td>.7836902</td>
</tr>
</tbody>
</table>

\[
diff = \text{mean}(0) - \text{mean}(1) \quad t = -1.4280
\]

H0: diff = 0  
Welch’s degrees of freedom = 23.2465

Ha: diff < 0  
Ha: diff ≠ 0  
Ha: diff > 0  
Pr(T < t) = 0.0833  
Pr(|T| > |t|) = 0.1666  
Pr(T > t) = 0.9167

**Technical note**

In two-sample randomized designs, subjects will sometimes refuse the assigned treatment but still be measured for an outcome. In this case, take care to specify the group properly. You might be tempted to let `varname` contain missing where the subject refused and thus let `ttest` drop such observations from the analysis. Zelen (1979) argues that it would be better to specify that the subject belongs to the group in which he or she was randomized, even though such inclusion will dilute the measured effect.
Example 3: Two-sample \( t \) test using variables

There is a second, inferior way to organize the data in the preceding example. We ran a test on 24 cars, 12 without the additive and 12 with. We now create two new variables, \( mpg1 \) and \( mpg2 \).

<table>
<thead>
<tr>
<th>( mpg1 )</th>
<th>( mpg2 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>24</td>
</tr>
<tr>
<td>23</td>
<td>25</td>
</tr>
<tr>
<td>21</td>
<td>21</td>
</tr>
<tr>
<td>25</td>
<td>22</td>
</tr>
<tr>
<td>18</td>
<td>23</td>
</tr>
<tr>
<td>17</td>
<td>18</td>
</tr>
<tr>
<td>18</td>
<td>17</td>
</tr>
<tr>
<td>24</td>
<td>28</td>
</tr>
<tr>
<td>20</td>
<td>24</td>
</tr>
<tr>
<td>24</td>
<td>27</td>
</tr>
<tr>
<td>23</td>
<td>21</td>
</tr>
<tr>
<td>19</td>
<td>23</td>
</tr>
</tbody>
</table>

This method is inferior because it suggests a connection that is not there. There is no link between the car with 20 mpg and the car with 24 mpg in the first row of the data. Each column of data could be arranged in any order. Nevertheless, if our data are organized like this, \texttt{ttest} can accommodate us.

```
. use https://www.stata-press.com/data/r18/fuel
. ttest mpg1==mpg2, unpaired
Two-sample \( t \) test with equal variances

Variable | Obs | Mean | Std. err. | Std. dev. | [95% conf. interval] |
----------|-----|------|-----------|-----------|---------------------|
\( mpg1 \) | 12  | 21   | .7881701  | 2.730301  | 19.26525 22.73475   |
\( mpg2 \) | 12  | 22.75| .9384465  | 3.250874  | 20.68449 24.81551  |
Combined  | 24  | 21.875| .6264476  | 3.068954  | 20.57909 23.17091  |

| diff | -1.75 | 1.225518 | -4.291568 | .7915684 |

\( t = -1.4280 \)
Degrees of freedom = 22
```

Example 4

Suppose that the preceding data were actually collected by running a test on 12 cars. Each car was run once with the fuel additive and once without. Our data are stored in the same manner as in example 3, but this time, there is most certainly a connection between the mpg values that appear in the same row. These come from the same car. The variables \( mpg1 \) and \( mpg2 \) represent mileage without and with the treatment, respectively.

Paired \( t \) test
. use https://www.stata-press.com/data/r18/fuel
. ttest mpg1==mpg2
Paired t test

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg1</td>
<td>12</td>
<td>21</td>
<td>.7881701</td>
<td>2.730301</td>
<td>19.26525 22.73475</td>
</tr>
<tr>
<td>mpg2</td>
<td>12</td>
<td>22.75</td>
<td>.9384465</td>
<td>3.250874</td>
<td>20.68449 24.81551</td>
</tr>
<tr>
<td>diff</td>
<td>12</td>
<td>-1.75</td>
<td>.7797144</td>
<td>2.70101</td>
<td>-3.46614 -.0338602</td>
</tr>
</tbody>
</table>

mean(diff) = mean(mpg1 - mpg2)  t = -2.2444
H0: mean(diff) = 0  Degrees of freedom = 11
Ha: mean(diff) < 0  Ha: mean(diff) != 0  Ha: mean(diff) > 0
Pr(T < t) = 0.0232  Pr(|T| > |t|) = 0.0463  Pr(T > t) = 0.9768

We find that the means are statistically different from each other at any level greater than 4.6%.

Two-sample t test compared with one-way ANOVA

Example 5

In example 2, we saw that `ttest` can be used to test the equality of a pair of means; see [R] `oneway` for an extension that allows testing the equality of more than two means.

Suppose that we have data on the 50 states. The dataset contains the median age of the population (`medage`) and the region of the country (`region`) for each state. Region 1 refers to the Northeast, region 2 to the North Central, region 3 to the South, and region 4 to the West. Using `oneway`, we can test the equality of all four means.

. use https://www.stata-press.com/data/r18/census
   (1980 Census data by state)
. oneway medage region

Analysis of variance
<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>F</th>
<th>Prob &gt; F</th>
</tr>
</thead>
<tbody>
<tr>
<td>Between groups</td>
<td>46.3961903</td>
<td>3</td>
<td>15.4653968</td>
<td>7.56</td>
<td>0.0003</td>
</tr>
<tr>
<td>Within groups</td>
<td>94.1237947</td>
<td>46</td>
<td>2.04616945</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>140.519985</td>
<td>49</td>
<td>2.8677548</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bartlett's equal-variances test: chi2(3) = 10.5757  Prob>chi2 = 0.014

We find that the means are different, but we are interested only in testing whether the means for the Northeast (`region==1`) and West (`region==4`) are different. We could use `oneway`:

. oneway medage region if region==1 | region==4

Analysis of variance
<table>
<thead>
<tr>
<th>Source</th>
<th>SS</th>
<th>df</th>
<th>MS</th>
<th>F</th>
<th>Prob &gt; F</th>
</tr>
</thead>
<tbody>
<tr>
<td>Between groups</td>
<td>46.241247</td>
<td>1</td>
<td>46.241247</td>
<td>20.02</td>
<td>0.0002</td>
</tr>
<tr>
<td>Within groups</td>
<td>46.1969169</td>
<td>20</td>
<td>2.30984584</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Total</td>
<td>92.4381638</td>
<td>21</td>
<td>4.40181733</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bartlett's equal-variances test: chi2(1) = 2.4679  Prob>chi2 = 0.116
We could also use `ttest`:

```
  . ttest medage if region==1 | region==4, by(region)

  Two-sample t test with equal variances

  Group | Obs  | Mean   | Std. err. | Std. dev. | [95% conf. interval]
  ------|------|--------|-----------|-----------|---------------------
        |      |        |           |           |                    |
  NE    | 9    | 31.23333 | .3411581  | 1.023474  | 30.44662 32.02005   |
  West  | 13   | 28.28462 | .4923577  | 1.775221  | 27.21186 29.35737   |
  Combined | 22 | 29.49091 | .4473059  | 2.098051  | 28.56069 30.42113   |
  diff  |      | 2.948718 | .6590372  | 2.098051  | 1.57399 4.323445    |

  diff = mean(NE) - mean(West)  t = 4.4743
  H0: diff = 0  Degrees of freedom = 20
  Ha: diff < 0    Ha: diff != 0    Ha: diff > 0
  Pr(T < t) = 0.9999  Pr(|T| > |t|) = 0.0002  Pr(T > t) = 0.0001

  The significance levels of both tests are the same.
```

### Immediate form

#### Example 6

`ttesti` is like `ttest`, except that we specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the mean number of sunspots per month as 62.6 with a standard deviation of 15.8. There are 24 months of data. We wish to test whether the mean is 75:

```
  . ttesti 24 62.6 15.8 75

  One-sample t test

<table>
<thead>
<tr>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td>62.6</td>
<td>3.225161</td>
<td>15.8</td>
<td>55.92825 69.27175</td>
</tr>
</tbody>
</table>

  mean = mean(x)  t = -3.8448
  H0: mean = 75  Degrees of freedom = 23
  Ha: mean < 75    Ha: mean != 75    Ha: mean > 75
  Pr(T < t) = 0.0004  Pr(|T| > |t|) = 0.0008  Pr(T > t) = 0.9996
```
Example 7

There is no immediate form of ttest with paired data because the test is also a function of the covariance, a number unlikely to be reported in any published source. For unpaired data, however, we might type

```
ttesti 20 20 5 32 15 4
```

Two-sample t test with equal variances

<table>
<thead>
<tr>
<th></th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>20</td>
<td>20</td>
<td>1.11834</td>
<td>5</td>
<td>17.65993</td>
</tr>
<tr>
<td>y</td>
<td>32</td>
<td>15</td>
<td>0.7071068</td>
<td>4</td>
<td>13.55785</td>
</tr>
<tr>
<td>Combined</td>
<td>52</td>
<td>16.92308</td>
<td>0.6943785</td>
<td>5.007235</td>
<td>15.52905</td>
</tr>
<tr>
<td>diff</td>
<td>5</td>
<td>1.256135</td>
<td>2.476979</td>
<td>7.523021</td>
<td></td>
</tr>
</tbody>
</table>

\[
\text{diff} = \text{mean}(x) - \text{mean}(y) \quad t = 3.9805
\]

H0: diff = 0

<table>
<thead>
<tr>
<th>Ha: diff &lt; 0</th>
<th>Ha: diff != 0</th>
<th>Ha: diff &gt; 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pr(T &lt; t) = 0.9999</td>
<td>Pr(</td>
<td>T</td>
</tr>
</tbody>
</table>

If we had typed ttesti 20 20 5 32 15 4, unequal, the test would have assumed unequal variances.

Video examples

One-sample t test in Stata

t test for two independent samples in Stata

t test for two paired samples in Stata

One-sample t-test calculator

Two-sample t-test calculator

Stored results

ttest and ttesti store the following in r():

Scalars

- \( r(N_1) \) sample size \( n_1 \)
- \( r(N_2) \) sample size \( n_2 \)
- \( r(p_{\text{one-sided}}) \) lower one-sided \( p \)-value
- \( r(p_{\text{upper}}) \) upper one-sided \( p \)-value
- \( r(p) \) two-sided \( p \)-value
- \( r(\text{se}) \) estimate of standard error
- \( r(t) \) \( t \) statistic
- \( r(\text{sd}_1) \) standard deviation for first variable
- \( r(\text{sd}_2) \) standard deviation for second variable
- \( r(\text{sd}) \) combined standard deviation
- \( r(\mu_1) \) \( \mu \) for population 1
- \( r(\mu_2) \) \( \mu \) for population 2
- \( r(df_t) \) degrees of freedom
- \( r(level) \) confidence level

Methods and formulas

See, for instance, Hoel (1984, 140–161) or Dixon and Massey (1983, 121–130) for an introduction and explanation of the calculation of these tests. Acock (2023, 165–179) and Hamilton (2013, 145–150) describe \( t \) tests using applications in Stata.
The test for $\mu = \mu_0$ for unknown $\sigma$ is given by

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}}$$

The statistic is distributed as Student’s $t$ with $n - 1$ degrees of freedom (Gosset [Student, pseud.] 1908).

The test for $\mu_x = \mu_y$ when $\sigma_x$ and $\sigma_y$ are unknown but $\sigma_x = \sigma_y$ is given by

$$t = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{(n_x-1)s_x^2 + (n_y-1)s_y^2}{n_x + n_y - 2}}^{1/2} \left( \frac{1}{n_x} + \frac{1}{n_y} \right)^{1/2}}$$

The result is distributed as Student’s $t$ with $n_x + n_y - 2$ degrees of freedom.

You could perform ttest (without the unequal option) in a regression setting given that regression assumes a homoskedastic error model. To compare with the ttest command, denote the underlying observations on $x$ and $y$ by $x_j, j = 1, \ldots, n_x$, and $y_j, j = 1, \ldots, n_y$. In a regression framework, typing ttest without the unequal option is equivalent to

1. creating a new variable $z_j$ that represents the stacked observations on $x$ and $y$ (so that $z_j = x_j$ for $j = 1, \ldots, n_x$ and $z_{n_x+j} = y_j$ for $j = 1, \ldots, n_y$)
2. and then estimating the equation $z_j = \beta_0 + \beta_1 d_j + \epsilon_j$, where $d_j = 0$ for $j = 1, \ldots, n_x$ and $d_j = 1$ for $j = n_x + 1, \ldots, n_x + n_y$ (that is, $d_j = 0$ when the $z$ observations represent $x$, and $d_j = 1$ when the $z$ observations represent $y$).

The estimated value of $\beta_1, b_1$, will equal $\bar{y} - \bar{x}$, and the reported $t$ statistic will be the same $t$ statistic as given by the formula above.

The test for $\mu_x = \mu_y$ when $\sigma_x$ and $\sigma_y$ are unknown and $\sigma_x \neq \sigma_y$ is given by

$$t = \frac{\bar{x} - \bar{y}}{\left(\frac{s_x^2/n_x + s_y^2/n_y}{n_x - 1 + n_y - 1}\right)^{1/2}}$$

The result is distributed as Student’s $t$ with $\nu$ degrees of freedom, where $\nu$ is given by (with Satterthwaite’s [1946] formula)

$$\frac{(s_x^2/n_x + s_y^2/n_y)^2}{\left(\frac{s_x^2/n_x}{n_x - 1}\right)^2 + \left(\frac{s_y^2/n_y}{n_y - 1}\right)^2}$$

With Welch’s formula (1947), the number of degrees of freedom is given by

$$-2 + \frac{(s_x^2/n_x + s_y^2/n_y)^2}{\left(\frac{s_x^2/n_x}{n_x + 1}\right)^2 + \left(\frac{s_y^2/n_y}{n_y + 1}\right)^2}$$
The test for $\mu_x = \mu_y$ for matched observations (also known as paired observations, correlated pairs, or permanent components) is given by

$$t = \frac{\overline{d} \sqrt{n}}{s_d}$$

where $\overline{d}$ represents the mean of $x_i - y_i$ and $s_d$ represents the standard deviation. The test statistic $t$ is distributed as Student’s $t$ with $n - 1$ degrees of freedom.

You can also use `ttest` without the `unpaired` option in a regression setting because a paired comparison includes the assumption of constant variance. The `ttest` with an unequal variance assumption does not lend itself to an easy representation in regression settings and is not discussed here. $(x_j - y_j) = \beta_0 + \epsilon_j$.

William Sealy Gosset (1876–1937) was born in Canterbury, England. He studied chemistry and mathematics at Oxford and worked as a chemist with the brewers Guinness in Dublin. Gosset became interested in statistical problems, which he discussed with Karl Pearson and later with Fisher and Neyman. He published several important papers under the pseudonym “Student”, and he lent that name to the $t$ test he invented.

Stella Cunliffe (1917–2012) was an advocate for increased understanding of the role of human nature in experiments and methodological rigor in social statistics. She was born in Battersea, England. She was the first person from her local public girls’ school to attend college, obtaining a bachelor of science from the London School of Economics. Her first job was with the Danish Bacon Company during World War II, where she was in charge of bacon rations for London. After the war, she moved to Germany and again helped to ration food, this time for refugees. She then spent a long career in quality control at the Guinness Brewing Company. Cunliffe observed that the weights of rejected casks skewed lighter. Noting that workers had to roll casks that were too light or too heavy uphill to be remade, she had the scales moved to the top of the hill. With workers able to roll rejected casks downhill, the weight of these casks began to follow a normal distribution.

After 25 years at Guinness, Cunliffe joined the British Home Office, where she would go on to become the first woman to serve as director of statistics. During her tenure at the Home Office, she emphasized applying principles of experimental design she had learned at Guinness to the study of such topics as birthrates, recidivism, and criminology. In 1975, she became the first woman to serve as president of the Royal Statistical Society.

### Description

The `update` command reports on the current update level and installs official updates to Stata. Official updates are updates to Stata as it was originally shipped from StataCorp, not the additions to Stata published in, for instance, the *Stata Journal (SJ)*. Those additions are installed using the `net` command and updated using the `ado update` command; see [R] `net` and [R] `ado update`.

`update` without arguments reports on the update level of the currently installed Stata.

`update from` sets an update source, which may be a directory name or URL. If you are on the Internet, type `update from https://www.stata.com`.

`update query` compares the update level of the currently installed Stata with that available from the update source and displays a report.

`update all` updates all necessary files. This is what you should type to check for and install updates.

`set update_query` determines if `update query` is to be automatically performed when Stata is launched. Only Mac and Windows platforms can be set for automatic updating.

`set update_interval #` sets the number of days to elapse before performing the next automatic `update query`. The default # is 7. The interval starts from the last time an `update query` was performed (automatically or manually). Only Mac and Windows platforms can be set for automatic updating.

`set update_prompt` determines whether a dialog is to be displayed before performing an automatic `update query`. The dialog allows you to perform an `update query` now, perform one the next time Stata is launched, perform one after the next interval has passed, or disable automatic `update query`. Only Mac and Windows platforms can be set for automatic updating.

### Menu

- Help > Check for updates
Syntax

Report on update level of currently installed Stata

update

Set update source

update from location

Compare update level of currently installed Stata with that of source

update query [, from(location)]

Perform update if necessary

update all [, from(location) detail force exit]

Set automatic updates (Mac and Windows only)

set update_query { on | off }
set update_interval #
set update_prompt { on | off }

Options

from(location) specifies the location of the update source. You can specify the from() option on the individual update commands or use the update from command. Which you do makes no difference. You typically do not need to use this option.
detail specifies to display verbose output during the update process.
force specifies to force downloading of all files even if, based on the date comparison, Stata does not think it is necessary. There is seldom a reason to specify this option.
exit instructs Stata to exit when the update has successfully completed. There is seldom a reason to specify this option.

Remarks and examples

update updates the official components of Stata from the official source: https://www.stata.com. If you are connected to the Internet, the easy thing to do is to type

update all

and follow the instructions. If Stata is up to date, update all will do nothing. Otherwise, it will download whatever is necessary and install the files. If you just want to know what updates are available, type

update query
update query will check if any updates are available and report that information. If updates are available, it will recommend that you type update all.

If you want to report the current update level, type

```
update
```

update will report the update level of the Stata installation. update will also show you the date that updates were last checked and if any updates were available at that time.

Stored results

update without a subcommand, update from, and update query store the following in r():

Scalars

- `r(inst_exe)` date of executable installed (*)
- `r(avbl_exe)` date of executable available over web (*) (**)
- `r(inst_ado)` date of ado-files installed (*)
- `r(avbl_ado)` date of ado-files available over web (*) (**)
- `r(inst_utilities)` date of utilities installed (*)
- `r(avbl_utilities)` date of utilities available over web (*) (**)
- `r(inst_docs)` date of documentation installed (*)
- `r(avbl_docs)` date of documentation available over web (*) (**)

Macros

- `r(name_exe)` name of the Stata executable
- `r(dir_exe)` directory in which executable is stored
- `r(dir_ado)` directory in which ado-files are stored
- `r(dir_utilities)` directory in which utilities are stored
- `r(dir_docs)` directory in which PDF documentation is stored

Notes:

* Dates are stored as integers counting the number of days since January 1, 1960; see [D] Datetime.

** These dates are not stored by update without a subcommand because update by itself reports information solely about the local computer and does not check what is available on the web.

Description

This entry describes the `vce()` option, which is common to most estimation commands. `vce()` specifies how to estimate the variance–covariance matrix (VCE) corresponding to the parameter estimates. The standard errors reported in the table of parameter estimates are the square root of the variances (diagonal elements) of the VCE.

Syntax

```
estimation_cmd ... [ , vce(vcetype) ... ]
```

vcetype Description

</thead>
<tbody>
<tr>
<td><code>bootstrap [, bootstrap_options]</code></td>
<td>bootstrap estimation</td>
</tr>
<tr>
<td><code>jackknife [, jackknife_options]</code></td>
<td>jackknife estimation</td>
</tr>
</tbody>
</table>

Options

`vce(oim)` is usually the default for models fit using maximum likelihood. `vce(oim)` uses the observed information matrix (OIM); see [R] ml.

`vce(opg)` uses the sum of the outer product of the gradient (OPG) vectors; see [R] ml. This is the default VCE when the `technique(bhhh)` option is specified; see [R] Maximize.

`vce(robust)` uses the robust or sandwich estimator of variance. This estimator is robust to some types of misspecification so long as the observations are independent; see [U] 20.22 Obtaining robust variance estimates.
If the command allows `pweights` and you specify them, `vce(robust)` is implied; see [U] 20.24.3 Sampling weights.

`vce(cluster clustvar)` specifies that the standard errors allow for intragroup correlation, relaxing the usual requirement that the observations be independent. That is, the observations are independent across groups (clusters) but not necessarily within groups. `clustvar` specifies to which group each observation belongs, for example, `vce(cluster personid)` in data with repeated observations on individuals. `vce(cluster clustvar)` affects the standard errors and variance–covariance matrix of the estimators but not the estimated coefficients; see [U] 20.22 Obtaining robust variance estimates.

`vce(bootstrap [, bootstrap_options])` uses a bootstrap; see [R] bootstrap. After estimation with `vce(bootstrap)`, see [R] bootstrap postestimation to obtain percentile-based or bias-corrected confidence intervals.

`vce(jackknife [, jackknife_options])` uses the delete-one jackknife; see [R] jackknife.

Remarks and examples

Remarks are presented under the following headings:

Prefix commands
Passing options in `vce()`

Prefix commands

Specifying `vce(bootstrap)` or `vce(jackknife)` is often equivalent to using the corresponding prefix command. Here is an example using `jackknife` with `regress`.

```
. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. regress mpg turn trunk, vce(jackknife)
   (running regress on estimation sample)
Jackknife replications (74): ........10.........20...........30.........40.......>
   ..50.........60.........70.... done
Linear regression
Number of obs = 74
Replications = 74
F(2, 73) = 66.26
Prob > F = 0.0000
R-squared = 0.5521
Adj R-squared = 0.5395
Root MSE = 3.9260

Coef.    Std. Err.      t    P>|t|     [95% Conf. Interval]

      mpg   Coefficient  std. err.     t     P>|t|     [95% conf. interval]
     turn  -.7610113    .150726   -5.05   0.000   -1.061408   -0.4606147
    trunk  -.3161825    .1282326   -2.47   0.016   -0.5717498   -0.0606152
      _cons   55.82001    5.031107    11.09   0.000     45.79303     65.84699
```
Here it does not matter whether we specify the `vce(jackknife)` option or instead use the `jackknife` prefix.

However, `vce(jackknife)` should be used in place of the `jackknife` prefix whenever available because they are not always equivalent. For example, to use the `jackknife` prefix with `clogit` properly, you must tell `jackknife` to omit whole groups rather than individual observations. Specifying `vce(jackknife)` does this automatically.

```stata
. jackknife: regress mpg turn trunk
(running regress on estimation sample)
Jackknife replications (74): ........10.........20...........30.........40....... > ..50.........60...........70.... done
Linear regression

|          | Coefficient | std. err. | t      | P>|t| | [95% conf. interval] |
|----------|-------------|-----------|--------|------|----------------------|
| mpg      |             |           |        |      |                      |
| turn     | -.7610113   | .150726   | -5.05  | 0.000| -1.061408 -.4606147  |
| trunk    | -.3161825   | .1282326  | -2.47  | 0.016| -.5717498 -.0606152  |
| _cons    | 55.82001    | 5.031107  | 11.09  | 0.000| 45.79303 65.84699    |
```

This extra information is automatically communicated to `jackknife` by `clogit` when the `vce()` option is specified.

```stata
. jackknife, cluster(id): clogit y x1 x2, group(id)
(output omitted)
```

```stata
. clogit y x1 x2, group(id) vce(jackknife)
(running clogit on estimation sample)
Jackknife replications (66): ........10.........20...........30.........40....... > ..50.........60...... done
Conditional (fixed-effects) logistic regression

|          | Coefficient | std. err. | t      | P>|t| | [95% conf. interval] |
|----------|-------------|-----------|--------|------|----------------------|
| y        |             |           |        |      |                      |
| x1       | .653363     | .3010608  | 2.17   | 0.034| .052103 1.254623    |
| x2       | .0659169    | .0487858  | 1.35   | 0.181| -.0315151 .1633469  |
```

(Log likelihood = -123.41386 (Replications based on 66 clusters in id))
Passing options in vce()

If you wish to specify more options to the bootstrap or jackknife estimation, you can include them within the vce() option. Below, we request 300 bootstrap replications and save the replications in bsreg.dta:

```
use https://www.stata-press.com/data/r18/auto
(1978 automobile data)
regress mpg turn trunk, vce(bootstrap, nodots seed(123) rep(300) saving(bsreg))
```

```
Linear regression
Number of obs = 74
Replications = 300
Wald chi2(2) = 144.17
Prob > chi2 = 0.0000
R-squared = 0.5521
Adj R-squared = 0.5395
Root MSE = 3.9260

<table>

```

Methods and formulas

By default, Stata’s maximum likelihood estimators display standard errors based on variance estimates given by the inverse of the negative Hessian (second derivative) matrix. If vce(robust), vce(cluster clustvar), or pweights is specified, standard errors are based on the robust variance estimator (see [U] 20.22 Obtaining robust variance estimates); likelihood-ratio tests are not appropriate here (see [SVY] Survey), and the model \( \chi^2 \) is from a Wald test. If vce(opg) is specified, the standard errors are based on the outer product of the gradients; this option has no effect on likelihood-ratio tests, though it does affect Wald tests.

If vce(bootstrap) or vce(jackknife) is specified, the standard errors are based on the chosen replication method; here the model \( \chi^2 \) or \( F \) statistic is from a Wald test using the respective replication-based covariance matrix. The \( t \) distribution is used in the coefficient table when the vce(jackknife) option is specified. vce(bootstrap) and vce(jackknife) are also available with some commands that are not maximum likelihood estimators.

Title

**view** — View files and logs

<table>
<thead>
<tr>
<th>Description</th>
<th>Menu</th>
<th>Syntax</th>
<th>Options</th>
<th>Remarks and examples</th>
<th>Also see</th>
</tr>
</thead>
</table>

**Description**

`view` displays file contents in the Viewer.

`view file` displays the specified file. `file` is optional, so if you had a SMCL session log created by typing `log using mylog, smcl`. `view file` can properly display .smcl files (logs and the like), .sthlp files, and text files. `view file`'s `asis` option specifies that the file be displayed as plain text, regardless of the `filename`’s extension.

`view browse` opens your browser pointed to `url`. Typing `view browse https://www.stata.com` would bring up your browser pointed to the website https://www.stata.com.

`[view] help` displays the specified topic in the Viewer. For example, to review the help for Stata’s `print` command, you could type `help print`. See [R] help for more details.

`[view] search` displays the results of the `search` command in the Viewer. For instance, to search the system help for information on robust regression, you could type `search robust regression`. See [R] search for more details.

`view net` does the same as the `net` command—see [R] net—but displays the result in the Viewer. For instance, typing `view net search hausman test` would search the Internet for additions to Stata related to the Hausman test. Typing `view net from https://www.stata.com` would go to the Stata additions download site at https://www.stata.com.

`view ado` does the same as the `ado` command—see [R] net—but displays the result in the Viewer. For instance, typing `view ado dir` would show a list of files you have installed.

`view update` does the same as the `update` command—see [R] update—but displays the result in the Viewer. Typing `view update` would show the dates of what you have installed, and from there you could click to compare those dates with the latest updates available. Typing `view update query` would skip the first step and show the comparison.

**Menu**

view ado [adocmd]

Display update results in Viewer

view update [updatecmd]

Options

asis, allowed with view file, specifies that the file be displayed as text, regardless of the filename’s extension. view file’s default action is to display files ending in .smcl and .sthlp as SMCL; see [P] smcl.

adopath, allowed with view file, specifies that Stata search the S_ADO path for filename and display it, if found.

Remarks and examples

Most users access the Viewer by selecting File > View... and proceeding from there. Some commands allow you to skip that step. Some common interactive uses of commands that display their results in the Viewer are the following:
view — View files and logs

- view mysession.smcl
- view mysession.log
- help print
- help regress
- search hausman test
- view net
- view ado
- view update query

vwls estimates a linear regression using variance-weighted least squares. It differs from ordinary least-squares (OLS) regression in that it does not assume homogeneity of variance, but requires that the conditional variance of \textit{depvar} be estimated prior to the regression. The estimated variance need not be constant across observations. \texttt{vwls} treats the estimated variance as if it were the true variance when it computes standard errors of the coefficients.

You must supply an estimate of the conditional standard deviation of \textit{depvar} to \texttt{vwls} by using the \texttt{sd(varname)} option, or you must have grouped data with the groups defined by the \textit{indepvars} variables. In the latter case, \texttt{vwls} treats all \textit{indepvars} as categorical variables, computes the mean and standard deviation of \textit{depvar} separately for each subgroup, and computes the regression of the subgroup means on \textit{indepvars}.

\texttt{regress} with analytic weights can be used to produce another kind of “variance-weighted least squares”; see \textit{Remarks and examples} for an explanation of the difference.

\textbf{Quick start}

\begin{verbatim}
Variance-weighted least-squares regression of \textit{y} on \textit{x1} and \textit{x2}, with the estimated conditional std.
dev. of \textit{y} stored in \textit{sd}
\texttt{vwls y1 x1 x2, sd(sd)}
\end{verbatim}

Add categorical variable \textit{a} using factor-variable syntax
\begin{verbatim}
vwls y1 x1 x2 i.a, sd(sd)
\end{verbatim}

Same as above, but restrict the sample to cases where \textit{v} is greater than 1
\begin{verbatim}
vwls y1 x1 x2 i.a if \textit{v}>1, sd(sd)
\end{verbatim}

Variance-weighted least-squares regression for grouped data with subgroups defined by \textit{a2} and \textit{a3}
\begin{verbatim}
vwls y2 i.a2 i.a3
\end{verbatim}

\textbf{Menu}

\begin{verbatim}
Statistics > Linear models and related > Other > Variance-weighted least squares
\end{verbatim}
vwls — Variance-weighted least squares

Syntax

vwls depvar indepvars [if] [in] [weight] [, options]

options                  Description

Model                   
noconstant              suppress constant term
sd(varname)             variable containing estimate of conditional standard deviation

Reporting               
level(#)                set confidence level; default is level(95)
display_options         control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

coeflegend              display legend instead of statistics

Indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
bootstrap, by, collect, jackknife, rolling, and statsby are allowed; see [U] 11.1.10 Prefix commands.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
fweights are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

noconstant; see [R] Estimation options.

sd(varname) is an estimate of the conditional standard deviation of depvar (that is, it can vary observation by observation). All values of varname must be > 0. If you specify sd(), you cannot use fweights.

If sd() is not given, the data will be grouped by indepvars. Here indepvars are treated as categorical variables, and the means and standard deviations of depvar for each subgroup are calculated and used for the regression. Any subgroup for which the standard deviation is zero is dropped.

level(#); see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels,nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

The following option is available with vwls but is not shown in the dialog box:

coefflegend; see [R] Estimation options.
Remarks and examples

The `vwls` command is intended for use with two special—and different—types of data. The first contains data that consist of measurements from physical science experiments in which all error is due solely to measurement errors and the sizes of the measurement errors are known.

You can also use variance-weighted least-squares linear regression for certain problems in categorical data analysis, such as when all the independent variables are categorical and the outcome variable is either continuous or a quantity that can sensibly be averaged. If each of the subgroups defined by the categorical variables contains a reasonable number of subjects, then the variance of the outcome variable can be estimated independently within each subgroup. For the purposes of estimation, `vwls` treats each subgroup as one observation, with the dependent variable being the subgroup mean of the outcome variable.

The `vwls` command fits the model

\[ y_i = x_i \beta + \varepsilon_i \]

where the errors \( \varepsilon_i \) are independent normal random variables with the distribution \( \varepsilon_i \sim N(0, \nu_i) \). The independent variables \( x_i \) are assumed to be known without error.

As described above, `vwls` assumes that you already have estimates \( s_i^2 \) for the variances \( \nu_i \). The error variance is not estimated in the regression. The estimates \( s_i^2 \) are used to compute the standard errors of the coefficients; see `Methods and formulas` below.

In contrast, weighted OLS regression assumes that the errors have the distribution \( \varepsilon_i \sim N(0, \sigma^2/w_i) \), where the \( w_i \) are known weights and \( \sigma^2 \) is an unknown parameter that is estimated in the regression. This is the difference from variance-weighted least squares: in weighted OLS, the magnitude of the error variance is estimated in the regression using all the data.

Example 1

An artificial, but informative, example illustrates the difference between variance-weighted least squares and weighted OLS.

We measure the quantities \( x_i \) and \( y_i \) and estimate that the standard deviation of \( y_i \) is \( s_i \). We enter the data into Stata:

```
. use https://www.stata-press.com/data/r18/vwlsxmpl
. list
```

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
<th>s</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1.2</td>
<td>.5</td>
</tr>
<tr>
<td>2</td>
<td>1.9</td>
<td>.5</td>
</tr>
<tr>

<td>1</td>
</tr>
</tbody>
</table>

| 6  | 6.0| 2  |
| 7  | 7.2| 2  |
| 8  | 7.9| 2  |

Because we want observations with smaller variance to carry larger weight in the regression, we compute an OLS regression with analytic weights proportional to the inverse of the squared standard deviations:
If we compute a variance-weighted least-squares regression by using \texttt{vwls}, we get the same results for the coefficient estimates but very different standard errors:

\begin{verbatim}
. vwls y x, sd(s)

Variance-weighted least-squares regression                   Number of obs =  8
Goodness-of-fit chi2(6) =  0.28                          Model chi2(1) =  33.24
Prob > chi2 =  0.9996                                      Prob > chi2 =  0.0000

+-----------------+-----------------+-----------------+-----------------+
| y    | Coefficient   | Std. err. | t    | P>|t| | [95% conf. interval] |
|------|---------------|-----------|------|------|----------------------------|
| x    | .9824683      | .170409   | 5.77 | 0.000| .6484728  1.316464         |
| _cons| .1138554      | .51484    | 0.22 | 0.825| -.8952124 1.122923         |
+-----------------+-----------------+-----------------+-----------------+
\end{verbatim}

Although the values of $y_i$ were nicely linear with $x_i$, the \texttt{vwls} regression used the large estimates for the standard deviations to compute large standard errors for the coefficients. For weighted OLS regression, however, the scale of the analytic weights has no effect on the standard errors of the coefficients—only the relative proportions of the analytic weights affect the regression.

If we are sure of the sizes of our error estimates for $y_i$, using \texttt{vwls} is valid. However, if we can estimate only the relative proportions of error among the $y_i$, then \texttt{vwls} is not appropriate.

\section*{Example 2}

Let’s now consider an example of the use of \texttt{vwls} with categorical data. Suppose that we have blood pressure data for $n = 400$ subjects, categorized by gender and race (black or white). Here is a description of the data:
Performing a variance-weighted regression using \texttt{vwls} gives

\begin{verbatim}
. vwls bp gender race

Variance-weighted least-squares regression
Number of obs = 400
Goodness-of-fit chi2(1) = 0.88 Model chi2(2) = 27.11
Prob > chi2 = 0.3486 Prob > chi2 = 0.0000

|     | Coefficient | Std. err. | z    | P>|z| | [95% conf. interval] |
|-----|-------------|-----------|------|------|-----------------------|
| gender | 5.876522 | 1.170241 | 5.02 | 0.000 | 3.582892 to 8.170151 |
| race | 2.372818 | 1.191683 | 1.99 | 0.046 | 0.0371631 to 4.708473 |
| _cons | 116.6486 | 0.9296297 | 125.48 | 0.000 | 114.8266 to 118.4707 |
\end{verbatim}

By comparison, an OLS regression gives the following result:

\begin{verbatim}
. regress bp gender race

Source | SS | df | MS  | Number of obs = 400
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>F(2, 397) = 15.24</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Model</td>
<td>4485.66639</td>
<td>2</td>
<td>2242.83319</td>
<td>Prob &gt; F = 0.0000</td>
</tr>
<tr>
<td>Residual</td>
<td>58442.7305</td>
<td>397</td>
<td>147.210908</td>
<td>R-squared = 0.0713</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Adj R-squared = 0.0666</td>
</tr>
<tr>
<td>Total</td>
<td>62928.3969</td>
<td>399</td>
<td>157.71528</td>
<td>Root MSE = 12.133</td>
</tr>
</tbody>
</table>

|     | Coefficient | Std. err. | t    | P>|t| | [95% conf. interval] |
|-----|-------------|-----------|------|------|-----------------------|
| gender | 6.1775 | 1.213305 | 5.09 | 0.000 | 3.792194 to 8.562806 |
| race | 2.5875 | 1.213305 | 2.13 | 0.034 | 0.2021938 to 4.972806 |
| _cons | 116.4862 | 1.050753 | 110.86 | 0.000 | 114.4205 to 118.552 |
\end{verbatim}

Note the larger value for the \texttt{race} coefficient (and smaller \textit{p}-value) in the OLS regression. The assumption of homogeneity of variance in OLS means that the mean for black men pulls the regression line higher than in the \texttt{vwls} regression, which takes into account the larger variance for black men and reduces its effect on the regression.
Stored results

vwls stores the following in e():

Scalars
- e(N) number of observations
- e(df_m) model degrees of freedom
- e(chi2) model $\chi^2$
- e(df_gf) goodness-of-fit degrees of freedom
- e(chi2_gf) goodness-of-fit $\chi^2$
- e(rank) rank of e(V)

Macros
- e(cmd) vwls
- e(cmdline) command as typed
- e(depvar) name of dependent variable
- e(properties) b V
- e(predict) program used to implement predict
- e(asbalanced) factor variables fvset as asbalanced
- e(asobserved) factor variables fvset as asobserved

Matrices
- e(b) coefficient vector
- e(V) variance–covariance matrix of the estimators

Functions
- e(sample) marks estimation sample

In addition to the above, the following is stored in r():

Matrices
- r(table) matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in r() are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

Methods and formulas

Let $y = (y_1, y_2, \ldots, y_n)'$ be the vector of observations of the dependent variable, where $n$ is the number of observations. When sd() is specified, let $s_1, s_2, \ldots, s_n$ be the standard deviations supplied by sd(). For categorical data, when sd() is not given, the means and standard deviations of $y$ for each subgroup are computed, and $n$ becomes the number of subgroups, $y$ is the vector of subgroup means, and $s_i$ are the standard deviations for the subgroups.

Let $V = \text{diag}(s_1^2, s_2^2, \ldots, s_n^2)$ denote the estimate of the variance of $y$. Then the estimated regression coefficients are

$$b = (X'V^{-1}X)^{-1}X'V^{-1}y$$

and their estimated covariance matrix is

$$\hat{\text{Cov}}(b) = (X'V^{-1}X)^{-1}$$

A statistic for the goodness of fit of the model is

$$Q = (y - Xb)'V^{-1}(y - Xb)$$

where $Q$ has a $\chi^2$ distribution with $n - k$ degrees of freedom ($k$ is the number of independent variables plus the constant, if any).

predict

Description for predict

**predict** creates a new variable containing predictions such as linear predictions and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, xb stdp]
```

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Options for predict

- **xb**, the default, calculates the linear prediction.
- **stdp** calculates the standard error of the linear prediction.
margins

Description for margins

margins estimates margins of response for linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ... ) [ options ]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xb</td>
<td>linear prediction; the default</td>
</tr>
<tr>
<td>stdp</td>
<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than e(b).
For the full syntax, see [R] margins.

Also see

[R] vwls — Variance-weighted least squares
[U] 20 Estimation and postestimation commands
which — Display location of an ado-file

Description
which looks for file *fname*.ftype along the $S\_ADO$ path. If Stata finds the file, which displays the full path and filename, along with, if the file is text, all lines in the file that begin with “*!” in the first column. If Stata cannot find the file, which issues the message “file not found along ado-path” and sets the return code to 111. *ftype* must be a file type for which Stata usually looks along the ado-path to find. Allowable *ftypes* are

-ado, .class, .dlg, .idlg, .sthlp, .ihlp, .hlp, .jar, .key, .maint, .mata, .mlib, .mo, .mnu, .plugin, .png, .py, .scheme, .stbcal, and .style

If *ftype* is omitted, which assumes .ado. When searching for .ado files, if Stata cannot find the file, Stata then checks to see if *fname* is a built-in Stata command, allowing for valid abbreviations. If it is, the message “built-in command” is displayed; if not, the message “command not found as either built-in or ado-file” is displayed and the return code is set to 111.

Syntax

```
which *fname*[.*ftype] [ , all ]
```

Option

all forces which to report the location of all files matching the *fname*.ftype found along the search path. The default is to report just the first one found.

Remarks and examples

If you write programs, you know that you make changes to the programs over time. If you are like us, you also end up with multiple versions of the program stored on your disk, perhaps in different directories. You may even have given copies of your programs to other Stata users, and you may not remember which version of a program you or your friends are using. The which command helps you solve this problem.

Example 1

The which command displays the path for *filename*.ado and any lines in the code that begin with “*!””. For example, we might want information about the test command, described in [R] test, which is an ado-file written by StataCorp. Here is what happens when we type which test:

```
. which test
C:\Program Files\Stata18\ado\base\t\test.ado
*! version 2.4.1 28jan2021
```

3178
which displays the path for the test.ado file and also a line beginning with “*!” that indicates the version of the file.

Do not confuse “version 2.4.1” above with the version command or the version of Stata. The “*!” code indicates notes. In this case, the *! version 2.4.1 line is merely a note to the author to identify the iteration (version) of the test program. It is an unfortunate coincidence that the word version is overloaded in this manner.

We do not need to be so formal. which will display anything typed after lines that begin with ‘*!’. For instance, we might write myprog.ado:

```
. which myprog
.myprog.ado
*! first written 1/03/2023
*! bug fix on 1/05/2023 (no variance case)
*! updated 1/24/2023 to include noconstant option
*! still suspicious if variable takes on only two values
```

It does not matter where in the program the lines beginning with *! are—which will list them (in particular, our “still suspicious” comment was buried about 50 lines down in the code). All that is important is that the *! marker appear in the first two columns of a line.

Example 2

If we type which command, where command is a built-in command rather than an ado-file, Stata responds with

```
. which summarize
 Built-in command: summarize
```

If command was neither a built-in command nor an ado-file, Stata would respond with

```
. which junk
 command junk not found as either built-in or ado-file
 r(111);
```

**Description**

`wildbootstrap` performs wild cluster bootstrap (WCB) inference for linear hypotheses about parameters in linear regression models. These hypotheses can be simple or composite. When the assumptions required for the consistency of the cluster-robust variance estimator (CRVE) do not hold, the WCB is a good alternative.

**Quick start**

Estimate the WCB $p$-value and confidence interval (CI) for the coefficient on $x_1$ in a linear regression of $y$ on $x_1$ with clusters identified in `cvar`:

```
   wildbootstrap regress y x1, cluster(cvar)
```

Same as above, but test whether the coefficients on $x_1$ and $x_2$ are equal in a regression of $y$ on $x_1$ and $x_2$:

```
   wildbootstrap regress y x1 x2, cluster(cvar) test(x1 = x2)
```

**Menu**

Statistics > Resampling > Wild cluster bootstrap
Syntax

indepvars and coeflist may contain factor variables; see [U] 11.4.3 Factor variables.
depvar, indepvars, and coeflist may contain time-series operators; see [U] 11.4.4 Time-series varlists.
collect is allowed; see [U] 11.1.10 Prefix commands.

Any weight that is allowed by the estimator is allowed; see [U] 11.1.6 weight.

Options

- noconstant and hascons; see [R] regress. These options may be specified only when estimator regress is specified.

- absorb(varname); see [R] areg. This option must be specified when estimator areg is specified.
coefficients(coeflist) performs an inference for a subset of coefficients. It reports the bootstrap
$p$-value for a test of the subset of coefficients, coeflist, equal to 0 and the bootstrap CI. The default
is to perform inference for all variables specified in indepvars. coefficients() may not be
specified with test().

test(testspec) specifies a linear test. You may also specify multiple linear tests by using
test((testspec1) (testspec2) ...). The test specification must be consistent with specifying
a linear constraint. See [R] test and [R] constraint.

cluster(clustvar) specifies the variable identifying the cluster groups. cluster() is required with
estimators regress and areg. With estimator xtreg, clustvar defaults to the xtset panelvar.

ptype(ptype) specifies the $p$-value criterion: symmetric (symmetric) or equal tailed (equal). The
default is ptype(equal). See Methods and formulas for more details.

errorweight(wcbwtype) specifies the type of wild weight. wcbwtype may be one of the following:

<table>
<thead>
<tr>
<th>wcbwtype</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rademacher</td>
<td>two-point distribution assigns values 1 and $-1$ with equal probability; the default</td>
</tr>
<tr>
<td>mammen</td>
<td>two-point distribution assigns value $1 - \phi$ with probability $\phi/\sqrt{5}$ and value $\phi$ otherwise, where $\phi = (1 + \sqrt{5})/2$</td>
</tr>
<tr>
<td>webb</td>
<td>six-point distribution assigns probability of $1/6$ to the points $\pm \sqrt{1/2}$, $\pm 1$, and $\pm \sqrt{3/2}$</td>
</tr>
<tr>
<td>normal</td>
<td>standard normal distribution</td>
</tr>
<tr>
<td>gamma</td>
<td>gamma distribution with shape parameter 4 and scale parameter 1/2 centered on its mean of 2</td>
</tr>
</tbody>
</table>

reps(#) sets the number of repetitions for the bootstrap. The default is reps(1000). For the
ptype(equal) option, the values of level() and reps() should be chosen so that $\alpha/2 \times \text{reps(#)}$
is an integer, where $\alpha = (100 - \text{level(#)})/100$. For the ptype(symmetric) option, such values
should be chosen so that $\alpha \times \text{reps(#)}$ is an integer. When the product is not an integer, the
number of repetitions is increased so that it is. Integer values improve the search efficiency of the
wildbootstrap algorithm.

rseed(# | statecode) sets the random-number seed to # or statecode. See [R] set seed.

blocksize(#) sets the bootstrap block size. This is an integer less than or equal to reps(#) and
is used to reduce the amount of memory the bootstrap computation will consume. The default is
min(reps(#),1000).

cistop(largest | first) specifies the stopping rule for the CI computation. The bootstrap distribu-
tion is a step function, so for each bound, there is an interval of values that meet the CI level
criterion. cistop(largest), the default, specifies that the largest value within the interval be
selected. cistop(first) specifies that the first value the algorithm finds within the interval be
selected; therefore, specifying cistop(first) will result in faster CI computation. The cistop() option
may not be combined with the noCI option.

level(#); see [R] Estimation options. The level() option will not work on replay because CIs
are based on estimator-specific enumerations. To change the confidence level, you must refit the
model.
**Remarks and examples**

`wildbootstrap` implements the WCB, which was proposed by Cameron, Gelbach, and Miller (2008). It is an extension of the original wild bootstrap procedure proposed by Wu (1986), which was designed to work well for models with heteroskedasticity, to the case of cluster-level correlation. The wild bootstrap has proven to work well in cases where cluster-robust standard errors do not perform well. A good discussion of the methodology can be found in Cameron and Miller (2015), MacKinnon (2019), MacKinnon and Webb (2018), and MacKinnon, Nielsen, and Webb (2023), and the references therein. Specifically, the WCB is a good inference tool when one or more of the CRVE t-statistic consistency assumptions are violated. MacKinnon and Webb list the assumptions as follows:

1. The number of clusters goes to infinity.
2. The within-cluster error correlations are the same for all clusters.
3. Each cluster contains an equal number of observations.

Below, we illustrate how to use `wildbootstrap`; however, note that alternatives exist in the literature to address the inference problems noted above. For example, the Bell and McCaffrey (2002) t-statistic degrees-of-freedom correction is an alternative to `wildbootstrap` when at least one of the above assumptions is violated. The degrees-of-freedom correction is computed with option `vce(hc2 clustvar, dfadjust)` for `regress`, `areg`, and `xtreg, fe`.

#### Example 1: Simple regression

Say we are interested in the effect of tenure on wages for a panel of individuals sampled from 2013 to 2016. We would like to use wild bootstrap CIs clustering at the `personid` level. For reproducibility, we set the seed by using option `rseed()`.

```
. use https://www.stata-press.com/data/r18/wagework  
(Wages for 20 to 77 year olds, 2013-2016)
. wildbootstrap regress wage tenure, cluster(personid) rseed(12345)
Performing 1,000 replications for p-value for tenure = 0 ... 
Computing confidence interval for tenure
   Lower bound: ..........10............20. done (21)
   Upper bound: ..........10............ done (17)
```

</tbody>
</table>

The iteration log indicates the number of iterations used to compute the lower and upper bound for the CIs. In *Methods and formulas* below, we discuss how these bounds are computed. Notably, there is a separate optimization procedure used to compute each one of these bounds.
The table header also tells us the error weights used for the sampling algorithm of the wild bootstrap, which, by default, are Rademacher weights. See the `errorweight()` option for more details about error weights.

The column header labeled p-value indicates that the *t*-statistic equal-tailed *p*-value has been computed. The `ptype(equal)` option is the default. Alternatively, the symmetric *p*-value is computed when the `ptype(symmetric)` option is specified and is identified with the column header of `P>|t|`.

```
. wildbootstrap regress wage tenure, cluster(personid) rseed(12345) > ptype(symmetric)
Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
   Lower bound: ........10...........20.. done (22)
   Upper bound: ........10..... done (15)
Wild cluster bootstrap Number of obs = 1,928
Linear regression Number of clusters = 589
Cluster size:
   Cluster variable: personid min = 1
   Error weight: Rademacher avg = 3.3
                max = 4

| wage     | Estimate | t    | P>|t| | [95% conf. interval] |
|----------|----------|------|------|----------------------|
| constraint | tenure = 0 | .7807403 | 27.19 | 0.000 | .7240502 .8399896 |
```

We can always compare the CIs from the wild bootstrap with what we would have obtained using the underlying command, in this case, `regress`.

```
. regress
Linear regression
   Number of obs = 1,928
   F(1, 588) = 739.36
   Prob > F = 0.0000
   R-squared = 0.4212
   Root MSE = 3.5097

   (Std. err. adjusted for 589 clusters in personid)

| wage  | Coefficient     | std. err. | t    | P>|t|         | [95% conf. interval] |
|-------|-----------------|-----------|------|-------------|----------------------|
| tenure | .7807403        | .028713   | 27.19| 0.000       | .7243477 .8371328   |
| _cons | 20.89884        | .2135686  | 97.86| 0.000       | 20.47939 21.31829  |
```

Note that typing this command will replace the return matrix `r(table)`. Observe that the *t* statistics are the same in both tables because `regress` and `wildbootstrap` use the same CRVE, but the *p*-values and CIs may vary between tables.

Similarly, you can redisplay the wildbootstrap table by typing `wildbootstrap`, which may be abbreviated as `wildboot`.

### Example 2: Small number of clusters with wildly varying cluster sizes

As in example 1, we would like to see the effect of tenure on wages; in this case, however, we would like to cluster at the industry level. Here, for year 1988, we use a wage dataset with only 12 clusters, for which cluster sizes vary wildly from 4 to 817, violating the CRVE *t*-statistic consistency assumptions 1 and 3 outlined previously.
Example 3: Small number of clusters with more regressors

Continuing with example 2, we look at a more complex and perhaps more realistic example. We add to the model explanatory variables for total work experience, \texttt{ttl}\_\texttt{exp}; a college graduate indicator, \texttt{collgrad}; and an indicator for union membership, \texttt{union}.

```stata
. wildbootstrap regress wage c.tenure##c.ttl_exp ib0.collgrad ib0.union, cluster(industry) rseed(12345)
Performing 1,000 replications for p-value for tenure = 0 ...
Computing confidence interval for tenure
   Lower bound: ........10.........20.........30.... done (34)

We did not specify the coefficients() option, so wildbootstrap computes p-values and CIs for all coefficients in the model, with the exception of the constant term, using the default ptype(equal) option to compute the equal-tailed p-values.

The iteration log states that the CI-target tail values were not achieved for two of the reported constraints. This is because the sorted vector of bootstrap t statistics can have ties due to computer finite numeric precision and the finite number of draws for the Rademacher, Mammen, and Webb distributions. When ties occur with the t statistic under the null, or those adjacent to it, and the desired CI tail area cannot be achieved, wildbootstrap will choose a bound that results in a smaller tail area. This is the case when wildbootstrap searches for the c.tenure#c.ttl_exp CI upper bound and the 1.collgrad CI lower bound.

Numerical computations will contain a roundoff error; wildbootstrap retains 13 digits on the mantissa of the t statistics before making comparisons.

Example 4: Linear regression with an indicator-variable set

We would like to include an individual’s occupation code (occupation) as an additional control in the regression to avoid potential omitted-variable bias. We keep the other control variables we introduced in example 3. For this analysis, we use the estimator areg with the absorb(occupation) option. We use the test() option to test linear combinations of regression estimates.

. wildbootstrap areg wage c.tenure##c.ttl_exp ib0.collgrad ib0.union,
   > absorb(occupation) cluster(industry) rseed(12345)
   > test((tenure=ttl_exp) (1.collgrad-1.union=1)) reps(1250)
   note: for equal-tailed 95% CI, better performance is obtained when
   .025*reps() is an integer.

\end{tabular}

The \texttt{test()} option allows us to specify a linear combination of the regression coefficients that we would like to test. The syntax is the same as specifying linear constraints, \texttt{constraint}, or linear hypothesis tests, \texttt{test}. In this example, we are inquiring how probable it would be for \(tenure = ttl\_exp\) and \(1.collgrad - 1.union = 1\).

The \texttt{reps()} option allows us to set the number of bootstrap repetitions. The default is 1,000. Because the Rademacher and Mammen distributions have two possible realizations, the maximum number of possible bootstrap samples is \(2^G\), where \(G\) is the number of clusters. The Webb distribution, on the other hand, has six outcomes and therefore \(6^G\) possible combinations.

In this example, we intentionally specify a number of bootstrap repetitions that results in a noninteger product, \(\texttt{reps()} \times \frac{\alpha}{2} = \texttt{reps()} \times \frac{(100 - \texttt{level}())}{200} = 1250 \times 0.025 = 31.25\). In this case, we lose efficiency in searching for the CI bounds, so \texttt{wildbootstrap} adjusts the number of repetitions to 1,280; when we specify \texttt{reps(1250)} with \texttt{level(95)}, \texttt{wildbootstrap} chooses \(\texttt{reps()} = \texttt{ceil}(1250 \times \frac{\alpha}{2})/(\alpha/2) = 32/0.025 = 1280\). If an integer alternative cannot be found, the original \texttt{reps()} specification will be used. For details, see \textit{Methods and formulas} below.

Because the WCB distribution is a step function, there is a range of values for each CI bound. For example, the lower-bound interval of values for the linear combination \(tenure - ttl\_exp\) is \(-0.191586 \leq \alpha_{lb} \leq -0.191553\). The reported bounds are the largest value of each interval. We obtain \(-0.191586\) by running \texttt{wildbootstrap} specifying \texttt{level(#)} with \# = \(0.95 + 2/1280\) \times 100. We would likely report the CIs using three digits of precision, for instance, \([-0.192, 0.150]\), so this interval is negligible but significant in a numerical root search where a convergence tolerance for \(r_l\) might be \(10^{-8}\).

The estimate of \(tenure - ttl\_exp\) is reported to be \(-0.0391\) with a 95\% CI of \([-0.192, 0.150]\). We therefore fail to reject the hypothesis that \(tenure = ttl\_exp\). Similarly, the estimate of \(1.collgrad - 1.union\) is 1.36 with a CI of \([-0.188, 3.91]\), and we conclude the difference of 1 is feasible.
Example 5: Fixed-effects linear regression with panels

Our final example demonstrates the use of `wildbootstrap` with estimator `xtreg`. Continuing with the data in the previous example, we use `industry` as the variable defining the panels.

We specify normal error weights, `errorweight(normal)`, thereby reducing the chance of identical draws for the error weights. Draws from the Rademacher distribution for 12 clusters have $2^{12} = 4096$ combinations.

We compute $p$-values and CIs on a subset of the model estimates: work tenure, work experience, and their interaction. If we replay the `xtreg` coefficient table, we will see that the fitted model includes `tenure`, `ttl_exp`, `c.tenure#c.ttl_exp`, `1.collgrad`, and `1.union`.

Finally, we use the symmetric $p$-value, option `ptype(symmetric)`, instead of the default equal-tailed, `ptype(equal)`. The table identifies the symmetric $p$-value with the header $P>|t|$.

The command and the results are as follows:

```
. xtset industry
Panel variable: industry (unbalanced)
. wildbootstrap xtreg wage c.tenure##c.ttl_exp i.collgrad i.union, > rseed(12345) coef(ten ttl ten#ttl) errorweight(normal) > ptype(symmetric)

```

The fixed-effects model is the only `xtreg` model allowed with `wildbootstrap`, so specifying the `fe` option is not required.

Also note that the `cluster()` option is not specified. When the estimator `xtreg` is specified, the default cluster variable is the panel variable that is `xtset`. If the specified cluster variable is different...
from the panel variable, then the levels of the panel variable must be nested within the cluster variable levels.

Stored results

wildbootstrap stores the following in \texttt{e()}:  

Scalars 

- \texttt{e(N_clust)} number of clusters
- \texttt{e(N_wbreps)} number of bootstrap repetitions
- \texttt{e(vb_block)} bootstrap block size
- \texttt{e(n_wbcns)} number of bootstrap constraint restrictions
- \texttt{e(min_c)} smallest cluster size
- \texttt{e(max_c)} largest cluster size
- \texttt{e(avg_c)} average cluster size

Macros 

- \texttt{e(cmdline)} command as typed
- \texttt{e(cmd0)} wildbootstrap
- \texttt{e(wb_stat)} WCB statistic, $t$
- \texttt{e(wb_weight)} WCB weights
- \texttt{e(wb_pvalue)} WCB $p$-value criterion
- \texttt{e(wb_level)} WCB CI level
- \texttt{e(wb_cisop)} WCB CI interval type
- \texttt{e(wb_rseed)} random-number state
- \texttt{e(wb_cnsi)} WCB constraint $i$, where $i=1,...,\texttt{e(n_wbcns)}$
- \texttt{e(clustvar)} name of cluster variable

Matrices 

- \texttt{e(wboot)} WCB table
- \texttt{e(wb_pci)} WCB CI coverage
- \texttt{e(wb_CMs)} WCB constraint matrix

wildbootstrap will also carry forward most of the results already in \texttt{e()} from \texttt{command}. 

In addition to the above, the following is stored in \texttt{r()}:

Matrices 

- \texttt{r(table)} matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in \texttt{r()} are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

Methods and formulas

Methods and formulas are presented under the following headings:

- Introduction
- CIs for linear combinations of coefficients
- Constructing a CI inverting the hypothesis test
Introduction

We will focus our discussion of the WCB on linear regression, which easily extends to the other fixed-effects estimators. A linear regression model with clustered errors and $G$ clusters can be written as

$$y = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_G \end{pmatrix} = X\beta + \epsilon = \begin{pmatrix} X_1 \\ X_2 \\ \vdots \\ X_G \end{pmatrix} \begin{pmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_k \end{pmatrix} + \begin{pmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_G \end{pmatrix} \quad (1)$$

where for each cluster $g$, $N_g$ is the number of observations, $y_g$ is an $N_g \times 1$ vector of outcomes, $X_g$ is an $N_g \times k$ matrix of covariates, and $\epsilon_g$ is an $N_g \times 1$ vector of errors. The parameter of interest is the $k \times 1$ vector of coefficients $\beta$. Error terms are assumed uncorrelated between observations of different clusters but possibly correlated between observations within the same cluster.

Without loss of generality, we will first focus on testing the null hypothesis $H_0: \beta_k = 0$ using the WCB algorithm. Let $\hat{\beta}$ denote the ordinary least-squares estimator for $\beta$. We compute the $t$ statistic for the $k$th coefficient as

$$t_k = \frac{\hat{\beta}_k}{\sqrt{\hat{\nu}_{k,k}}}$$

where $\hat{\nu}_{k,k}$ is the CRVE for $\hat{\beta}_k$. This is the $k$th diagonal element of the matrix

$$\hat{\nu} = \frac{G(N-1)}{(G-1)(N-k)}(XX')^{-1}\left(\sum_{g=1}^{G} X'_g \hat{\epsilon}_g \hat{\epsilon}_g' X_g\right)(XX')^{-1} \quad (2)$$

where $\hat{\epsilon}_g$ is the $N_g \times 1$ vector of ordinary least-squares residuals for cluster $g$ and $N = \sum_{g=1}^{G} N_g$ is the total number of observations.

The WCB algorithm proceeds as follows:

1. Refit model (1) subject to the restriction $\beta_k = 0$. Let $\tilde{\beta}$ denote the restricted estimates and $\tilde{\epsilon}$ denote the restricted residuals.

2. For each individual bootstrap replication $b$ (out of a total of $B$ replications):
   2a. Generate random variable $\nu^b_g$ for each cluster $g$ according to the distribution specified in the errorweight() option.
   2b. For each cluster $g$ and each observation in the cluster $i = 1, 2, \ldots, N_g$, generate a new bootstrap-dependent variable $y^b_{ig}$ using the data-generating process:

   $$y^b_{ig} = X_{ig}\tilde{\beta} + \tilde{\epsilon}_{ig}\nu^b_g$$

2c. Fit model (1) using the bootstrap variable $y^b_{ig}$ as regressand. Calculate the $t$ statistic for $\beta_k = 0$,

$$t^b_k = \frac{\hat{\beta}^b_k}{\sqrt{\hat{\nu}^b_{k,k}}}$$

where $\hat{\beta}^b_k$ and $\hat{\nu}^b_{k,k}$ are the ordinary least-squares coefficient and the CRVE for that coefficient in the bootstrap replication, respectively. In this case, the CRVE is the $k$th diagonal element of matrix (2) obtained when using the residuals from bootstrap replication $b$. 
3. The $p$-values for the one-sided alternative hypotheses $H_1: \beta_k > 0$ and $H_2: \beta_k < 0$ are given by

$$p_1 = \frac{1}{B} \sum_{b=1}^{B} I\left(t^b_k > t_k\right)$$

$$p_2 = \frac{1}{B} \sum_{b=1}^{B} I\left(t^b_k < t_k\right)$$

For the alternative hypothesis $H_3: \beta_k \neq 0$, the $p$-value assuming that the distribution of the $t$ statistic is symmetric around 0 is given by

$$p_S = \frac{1}{B} \sum_{b=1}^{B} I\left(|t^b_k| > |t_k|\right)$$

If the assumption of symmetry is not appropriate, then the $p$-value is given by the equal-tailed $p$-value $p_e = 2 \min(p_1, p_2)$. See Djogbenou, MacKinnon, and Nielsen (2019).

To increase computational speed, at the expense of computer memory usage, the wildbootstrap command uses the matrix algebra of Roodman et al. (2019). By doing this, the computational complexity (run time) of the WCB algorithm is reduced from the order $O(\mathcal{N}B)$ to the order $O(GB)$. The WCB uses a $G \times B$ matrix of random variables. By organizing these variables in column-major order, wildbootstrap reduces overall memory usage with minimal extra computation by breaking up the number of bootstrap replicates into blocks (the blocksize(#) option).

**CIs for linear combinations of coefficients**

By inverting hypotheses tests, we can apply the WCB algorithm to find CIs for any linear combination of coefficients. Suppose we wanted to compute a CI for the linear combination of parameters $\mathbf{R}\beta$, where $\mathbf{R}$ is a $1 \times k$ vector. In this case, the associated null hypothesis is $H_0: \mathbf{R}\hat{\beta} = r$, where $r$ is an arbitrary scalar. We can test this null hypothesis with the WCB algorithm described in the previous section by using the bootstrap $t$ statistics

$$t^b(r) = \frac{\mathbf{R}\hat{\beta}^b - r}{\sqrt{\mathbf{R}\tilde{V}^b\mathbf{R}'}}$$

for $b = 1, \ldots, B$. For more on restricted regression with linear constraints on multiple coefficients, see [P] makecns.

The associated one-sided alternative hypotheses are now $H_1: \mathbf{R}\beta > r$ and $H_2: \mathbf{R}\beta < r$. As before, their respective bootstrap $p$-values are given by

$$p_1(r) = \frac{1}{B} \sum_{b=1}^{B} I\left\{t^b(r) > t(r)\right\}$$

$$p_2(r) = \frac{1}{B} \sum_{b=1}^{B} I\left\{t^b(r) < t(r)\right\}$$
where \( t(r) \) is the \( t \) statistic from the original sample:

\[
t(r) = \frac{\hat{R}\hat{\beta} - r}{\sqrt{\hat{V}R'}}
\]

The associated two-sided alternative hypothesis is \( H_3: R\beta \neq r \), and its bootstrap \( p \)-value under the assumption of symmetry is given by

\[
p_S(r) = \frac{1}{B} \sum_{b=1}^{B} I \{ |t^b(r)| > |t(r)| \}
\]

When using the equal-tailed criterion (the `ptype(equal)` option), the 100(1 - \( \alpha \))% CI for \( R\beta \) is given by \([r_l, r_u] \), where \( r_l \) and \( r_u \) satisfy \( p_1(r_l) = p_2(r_u) = \alpha/2 \). On the other hand, when using the symmetric criterion (the `ptype(symmetric)` option), \( r_l \) and \( r_u \) satisfy \( p_S(r_l) = p_S(r_u) = \alpha \). The parameter \( \alpha \) can be specified with the `level()` option, that is, \( \alpha = (100 - \text{level()})/100 \).

The bootstrap \( p \)-values are step functions on \( r \), and therefore a range of values for \( r_l \) and for \( r_u \) will solve the \( p \)-value conditions above. Because distribution functions are right continuous, `wildbootstrap` chooses the rightmost point in each range of solutions.

For the equal-tailed CIs, the starting values for the search of solutions to the \( p \)-value conditions are chosen as follows. First, the bootstrap \( t \) statistics are sorted \( t(1) \leq t(2) \leq \ldots < t(B) \). Second, we define \( b_l = \text{ceil}\{B(1 - \alpha/2)\} \) so that \( t^{(b_l)} \) is smaller than \( B(\alpha/2) \) of the \( t \) statistics. Similarly, we define \( b_u = \text{floor}\{B(\alpha/2)\} \) so that \( t^{(b_u)} \) is larger than \( B(\alpha/2) \) of the \( t \) statistics. Third and finally, the initial lower and upper bounds of the CI are given by

\[
\begin{align*}
r_l &= R\hat{\beta} - t^{(b_l)} \sqrt{\hat{V}R'} \\
r_u &= R\hat{\beta} - t^{(b_u)} \sqrt{\hat{V}R'}
\end{align*}
\]

where \( \hat{\beta} \) and \( \hat{V} \) are the unrestricted estimator for \( \beta \) and the unrestricted CRVE in the original sample.

**Constructing a CI inverting the hypothesis test**

For a linear combination of coefficients \( \sum R_j \beta_j \), we can construct a CI by inverting the hypothesis test \( H_0: R\beta = r \), where \( R \) is a row vector that includes the coefficients \( R_j \) and \( r \) is an arbitrary scalar. To do this, `wildbootstrap` searches for the CI lower bound \( r_l \) such that \( \Pr(R\beta \leq r_l) = \alpha/2 \) (equal-tailed criterion, the `ptype(equal)` option). The WCB distribution of \( R\beta \) is a step function with a step size of \( 1/\text{reps}(\#) \). When \( \text{reps}(\#) \times \alpha/2 \) is an integer, call it \( S \), then we search for the \( r_l \) that produces the ordered bootstrapped \( t \) statistics

\[
t^{(b)} = \frac{R\hat{\beta}^{(b)} - r_l}{\sqrt{R'\hat{V}^{(b)}R}}
\]

with the property \( \sum_{b=1}^{\text{reps}(\#)} I(t^{(b)} > t) = S \) and therefore \( \Pr(R\beta \leq r_l) = S/\text{reps}(\#) = \alpha/2 \).
Acknowledgments

We thank David Roodman of Open Philanthropy for his insights on the wild bootstrap computation.

We also acknowledge previous and ongoing contributions to this area from the Stata community. In particular, we acknowledge David Roodman, James G. MacKinnon, Morten Ørregaard Nielsen, and Matthew D. Webb for their command \texttt{boottest} and Mitchell Petersen, Douglas Miller, and Judson Caskey for their command \texttt{cgmwildboot}.

xi — Interaction expansion

Description

xi expands terms containing categorical variables into indicator (also called dummy) variable sets by creating new variables and, in the second syntax (xi: any stata command), executes the specified command with the expanded terms. The dummy variables created are

- `i.varname` creates dummies for categorical variable `varname`
- `i.varname1*i.varname2` creates dummies for categorical variables `varname1` and `varname2`: all interactions and main effects
- `i.varname1*varname3` creates dummies for categorical variable `varname1` and continuous variable `varname3`: all interactions and main effects
- `i.varname1|varname3` creates dummies for categorical variable `varname1` and continuous variable `varname3`: all interactions and main effect of `varname3`, but no main effect of `varname1`

Menu

Data > Create or change data > Other variable-creation commands > Interaction expansion

Most commands in Stata now allow factor variables; see [U] 11.4.3 Factor variables. To determine if a command allows factor variables, see the information printed below the options table for the command. If the command allows factor variables, it will say something like “indepvars may contain factor variables”.

We recommend that you use factor variables instead of xi if a command allows factor variables. We include [R] xi in our documentation so that readers can consult it when using a Stata command that does not allow factor variables.
Syntax

\texttt{xi [, prefix(string) noomit] \textit{term(s)}}

\texttt{xi [, prefix(string) noomit] : any_stata_command \textit{varlist\_with\_terms} ...}

where a \textit{term} has the form

\texttt{i.varname} \quad \text{or} \quad \texttt{I.varname}

\texttt{i.varname\_1*i.varname\_2} \quad \texttt{I.varname\_1*I.varname\_2}

\texttt{i.varname\_1*varname\_3} \quad \texttt{I.varname\_1*varname\_3}

\texttt{i.varname\_1|varname\_3} \quad \texttt{I.varname\_1|varname\_3}

\textit{varname}, \textit{varname\_1}, and \textit{varname\_2} denote numeric or string categorical variables. \textit{varname\_3} denotes a continuous, numeric variable.

Options

prefix\textit{(string)} allows you to choose a prefix other than \_I for the newly created interaction variables.

The prefix cannot be longer than four characters. By default, \texttt{xi} will create interaction variables starting with \_I. When you use \texttt{xi}, it drops all previously created interaction variables starting with the prefix specified in the prefix\textit{(string)} option or with \_I by default. Therefore, if you want to keep the variables with a certain prefix, specify a different prefix in the prefix\textit{(string)} option.

noomit prevents \texttt{xi} from omitting groups. This option provides a way to generate an indicator variable for every category having one or more variables, which is useful when combined with the noconstant option of an estimation command.

Remarks and examples

Remarks are presented under the following headings:

- Background
- Indicator variables for simple effects
- Controlling the omitted dummy
- Categorical variable interactions
- Interactions with continuous variables
- Using \texttt{xi}: Interpreting output
- How \texttt{xi} names variables
- \texttt{xi} as a command rather than a command prefix
- Warnings

\texttt{xi} provides a convenient way to include dummy or indicator variables when fitting a model (say, with \texttt{regress} or \texttt{logistic}). For instance, assume that the categorical variable \texttt{agegrp} contains 1 for ages 20–24, 2 for ages 25–39, 3 for ages 40–44, etc. Typing

\begin{verbatim}
  . xi: logistic outcome weight i.agegrp bp
\end{verbatim}

estimates a logistic regression of \textit{outcome} on \textit{weight}, dummies for each \texttt{agegrp} category, and \texttt{bp}. That is, \texttt{xi} searches out and expands terms starting with “\texttt{i.”} or “\texttt{I.”} but ignores the other variables. \texttt{xi} will expand both numeric and string categorical variables, so if you had a string variable \textit{race} containing “white”, “black”, and “other”, typing

\begin{verbatim}
  . xi: logistic outcome weight bp i.agegrp i.race
\end{verbatim}

would include indicator variables for the race group as well.
The `i.` indicator variables `xi` expands may appear anywhere in the `varlist`, so

```
   . xi: logistic outcome i.agegrp weight i.race bp
```

would fit the same model.

You can also create interactions of categorical variables; typing

```
   xi: logistic outcome weight bp i.agegrp*i.race
```

fits a model with indicator variables for all `agegrp` and `race` combinations, including the `agegrp` and `race` main-effect terms (that is, the terms that are created when you just type `i.agegrp i.race`).

You can interact dummy variables with continuous variables; typing

```
   xi: logistic outcome bp i.agegrp*weight i.race
```

fits a model with indicator variables for all `agegrp` categories interacted with `weight`, plus the main-effect terms `weight` and `i.agegrp`.

You can get the interaction terms without the `agegrp` main effect (but with the `weight` main effect) by typing

```
   xi: logistic outcome bp i.agegrp|weight i.race
```

You can also include multiple interactions:

```
   xi: logistic outcome bp i.agegrp*weight i.agegrp*i.race
```

We will now back up and describe the construction of dummy variables in more detail.

**Background**

The terms continuous, categorical, and indicator or dummy variables are used below. Continuous variables measure something—such as height or weight—and at least conceptually can take on any real number over some range. Categorical variables, on the other hand, take on a finite number of values, each denoting membership in a subclass—for example, excellent, good, and poor, which might be coded 0, 1, 2, or 1, 2, 3, or even “Excellent”, “Good”, and “Poor”. An indicator or dummy variable—the terms are used interchangeably—is a special type of two-valued categorical variable that contains values 0, denoting false, and 1, denoting true. The information contained in any `k`-valued categorical variable can be equally well represented by `k` indicator variables. Instead of one variable recording values representing excellent, good, and poor, you can have three indicator variables, indicating the truth or falseness of “result is excellent”, “result is good”, and “result is poor”.

`xi` provides a convenient way to convert categorical variables to dummy or indicator variables when you fit a model (say, with `regress` or `logistic`).

➤ **Example 1**

For instance, assume that the categorical variable `agegrp` contains 1 for ages 20–24, 2 for ages 25–39, and 3 for ages 40–44. (There is no one over 44 in our data.) As it stands, `agegrp` would be a poor candidate for inclusion in a model even if we thought age affected the outcome. The reason is that the coding would restrict the effect of being in the second age group to be twice the effect of being in the first, and, similarly, the effect of being in the third to be three times the first. That is, if we fit the model,

\[
y = \beta_0 + \beta_1 \text{agegrp} + X\beta_2
\]
the effect of being in the first age group is $\beta_1$, the second $2\beta_1$, and the third $3\beta_1$. If the coding 1, 2, and 3 is arbitrary, we could just as well have coded the age groups 1, 4, and 9, making the effects $\beta_1$, $4\beta_1$, and $9\beta_1$.

The solution is to convert the categorical variable `agegrp` to a set of indicator variables, $a_1$, $a_2$, and $a_3$, where $a_i$ is 1 if the individual is a member of the $i$th age group and 0 otherwise. We can then fit the model

$$y = \beta_0 + \beta_{11}a_1 + \beta_{12}a_2 + \beta_{13}a_3 + X\beta$$

The effect of being in age group 1 is now $\beta_{11}$; 2, $\beta_{12}$; and 3, $\beta_{13}$; and these results are independent of our (arbitrary) coding. The only difficulty at this point is that the model is unidentified in the sense that there are an infinite number of $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13})$ that fit the data equally well.

To see this, pretend that $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (1, 1, 3, 4)$. The predicted values of $y$ for the various age groups are

$$y = \begin{cases} 
1 + 1 + X\beta_2 = 2 + X\beta_2 & \text{(age group 1)} \\
1 + 3 + X\beta_2 = 4 + X\beta_2 & \text{(age group 2)} \\
1 + 4 + X\beta_2 = 5 + X\beta_2 & \text{(age group 3)} 
\end{cases}$$

Now, pretend that $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (2, 0, 2, 3)$. The predicted values of $y$ are

$$y = \begin{cases} 
2 + 0 + X\beta_2 = 2 + X\beta_2 & \text{(age group 1)} \\
2 + 2 + X\beta_2 = 4 + X\beta_2 & \text{(age group 2)} \\
2 + 3 + X\beta_2 = 5 + X\beta_2 & \text{(age group 3)} 
\end{cases}$$

These two sets of predictions are indistinguishable: for age group 1, $y = 2 + X\beta_2$ regardless of the coefficient vector used, and similarly for age groups 2 and 3. This arises because we have three equations and four unknowns. Any solution is as good as any other, and, for our purposes, we merely need to choose one of them. The popular selection method is to set the coefficient on the first indicator variable to 0 (as we have done in our second coefficient vector). This is equivalent to fitting the model

$$y = \beta_0 + \beta_{12}a_2 + \beta_{13}a_3 + X\beta$$

How we select a particular coefficient vector (identifies the model) does not matter. It does, however, affect the interpretation of the coefficients.

For instance, we could just as well choose to omit the second group. In our artificial example, this would yield $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (4, -2, 0, 1)$ instead of $(2, 0, 2, 3)$. These coefficient vectors are the same in the sense that

$$y = \begin{cases} 
2 + 0 + X\beta_2 = 2 + X\beta_2 & \text{(age group 1)} \\
2 + 2 + X\beta_2 = 4 + X\beta_2 & \text{(age group 2)} \\
2 + 3 + X\beta_2 = 5 + X\beta_2 & \text{(age group 3)} 
\end{cases}$$

But what does it mean that $\beta_{13}$ can just as well be 3 or 1? We obtain $\beta_{13} = 3$ when we set $\beta_{11} = 0$, so $\beta_{13} = \beta_{13} - \beta_{11}$ and $\beta_{13}$ measures the difference between age groups 3 and 1.

In the second case, we obtain $\beta_{13} = 1$ when we set $\beta_{12} = 0$, so $\beta_{13} - \beta_{12} = 1$ and $\beta_{13}$ measures the difference between age groups 3 and 2. There is no inconsistency. According to our $\beta_{12} = 0$ model, the difference between age groups 3 and 1 is $\beta_{13} - \beta_{11} = 1 - (-2) = 3$, the same result we got in the $\beta_{11} = 0$ model.
Example 2

The issue of interpretation is important because it can affect the way we discuss results. Imagine that we are studying recovery after a coronary bypass operation. Assume that the age groups are children under 13 (we have two of them), young adults under 25 (we have a handful of them), adults under 46 (of which we have even more), mature adults under 56, older adults under 65, and elderly adults. We follow the prescription of omitting the first group, so all our results are reported relative to children under 13. While there is nothing statistically wrong with this, readers will be suspicious when we make statements like “compared with young children, older and elder adults . . .”. Moreover, we will probably have to end each statement with “although results are not statistically significant” because we have only two children in our comparison group. Of course, even with results reported in this way, we can do reasonable comparisons (say, with mature adults), but we will have to do extra work to perform the appropriate linear hypothesis test using Stata’s test command.

Here it would be better to force the omitted group to be more reasonable, such as mature adults. There is, however, a generic rule for automatic comparison group selection that, although less popular, tends to work better than the omit-the-first-group rule. That rule is to omit the most prevalent group. The most prevalent is usually a reasonable baseline.

In any case, the prescription for categorical variables is

1. Convert each $k$-valued categorical variable to $k$ indicator variables.
2. Drop one of the $k$ indicator variables; any one will do, but dropping the first is popular, dropping the most prevalent is probably better in terms of having the computer guess at a reasonable interpretation, and dropping a specified one often eases interpretation the most.
3. Fit the model on the remaining $k - 1$ indicator variables.

`xi` automates this procedure.

We will now consider each of `xi`’s features in detail.

Indicator variables for simple effects

When you type `i.varname`, `xi` internally tabulates `varname` (which may be a string or a numeric variable) and creates indicator (dummy) variables for each observed value, omitting the indicator for the smallest value. For instance, say that `agegrp` takes on the values 1, 2, 3, and 4. Typing

```stata
xi: logistic outcome i.agegrp
```

creates indicator variables named `_Iagegrp_2`, `_Iagegrp_3`, and `_Iagegrp_4`. (`xi` chooses the names and tries to make them readable; `xi` guarantees that the names are unique.) The expanded logistic model is

```stata
.logistic outcome _Iagegrp_2 _Iagegrp_3 _Iagegrp_4
```

Afterward, you can drop the new variables `xi` leaves behind by typing `drop _I*` (note the capitalization).

`xi` provides the following features when you type `i.varname`:

- `varname` may be string or numeric.
- Dummy variables are created automatically.
• By default, the dummy-variable set is identified by dropping the dummy corresponding to the smallest value of the variable (how to specify otherwise is discussed below).

• The new dummy variables are left in your dataset. By default, the names of the new dummy variables start with `_I`; therefore, you can drop them by typing `drop _I*`. You do not have to do this; each time you use `xi`, any automatically generated dummies with the same prefix as the one specified in the `prefix(string)` option, or `_I` by default, are dropped and new ones are created.

• The new dummy variables have variable labels so that you can determine what they correspond to by typing `describe`.

• `xi` may be used with any Stata command (not just `logistic`).

Controlling the omitted dummy

By default, `i.varname` omits the dummy corresponding to the smallest value of `varname`; for a string variable, this is interpreted as dropping the first in an alphabetical, case-sensitive sort. `xi` provides two alternatives to dropping the first: `xi` will drop the dummy corresponding to the most prevalent value of `varname`, or `xi` will let you choose the particular dummy to be dropped.

To change `xi`’s behavior to dropping the most prevalent dummy, type

```
. char _dta[omit] prevalent
```

although whether you type “prevalent” or “yes” or anything else does not matter. Setting this characteristic affects the expansion of all categorical variables in the dataset. If you resave your dataset, the prevalent preference will be remembered. If you want to change the behavior back to the default drop-the-first rule, type

```
. char _dta[omit]
```

to clear the characteristic.

Once you set `_dta[omit]`, `i.varname` omits the dummy corresponding to the most prevalent value of `varname`. Thus, the coefficients on the dummies have the interpretation of change from the most prevalent group. For example,

```
. char _dta[omit] prevalent
. xi: regress y i.agegrp
```

might create `_Iagegrp_1` through `_Iagegrp_4`, resulting in `_Iagegrp_2` being omitted if `agegrp = 2` is most common (as opposed to the default dropping of `_Iagegrp_1`). The model is then

\[
y = b_0 + b_1 \_Iagegrp_1 + b_3 \_Iagegrp_3 + b_4 \_Iagegrp_4 + u
\]

Then,

<table>
<thead>
<tr>
<th>Group</th>
<th>Predicted y</th>
<th>Predicted y</th>
</tr>
</thead>
<tbody>
<tr>
<td>agegrp 1</td>
<td>$b_0 + b_1$</td>
<td>$b_0 + b_3$</td>
</tr>
<tr>
<td>agegrp 2</td>
<td>$b_0$</td>
<td>$b_0 + b_4$</td>
</tr>
<tr>
<td>agegrp 3</td>
<td></td>
<td></td>
</tr>
<tr>
<td>agegrp 4</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Thus, the model’s reported $t$ or $Z$ statistics are for a test of whether each group is different from the most prevalent group.

Perhaps you wish to omit the dummy for `agegrp 3` instead. You do this by setting the variable’s omit characteristic:

```
. char agegrp[omit] 3
```
This overrides _dta[omit] if you have set it. Now, when you type

```
  . xi: regress y i.agegrp
```

_Iagegrp_3 will be omitted, and you will fit the model

\[
y = b_0 + b'_1 _\text{Iagegrp}_1 + b'_2 _\text{Iagegrp}_2 + b'_4 _\text{Iagegrp}_4 + u
\]

Later, if you want to return to the default omission, type

```
  . char agegrp[omit]
```

to clear the characteristic.

In summary, \text{i.varname} omits the first group by default, but if you define

```
  . char _dta[omit] prevalent
```

the default behavior changes to dropping the most prevalent group. Either way, if you define a characteristic of the form

```
  . char varname[omit] #
```

or, if \text{varname} is a string,

```
  . char varname[omit] string-literal
```

the specified value will be omitted.

Examples:

```
  . char agegrp[omit] 1
  . char race[omit] White (for race, a string variable)
  . char agegrp[omit] (to restore default for agegrp)
```

### Categorical variable interactions

\text{i.varname}_1*\text{i.varname}_2 creates the dummy variables associated with the interaction of the categorical variables \text{varname}_1 and \text{varname}_2. The identification rules— which categories are omitted—are the same as those for \text{i.varname}. For instance, assume that \text{agegrp} takes on four values and \text{race} takes on three values. Typing

```
  . xi: regress y i.agegrp*i.race
```

results in

model:

\[
y = a + b_2 _{\text{Iagegrp}}_2 + b_3 _{\text{Iagegrp}}_3 + b_4 _{\text{Iagegrp}}_4 \quad \text{(agegrp)}
\]
\[
+ c_2 _{\text{Irace}}_2 + c_3 _{\text{Irace}}_3 \quad \text{(race)}
\]
\[
+ d_{22} _{\text{IageXrac}}_2_2 + d_{23} _{\text{IageXrac}}_2_3 \quad \text{(agegrp*race)}
\]
\[
+ d_{32} _{\text{IageXrac}}_3_2 + d_{33} _{\text{IageXrac}}_3_3
\]
\[
+ u
\]
The model fit is

\[
y = a + b_2 \text{ _Iagegrp}_2 + b_3 \text{ _Iagegrp}_3 + b_4 \text{ _Iagegrp}_4 + c_2 \text{ _Irace}_2 + c_3 \text{ _Irace}_3 + d_{22} \text{ _IageXrac}_2_2 + d_{23} \text{ _IageXrac}_2_3 + d_{32} \text{ _IageXrac}_3_2 + d_{33} \text{ _IageXrac}_3_3 + d_{42} \text{ _IageXrac}_4_2 + d_{43} \text{ _IageXrac}_4_3 + e_2 \text{ _Isex}_2 + f_{22} \text{ _IageXsex}_2_2 + f_{23} \text{ _IageXsex}_2_3 + f_{24} \text{ _IageXsex}_2_4 + u
\]

The agegrp dummies are (correctly) included only once.

Interactions with continuous variables

\text{i.varname}_1*\text{varname}_2 (as distinguished from \text{i.varname}_1*\text{i.varname}_2—note the second \text{i}.) specifies an interaction of a categorical variable with a continuous variable. For instance,

\text{. xi: regress y i.agegr*wgt}

results in the model

\[
y = a + b_2 \text{ _Iagegrp}_2 + b_3 \text{ _Iagegrp}_3 + b_4 \text{ _Iagegrp}_4 + \text{c wgt} + d_2 \text{ _IageXwgt}_2 + d_3 \text{ _IageXwgt}_3 + d_4 \text{ _IageXwgt}_4 + u
\]
A variation on this notation, using | rather than *, omits the agegrp dummies. Typing

\[ . \text{xi: regress y i.agegrp|wgt} \]

fits the model

\[ y = a' + c' \text{wgt} \]
\[ + d_2' \text{IageXwgt}_2 + d_3' \text{IageXwgt}_3 + d_4' \text{IageXwgt}_4 \] (agegrp|wgt interactions)
\[ + u' \]

The predicted values of \( y \) are

\[ \begin{array}{ll}
\text{agegrp|wgt model} & \text{agegrp\|wgt model} \\
\hline
y = a + c \text{wgt} & a' + c' \text{wgt} \quad \text{if agegrp} = 1 \\
a + c \text{wgt} + b_2 + d_2 \text{wgt} & a' + c' \text{wgt} + d_2' \text{wgt} \quad \text{if agegrp} = 2 \\
a + c \text{wgt} + b_3 + d_3 \text{wgt} & a' + c' \text{wgt} + d_3' \text{wgt} \quad \text{if agegrp} = 3 \\
a + c \text{wgt} + b_4 + d_4 \text{wgt} & a' + c' \text{wgt} + d_4' \text{wgt} \quad \text{if agegrp} = 4
\end{array} \]

That is, typing

\[ . \text{xi: regress y i.agegrp\|wgt} \]

is equivalent to typing

\[ . \text{xi: regress y i.agegrp i.agegrp\|wgt} \]

In either case, you do not need to specify separately the continuous variable \( \text{wgt} \); it is included automatically.

**Using xi: Interpreting output**

\[ . \text{xi: regress mpg i.rep78} \]
\[ i.rep78 _\text{Irep78}_1-5 \quad \text{(naturally coded; _\text{Irep78}_1 omitted)} \]
\[ \text{(output from regress appears)} \]

Interpretation: \( i.\text{rep78} \) expanded to the dummies \(_\text{Irep78}_1, \_\text{Irep78}_2, \ldots, \_\text{Irep78}_5\). The numbers on the end are “natural” in the sense that \(_\text{Irep78}_1\) corresponds to \( \text{rep78} = 1 \), \(_\text{Irep78}_2\) to \( \text{rep78} = 2 \), and so on. Finally, the dummy for \( \text{rep78} = 1 \) was omitted.

\[ . \text{xi: regress mpg i.make} \]
\[ i.\text{make} _\text{Imake}_1-74 \quad \text{(_Imake_1 for make==AMC Concord omitted)} \]
\[ \text{(output from regress appears)} \]

Interpretation: \( i.\text{make} \) expanded to \(_\text{Imake}_1, \_\text{Imake}_2, \ldots, \_\text{Imake}_74\). The coding is not natural because \( \text{make} \) is a string variable. \(_\text{Imake}_1\) corresponds to one make, \(_\text{Imake}_2\) to another, and so on. You can find out the coding by typing \text{describe} \(_\text{Imake}_1\) for the AMC Concord was omitted.
How xi names variables

By default, xi assigns to the dummy variables it creates names having the form

\[ _Istub\_groupid \]

You may subsequently refer to the entire set of variables by typing `Istub*’. For example,

<table>
<thead>
<tr>
<th>name</th>
<th>_I + stub + _ + groupid</th>
<th>Entire set</th>
</tr>
</thead>
<tbody>
<tr>
<td>_Iagegrp_1</td>
<td>_I agegrp _ 1</td>
<td>_Iagegrp*</td>
</tr>
<tr>
<td>_Iagegrp_2</td>
<td>_I agegrp _ 2</td>
<td>_Iagegrp*</td>
</tr>
<tr>
<td>_IageXwgt_1</td>
<td>_I ageXwgt _ 1</td>
<td>_IageXwgt*</td>
</tr>
<tr>
<td>_IageXrac_1_2</td>
<td>_I ageXrac _ 1_2</td>
<td>_IageXrac*</td>
</tr>
<tr>
<td>_IageXrac_2_1</td>
<td>_I ageXrac _ 2_1</td>
<td>_IageXrac*</td>
</tr>
</tbody>
</table>

If you specify a prefix in the `prefix(string)` option, say, `S`, then xi will name the variables starting with the prefix

\[ _Sstub\_groupid \]

xi as a command rather than a command prefix

xi can be used as a command prefix or as a command by itself. In the latter form, xi merely creates the indicator and interaction variables. Typing

```
  . xi: regress y i.agegrp*wgt
  i.agegrp       _Iagegrp_1-4 (naturally coded; _Iagegrp_1 omitted)
  i.agegrp*wgt   _IageXwgt_1-4 (coded as above)
  (output from regress appears)
```

is equivalent to typing

```
  . xi i.agegrp*wgt
  i.agegrp       _Iagegrp_1-4 (naturally coded; _Iagegrp_1 omitted)
  i.agegrp*wgt   _IageXwgt_1-4 (coded as above)
  . regress y _Iagegrp* _IageXwgt* 
  (output from regress appears)
```

Warnings

1. xi creates new variables in your dataset; most are bytes, but interactions with continuous variables will have the storage type of the underlying continuous variable. You may get the error message “no room to add more variables” or “insufficient memory”. You may need to adjust the `maxvar` setting or reset `max_memory` if it has been set too low; see [U] 6 Managing memory.

2. When using xi with an estimation command, you may get the error message “unable to allocate matrix”. This usually occurs because you attempted to create a matrix that is too large; see [R] Limits.
Stored results

\texttt{xi} stores the following characteristics:

\begin{itemize}
\item \texttt{\_dta[\_\_xi\_\_Vars\_\_Prefix\_\_]} prefix names
\item \texttt{\_dta[\_\_xi\_\_Vars\_\_To\_\_Drop\_\_]} variables created
\end{itemize}

zinb — Zero-inflated negative binomial regression

Description

zinb fits a zero-inflated negative binomial (ZINB) model to overdispersed count data with excess zero counts. The ZINB model assumes that the excess zero counts come from a logit or probit model and the remaining counts come from a negative binomial model.

Quick start

Zero-inflated negative binomial model of y on x1 and x2 with inflation modeled using x3
zinb y x1 x2, inflate(x3)

And conduct likelihood-ratio test against ZIP model
zinb y x1 x2, inflate(x3) zip

Use a probit model instead of a logit model to predict excess zeros
zinb y x1 x2, inflate(x3) probit

Menu

Statistics > Count outcomes > Zero-inflated negative binomial regression
3206  zinb — Zero-inflated negative binomial regression

Syntax

```
zinb depvar [indepvars] [if] [in] [weight],
    inflate(varlist[, offset(varname)] | _cons) [options]
```

*inflate(varlist[, offset(varname)] | _cons) is required.

indepvars and varlist may contain factor variables; see [U] 11.4.3 Factor variables.

bayes, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: zinb.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce(), zip, and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
Options

Model

`inflate(varlist[, offset(varname)] | _cons)` specifies the equation that determines whether the observed count is zero. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `nbreg`.

`inflate(varlist[, offset(varname)])` specifies the variables in the equation. You may optionally include an offset for this `varlist`.

`inflate(_cons)` specifies that the equation determining whether the count is zero contains only an intercept. To run a zero-inflated model of `depvar` with only an intercept in both equations, type `zinb depvar`, inflate(_cons).

`noconstant`, `exposure(varname_e)`, `offset(varname_o)`, `constraints(constraints)`; see [R] Estimation options.

`probit` requests that a probit, instead of logit, model be used to characterize the excess zeros in the data.

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] vce option.

Reporting

`level(#)`; see [R] Estimation options.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is, $e^{\beta_i}$ rather than $\beta_i$.

Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`zip` requests that a likelihood-ratio test comparing the ZINB model with the zero-inflated Poisson model be included in the output.

`nocnsreport`; see [R] Estimation options.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fwrapon(style)`, `cformat(%)`, `pformat(%)`, `sformat(%)`, and `nolstretch`; see [R] Estimation options.

Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] Maximize. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `zinb` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] Estimation options.
## Remarks and examples

Zero-inflated negative binomial (ZINB) models are used to model count data that have a higher fraction of zeros than is likely to be generated by a standard negative binomial model. To account for excess zeros, ZINB models assume that these excess zeros come from a model other than the negative binomial model. A zero that comes from this other model is known as a “degenerate zero”.

The negative binomial overdispersion parameter, $\alpha$, differentiates the ZINB model from the zero-inflated Poisson (ZIP) model (see [R] zip). Here overdispersion refers to the fact that the negative binomial variance is greater than its mean, whereas the Poisson variance is equal to its mean. Thus, values of $\alpha > 1$ indicate overdispersion. The larger the $\alpha$, the greater the negative binomial variance. See Methods and formulas in [R] nbreg for further discussion of negative binomial overdispersion.

The `zinb` command fits ZINB models and provides two choices for modeling the excess zeros: the default logit function or, when the `probit` option is specified, the probit function. Both functions are symmetric about zero, but the logistic function has more area under the tails.

### Example 1: Fitting a ZINB model

In example 1 of [R] zip, we fit a zero-inflated Poisson model using the `zip` command to the fictional data on the number of fish caught by visitors to a national park. Let’s fit a ZINB model to these data.

Just like with `zip`, we use the required option `inflate()` to model whether a visitor fishes as a function of the number of accompanying children (`child`) and whether the visitor is camping (`camper`). Next, we assume the response variable, `count`, depends on whether the visitor used a live bait (`livebait`) and the number of persons in the party (`persons`), which includes the visitor plus other adults and children.
. use https://www.stata-press.com/data/r18/fish
(Fictional fishing data)
. zinb count persons livebait, inflate(child camper)

Fitting constant-only model:

Iteration 0: Log likelihood = -519.33992
Iteration 1: Log likelihood = -451.38662
Iteration 2: Log likelihood = -444.49118
Iteration 3: Log likelihood = -442.96272
Iteration 4: Log likelihood = -442.71065
Iteration 5: Log likelihood = -442.66718
Iteration 6: Log likelihood = -442.6631
Iteration 7: Log likelihood = -442.66299
Iteration 8: Log likelihood = -442.66299

Fitting full model:

Iteration 0: Log likelihood = -442.66299 (not concave)
Iteration 1: Log likelihood = -432.83107 (not concave)
Iteration 2: Log likelihood = -426.32934
Iteration 3: Log likelihood = -413.75019
Iteration 4: Log likelihood = -403.09586
Iteration 5: Log likelihood = -401.56013
Iteration 6: Log likelihood = -401.54781
Iteration 7: Log likelihood = -401.54776
Iteration 8: Log likelihood = -401.54776

Zero-inflated negative binomial regression
Number of obs = 250
Inflation model: logit Nonzero obs = 108
Zero obs = 142
LR chi2(2) = 82.23
Log likelihood = -401.5478 Prob > chi2 = 0.0000

| Coefficient Std. err. | z | P>|z| | [95% conf. interval] |
|------------------------|-----------------|-----------------|-----------------|-----------------|
| count                  |                 |                 |                 |                 |

| child                  | 3.185999        | .7468551        | 4.27            | 0.000           | 1.72219         | 4.649808         |
| camper                 | -2.020951       | .872054         | -2.32           | 0.020           | -3.730146       | -.3117567        |
| _cons                  | -2.695385       | .8929071        | -3.02           | 0.003           | -4.44545        | -.9453189        |
| /lnalpha               | .5110429        | .1816816        | 2.81            | 0.005           | .1549535        | .8671323         |
| alpha                  | 1.667029        | .3028685        |                 |                 | 1.167604        | 2.380076         |

The coefficients in the first equation of the coefficient table, labeled count, correspond to the negative binomial model for individuals who fished. For instance, among visitors who fished, using a live bait increases the expected number of caught fish by a factor of \( \exp(1.5575) \approx 4.7 \), holding other covariates constant.

The confidence interval for alpha indicates that the ZINB model is more appropriate than the ZIP model. To confirm this, you can run zinb and specify the zip option to obtain the ZIP likelihood-ratio test.

The inflate equation models whether the visitor does not fish. We can use margins to obtain a better understanding of how the inflate equation affects the occurrence of the excess zero counts. We specify margins's options dydx(child camper) and predict(pr). pr is predict's option
for estimating the probability of a degenerate zero or, in our example, the probability of not fishing; see the *margins* section in [R] *zinb postestimation*.

```
. margins, dydx(child camper) predict(pr)
```

Average marginal effects Number of obs = 250
Model VCE: OIM
Expression: Pr(count=0), predict(pr)
dy/dx wrt: child camper

|         | dy/dx | std. err. | z     | P>|z|      | [95% conf. interval] |
|---------|-------|-----------|-------|----------|--------------------|
| child   | .257531 | .029941   | 8.60  | 0.000    | .1988477 -.3162144 |
| camper  | -.1633578 | .0503938 | -3.24 | 0.001    | -.2621277 -.0645878 |

The *margins* output tells us that a visitor is less likely to be visiting the park to fish if accompanied by children and more likely to fish if camping.

You also may want to evaluate whether a standard negative binomial model is adequate to fit the data. This can be done using information criteria; see example 2 in [R] *zip*.

### Stored results

*zinb* stores the following in *e()*:

**Scalars**

- `e(N)` number of observations
- `e(N_zero)` number of zero observations
- `e(k)` number of parameters
- `e(k_eq)` number of equations in *e(b)*
- `e(k_eq_model)` number of equations in overall model test
- `e(k_aux)` number of auxiliary parameters
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(df_c)` degrees of freedom for comparison test
- `e(N_clust)` number of clusters
- `e(chi2)` \(\chi^2\)
- `e(p)` \(p\)-value for model test
- `e(chi2_cp)` \(\chi^2\) for test of \(\alpha = 0\)
- `e(rank)` rank of *e(V)*
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

**Macros**

- `e(cmd)` `zinb`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(inflate)` logit or probit
- `e(utepe)` weight type
- `e(dexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset1)` offset
- `e(offset2)` offset for inflate()
- `e(chi2type)` Wald or LR: type of model \(\chi^2\) test
Methods and formulas

The \texttt{zinb} command maximizes a likelihood function that is a mixture of the logistic (or probit) and negative binomial distributions. The logistic distribution models the unobserved process that creates the excess zeros, and the negative binomial distribution models the counts. Define

\[
\begin{align*}
\xi_j^{\beta} &= x_j \beta + \text{offset}_j^{\beta} \\
\xi_j^{\gamma} &= z_j \gamma + \text{offset}_j^{\gamma} \\
\mu_j &= \exp(\xi_j^{\beta}) \\
p_j &= 1 / (1 + \alpha \mu_j) \\
m &= 1 / \alpha
\end{align*}
\]

Here the vector \( x_j \) contains the covariates specified in \texttt{indepvars} for the \( j \)th observation, and \( z_j \) contains the covariates specified in the \texttt{inflate()} option. Similarly, estimates for \( \beta \) are found in the first equation of the \texttt{zinb} coefficient table (labeled after \texttt{depvar}), and the estimates for \( \gamma \) are found in the second equation of the coefficient table (labeled \texttt{inflate}). The parameter \( \alpha \) is the negative binomial overdispersion parameter, and its estimate is the ancillary parameter labeled \texttt{alpha} in the coefficient table. Parameters \( p_j, m, \) and \( \mu_j \) are parameters of a negative binomial distribution; see \textit{Methods and formulas} in \cite{nbreg} for details.
The log likelihood maximized by zinb is

\[
\ln L = \sum_{j \in S} w_j \ln \left\{ F_j + (1 - F_j) p_j^m \right\} + \sum_{j \notin S} w_j \left\{ \ln(1 - F_j) + \ln \Gamma(m + y_j) - \ln \Gamma(y_j + 1) \right\} - \ln \Gamma(m) + m \ln p_j + y_j \ln(1 - p_j)
\]

where \( w_j \) are the weights, \( S \) is the set of observations for which the observed outcome \( y_j = 0 \), and \( F_j \) is the logistic distribution function

\[
F_j = F(\xi_j^\gamma) = \exp(\xi_j^\gamma) / \{1 + \exp(\xi_j^\gamma)\}
\]

or, if the probit option is specified, the standard normal distribution function

\[
F_j = F(\xi_j^\gamma) = \Phi(\xi_j^\gamma)
\]

From Long (1997), the variance of the mixture distribution is

\[
\text{Var}(y_j | x_i, z_i) = \mu_j (1 - F_j) \{1 + \mu_j (F_j + \alpha)\}
\]

When \( F_j \) is zero, we have the variance of the negative binomial distribution; when \( F_j > 0 \), the variance can exceed that of the negative binomial distribution.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.

zinb also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

*forecast, hausman, and lrtest are not appropriate with svy estimation results.*
predict

Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

predict [type] newvar [if] [in] [, statistic nooffset]

predict [type] stub* [if] [in], scores

statistic Description

Main
n number of events; the default
ir incidence rate
pr probability of a degenerate zero
pr(n) probability Pr(y_j = n)
pr(a,b) probability Pr(a \leq y_j \leq b)
xb linear prediction
stdp standard error of the linear prediction

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

n, the default, calculates the predicted number of events, which is \((1 - F_j) \exp(x_j \beta)\) if neither offset() nor exposure() was specified when the model was fit, where \(F_j\) is the predicted probability of a zero outcome; \((1 - F_j) \exp(x_j \beta + offset)\) if offset() was specified; or \((1 - F_j)\{ \exp(x_j \beta) \times \text{exposure}_j \}\) if exposure() was specified.

ir calculates the incidence rate, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the n and the nooffset options.

pr calculates the probability of a degenerate zero, predicted from the fitted degenerate distribution \(F_j = F(z_j \gamma)\). If offset() was specified within the inflate() option, then \(F_j = F(z_j \gamma + \text{offset}_j)\) is calculated.

pr(n) calculates the probability \(Pr(y_j = n)\), where \(n\) is a nonnegative integer that may be specified as a number or a variable. Note that pr is not equivalent to pr(0).
pr(a, b) calculates the probability $\Pr(a \leq y_j \leq b)$, where $a$ and $b$ are nonnegative integers that may be specified as numbers or variables;

$b$ missing ($b \geq .$) means $+\infty$;

pr(20, .) calculates $\Pr(y_j \geq 20)$;

pr(20, b) calculates $\Pr(y_j \geq 20)$ in observations for which $b \geq .$ and calculates $\Pr(20 \leq y_j \leq b)$ elsewhere.

pr(. , b) produces a syntax error. A missing value in an observation of the variable $a$ causes a missing value in that observation for pr(a, b).

xb calculates the linear prediction, which is $x_j\beta$ if neither offset() nor exposure() was specified; $x_j\beta + \text{offset}_j\beta$ if offset() was specified; or $x_j\beta + \ln(\text{exposure}_j)$ if exposure() was specified; see nooffset below.

stdp calculates the standard error of the linear prediction.

nooffset is relevant only if you specified offset() or exposure() when you fit the model. It modifies the calculations made by predict so that they ignore the offset or exposure variable; the linear prediction is treated as $x_j\beta$ rather than as $x_j\beta + \text{offset}_j\beta$ or $x_j\beta + \ln(\text{exposure}_j)$. Specifying predict ..., nooffset is equivalent to specifying predict ..., ir.

scores calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (x_j\beta)$.

The second new variable will contain $\partial \ln L / \partial (z_j\gamma)$.

The third new variable will contain $\partial \ln L / \partial \ln \alpha$. 
margins

Description for margins

margins estimates margins of response for number of events, incidence rates, probabilities, and linear predictions.

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.

Methods and formulas

See Methods and formulas in [R] zinb for the model definition and notation.

The probabilities calculated using the pr(n) option are the probability Pr(yj = n). These are calculated using

Pr(yj = 0|xj, zj) = Fj + (1 - Fj) p2(0|xj) 
Pr(yj = n|xj, zj) = (1 - Fj) p2(n|xj) for n = 1, 2, . . .

where Fj is the probability of obtaining an observation from the degenerate distribution whose mass is concentrated at zero, and p2(n|xj) is the probability of yj = n from the nondegenerate, negative binomial distribution. Fj can be obtained by using the pr option.

See Cameron and Trivedi (2013, sec. 4.6) for further details.

[R] zinb — Zero-inflated negative binomial regression

[U] 20 Estimation and postestimation commands
ziologit — Zero-inflated ordered logit regression

Description

ziologit fits a model for an ordinal outcome with excess zeros, a higher fraction of zeros than would be expected from a standard ordered logit model, also known as zero inflation. This model is known as a zero-inflated ordered logit (ZIOL) model. In the context of ZIOL models, zero is the lowest outcome category. The ZIOL model accounts for the zero inflation by assuming that the zero-valued outcomes come from both a logit model and an ordered logit model, allowing potentially different sets of covariates for each model.

Quick start

Zero-inflated ordered logit model of \( y \) on \( x_1 \) and categorical variable \( a \) with excess zeros modeled using \( x_2 \)

\[
\text{ziologit } y \ x_1 \ i.a, \text{ inflate}(x_2)
\]

Add offset \( x_3 \) to the ordered logit model

\[
\text{ziologit } y \ x_1 \ i.a, \text{ inflate}(x_2) \text{ offset}(x_3)
\]

Model excess zeros using only a constant

\[
\text{ziologit } y \ x_1 \ i.a, \text{ inflate}(_\text{cons})
\]

Model excess zeros with \( x_2 \), and offset \( x_5 \) while suppressing the constant term

\[
\text{ziologit } y \ x_1 \ i.a, \text{ inflate}(x_2, \text{ offset}(x_5) \text{ noconstant})
\]

Account for complex sampling design using \textit{svyset} data

\[
\text{svy: ziologit } y \ x_1 \ i.a, \text{ inflate}(x_2)
\]

Syntax

ziologit depvar [indepvars] [if] [in] [weight],

    inflate(varlist[, noconstant offset(varname)] | _cons) [options]

options                      Description

Model
    * inflate()                 inflation equation that determines excess zero values
    offset(varname)            include varname in model with coefficient constrained to 1
    constraints(constraints)   apply specified linear constraints

SE/Robust
    vce(vcetype)               vcetype may be oim, robust, cluster clustvar, opg, bootstrap,
                               or jackknife

Reporting
    level(#)                   set confidence level; default is level(95)
    nocnsreport                do not display constraints
    or display_options        control columns and column formats, row spacing, line width,
                               display of omitted variables and base and empty cells, and
                               factor-variable labeling

Maximization
    maximize_options          control the maximization process; seldom used
    collinear                 keep collinear variables
    coeflegend                display legend instead of statistics

* inflate(varlist[, noconstant offset(varname)] | _cons) is required.

indepvars and varlist may contain factor variables; see [U] 11.4.3 Factor variables.

bayes, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: ziologit.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

    inflate(varlist[, noconstant offset(varname)] | _cons) specifies the inflation equation for the logit model that determines the excess zero values; this option is required. Conceptually, omitting inflate() would be equivalent to fitting the model with ologit; see [R] ologit.

    inflate(varlist[, noconstant offset(varname)]) specifies the independent variables in the inflation equation. To suppress the constant in this equation, specify the noconstant suboption. You may optionally include an offset for this varlist; see offset(varname) in [R] Estimation options.
inflated(_cons) specifies that the inflation equation contains only an intercept. To run a zero-inflated model of `depvar` with only an intercept in both equations, type `ziologit depvar, inflated(_cons)`.

`offset(varname), constraints(.constraints);` see [R] Estimation options.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce option.

`level(#), nocnsreport;` see [R] Estimation options.

or reports the estimated coefficients transformed to odds ratios, that is, $e^b$ rather than $b$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or may be specified at estimation or when replaying previously estimated results.

`display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch;` see [R] Estimation options.

`maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs);` see [R] Maximize. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `ziologit` but are not shown in the dialog box: collinear, coeflegend; see [R] Estimation options.

**Remarks and examples**

ZIOL models (Kelley and Anderson 2008) are used when the outcome of interest is an ordinal response with a higher fraction of observations in the lowest level than would be expected from a standard ordered logit model. The observations in the lowest category are often referred to as zeros because they typically correspond to the absence of a behavior or trait. Examples include measurements of symptoms, diet, exercise, drug use, and other ordinal outcomes where the lowest level is “none” or “never”.

With ordinal outcomes, larger values of the response variable represent higher outcome levels, but the precise numeric value is irrelevant. For consistency, we will refer to the lowest category as zero regardless of whether that outcome takes the number 0 in the dataset.

The presence of a high fraction of zeros, also known as zero inflation, is driven by the fact that the lowest-level observations represent two latent (unobservable) groups: subjects with excess zeros and subjects with conditional zeros. Excess zeros are subjects who are not susceptible to the outcome, whereas conditional zeros are susceptible to higher outcomes even though they currently demonstrate
zero response. For example, if the outcome is alcohol consumption, a teetotaler who completely abstains from alcohol would be an excess zero, whereas a drinker who chose not to drink on the day of the survey would be a conditional zero.

To determine susceptibility (that is, to identify excess zeros), ZIOL regression uses a logit model for the inflation equation. For the main regression that determines the ordinal outcome of susceptible subjects, ZIOL uses an ordered logit model. The equation for the main regression is sometimes referred to as the intensity equation. These two equations can have different sets of covariates and different offsets. Parameters can be reported as coefficients or odds ratios with option or. See Methods and formulas for more details.

ZIOL models are similar in spirit to zero-inflated ordered probit (ZIOP) models (see [R] zioprobit), which use a probit model for the inflation equation and an ordered probit model for the intensity equation. Unlike ZIOP models, the results from ZIOL models can be presented as odds ratios. As such, ZIOL models often appeal to epidemiologists and health researchers, whereas ZIOP models are traditionally used by economists and social scientists. In general, the two types of models tend to produce similar predictions and yield similar inference.

In the context of ZIOL models, the excess-zero or “always-zero” group is often called the nonsusceptible group, and, likewise, the other group is called the susceptible group. In the context of ZIOP models, the terms “nonparticipation” and “participation” are used to refer to the groups. We will use both terminologies interchangeably depending on the context.

The ordered logit model is not nested within the ZIOL model, which means that a likelihood-ratio test cannot be used to check whether a standard ordered logit model is adequate. Instead, one can use information criteria; see example 2 in [R] zip.

Example 1: Zero-inflated ordered logit model

We use the fictional data on cigarette consumption from example 1 in [R] zioprobit. In that example, we fit a ZIOP model to these data; here we fit a ZIOL model. Both models are appropriate for analyzing this zero-inflated ordinal outcome, but the ZIOP model is more likely to be used by an economist studying consumer purchasing patterns, while the ZIOL model is more likely to be used by an epidemiologist studying smoking behavior.

The outcome of interest, tobacco, represents daily cigarette consumption as an ordinal response with four levels: 0 indicates “no cigarettes”, and responses 1 through 3 indicate increasing cigarette consumption. More than half of the respondents reported no cigarette consumption, and we suspect that these respondents belong to one of two latent groups. Individuals in the first group are excess zeros, which is to say that they are genuine nonsmokers and thus are not susceptible to cigarette consumption. Individuals in the second group are would-be smokers with no current smoking activity but who might smoke, say, if the price of cigarettes falls or their income increases. These individuals are called conditional zeros because they demonstrate zero cigarette consumption, conditional on being susceptible to smoking. We suspect that these two types of zeros are driven by different patterns of behavior; hence, we choose the ZIOL model over the traditional ordered logit model.

Here the inflation (logit) equation corresponds to the decision to smoke. The intensity (ordered logit) equation corresponds to the level of cigarette consumption by a smoker or would-be smoker. The intensity equation includes covariates for education in years (education), annual income in tens of thousands of dollars (income), age in decades (age), and gender (female). The inflation equation includes all the covariates from the intensity equation, plus indicators for whether either of the respondent’s parents smoked (parent) and whether the respondent’s religion discourages smoking (religion). Covariates for the intensity equation are specified in the ziologit command statement directly after the dependent variable tobacco. Covariates for the inflation equation are specified in the required inflate() option.

The first section of the coefficient table, labeled tobacco, corresponds to the tobacco intensity equation and contains coefficients from the ordered logit model fit to susceptible subjects. The second section, labeled inflate, corresponds to the inflation equation and contains coefficients from the logit model for susceptibility. ZIOL models allow different sets of covariates in the inflation and intensity equations, but when a variable is included in both equations, it is possible for the coefficients to have opposite signs. The third section of the coefficient table contains the cutpoints from the ordered logit model. See Remarks and examples in [R] ologit for an explanation of cutpoints.

Compared with the ZIOP model from example 1 in [R] ziprobit, the coefficients here are larger in absolute value, but the z scores and p-values are similar. This is consistent with the fact that the
The logistic distribution used by ZIOL has heavier tails than the normal distribution used by ZIOP. Perhaps the most important difference between these two models is that the estimated coefficients from the ZIOP model are difficult to interpret, but the coefficients from the ZIOL model can be exponentiated and reported as odds ratios with the *or* option.

We replay our results specifying *or*:

| age         | 1.368163  | .0208365  | 20.58  | 0.000 | 1.327928 - 1.409618 |
| female     | .6439897  | .0332785  | -8.52  | 0.000 | .5819593 - .712632  |
| Female     | .6439897  | .0332785  | -8.52  | 0.000 | .5819593 - .712632  |
| parent     | 3.605764  | .1902668  | 24.31  | 0.000 | 3.251484 - 3.998647 |
| Smoking    | .5834735  | .0486009  | -6.47  | 0.000 | .4955867 - .6869461 |
| Discourag.. | .807368  | .7950279  | 21.21  | 0.000 | 6.656599 - 9.792435 |
| _cons      | 8.07368   | .7950279  | 21.21  | 0.000 | 6.656599 - 9.792435 |

Note: Estimates are transformed only in the first 2 equations to odds ratios.
Note: _cons estimates baseline odds.

Examining the odds ratios from the *tobacco* intensity equation, we see that a one-unit increase in *income*, which corresponds to an increase of $10,000 in annual income, raises a smoker's odds of increased cigarette consumption by a factor of 3.63. Looking at the inflation equation, we see that a one-unit increase in *income* lowers the odds of being susceptible to smoking by a factor of 0.825. This suggests that wealthier individuals are less likely to smoke (consistent with *income* acting as a proxy for health consciousness), but if they do decide to smoke, they tend to smoke more cigarettes (perhaps because they can afford them).
**Stored results**

`ziologit` stores the following in `e()`:

**Scalars**

- `e(N)` number of observations
- `e(N_zero)` number of zeros or lowest-category observations
- `e(k_cat)` number of categories
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_aux)` number of auxiliary parameters
- `e(k_dv)` number of dependent variables
- `e(df_m)` number of degrees of freedom
- `e(ll)` log likelihood
- `e(N_clust)` number of clusters
- `e(chi2)` \( \chi^2 \)
- `e(p)` \( p \)-value for model test
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

**Macros**

- `e(cmd)` `ziologit` command as typed
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset1)` offset
- `e(offset2)` offset for `inflate()`
- `e(chi2type)` Wald or LR; type of model \( \chi^2 \) test
- `e(vce)` \( vcetype \) specified in `vce()`
- `e(vcetype)` title used to label Std. err.
- `e(opt)` type of optimization
- `e(which)` max or min; whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of \( ml \) method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` \( b V \)
- `e(predict)` program used to implement `predict`
- `e(marginsok)` predictions allowed by `margins`
- `e(marginsnotok)` predictions disallowed by `margins`
- `e(marginsdefault)` default `predict()` specification for `margins`
- `e(asbalanced)` factor variables \( fvset \) as `asbalanced`
- `e(asobserved)` factor variables \( fvset \) as `asobserved`

**Matrices**

- `e(b)` coefficient vector
- `e(Cns)` constraints matrix
- `e(ilog)` iteration log (up to 20 iterations)
- `e(gradient)` gradient vector
- `e(cat)` category values
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance

**Functions**

- `e(sample)` marks estimation sample
In addition to the above, the following is stored in r():

Matrices

\[ r(\text{table}) \]

matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in \( r() \) are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

### Methods and formulas

The modern class of zero-inflated models was originally developed by Lambert (1992) to address the problem of excess zeros in count data (see \( \text{R} \) \( \text{zip} \)). This model framework has been extended to ordinal outcomes with the ZIOL model by Kelley and Anderson (2008).

The precise numeric value of an ordinal outcome is irrelevant, so without loss of generality we consider an ordinal response variable \( Y \) with levels coded as 0, 1, 2, \ldots, \( H \). The first step in the ZIOL model is to determine susceptibility. Let \( s_j = 1 \) if the \( j \)th individual is susceptible to exhibiting a nonzero response, and let \( s_j = 0 \) if the \( j \)th individual is an excess zero. (Similarly, using alternative terminology, let individuals with \( s_j = 1 \) belong to the participation group and those with \( s_j = 0 \) belong to the nonparticipation group.) The ZIOL inflation equation uses a logit model to determine the probability of susceptibility (or participation) as

\[
\Pr(s_j = 1|z_j) = F(z_j \gamma) \quad (1)
\]

\( z_j \) is a vector of covariates that determines susceptibility, \( \gamma \) is a vector of coefficients that have to be estimated, and \( F(\cdot) \) is the logistic distribution function: \( F(x) = e^x/(1 + e^x) \).

Next, conditioning on \( s_j = 1 \), outcome intensity levels \( \tilde{y}_j \) are modeled using an ordered logit model whose levels may also include 0. The corresponding probabilities are given by

\[
\Pr(\tilde{y}_j = h|s_j = 1, x_j) = F(\kappa_h - x_j \beta) - F(\kappa_{h-1} - x_j \beta) \quad h = 0, 1, \ldots, H \quad (2)
\]

\( x_j \) is a vector of covariates that determine intensity (which can be different from \( z_j \)), \( \beta \) is a vector of coefficients to be estimated, and cutpoints \( \kappa_h \) are boundary parameters to be estimated (subject to \( \kappa_{-1} = -\infty, \kappa_H = +\infty \)). These cutpoints take the place of an intercept.

The observed response variable is \( y_j = s_j \tilde{y}_j \). Thus, a zero outcome occurs when \( s_j = 0 \) (the individual is an excess zero) or when \( s_j = 1 \) and \( \tilde{y}_j = 0 \) (the individual is a conditional zero). To observe a positive \( y_j \), there is a joint requirement that \( s_j = 1 \) and \( \tilde{y}_j > 0 \).

The distribution of \( Y \) is given by

\[
\Pr(Y) = \begin{cases} 
\Pr(y_j = 0|z_j, x_j) \\
\Pr(y_j = h|z_j, x_j) & h = 1, 2, \ldots, H 
\end{cases} 
\]

\[
= \begin{cases} 
\Pr(s_j = 0|z_j) + \Pr(s_j = 1|z_j) \Pr(\tilde{y}_j = 0|s_j = 1, x_j) \\
\Pr(s_j = 1|z_j) \Pr(\tilde{y}_j = h|s_j = 1, x_j) & h = 1, 2, \ldots, H 
\end{cases} 
\quad (3)
\]

The probability of zero outcome has been inflated because it is the sum of the probability of zero intensity from the ordered logit model and the probability of nonsusceptibility from the logit model.
Substituting (1) and (2) in (3), we get

\[
Pr(Y) = \begin{cases} 
Pr(y_j = 0 | z_j, x_j) \\
Pr(y_j = h | z_j, x_j) & h = 1, 2, \ldots, H - 1 \\
Pr(y_j = H | z_j, x_j) 
\end{cases}
\]

(4)

If the offset() option is specified, \(x_j \beta\) in the intensity equation is replaced with \(x_j \beta + \text{offset}_j\). If the offset() suboption is specified in option inflate(), \(z_j \gamma\) in the inflation equation is replaced with \(z_j \gamma + \text{offset}_j\).

The log-likelihood function is

\[
\ln L = \sum_{j=1}^{N} w_j \sum_{h=0}^{H} I(y_j = h) \ln \{Pr(y_j = h | z_j, x_j)\}
\]

where \(w_j\) is an optional weight for the \(j\)th observation and

\[
I(y_j = h) = \begin{cases} 
1 & \text{if } y_j = h \\
0 & \text{otherwise}
\end{cases}
\]

The choice between the ZIOL model and the ordered logit model cannot be made using a likelihood-ratio test because the two hypotheses are not nested in the usual sense of parameter restrictions. The inflation effect is removed, and all subjects are deemed susceptible when \(z_j \gamma \to \infty\), a condition that cannot be imposed. To compare the fits of nonnested models, you can use estat ic to display information criteria (see [R] estat ic).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version with vce(robust) and vce(cluster clustvar), respectively. See [P] _robust, particularly Maximum likelihood estimators and Methods and formulas.

ziologit also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

</tbody>
</table>

If you do not specify outcome(), pmargin, pjoint1, and pcond1 (with one new variable specified) assume outcome(#1).

You specify one or k new variables with pmargin, pjoint1, and pcond1, where k is the number of outcomes.

You specify one new variable with ps, pns, xb, xbinfl, stdp, and stdpinfl.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

<table>
<thead>
<tr>
<th>Main</th>
</tr>
</thead>
<tbody>
<tr>
<td>pmargin, the default, calculates the predicted marginal probabilities of outcome levels, Pr(y_j = h).</td>
</tr>
<tr>
<td>pjoint1 calculates the predicted joint probabilities of outcome levels and susceptibility, Pr(y_j = h, s_j = 1).</td>
</tr>
<tr>
<td>pcond1 calculates the predicted probabilities of outcome levels conditional on susceptibility, Pr(y_j = h</td>
</tr>
</tbody>
</table>
With `pmargin`, `pjoint1`, and `pcond1`, you can compute predicted probabilities for one or for all outcome levels. When you specify one new variable, `predict` computes probabilities for the first outcome level. You can specify the `outcome(#i)` option to obtain probabilities for the $i$th level. When you specify multiple new variables or a stub, `predict` computes probabilities for all outcome levels. The behavior of `predict` with one new variable is equivalent to specifying `outcome(#1)`.

`ps` and `pns` calculate the predicted marginal probability of susceptibility $[\Pr(s_j = 1)]$ and of nonsusceptibility $[\Pr(s_j = 0)]$, respectively.

In econometrics literature, probabilities of susceptibility and nonsusceptibility are known as probabilities of participation and nonparticipation. Similarly to `predict` after `zioprobit`, you can use options `ppar` and `pnpar` to compute these probabilities. Options `ppar` and `pnpar` produce identical results to the respective options `ps` and `pns` but label new variables as $\Pr(\text{participation})$ and $\Pr(\text{nonparticipation})$ instead of $\Pr(\text{susceptible})$ and $\Pr(\text{nonsusceptible})$.

`xb` calculates the linear prediction for the ordered logit equation, which is $x_j \beta$ if `offset()` was not specified with `ziologit` and is $x_j \beta + \text{offset}_j \beta$ if `offset()` was specified.

`xbinfl` calculates the linear prediction for the inflation equation, which is $z_j \gamma$ if `offset()` was not specified in `inflate()` and is $z_j \gamma + \text{offset}_j \gamma$ if `offset()` was specified in `inflate()`.

`stdp` calculates the standard error of the linear prediction for the ordered logit equation.

`stdpinfl` calculates the standard error of the linear prediction for the inflation equation.

`outcome(outcome)` specifies the outcome for which predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is allowed only with `pmargin`, `pjoint1`, and `pcond1`.

`nooffset` is relevant only if you specified `offset(varname)` with `ziologit` or within the `inflate()` option. It modifies the calculations made by `predict` so that they ignore the offset variable; that is, the linear prediction for the main regression equation is treated as $x_j \beta$ rather than as $x_j \beta + \text{offset}_j \beta$ and the linear prediction for the inflation equation is treated as $z_j \gamma$ rather than as $z_j \gamma + \text{offset}_j \gamma$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L/\partial(x_j \beta)$. In the absence of independent variables in the main equation, this variable is not stored.

The second new variable will contain $\partial \ln L/\partial(z_j \gamma)$.

When the dependent variable takes $k$ different values, the third new variable through new variable $k + 1$ will contain $\partial \ln L/\partial(\kappa_h)$ for $h = 0, 1, \ldots, k - 2$. 
margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics  >  Postestimation

</tbody>
</table>

pmargin, pjoint1, and pcond1 default to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than e(b).

For the full syntax, see [R] margins.
Remarks and examples

The ZIOL model allows all the predictions and marginal effects available with the standard ologit model (see [R] ologit postestimation), along with additional predictions and marginal effects related to the inflation equation for susceptibility. The probabilities of susceptibility and nonsusceptibility can be calculated using options ps and pns, respectively. If you prefer an alternative terminology of probabilities of participation and nonparticipation, you can instead use options ppar and pnpar, which will produce identical numerical results but label variables as Pr(participation) and Pr(nonparticipation) instead of Pr(susceptible) and Pr(nonsusceptible).

Example 1: Average marginal effect of gender on probability of nonsusceptibility

In example 1 of [R] ziologit, we fit a model for levels of cigarette consumption.

```
use https://www.stata-press.com/data/r18/tobacco
(Fictional tobacco consumption data)
ziologit tobacco education income age i.female,
inflate(education income age i.female i.parent i.religion)
```

This model parallels the zero-inflated ordered probit (ZIOP) model that was fit in example 1 of [R] zioprobit.

To continue the comparison between the ZIOL and ZIOP models, we re-create example 1 from [R] zioprobit postestimation by using margins to estimate the average marginal effect of gender on the probability of nonsusceptibility (being an excess zero) for individuals with a college degree (17 years of education) and a smoking parent.

```
margins, predict(pns) dydx(female) at(education = 17 parent = 1)
```

<table>
<thead>
<tr>
<th>Delta-method</th>
</tr>
</thead>
<tbody>
<tr>
<td>dy/dx</td>
</tr>
<tr>
<td>std. err.</td>
</tr>
<tr>
<td>z</td>
</tr>
<tr>
<td>P&gt;</td>
</tr>
<tr>
<td>[95% conf. interval]</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>female</th>
</tr>
</thead>
<tbody>
<tr>
<td>.085421</td>
</tr>
<tr>
<td>.010096</td>
</tr>
<tr>
<td>8.46</td>
</tr>
<tr>
<td>0.000</td>
</tr>
<tr>
<td>.0656333</td>
</tr>
<tr>
<td>.1052087</td>
</tr>
</tbody>
</table>

Note: dy/dx for factor levels is the discrete change from the base level.

Despite the differences between the ZIOL and ZIOP models, the conclusion is the same: women with a college degree and a smoking parent are expected to have an approximately 8.5% higher chance of being genuine nonsmokers (excess zeros) than comparable men.

Example 2: Predicted probabilities of conditional zeros

Next, we consider the effect of income on the probability of zero tobacco consumption, conditional on susceptibility. These would-be smokers are known as conditional zeros. In example 1 of [R] ziologit, we saw that increasing income raises a smoker’s odds of increased tobacco consumption dramatically, so we expect to see a larger fraction of conditional zeros at the lower end of the income scale.
We examine conditional probabilities of zero consumption for incomes ranging from $10,000 to $60,000, and we use the `noatlegend` option to suppress the default legend because we know the values 1 to 6 correspond to income in tens of thousands of dollars.

```
. margins, predict(pcond1 outcome(0)) at(income = (1/6)) noatlegend
```

Predictive margins Number of obs = 15,000
Model VCE: OIM
Expression: Pr(tobacco=0|susceptible=1), predict(pcond1 outcome(0))

<table>

<td>0.4306299</td>
<td>0.0023953</td>
<td>179.78</td>
<td>0.000</td>
<td>0.4259352</td>
</tr>
<tr>
<td>5</td>
<td>0.3741538</td>
<td>0.0024547</td>
<td>152.42</td>
<td>0.000</td>
<td>0.3693427</td>
</tr>
<tr>
<td>6</td>
<td>0.3152985</td>
<td>0.0026294</td>
<td>119.91</td>
<td>0.000</td>
<td>0.3101449</td>
</tr>
</tbody>
</table>

The influence of income is dramatic: susceptible individuals (potential smokers) who earn $10,000 a year are almost twice as likely to refrain from smoking as potential smokers who earn $60,000 per year (59% versus 32%).

Methods and formulas

See Methods and formulas in [R] ziologit for the model definition and notation. Specifically, see (1) for the formula for the probability of susceptibility, \( \Pr(s_j = 1|z_j) \); see (2) for the formula for the probabilities of outcome levels conditional on susceptibility, \( \Pr(y_j = h|s_j = 1, x_j) \); and see (4) for the formula for the marginal probabilities of outcome levels, \( \Pr(y_j = h|z_j, x_j) \).

The joint probability of susceptibility and outcome \( y_j = h \) can be expressed as

\[
\Pr(y_j = h, s_j = 1|z_j, x_j) = \Pr(s_j = 1|z_j) \Pr(y_j = h|s_j = 1, x_j)
\]

for \( h = 0, 1, \ldots, H \).

Reference

[R] ziologit — Zero-inflated ordered logit regression

[U] 20 Estimation and postestimation commands
**zioprobit** — Zero-inflated ordered probit regression

**Description**

zioprobit fits a model for an ordinal outcome with excess zeros, a higher fraction of zeros than would be expected from a standard ordered probit model, also known as zero inflation. This model is known as a zero-inflated ordered probit (ZIOP) model. In the context of ZIOP models, zero is an actual 0 value or the lowest outcome category. The ZIOP model accounts for the zero inflation by assuming that the zero-valued outcomes come from both a probit model and an ordered probit model, allowing potentially different sets of covariates for each model.

**Quick start**

Zero-inflated ordered probit model of \( y \) on \( x_1 \) and categorical variable \( a \) with excess zeros modeled using \( x_2 \)

\[
\text{zioprobit } y \ x_1 \ i.a, \text{ inflate}(x_2)
\]

Add offset \( x_3 \) to the ordered probit model

\[
\text{zioprobit } y \ x_1 \ i.a, \text{ inflate}(x_2) \text{ offset}(x_3)
\]

Model excess zeros using only a constant

\[
\text{zioprobit } y \ x_1 \ i.a, \text{ inflate}(_\text{cons})
\]

Model excess zeros with \( x_2 \), and offset \( x_5 \) while suppressing the constant term

\[
\text{zioprobit } y \ x_1 \ i.a, \text{ inflate}(x_2, \text{ offset}(x_5) \text{ noconstant})
\]

Account for complex sampling design using **svyset**

\[
\text{svy: zioprobit } y \ x_1 \ i.a, \text{ inflate}(x_2)
\]

**Menu**

Statistics > Ordinal outcomes > Zero-inflated ordered probit regression
Syntax

zioprobit depvar [ indepvars ] [ if ] [ in ] [ weight ] ,

   inflate(varlist[, noconstant offset(varname)] | _cons) [ options ]

options Description

Model
* inflate() inflation equation that determines excess zero values
   offset(varname) include varname in model with coefficient constrained to 1
   constraints(constraints) apply specified linear constraints

SE/Robust
vce(vcetype) vcetype may be oim, robust, cluster clustvar, opg, bootstrap,
   or jackknife

Reporting
level(#) set confidence level; default is level(95)
nocons report do not display constraints
display_options control columns and column formats, row spacing, line width,
                display of omitted variables and base and empty cells, and
                factor-variable labeling

Maximization
maximize_options control the maximization process; seldom used

collinear keep collinear variables
coefflegend display legend instead of statistics

* inflate(varlist[, noconstant offset(varname)] | _cons) is required.

indepvars and varlist may contain factor variables; see [U] 11.4.3 Factor variables.

byes, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix
commands. For more details, see [BAYES] bayes: zioprobit.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
collinear and coefflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

inflate(varlist[, noconstant offset(varname)] | _cons) specifies the inflation equation for the
   probit model that determines the excess zero values; this option is required. Conceptually, omitting
   inflate() would be equivalent to fitting the model with oprobit; see [R] oprobit.

inflate(varlist[, noconstant offset(varname)]) specifies the independent variables in the
   inflation equation. To suppress the constant in this equation, specify the noconstant suboption.
   You may optionally include an offset for this varlist; see offset(varname) in [R] Estimation
   options.
inflated(_cons) specifies that the inflation equation contains only an intercept. To run a zero-inflated model of `depvar` with only an intercept in both equations, type `zioprobit depvar inflated(_cons) offset(varname), constraints(constraints);` see [R] Estimation options.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] vce_option.

`level(#), nocnsreport;` see [R] Estimation options.

`display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%,fmt), pformat(%,fmt), sformat(%,fmt),` and `nolstretch;` see [R] Estimation options.

`maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs);` see [R] Maximize. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `zioprobit` but are not shown in the dialog box: `collinear, coeflegend;` see [R] Estimation options.

**Remarks and examples**

ZIOP models are used when the outcome of interest is an ordinal response variable and the data exhibit a high fraction of observations in the lowest category or what we will refer to from now on as “zero” but without quotes. Like the ordered probit model, the actual values taken by the ordinal response variable are irrelevant. While the outcome is typically coded as 0, 1, 2, ..., `H`, `zioprobit` interprets the lowest value present in the dataset as 0 to be consistent with the original derivation of the model and subsequent applications.

Like all zero-inflated models, the ZIOP model is an alternative when the data exhibit a higher fraction of zero-valued outcomes than is likely compatible with an ordered probit model. This concentration of zeros is referred to as zero inflation. Inflation is assumed to occur in the lowest value to ensure that shifting the levels of the ordinal response variable by a constant will not affect the estimated parameters in the model. This is common in ordered probit models; see [R] oprobit.

Without loss of generality, we consider an ordinal response variable with levels 0, 1, 2, ..., `H`. Traditional ordered probit models treat all observations with zero-valued outcomes as a homogeneous group. By contrast, ZIOP models assume that zeros could occur in the data as members of two latent (unobservable) groups. Individuals in the “always-zero” group have outcome 0 as the only possible value. This first group is often called the nonparticipation group. The second group, in addition to 0, may also assume any of the other values, 1, 2, ..., `H`. This group is often called the participation
group. Some disciplines, such as public health and medicine, refer to the process that determines the zeros rather than the groups. In this case, there is an incidence or occurrence process that determines whether an observation belongs to the always-zero group and a severity or intensity process that determines the level in the second group. The result of having two groups or processes is an inflation in the proportion of zero-valued observations in the data.

The ZIOP model has been used in studies of international and domestic conflicts (Bagozzi et al. 2015), sports participation (Downward, Lera-Lopez, and Rasciute 2011), and the adoption of new building technologies (Ganguly, Koebel, and Cantrell 2010), to name a few. See Kelley and Anderson (2008) for a discussion of zero-inflated ordinal models in the context of health.

The classic application of the ZIOP model is the study of tobacco use by Harris and Zhao (2007). Like the zero-inflated Poisson models in the count-data literature (Lambert 1992), Harris and Zhao derived the ZIOP model using a two-stage decision process. An individual must decide whether to participate in an activity (for example, smoking or drug consumption) and, conditional on participating, must decide on the level of participation, which also includes zero participation. The first decision is a binary choice and is modeled using a probit model, while the second is an ordered choice and is modeled using an ordered probit model. In other terms, to account for the excess of zeros, Harris and Zhao allowed for zero observations to occur in two ways: as a realization of the probit model (nonparticipants) and as a realization of the ordered probit model when the binary random variable in the probit model is 1 (participant with zero activity). See Methods and formulas for more details. For a Bayesian derivation of the ZIOP model, see Gurmu and Dagne (2012).

You may want to check whether a standard ordered probit model is adequate to fit the data. You can do this, for instance, using information criteria; see example 2 in [R] zip.

Example 1: Zero-inflated ordered probit model

We have fictional data on cigarette consumption per day for 15,000 subjects between ages 14 and 84. The outcome of interest, tobacco, is an ordinal response with four levels coded as 0 for “no cigarettes”, 1 for “up to 8 cigarettes/day”, 2 for “8 to 12 cigarettes/day”, and 3 for “more than 12 cigarettes/day”. The exact number of daily consumed cigarettes is unknown.

About 63% of the respondents identified themselves as current nonsmokers. We suspect that these self-identified current nonsmokers belong to one of two groups. Individuals in the first group are genuine nonsmokers (always-zero group) who have never smoked and will never smoke. Individuals in the second group are smokers with no smoking activity who could be the corner solution of a standard consumer demand problem and who may smoke, say, if the price of tobacco falls or their income increases. It is likely that these two types of zeros are driven by different patterns of consumer behavior and a ZIOP model is a good candidate in this case.

We model tobacco consumption levels for subjects who choose to smoke as a function of years of education (education), annual income in tens of thousands of dollars (income), age in tens of years (age), and whether the respondent is a female (female). In addition to education, income, age, and female, the decision to smoke is modeled as a function of whether either of the respondent’s parents smoked (parent) and whether the respondent’s religion discourages smoking (religion). We list all the covariates in the required inflate() option.
. use https://www.stata-press.com/data/r18/tobacco

In the output table, the first set of coefficients, labeled tobacco, corresponds to the participation (smoking) levels. These coefficients are interpreted in the same way as coefficients from an ordered probit model. The second set of coefficients, labeled inflate, corresponds to the equation for the participation decision. These are interpreted in the same way as coefficients from a binary probit model. ZIOP models do not require the variables to be the same in the participation level and decision equations. However, the same variables can appear in both. If the same variables are included, it is not uncommon for the coefficients to have opposite signs. For example, income and education in the model above have positive signs in the level equation and negative signs in the decision equation.

The estimated coefficients are not particularly informative, and as with all discrete choice models, marginal effects are better to interpret. We use margins to estimate the average marginal effect of
having a smoking parent on the probability of being a genuine nonsmoker. Specifying \texttt{pnpar} within the \texttt{predict()} option means that we are requesting the predicted probability of nonparticipation, which in our example is equivalent to being a genuine nonsmoker.

\begin{verbatim}

\end{verbatim}

On average, individuals whose parents are smokers are about 18% less likely to be nonsmokers themselves than individuals whose parents did not use tobacco. See [R] \texttt{zioprobit postestimation} for more information and examples.

**Stored results**

\texttt{zioprobit} stores the following in \texttt{e()}:  

**Scalars**

- \texttt{e(N)}: number of observations
- \texttt{e(N_zero)}: number of zeros or lowest-category observations
- \texttt{e(k_cat)}: number of categories
- \texttt{e(k)}: number of parameters
- \texttt{e(k_eq)}: number of equations in \texttt{e(b)}
- \texttt{e(k_eq_model)}: number of equations in overall model test
- \texttt{e(k_aux)}: number of auxiliary parameters
- \texttt{e(k_dv)}: number of dependent variables
- \texttt{e(df_m)}: model degrees of freedom
- \texttt{e(ll)}: log likelihood
- \texttt{e(N_clust)}: number of clusters
- \texttt{e(chi2)}: $\chi^2$
- \texttt{e(p)}: $p$-value for model test
- \texttt{e(rank)}: rank of \texttt{e(V)}
- \texttt{e(ic)}: number of iterations
- \texttt{e(rc)}: return code
- \texttt{e(converged)}: 1 if converged, 0 otherwise
Macros

- `e(cmd)` zioprobit
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset1)` offset
- `e(chi2type)` Wald or LR; type of model $\chi^2$ test
- `e(vce)` vcetype specified in vce()
- `e(vcetype)` title used to label Std. err.
- `e(opt)` type of optimization
- `e(ml_method)` type of ml method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` b V
- `e(predict)` program used to implement predict
- `e(marginsok)` predictions allowed by margins
- `e(marginsnotok)` predictions disallowed by margins
- `e(marginsdefault)` default predict() specification for margins
- `e(asbalanced)` factor variables fvset as abalanced
- `e(asobserved)` factor variables fvset as aobserved

Matrices

- `e(b)` coefficient vector
- `e(Cns)` constraints matrix
- `e(ilog)` iteration log (up to 20 iterations)
- `e(gradient)` gradient vector
- `e(cat)` category values
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance

Functions

- `e(sample)` marks estimation sample

In addition to the above, the following is stored in `r()`: Matrices

- `r(table)` matrix containing the coefficients with their standard errors, test statistics, $p$-values, and confidence intervals

Note that results stored in `r()` are updated when the command is replayed and will be replaced when any r-class command is run after the estimation command.

### Methods and formulas

Consider an ordinal response variable $Y$ with levels coded as 0, 1, 2, ..., $H$. For notational simplicity, we assume that the zeros are inflated, but the following derivation may be adapted to accommodate inflation in the lowest outcome category. Harris and Zhao (2007) derived the ZIOP model in two steps. First, the group membership (participants versus nonparticipants) can be modeled using a probit model. Let $s_j = 1$ if the $j$th individual belongs to the participation group or let $s_j = 0$ otherwise. With the probit model, the probability of participation is given by

$$Pr(s_j = 1|z_j) = \Phi(z_j \gamma)$$  \hspace{1cm} (1)

$z_j$ is a vector of covariates that determines group membership, $\gamma$ is a vector of coefficients that have to be estimated, and $\Phi(\cdot)$ is the standard normal distribution function. Next, conditioning on $s_j = 1$, participation levels $\tilde{y}_j$ are modeled using an ordered probit model; these levels may also include 0. The corresponding probabilities are given by
\begin{equation}
\Pr(\tilde{y}_j = h | s_j = 1, x_j) = \Phi(\kappa_h - x_j \beta) - \Phi(\kappa_{h-1} - x_j \beta) \hspace{1cm} h = 0, 1, \ldots, H
\end{equation}

where \( \kappa_{-1} = -\infty, \kappa_H = +\infty, \) and \( x_j \) is a vector of covariates that could be different from \( z_j \). \( \kappa_h \) are boundary parameters that need to be estimated in addition to the coefficients vector \( \beta \).

The intercept \( \beta_0 \) is set equal to 0 in (2) for identification. Note that \( s_j \) and \( \tilde{y}_j \) are both unobservable in terms of the zeros. The observed response variable is \( y_j = s_j \tilde{y}_j \). Thus, the zero outcome occurs when \( s_j = 0 \) (the individual is not a participant) or occurs when \( s_j = 1 \) and \( \tilde{y}_j = 0 \) (the individual is a participant with zero activity). To observe a positive \( y_j \), it is a joint requirement that \( s_j = 1 \) and \( \tilde{y}_j > 0 \).

The distribution of \( Y \) is given by

\begin{equation}
\Pr(Y) = \left\{ \begin{array}{ll}
\Pr(y_j = 0 | z_j, x_j) & h = 1, 2, \ldots, H - 1 \\
\Pr(y_j = h | z_j, x_j) & h = 1, 2, \ldots, H - 1 \\
\Pr(y_j = H | z_j, x_j) & h = 1, 2, \ldots, H - 1
\end{array} \right.
\end{equation}

The probability of zero outcome has been inflated because it is the sum of the probability of zero activity from the ordered probit model and the probability of nonparticipation from the probit model.

Substituting (1) and (2) in (3), we get

\begin{equation}
\Pr(Y) = \left\{ \begin{array}{ll}
\Pr(y_j = 0 | z_j, x_j) & h = 1, 2, \ldots, H - 1 \\
\Pr(y_j = h | z_j, x_j) & h = 1, 2, \ldots, H - 1 \\
\Pr(y_j = H | z_j, x_j) & h = 1, 2, \ldots, H - 1
\end{array} \right.
\end{equation}

\begin{equation}
\Pr(Y) = \left\{ \begin{array}{ll}
1 - \Phi(z_j \gamma) + \Phi(z_j \gamma) \Phi(\kappa_0 - x_j \beta) & h = 1, 2, \ldots, H - 1 \\
\Phi(z_j \gamma) \{\Phi(\kappa_h - x_j \beta) - \Phi(\kappa_{h-1} - x_j \beta)\} & h = 1, 2, \ldots, H - 1 \\
\Phi(z_j \gamma) \{1 - \Phi(\kappa_{H-1} - x_j \beta)\} & h = 1, 2, \ldots, H - 1
\end{array} \right.
\end{equation}

If the respective \texttt{offset()} option is specified, \( x_j \beta \) and \( z_j \gamma \) are replaced with \( x_j \beta + \text{offset}_j \) and \( z_j \gamma + \text{offset}_j \), respectively.

The log-likelihood function is

\begin{equation}
\ln L = \sum_{j=1}^{N} w_j \sum_{h=0}^{H} I(y_j = h) \ln \left\{ \Pr(y_j = h | z_j, x_j) \right\}
\end{equation}

where \( w_j \) is an optional weight for the \( j \)th observation and

\begin{equation}
I(y_j = h) = \left\{ \begin{array}{ll}
1 & \text{if } y_j = h \\
0 & \text{otherwise}
\end{array} \right.
\end{equation}

The choice between the ZIOP model and the ordered probit model cannot be made using a likelihood-ratio test because the two hypotheses are not nested in the usual sense of parameter restrictions. The restriction \( \gamma = 0 \) does not eliminate the inflation effect; it makes the group membership probabilities both equal to 0.5 [see (1)]. What is needed to remove the inflation effect is \( z_j \gamma \rightarrow \infty \), which cannot be imposed. Because ZIOP and ordered probit models are not nested, you can compare the fits of the two models using information criteria.
This command supports the Huber/White/sandwich estimator of the variance and its clustered version with \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] \_robust}, particularly \textit{Maximum likelihood estimators} and \textit{Methods and formulas}.

\texttt{zioprobit} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] Variance estimation}.

predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

Menu for predict

Statistics  >  Postestimation

Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [ , statistic
    outcome(outcome) nooffset ]
```

```
predict [type] stub* [if] [in], scores
```

```
statistic Description

Main

pmargin marginal probabilities of levels, Pr(yj = h); the default
pjoint1 joint probabilities of levels and participation, Pr(yj = h, sj = 1)
pcond1 probabilities of levels conditional on participation, Pr(yj = h|sj = 1)
ppar probability of participation, Pr(sj = 1)
pnpar probability of nonparticipation, Pr(sj = 0)
xb linear prediction
xbinfl linear prediction for inflation equation
stdp standard error of the linear prediction
stdpinfl standard error of the linear prediction for inflation equation
```

If you do not specify outcome(), pmargin, pjoint1, and pcond1 (with one new variable specified) assume outcome(#1).

You specify one or k new variables with pmargin, pjoint1, and pcond1, where k is the number of outcomes.

You specify one new variable with ppar, pnpar, xb, xbinfl, stdp, and stdpinfl.

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

- pmargin, the default, calculates the predicted marginal probabilities of outcome levels, Pr(yj = h).
- pjoint1 calculates the predicted joint probabilities of outcome levels and participation, Pr(yj = h, sj = 1).
- pcond1 calculates the predicted probabilities of outcome levels conditional on participation, Pr(yj = h|sj = 1).
With `pmargin`, `pjoint1`, and `pcond1`, you can compute predicted probabilities for one or for all outcome levels. When you specify one new variable, `predict` computes probabilities for the first outcome level. You can specify the `outcome(#i)` option to obtain probabilities for the $i$th level. When you specify multiple new variables or a stub, `predict` computes probabilities for all outcome levels. The behavior of `predict` with one new variable is equivalent to specifying `outcome(#1)`.

`ppar` and `pnpar` calculate the predicted marginal probability of participation [$\Pr(s_j = 1)$] and of nonparticipation [$\Pr(s_j = 0)$], respectively.

In health-related fields, probabilities of participation and nonparticipation are known as probabilities of susceptibility and nonsusceptibility. Similarly to `predict` after `ziologit`, you can use options `ps` and `pns` to compute these probabilities. Options `ps` and `pns` produce identical results to the respective options `ppar` and `pnpar` but label new variables as $\Pr(\text{susceptible})$ and $\Pr(\text{nonsusceptible})$ instead of $\Pr(\text{participation})$ and $\Pr(\text{nonparticipation})$.

`xb` calculates the linear prediction for the ordered probit equation, which is $x_j\beta$ if `offset()` was not specified with `zioprobit` and is $x_j\beta + \text{offset}_j\beta$ if `offset()` was specified.

`xbinfl` calculates the linear prediction for the inflation equation, which is $z_j\gamma$ if `offset()` was not specified in `inflate()` and is $z_j\gamma + \text{offset}_j\gamma$ if `offset()` was specified in `inflate()`.

`stdp` calculates the standard error of the linear prediction for the ordered probit equation.

`stdpinfl` calculates the standard error of the linear prediction for the inflation equation.

`outcome(outcome)` specifies the outcome for which predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is allowed only with `pmargin`, `pjoint1`, and `pcond1`.

`nooffset` is relevant only if you specified `offset(varname)` with `zioprobit` or within the `inflate()` option. It modifies the calculations made by `predict` so that they ignore the offset variable; that is, the linear prediction for the main regression equation is treated as $x_j\beta$ rather than as $x_j\beta + \text{offset}_j\beta$ and the linear prediction for the inflation equation is treated as $z_j\gamma$ rather than as $z_j\gamma + \text{offset}_j\gamma$.

`scores` calculates equation-level score variables.

The first new variable will contain $\partial \ln L / \partial (x_j\beta)$. In the absence of independent variables in the main equation, this variable is not stored.

The second new variable will contain $\partial \ln L / \partial (z_j\gamma)$.

When the dependent variable takes $k$ different values, the third new variable through new variable $k + 1$ will contain $\partial \ln L / \partial (\kappa_h)$ for $h = 0, 1, \ldots, k - 2$. 
margins

Description for margins

margins estimates margins of response for probabilities and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [ marginlist ] [, options ]
margins [ marginlist ], predict(statistic ...) [ predict(statistic ...) ... ] [ options ]

</table>

pmargin, pjoint1, and pcond1 default to the first outcome.

Statistics not allowed with margins are functions of stochastic quantities other than \( e(b) \).

For the full syntax, see [R] margins.
Remarks and examples

Various sets of predictions and marginal effects may be of interest for the ZIOP model. For instance, we may want to investigate the marginal effects of a covariate on the probability of participation, or on the probabilities for levels of consumption conditional on participation, or on the overall probabilities for different consumption levels. We explore these options in greater detail in the following examples.

Example 1: Average marginal effects on probability of nonparticipation

In example 1 of [R] zioprobit, we fit a model for level of cigarette consumption.

```
use https://www.stata-press.com/data/r18/tobacco
(Fictional tobacco consumption data)
zioprobit tobacco education income i.female age,
> inflate(education income i.parent age i.female i.religion)
(output omitted)
```

We can use margins to estimate the expected marginal effect of gender for individuals with a college degree (17 years of education) and a smoking parent on the probability of nonparticipation (being a genuine nonsmoker). To do this, we specify `predict(pnpar)` with `margins` as follows:

```
margins, predict(pnpar) dydx(female) at(education = 17 parent = 1)
```

```
Average marginal effects Number of obs = 15,000
Model VCE: OIM
Expression: Pr(nonparticipation), predict(pnpar)
dy/dx wrt: 1.female
At: education = 17
parent = 1
```

| Female | Delta-method  | dy/dx | std. err. | z | P>|z| | [95% conf. interval] |
|--------|---------------|-------|-----------|---|------|---------------------|
| Female | .0855995      | .0100239 | 8.54      | 0.000 | .0659531 | .105246 |

Note: dy/dx for factor levels is the discrete change from the base level.

Women with a college degree and a smoking parent are expected to have about an 8.5% higher chance of being genuine nonsmokers than do men.

Example 2: Predicted probabilities of zero-valued outcomes

In example 1 of [R] zioprobit, we found that the coefficient on income was positive in the level equation but negative in the participation equation. In the case of our tobacco consumption example, economic theory offers a reasonable interpretation for this. Higher income may act as an indicator for health awareness, which accounts for its association with an increased probability of being a genuine nonsmoker. However, if cigarettes are a normal good—that is, something for which demand increases when income increases—then smokers with higher income should have a lower probability of having zero consumption at the time of the survey.

We first consider the effect of income at six prespecified values ranging from $10,000 to $60,000 on the probability of being a genuine nonsmoker (nonparticipation). Because we know the values 1 to 6 correspond to income in tens of thousands, we conserve space and suppress the default legend by using the noatlegend option.
The probability of being a genuine nonsmoker increases with income. For instance, for individuals who earn $10,000 a year, the expected increase in the probability of being a genuine nonsmoker is about \((0.1945 - 0.1728) \times 100\% = 2.17\%\) if they earn an additional $10,000.

We next investigate the effect of income on the joint probability of being a smoker (participation equals 1) with zero consumption. We do this by specifying `predict(pjoint1 outcome(0))` with `margins`:

```stata
. margins, predict(pjoint1 outcome(0)) at(income = (1/6)) noatlegend
```

The probability of zero consumption decreases as income increases, suggesting that tobacco is like a normal good for smokers. For example, for individuals who earn $10,000 a year, earning an additional $10,000 will decrease their probability of being a smoker with zero consumption by about \((0.5595 - 0.5080) \times 100\% = 5.15\%\).

If we wanted to compute the effect of income on the overall probability of zero consumption instead of the probability of zero consumption among smokers, we would omit `pjoint1` from within the `predict` option.

```stata
. margins, predict(outcome(0)) at(income = (1/6)) noatlegend
```

This version of the `margins` command gives the sum of the probability of nonparticipation and the joint probability of participation with zero consumption.
Methods and formulas

The participation equation is
\[ s_j = I(z_j \gamma + u_{1j} > 0) \quad j = 1, 2, \ldots, n \]
where \( s_j \) is 1 if the \( j \)th subject belongs to the participation group (for example, smokers) and is 0 if the subject belongs to the nonparticipation group (for example, genuine nonsmokers), \( z_j \) are the covariates used to model the group membership, \( \gamma \) is a vector of coefficients, and \( u_{1j} \) is a random-error term following a standard normal distribution.

The ordinal outcome equation is
\[ \tilde{y}_j = \sum_{h=0}^{H} h I(\kappa_{h-1} < x_j \beta + u_{2j} \leq \kappa_h) \]
where \( \tilde{y}_j \) is the ordinal outcome conditional on participation, \( x_j \) are the outcome covariates, \( \beta \) are the coefficients, and \( u_{2j} \) is a random-error term following a standard normal distribution. The observed outcome values are 0, 1, \ldots, \( H \). \( \kappa_0, \kappa_1, \ldots, \kappa_{H-1} \) are real numbers such that \( \kappa_i < \kappa_m \) for \( i < m \). \( \kappa_{-1} \) is taken as \(-\infty\) and \( \kappa_{H} \) is taken as \(+\infty\). We assume that the error terms \( u_{1j} \) and \( u_{2j} \) are independent. We observe \( y_j = s_j \tilde{y}_j \).

The probability of participation is
\[ \Pr(s_j = 1|z_j) = \Phi(z_j \gamma) \quad (1) \]
where \( \Phi(\cdot) \) is the standard normal distribution function.

The probability of nonparticipation is
\[ \Pr(s_j = 0|z_j) = 1 - \Phi(z_j \gamma) \quad (2) \]

The probability of outcome \( y_j = h \) given that the \( j \)th subject belongs to the participation group is
\[ \Pr(y_j = h|s_j = 1, x_j) = \Pr(\tilde{y}_j = h|x_j) = \Phi(\kappa_h - x_j \beta) - \Phi(\kappa_{h-1} - x_j \beta) \quad (3) \]
for \( h = 0, 1, \ldots, H \), where \( \Phi(\kappa_{-1} - x_j \beta) = 0 \) and \( \Phi(\kappa_{H} - x_j \beta) = 1 \).

The joint probability of outcome \( y_j = h \) and participation can be expressed as
\[ \Pr(y_j = h, s_j = 1|z_j, x_j) = \Pr(s_j = 1|z_j) \Pr(y_j = h|s_j = 1, x_j) \]
for \( h = 0, 1, \ldots, H \), and computed using (1) and (3).

The marginal probabilities of the outcome \( y_j \) are

\[ \Pr(y_j = 0|z_j, x_j) = \Pr(s_j = 0|z_j) + \Pr(s_j = 1|z_j) \Pr(\tilde{y}_j = 0|x_j) \]
\[ \Pr(y_j = h|z_j, x_j) = \Pr(s_j = 1|z_j) \Pr(\tilde{y}_j = h|x_j) \quad h = 1, 2, \ldots, H - 1 \]
\[ \Pr(y_j = H|z_j, x_j) = \Pr(s_j = 1|z_j) \Pr(\tilde{y}_j = H|x_j) \]
and can be computed using (1), (2), and (3).

If the offset() option is specified with zioprobit, \( x_j \beta \) is replaced with \( x_j \beta + \text{offset}_j^\beta \). If the offset() option is specified within the inflate() option, \( z_j \gamma \) is replaced with \( z_j \gamma + \text{offset}_j^\gamma \).

Also see

[R] zioprobit — Zero-inflated ordered probit regression

[U] 20 Estimation and postestimation commands
Description

zip fits a zero-inflated Poisson (ZIP) model to count data with excess zero counts. The ZIP model assumes that the excess zero counts come from a logit or probit model and the remaining counts come from a Poisson model.

Quick start

Zero-inflated Poisson model of \( y \) on \( x_1 \) and \( x_2 \) with inflation modeled using \( x_3 \)

\[
\text{zip } y \ x_1 \ x_2, \text{ inflate}(x3)
\]

Use a probit model instead of a logit model to predict excess zeros

\[
\text{zip } y \ x_1 \ x_2, \text{ inflate}(x3) \text{ probit}
\]
Syntax

zip depvar [indepvars] [if] [in] [weight],
    inflate(varlist, offset(varname) | _cons) [options]

options                         Description

Model
* inflate()                     equation that determines whether the count is zero
    noconstant                   suppress constant term
    exposure(varname_e)          include ln(varname_e) in model with coefficient constrained to 1
    offset(varname_o)           include varname_o in model with coefficient constrained to 1
    constraints(constraints)    apply specified linear constraints
    probit                      use probit model to characterize excess zeros; default is logit

SE/Robust
    vce(vcetype)                 vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife

Reporting
    level(#)                     set confidence level; default is level(95)
    irr                         report incidence-rate ratios
    nocnsreport                 do not display constraints
    display_options             control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

Maximization
    maximize_options            control the maximization process; seldom used
    collinear                   keep collinear variables
    coeflegend                  display legend instead of statistics

*inflate(varlist, offset(varname) | _cons) is required.
indepvars and varlist may contain factor variables; see [U] 11.4.3 Factor variables.
bayes, bootstrap, by, collect, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: zip.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweight, iweight, and pweight are allowed; see [U] 11.1.6 weight.
collinear and coeflegend do not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

Model

inflation(varlist, offset(varname) | _cons) specifies the equation that determines whether the observed count is zero. Conceptually, omitting inflate() would be equivalent to fitting the model with poisson; see [R] poisson.
inflat(varlist[, offset(varname)]) specifies the variables in the equation. You may optionally include an offset for this varlist.

inflate(_cons) specifies that the equation determining whether the count is zero contains only an intercept. To run a zero-inflated model of depvar with only an intercept in both equations, type zip depvar, inflate(_cons).

noconstant, exposure(varname_e), offset(varname_o), constraints(constraints); see [R] Estimation options.

probit requests that a probit, instead of logit, model be used to characterize the excess zeros in the data.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

level(#); see [R] Estimation options.

irr reports estimated coefficients transformed to incidence-rate ratios, that is, $e^b$ rather than $b$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. irr may be specified at estimation or when replaying previously estimated results.

nocnsreport; see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fwrap(#), fwrap(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following options are available with zip but are not shown in the dialog box: collinear, coeflegend; see [R] Estimation options.

**Remarks and examples**

Zero-inflated Poisson (ZIP) models address the case when the data contain a higher fraction of zeros than is likely to be generated from a Poisson model. Having a large proportion of zero observations, in itself, does not necessarily mean that we have the excess zeros problem. For instance, a Poisson model with a mean value of 0.2 predicts that $P(Y = 0) = \exp(-0.2) \approx 0.82$. However, the range of possible outcomes is restricted because of the small variance, 0.2 (mean and variance are equal for a Poisson model), as shown by $P(Y > 3) \approx 0.00006$. Unlike Poisson models, ZIP models allow us to have a large fraction of zeros without restricting the range of outcomes.
ZIP models assume that an observation is 0 with a probability \( p \) or is a realization of a Poisson random variable, which can also be 0, with a probability \( 1 - p \). For instance, you might count how many fish each visitor to a park catches. Many visitors may catch zero, because they do not fish (as opposed to being unsuccessful). Using a logit or probit model, you may model the probability \( p \) of whether a person does not fish depending on several covariates related to fishing. Using a Poisson distribution, you may model how many fish a person catches depending on several covariates having to do with the success of catching fish (type of lure or bait, time of day, temperature, season, etc.). This is the type of data for which the \texttt{zip} command is useful.

\section*{Example 1: Fitting a ZIP model}

We have fictional data on the number of fish caught (\texttt{count}) by visitors to a national park on a particular day. Some of the visitors do not fish, but we do not have the data on whether a person fished; we merely have data on how many fish were caught together with several covariates.

Variable \texttt{count} exhibits an excess of zero observations (142 of 250 observations), beyond what would be expected from a Poisson model. We suspect that the number of zeros may be inflated because many visitors are not fishing. That is, a zero observation may be the result of a visitor who was unfortunate and caught no fish but may also be because the visitor did not fish. A standard Poisson model (see \texttt{R poisson}) treats these two types of zero observations as a homogeneous group, which typically leads to biased statistical results. We would like to distinguish between the two types of zeros and possibly draw inference for them separately (see example 1 in \texttt{R zip postestimation}).

The \texttt{zip} command allows us to model the two types of zeros. First, using the required option \texttt{inflate()}, we model whether a visitor fishes as a function of the number of children accompanying him or her (\texttt{child}) and whether he or she is camping (\texttt{camper}). Next, we assume the response variable, \texttt{count}, depends on whether the visitor used a live bait (\texttt{livebait}) and the number of persons (\texttt{persons}), which includes the visitor and any adults or children accompanying him. Note that \texttt{persons} is always greater than \texttt{child}. 

\section*{Note}

This is a simplified example to illustrate the use of the \texttt{zip} command. In practice, the \texttt{zipline} package is recommended for fitting zero-inflated models in \texttt{R}.
. use https://www.stata-press.com/data/r18/fish
(Fictional fishing data)
. zip count persons livebait, inflate(child camper)

Fitting constant-only model:
Iteration 0: Log likelihood = -1347.807
Iteration 1: Log likelihood = -1305.3245
Iteration 2: Log likelihood = -1104.3005
Iteration 3: Log likelihood = -1103.9426
Iteration 4: Log likelihood = -1103.9425

Fitting full model:
Iteration 0: Log likelihood = -1103.9425
Iteration 1: Log likelihood = -896.2346
Iteration 2: Log likelihood = -851.61723
Iteration 3: Log likelihood = -850.70435
Iteration 4: Log likelihood = -850.70142
Iteration 5: Log likelihood = -850.70142

Zero-inflated Poisson regression
Number of obs = 250
Inflation model: logit
Nonzero obs = 108
Zero obs = 142
LR chi2(2) = 506.48
Prob > chi2 = 0.0000

| count       | Coefficient | Std. err. | z    | P>|z| | [95% conf. interval] |
|-------------|-------------|-----------|------|-----|----------------------|
| persons     | .8068853    | .0453288  | 17.80| 0.000| .7180424 .8957281    |
| livebait    | 1.757289    | .2446082  | 7.18 | 0.000| 1.277866 2.236713    |
| _cons       | -.2178472   | .2860289  | -7.62| 0.000| -2.739078 -1.617865  |

| inflate     | Coefficient | Std. err. | z    | P>|z| | [95% conf. interval] |
|-------------|-------------|-----------|------|-----|----------------------|
| child       | 1.602571    | .2797719  | 5.73 | 0.000| 1.054228 2.150913    |
| camper      | -1.015698   | .365259   | -2.78| 0.005| -1.731593 -.2998038  |
| _cons       | -.4922872   | .3114562  | -1.58| 0.114| -1.10273 .1181558   |

Coefficients in the upper half of the table correspond to the Poisson model for individuals who fished. For instance, among visitors who fished, using a live bait increases the expected number of caught fish by a factor of \( \exp(1.7572) \approx 5.8 \), holding other covariates constant.

Example 2: Comparing model fit

When you have count data, you may want to test whether a conventional count data model or a zero-inflated count data model is preferable. The classical likelihood-ratio test cannot be used here because the models are not nested. But we can use information criteria such as the \( \text{AIC} \) and \( \text{BIC} \) to check whether the standard or zero-inflated model is more appropriate.

Continuing with our fishing example, let's check whether the standard Poisson or ZIP model is more appropriate for our data. First, we store the estimation results from the previous ZIP model by typing

. estimates store zip
Next, we fit the Poisson model corresponding to the main equation of the ZIP model and store its results as `pois`:

```
. poisson count persons livebait
(output omitted)
. estimates store pois
```

We use `estimates stats` to display the AIC and BIC values for the two models.

```
. estimates stats pois zip
```

Akaike’s information criterion and Bayesian information criterion

<table>
<thead>
<tr>
<th>Model</th>
<th>N</th>
<th>ll(null)</th>
<th>ll(model)</th>
<th>df</th>
<th>AIC</th>
<th>BIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>pois</td>
<td>250</td>
<td>-1647.716</td>
<td>-1312.178</td>
<td>3</td>
<td>2630.356</td>
<td>2640.92</td>
</tr>
<tr>
<td>zip</td>
<td>250</td>
<td>-1103.942</td>
<td>-850.7014</td>
<td>6</td>
<td>1713.403</td>
<td>1734.532</td>
</tr>
</tbody>
</table>

Note: BIC uses N = number of observations. See [R] IC note.

The ZIP model has smaller AIC and BIC values; we thus conclude that it fits our data better than the standard Poisson model.

 Stored results

`zip` stores the following in `e()`:

Scalars

- `e(N)` number of observations
- `e(N_zero)` number of zero observations
- `e(k)` number of parameters
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_dv)` number of dependent variables
- `e(df_m)` model degrees of freedom
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(N_clust)` number of clusters
- `e(chi2)` \( \chi^2 \)
- `e(p)` \( p \)-value for model test
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

Macros

- `e(cmd)` `zip`
- `e(cmdline)` command as typed
- `e(depvar)` name of dependent variable
- `e(inflate)` logit or probit
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset1)` offset
- `e(offset2)` offset for `inflate()`
- `e(chi2type)` Wald or LR: type of model \( \chi^2 \) test
- `e(vce)` `vcetype` specified in `vce()`
- `e(vcetype)` title used to label Std. err.
- `e(opt)` type of optimization
e(which) \( \text{max} \) or \( \text{min} \): whether optimizer is to perform maximization or minimization

e(ml_method) \( \text{type of ml method} \)

e(user) \( \text{name of likelihood-evaluator program} \)

e(technique) \( \text{maximization technique} \)

e(properties) \( b \ V \)

e(predict) \( \text{program used to implement predict} \)

e(asbalanced) \( \text{factor variables fvset as asbalanced} \)

e(asobserved) \( \text{factor variables fvset as asobserved} \)

Matrices

\( e(b) \) \( \text{coefficient vector} \)

\( e(Cns) \) \( \text{constraints matrix} \)

\( e(ilog) \) \( \text{iteration log (up to 20 iterations)} \)

\( e(gradient) \) \( \text{gradient vector} \)

\( e(V) \) \( \text{variance–covariance matrix of the estimators} \)

\( e(V_{modelbased}) \) \( \text{model-based variance} \)

Functions

\( e(sample) \) \( \text{marks estimation sample} \)

In addition to the above, the following is stored in \( r() \):

Matrices

\( r(table) \) \( \text{matrix containing the coefficients with their standard errors, test statistics, } p\text{-values, and confidence intervals} \)

Note that results stored in \( r() \) are updated when the command is replayed and will be replaced when any \( r\)-class command is run after the estimation command.

## Methods and formulas

Consider the formulation of a zero-inflated model as presented in Lambert (1992). Define

\[
\begin{align*}
\xi^\beta_j &= x_j \beta + \text{offset}_j^\beta \\
\xi^\gamma_j &= z_j \gamma + \text{offset}_j^\gamma \\
\lambda_j &= \exp \left( \xi^\beta_j \right) \\
F_j &= F \left( \xi^\gamma_j \right)
\end{align*}
\]

where \( F(\cdot) \) is the inverse of the logit function or, if the \( \text{probit} \) option was specified, the inverse of the probit function (or the standard normal cumulative distribution function). All subjects are assumed to be independent with the \( j \)th response determined as follows:

\[
\begin{align*}
Y_j &= 0 \quad \text{with probability } F_j \\
Y_j &\sim \text{Poisson} \left( \lambda_j \right) \quad \text{with probability } 1 - F_j
\end{align*}
\]

In other words,

\[
\begin{align*}
\Pr(Y_j = 0|x_j, z_j) &= F_j + (1 - F_j) \exp (-\lambda_j) \\
\Pr(Y_j = n|x_j, z_j) &= (1 - F_j) \exp (-\lambda_j) \frac{\lambda_j^n}{n!} \quad \text{for } n = 1, 2, \ldots
\end{align*}
\]
The `zip` command maximizes the log-likelihood \( \ln L \), defined by

\[
\ln L = \sum_{j \in S} w_j \ln \{ F_j + (1 - F_j) \exp(-\lambda_j) \} \\
+ \sum_{j \not\in S} w_j \{ \ln(1 - F_j) - \lambda_j + \xi_j y_j - \ln(y_j!) \}
\]

where \( w_j \) are the weights and \( S \) is the set of observations for which the observed outcome \( y_j = 0 \).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `robust`, particularly Maximum likelihood estimators and Methods and formulas.

`zip` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] Variance estimation.

predict

Description for predict

predict creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

predict [type] newvar [if] [in] [, statistic nooffset]

predict statistic [type] stub* [if] [in], scores

Main

n number of events; the default
ir incidence rate
pr probability of a degenerate zero
pr(n) probability Pr(yj = n)
pr(a,b) probability Pr(a ≤ yj ≤ b)
xb linear prediction
stdp standard error of the linear prediction

These statistics are available both in and out of sample; type predict ... if e(sample) ... if wanted only for the estimation sample.

Options for predict

n, the default, calculates the predicted number of events, which is (1 – Fj) exp(xjβ) if neither offset() nor exposure() was specified when the model was fit, where Fj is the predicted probability of a zero outcome; (1 – Fj) exp(xjβ + offsetβ) if offset() was specified; or (1 – Fj) exp(xjβ) × exposurej} if exposure() was specified.

ir calculates the incidence rate, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the n and the nooffset options.

pr calculates the probability of a degenerate zero, predicted from the fitted degenerate distribution Fj = F(zjγ). If offset() was specified within the inflate() option, then Fj = F(zjγ + offsetj) is calculated.

pr(n) calculates the probability Pr(yj = n), where n is a nonnegative integer that may be specified as a number or a variable. Note that pr is not equivalent to pr(0).

pr(a,b) calculates the probability Pr(a ≤ yj ≤ b), where a and b are nonnegative integers that may be specified as numbers or variables;
\( b \) missing (\( b \geq . \)) means \(+\infty\);
\( \text{pr}(20, .) \) calculates \( \text{Pr}(y_j \geq 20) \);
\( \text{pr}(20, b) \) calculates \( \text{Pr}(y_j \geq 20) \) in observations for which \( b \geq . \) and calculates \( \text{Pr}(20 \leq y_j \leq b) \) elsewhere.

\( \text{pr}(., b) \) produces a syntax error. A missing value in an observation of the variable \( a \) causes a missing value in that observation for \( \text{pr}(a, b) \).

\( \text{xb} \) calculates the linear prediction, which is \( x_j\beta \) if neither \( \text{offset()} \) nor \( \text{exposure()} \) was specified;
\( x_j\beta + offset_j^{\beta} \) if \( \text{offset()} \) was specified; or \( x_j\beta + \ln(\text{exposure}_j) \) if \( \text{exposure()} \) was specified; see \( \text{nooffset} \) below.

\( \text{stdp} \) calculates the standard error of the linear prediction.

\( \text{nooffset} \) is relevant only if you specified \( \text{offset()} \) or \( \text{exposure()} \) when you fit the model. It modifies the calculations made by \( \text{predict} \) so that they ignore the offset or exposure variable; the linear prediction is treated as \( x_j\beta \) rather than as \( x_j\beta + offset_j^{\beta} \) or \( x_j\beta + \ln(\text{exposure}_j) \). Specifying \( \text{predict ...}, \text{nooffset} \) is equivalent to specifying \( \text{predict ...}, \text{ir} \).

\( \text{scores} \) calculates equation-level score variables.

The first new variable will contain \( \partial \ln L / \partial (x_j\beta) \).

The second new variable will contain \( \partial \ln L / \partial (z_j\gamma) \).
margins

Description for margins

margins estimates margins of response for the numbers of events, incidence rates, probabilities, and linear predictions.

Menu for margins

Statistics > Postestimation

Syntax for margins

margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>

<td>not allowed with margins</td>
</tr>
</tbody>
</table>

Statistics not allowed with margins are functions of stochastic quantities other than \( e(b) \).

For the full syntax, see [R] margins.

Remarks and examples

Example 1: Obtaining predicted counts

Continuing with example 1 from [R] zip, we will use predict to compute the predicted number of fish captured by each individual.

. use https://www.stata-press.com/data/r18/fish
   (Fictional fishing data)
. zip count persons livebait, inflate(child camper)
   (output omitted)
. predict numfish
   (option n assumed; predicted number of events)
. summarize numfish

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. dev.</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>numfish</td>
<td>250</td>
<td>2.770999</td>
<td>3.269588</td>
<td>.079269</td>
<td>13.55015</td>
</tr>
</tbody>
</table>
The average predicted number of fish caught by all visitors, regardless of whether or not they fished, is 2.77 fish.

> Example 2: Obtaining predicted probabilities

```
predict with the `pr` option computes the probability that an individual does not fish.
    . predict pr, pr
```

On the other hand, `predict` with the `pr(n)` option computes the probability of catching *n* fish; particularly, the probability of catching zero fish will be

```
. predict pr0, pr(0)
. list pr pr0 in 1
```

<table>
<thead>
<tr>
<th></th>
<th>pr</th>
<th>pr0</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>.3793549</td>
<td>.8609267</td>
</tr>
</tbody>
</table>

Notice that `pr0` is always equal to or greater than `pr`. For example, for the first individual, the probability of not fishing is 0.38; on the other hand, the probability of catching zero fish (0.86) is equal to the sum of the probability of not fishing and the probability of fishing but not catching any fish. `pr0` can be also computed as one minus the probability of catching at least one fish, that is:

```
. predict pr_catch, pr(1,.)
. gen pr0b = 1-pr_catch
```

Methods and formulas

See Methods and formulas in [R] zip for the model definition and notation.

The probabilities calculated using the `pr(n)` option are the probability \( \Pr(y_j = n) \). These are calculated using

\[
\Pr(y_j = 0|x_j, z_j) = F_j + (1 - F_j) \exp(-\lambda_j) \\
\Pr(y_j = n|x_j, z_j) = (1 - F_j) \lambda_j^n \exp(-\lambda_j) \quad \text{for } n = 1, 2, \ldots
\]

where \( F_j \) is the probability of obtaining an observation from the degenerate distribution whose mass is concentrated at zero. \( F_j \) can be obtained by using the `pr` option.

See Cameron and Trivedi (2013, sec. 4.6) for further details.

[U] 20 Estimation and postestimation commands
**Description**

`ztest` performs z tests on the equality of means, assuming known variances. The test can be performed for one sample against a hypothesized population value or for no difference in population means estimated from two samples. Two-sample tests can be conducted for paired and unpaired data. Clustered data are also supported.

`ztesti` is the immediate form of `ztest`; see [U] 19 Immediate commands.

For the comparison of means when variances are unknown, use `ttest`; see [R] `ttest`.

**Quick start**

One-sample test that the mean of `v1` is 3 at the 90% confidence level

```
ztest v1 == 3, level(90)
```

Same as above, and adjust for clustering with clusters defined by `cvar` and an intraclass correlation of 0.5

```
ztest v1 == 3, level(90) cluster(cvar) rho(0.5)
```

Unpaired z test that the mean of `v1` is equal between two groups defined by `catvar`

```
ztest v1, by(catvar)
```

Same as above, and adjust for clustering with clusters defined by `cvar` and an intraclass correlation of 0.5 in the two groups

```
ztest v1, by(catvar) cluster(cvar) rho(0.5)
```

Unpaired test of equality of the means of `v2` and `v3`

```
ztest v2 == v3, unpaired
```

Paired test of equality of the means of `v2` and `v3` with standard deviation of the differences between paired observations of 2.4

```
ztest v2 == v3, sddiff(2.4)
```

Same as above, specified using a common standard deviation of 2 and correlation between observations of 0.28

```
ztest v2 == v3, sd(2) corr(0.28)
```

Immediate form unpaired test of $\mu_1 = \mu_2$ if $\bar{x}_1 = 3.2$, $sd_1 = 0.1$, $\bar{x}_2 = 3.4$, and $sd_2 = 0.15$ with $n_1 = n_2 = 120$

```
ztesti 120 3.2 0.1 120 3.4 0.15
```

`*corr(#)` is required.

`by` and `collect` are allowed with `ztest` and `ztesti`; see [U] 11.1.10 Prefix commands.
Options

by(groupvar) specifies the groupvar that defines the two groups that ztest will use to test the hypothesis that their means are equal. Specifying by(groupvar) implies an unpaired (two-sample) z test. Do not confuse the by() option with the by prefix; you can specify both.

unpaired specifies that the data be treated as unpaired. The unpaired option is used when the two sets of values to be compared are in different variables.

sddiff(#) specifies the population standard deviation of the differences between paired observations for a paired z test. For this kind of test, either sddiff() or corr() must be specified.

corr(#) specifies the correlation between paired observations for a paired z test. This option along with sd1() and sd2() or with sd() is used to compute the standard deviation of the differences between paired observations unless that standard deviation is supplied directly in the sddiff() option. For a paired z test, either sddiff() or corr() must be specified.

sd(#) specifies the population standard deviation for a one-sample z test or the common population standard deviation for a two-sample z test. The default is sd(1). sd() may not be combined with sd1(), sd2(), or sddiff().

sd1(#) specifies the standard deviation of the first population or group. When sd1() is specified with by(groupvar), the first group is defined by the first category of the sorted groupvar. sd1() requires sd2() and may not be combined with sd() or sddiff().

sd2(#) specifies the standard deviation of the second population or group. When sd2() is specified with by(groupvar), the second group is defined by the second category of the sorted groupvar. sd2() requires sd1() and may not be combined with sd() or sddiff().

level(#) specifies the confidence level, as a percentage, for confidence intervals. The default is level(95) or as set by set level; see [U] 20.8 Specifying the width of confidence intervals.

cluster(varname) specifies the variable that identifies clusters. The cluster() option is required to adjust the computation for clustering.

rho(#) specifies the intraclass correlation for a one-sample test or the common intraclass correlation for a two-sample test. The rho() option is required to adjust the computation for clustering for a one-sample test.

rho1(#) specifies the intraclass correlation of the first group for a two-sample test using groups. The rho() option or both rho1() and rho2() options are required to adjust the computation for clustering.

rho2(#) specifies the intraclass correlation of the second group for a two-sample test using groups. The rho() option or both rho1() and rho2() options are required to adjust the computation for clustering.

When by() is used, sd1() and sd2() or sd() is used to specify the population standard deviations of the two groups defined by groupvar for an unpaired two-sample z test (using groups). By default, a common standard deviation of one, sd(1), is assumed.

When unpaired is used, sd1() and sd2() or sd() is used to specify the population standard deviations of varname1 and varname2 for an unpaired two-sample z test (using variables). By default, a common standard deviation of one, sd(1), is assumed.

Options corr(), sd1(), and sd2() or corr() and sd() are used for a paired z test to compute the standard deviation of the differences between paired observations. By default, a common standard
deviation of one, \( sd(1) \), is assumed for both populations. Alternatively, the standard deviation of the differences between paired observations may be supplied directly with the \( sddiff() \) option.

### Remarks and examples

Remarks are presented under the following headings:

- **One-sample z test**
- **Two-sample z test**
- **Paired z test**
- **Adjust for clustering**
- **Immediate form**

For the purpose of illustration, we assume that variances are known in all the examples below.

### One-sample z test

#### Example 1

In the first form, `ztest` tests whether the mean of the sample is equal to a known constant under the assumption of known variance. Assume that we have a sample of 74 automobiles. We know each automobile’s average mileage rating and wish to test whether the overall average for the sample is 20 miles per gallon. We also assume that the population standard deviation is 6.

```
. use https://www.stata-press.com/data/r18/auto
   (1978 automobile data)
. ztest mpg==20, sd(6)

One-sample z test
```

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg</td>
<td>74</td>
<td>21.2973</td>
<td>.6974858</td>
<td>6</td>
<td>19.93025 22.66434</td>
</tr>
</tbody>
</table>

\[
\text{mean} = \text{mean}(mpg) \quad z = 1.8600 \\
\text{HO: mean} = 20 \\
\text{Ha: mean} < 20 \quad \text{Ha: mean} > 20 \quad \text{Ha: mean} \neq 20 \\
\text{Pr}(Z < z) = 0.9686 \quad \text{Pr}(|Z| > |z|) = 0.0629 \quad \text{Pr}(Z > z) = 0.0314
\]

The \( p \)-value for the two-sided test is 0.0629, so we do not have statistical evidence to reject the null hypothesis that the mean equals 20 at a 5% significance level, but we would reject the null hypothesis at a 10% level.
Two-sample z test

Example 2: Two-sample z test using groups

We are testing the effectiveness of a new fuel additive. We run an experiment in which 12 cars are given the fuel treatment and 12 cars are not. The results of the experiment are as follows:

<table>
<thead>
<tr>
<th>treated</th>
<th>mpg</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
</tr>
<tr>
<td>0</td>
<td>23</td>
</tr>
<tr>
<td>0</td>
<td>21</td>
</tr>
<tr>
<td>0</td>
<td>25</td>
</tr>
<tr>
<td>0</td>
<td>18</td>
</tr>
<tr>
<td>0</td>
<td>17</td>
</tr>
<tr>
<td>0</td>
<td>18</td>
</tr>
<tr>
<td>0</td>
<td>24</td>
</tr>
<tr>
<td>0</td>
<td>20</td>
</tr>
<tr>
<td>0</td>
<td>24</td>
</tr>
<tr>
<td>0</td>
<td>23</td>
</tr>
<tr>
<td>0</td>
<td>19</td>
</tr>
<tr>
<td>1</td>
<td>24</td>
</tr>
<tr>
<td>1</td>
<td>25</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
</tr>
<tr>
<td>1</td>
<td>22</td>
</tr>
<tr>
<td>1</td>
<td>23</td>
</tr>
<tr>
<td>1</td>
<td>18</td>
</tr>
<tr>
<td>1</td>
<td>17</td>
</tr>
<tr>
<td>1</td>
<td>28</td>
</tr>
<tr>
<td>1</td>
<td>24</td>
</tr>
<tr>
<td>1</td>
<td>27</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
</tr>
<tr>
<td>1</td>
<td>23</td>
</tr>
</tbody>
</table>

The treated variable is coded as 1 if the car received the fuel treatment and 0 otherwise.

We can test the equality of means of the treated and untreated group by typing

```
use https://www.stata-press.com/data/r18/fuel3
ztest mpg, by(treated) sd(3)
```

```
<table>
<thead>
<tr>
<th>Group</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>12</td>
<td>21</td>
<td>.8660254</td>
<td>3</td>
<td>19.30262 22.69738</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>22.75</td>
<td>.8660254</td>
<td>3</td>
<td>21.05262 24.44738</td>
</tr>
</tbody>
</table>

diff = mean(0) - mean(1)  z = -1.4289
H0: diff = 0
Ha: diff < 0  Ha: diff != 0  Ha: diff > 0
Pr(Z < z) = 0.0765  Pr(|Z| > |z|) = 0.1530  Pr(Z > z) = 0.9235
```

We do not have evidence to reject the null hypothesis that the means of the two groups are equal at a 5% significance level.

In the above, we assumed that the two groups have the same standard deviation of 3. If the standard deviations for the two groups are different, we can specify group-specific standard deviations in options sd1() and sd2():
. ztest mpg, by(treated) sd1(2.7) sd2(3.2)
Two-sample z test

<table>
<thead>
<tr>
<th>Group</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>12</td>
<td>21</td>
<td>.7794229</td>
<td>2.7</td>
<td>19.47236 22.52764</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>22.75</td>
<td>.9237604</td>
<td>3.2</td>
<td>20.93946 24.56054</td>
</tr>
<tr>
<td>diff</td>
<td>12</td>
<td>-1.75</td>
<td>1.208649</td>
<td>-4.118909</td>
<td>.6189093</td>
</tr>
</tbody>
</table>

\[ \text{diff} = \text{mean}(0) - \text{mean}(1) \]
\[ z = -1.4479 \]

H0: diff = 0
Ha: diff < 0  Ha: diff != 0  Ha: diff > 0
Pr(Z < z) = 0.0738  Pr(|Z| > |z|) = 0.1476  Pr(Z > z) = 0.9262

Technical note

In two-sample randomized designs, subjects will sometimes refuse the assigned treatment but still be measured for an outcome. In this case, take care to specify the group properly. You might be tempted to let varname contain missing where the subject refused and thus let ztest drop such observations from the analysis. Zelen (1979) argues that it would be better to specify that the subject belongs to the group in which he or she was randomized, even though such inclusion will dilute the measured effect.

Example 3: Two-sample $z$ test using variables

There is a second, inferior way to organize the data in the preceding example. We ran a test on 24 cars, 12 without the additive and 12 with. We now create two new variables, mpg1 and mpg2.

<table>
<thead>
<tr>
<th>mpg1</th>
<th>mpg2</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>24</td>
</tr>
<tr>
<td>23</td>
<td>25</td>
</tr>
<tr>
<td>21</td>
<td>21</td>
</tr>
<tr>
<td>25</td>
<td>22</td>
</tr>
<tr>
<td>18</td>
<td>23</td>
</tr>
<tr>
<td>17</td>
<td>18</td>
</tr>
<tr>
<td>18</td>
<td>17</td>
</tr>
<tr>
<td>24</td>
<td>28</td>
</tr>
<tr>
<td>20</td>
<td>24</td>
</tr>
<tr>
<td>24</td>
<td>27</td>
</tr>
<tr>
<td>23</td>
<td>21</td>
</tr>
<tr>
<td>19</td>
<td>23</td>
</tr>
</tbody>
</table>

This method is inferior because it suggests a connection that is not there. There is no link between the car with 20 mpg and the car with 24 mpg in the first row of the data. Each column of data could be arranged in any order. Nevertheless, if our data are organized like this, ztest can accommodate us.
. use https://www.stata-press.com/data/r18/fuel
. ztest mpg1==mpg2, unpaired sd(3)

Two-sample z test

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg1</td>
<td>12</td>
<td>21</td>
<td>.8660254</td>
<td>3</td>
<td>19.30262 22.69738</td>
</tr>
<tr>
<td>mpg2</td>
<td>12</td>
<td>22.75</td>
<td>.8660254</td>
<td>3</td>
<td>21.05262 24.44738</td>
</tr>
<tr>
<td>diff</td>
<td>12</td>
<td>-1.75</td>
<td>1.224745</td>
<td>-4.150456</td>
<td>.6504558</td>
</tr>
</tbody>
</table>

\[ diff = \text{mean}(\text{mpg1}) - \text{mean}(\text{mpg2}) \]
\[ z = -1.4289 \]

\( H_0: \text{diff} = 0 \)
\( H_a: \text{diff} < 0 \) \( H_a: \text{diff} \neq 0 \) \( H_a: \text{diff} > 0 \)

\( \Pr(Z < z) = 0.0765 \) \( \Pr(|Z| > |z|) = 0.1530 \) \( \Pr(Z > z) = 0.9235 \)

Paired z test

Example 4

Suppose that the preceding data were actually collected by running a test on 12 cars. Each car was run once with the fuel additive and once without. Our data are stored in the same manner as in example 3, but this time, there is most certainly a connection between the mpg values that appear in the same row. These come from the same car. The variables mpg1 and mpg2 represent mileage without and with the treatment, respectively. Suppose that the two variables have a common standard deviation of 2 and the correlation between them is 0.4.

. use https://www.stata-press.com/data/r18/fuel
. ztest mpg1==mpg2, sd(2) corr(0.4)

Paired z test

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>mpg1</td>
<td>12</td>
<td>21</td>
<td>.5773503</td>
<td>2</td>
<td>19.86841 22.13159</td>
</tr>
<tr>
<td>mpg2</td>
<td>12</td>
<td>22.75</td>
<td>.5773503</td>
<td>2</td>
<td>21.61841 23.88159</td>
</tr>
<tr>
<td>diff</td>
<td>12</td>
<td>-1.75</td>
<td>.6324555</td>
<td>2.19089</td>
<td>-2.98959 -.5104099</td>
</tr>
</tbody>
</table>

\[ \text{mean(diff)} = \text{mean}(\text{mpg1}) - \text{mean}(\text{mpg2}) \]
\[ z = -2.7670 \]

\( H_0: \text{mean(diff)} = 0 \)
\( H_a: \text{mean(diff)} < 0 \) \( H_a: \text{mean(diff)} \neq 0 \) \( H_a: \text{mean(diff)} > 0 \)

\( \Pr(Z < z) = 0.0028 \) \( \Pr(|Z| > |z|) = 0.0057 \) \( \Pr(Z > z) = 0.9972 \)

The \( p \)-value for the two-sided test is 0.0057, so we reject, for example, the null hypothesis that the two means are equal at a 5% significance level.

Equivalently, we could specify directly the standard deviation of the differences between paired observations with the \texttt{sddiff()} option:
. ztest mpg1==mpg2, sddiff(2.191)

Paired z test

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>diff</td>
<td>12</td>
<td>-1.75</td>
<td>.6324872</td>
<td>2.191</td>
<td>-2.989652 -.5103478</td>
</tr>
</tbody>
</table>

\[
\text{mean(diff)} = \text{mean(mpg1 - mpg2)} \quad z = -2.7669
\]

H0: mean(diff) = 0
Ha: mean(diff) < 0  Ha: mean(diff) != 0  Ha: mean(diff) > 0
Pr(Z < z) = 0.0028  Pr(|Z| > |z|) = 0.0057  Pr(Z > z) = 0.9972

Adjust for clustering

When observations are not independent and can be grouped into clusters, we need to adjust for clustering in a \( z \) test. For example, in a cluster randomized design, groups of individuals are randomized instead of individuals. To adjust for clustering, we need to specify the cluster identifier variable in the \texttt{cluster()} option. In the case of a one-sample \( z \) test, we need to also specify the intraclass correlation in the \texttt{rho()} option. In the case of a two-sample \( z \) test, we need to also specify the common population intraclass correlation in the \texttt{rho()} option or group-specific population intraclass correlations in the \texttt{rho1()} and \texttt{rho2()} options.

\textbf{Example 5: One-sample \( z \) test, adjusting for clusters}

Consider data on the SAT score of 75 students from 15 classes, with 5 students in each class. We want to test whether the mean verbal SAT score is different from 600. We assume a known standard deviation of 132 and a known intraclass correlation of 0.7. To perform the test, we specify the options \texttt{cluster(class)}, \texttt{rho(0.7)}, and \texttt{sd(132)}:

\[
. \text{use https://www.stata-press.com/data/r18/sat (Fictional SAT data)}
. \text{ztest score == 600, cluster(class) rho(0.7) sd(132)}
\]

One-sample \( z \) test

<table>
<thead>
<tr>
<th>Variable</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>score</td>
<td>75</td>
<td>504.8</td>
<td>29.71222</td>
<td>132</td>
<td>446.5651 563.0349</td>
</tr>
</tbody>
</table>

\[
\text{mean = mean(score)} \quad z = -3.2041
\]

H0: mean = 600
Ha: mean < 600  Ha: mean != 600  Ha: mean > 600
Pr(Z < z) = 0.0007  Pr(|Z| > |z|) = 0.0014  Pr(Z > z) = 0.9993

We find statistical evidence to reject the null hypothesis of \( H_0: \mu_{\text{SAT}} = 600 \) versus a two-sided alternative \( H_a: \mu_{\text{SAT}} \neq 600 \) at the 5% significance level; the \( p \)-value = 0.0014 < 0.05.
Example 6: Two-sample \( z \) test using groups, adjusting for clusters

Consider a cluster randomized control trial that studies the effect of additional training of nurses and general practitioners in patient-centered care on the well-being and future disease risk of patients with type 2 diabetes (Kinmonth et al. [1998] and Campbell and Walters [2014]). Practices (\texttt{practice}) are randomly allocated to two groups—one trained to give patient-centered care (intervention group) and another trained to give routine care (comparison or control group). In our analysis, we transform the original \( \text{bmi} \) using the formula \( \ln(\text{bmi} - 14.67355) \) to obtain a variable that is approximately normally distributed, \( \text{lbmi} \). We want to test the equality of the means of \( \text{lbmi} \) for the two groups. We assume a known common standard deviation of 0.35 and a known common intraclass correlation of 0.028.

To perform the test, we need to specify the \( \text{rho}(0.028) \) and \( \text{sd}(0.35) \) options. We also need to specify the cluster identifier \texttt{practice} in the \texttt{cluster()} option and the group identifier \texttt{group} in the \texttt{by()} option.

```stata
. use https://www.stata-press.com/data/r18/dcfd_trial
  (BMI data from Diabetes Care from Diagnosis trial (Kinmonth et al., 1998))

```

Two-sample \( z \) test
Cluster variable: \texttt{practice}

<table>
<thead>
<tr>
<th>Group</th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control</td>
<td>102</td>
<td>2.62954</td>
<td>.0372502</td>
<td>.35</td>
<td>2.556531 – 2.702549</td>
</tr>
<tr>
<td>Interv.</td>
<td>138</td>
<td>2.749023</td>
<td>.0332182</td>
<td>.35</td>
<td>2.683916 – 2.81413</td>
</tr>
<tr>
<td>diff</td>
<td></td>
<td>-0.1194831</td>
<td>.0499102</td>
<td>-0.2173054</td>
<td>-0.0216608</td>
</tr>
</tbody>
</table>

\( \text{diff} = \text{mean(Control)} - \text{mean(Interv.)} \)
\( z = -2.3940 \)

\( \text{HO: diff} = 0 \)

\( \text{Ha: diff} < 0 \)
\( \text{Pr}(Z < z) = 0.0083 \)
\( \text{Pr}(|Z| > |z|) = 0.9917 \)

\( \text{Ha: diff} > 0 \)
\( \text{Pr}(Z > z) = 0.0167 \)

We find statistical evidence to reject the null hypothesis of \( H_0: \mu_{\text{diff}} = 0 \) versus a two-sided alternative \( H_a: \mu_{\text{diff}} \neq 0 \) at the 5% significance level; the \( p \)-value = 0.0167 < 0.05.

Immediate form

Example 7: One-sample \( z \) test

\( \texttt{ztesti} \) is like \( \texttt{ztest} \), except that we specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the mean number of sunspots per month as 62.6 with a standard deviation of 15.8. We assume this standard deviation is the population standard deviation. There are 24 months of data. We wish to test whether the mean is 75:
. ztesti 24 62.6 15.8 75

One-sample z test

<table>
<thead>
<tr>
<th></th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>24</td>
<td>62.6</td>
<td>3.225161</td>
<td>15.8</td>
<td>56.2788 – 68.9212</td>
</tr>
</tbody>
</table>

mean = mean(x)  
H0: mean = 75  
Ha: mean < 75  
Ha: mean != 75  
Ha: mean > 75  
Pr(Z < z) = 0.0001  
Pr(|Z| > |z|) = 0.0001  
Pr(Z > z) = 0.9999

Example 8: Two-sample z test

There is no immediate form of ztest with paired data because the test is also a function of the covariance, a number unlikely to be reported in any published source. For unpaired data, however, we might type

. ztesti 20 20 5 32 15 4

Two-sample z test

<table>
<thead>
<tr>
<th></th>
<th>Obs</th>
<th>Mean</th>
<th>Std. err.</th>
<th>Std. dev.</th>
<th>[95% conf. interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>20</td>
<td>20</td>
<td>1.118034</td>
<td>5</td>
<td>17.80869 – 22.19131</td>
</tr>
<tr>
<td>y</td>
<td>32</td>
<td>15</td>
<td>.7071068</td>
<td>4</td>
<td>13.6141 – 16.3859</td>
</tr>
<tr>
<td>diff</td>
<td>5</td>
<td>1.322876</td>
<td>2.407211</td>
<td>7.592789</td>
<td></td>
</tr>
</tbody>
</table>

diff = mean(x) - mean(y)  
z = 3.7796

H0: diff = 0  
Ha: diff < 0  
Ha: diff != 0  
Ha: diff > 0  
Pr(Z < z) = 0.9999  
Pr(|Z| > |z|) = 0.0002  
Pr(Z > z) = 0.0001

Stored results

One-sample ztest and ztesti store the following in r():

Scalars

r(N) sample size
r(mu) sample mean
r(sd) standard deviation
r(se) standard error
r(lb) lower confidence bound of one-sample mean
r(ub) upper confidence bound of one-sample mean
r(z) z statistic
r(p_l) lower one-sided p-value
r(p) two-sided p-value
r(p_u) upper one-sided p-value
r(level) confidence level
Cluster-adjusted one-sample \texttt{ztest} also stores the following in \texttt{r()}: 

<table>
<thead>
<tr>
<th>Scalars</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{r(K)}</td>
<td>number of clusters ( K )</td>
</tr>
<tr>
<td>\texttt{r(M)}</td>

</table>

\textbf{Methods and formulas} 

Methods and formulas are presented under the following headings: 

- \textit{One-sample \( z \) test} 
- \textit{Two-sample unpaired \( z \) test} 
- \textit{Paired \( z \) test}
For all the tests below, the test statistic $z$ is distributed as standard normal, and the $p$-value is computed as

$$p = \begin{cases} 1 - \Phi(z) & \text{for an upper one-sided test} \\ \Phi(z) & \text{for a lower one-sided test} \\ 2 \{1 - \Phi(|z|)\} & \text{for a two-sided test} \end{cases}$$

where $\Phi(\cdot)$ is the cdf of a standard normal distribution and $|z|$ is an absolute value of $z$.

Also see, for instance, Hoel (1984, 140–161), Dixon and Massey (1983, 100–130), and Tamhane and Dunlop (2000, 237–290) for more information about $z$ tests.

One-sample $z$ test

Suppose that we observe a random sample $x_1, x_2, \ldots, x_n$ of size $n$, which follows a normal distribution with mean $\mu$ and standard deviation $\sigma$. We are interested in testing the null hypothesis $H_0: \mu = \mu_0$ versus the two-sided alternative hypothesis $H_a: \mu \neq \mu_0$, the upper one-sided alternative $H_a: \mu > \mu_0$, or the lower one-sided alternative $H_a: \mu < \mu_0$. Assuming a known standard deviation $\sigma$, we use the following test statistic,

$$z = \frac{\bar{x} - \mu_0}{s}$$

where $\bar{x} = (\sum_{i=1}^{n} x_i)/n$ is the sample mean and $s = \sigma/\sqrt{n}$ is the standard error of $\bar{x}$.

The $100(1 - \alpha)\%$ confidence interval for $\bar{x}$ is given by

$$\bar{x} \pm z_{1-\alpha/2} s$$

where $z_{1-\alpha/2}$ is the $(1 - \alpha/2)$th quantile of the standard normal distribution.

With clustered data, suppose that there are $K$ clusters. The $i$th cluster of size $M_i$ contains the observations $x_{i1}, x_{i2}, \ldots, x_{iM_i}$, such that $n = \sum_{i=1}^{K} M_i$ and $\bar{x} = \frac{1}{n} \sum_{i=1}^{K} \sum_{j=1}^{M_i} x_{ij}$. Let $\rho$ be the intraclass correlation. Following Ahn, Heo, and Zhang (2015), we assume that the cluster sizes $M_i$ are independent and identically distributed. Let $C_{adj}$ be the adjustment to the standard error for clustered data,

$$C_{adj} = \sqrt{\sum_{i=1}^{K} M_i \{1 + \rho(M_i - 1)\}/n}$$

such that $s_{cl} = C_{adj} s$.

$C_{adj}$ can be equivalently written as

$$C_{adj} = \sqrt{1 + \rho(M - 1) + \rho MC_{cl}^2}$$

where $M = \sum_{i=1}^{K} M_i/K$ is the average cluster size and $C_{cl}$ is the coefficient of variation for cluster sizes:

$$C_{cl} = \sqrt{\sum_{i=1}^{K} (M_i - \bar{M})^2/K} \bar{M}$$
To adjust the test statistic $z$ and the confidence interval for clustering, replace $s$ with $s_{cl}$ in the corresponding formulas. In the presence of clustering, the test statistic $z$ is asymptotically normally distributed conditional on the empirical distribution of $M_i$’s.

Two-sample unpaired $z$ test

Suppose that we observe a random sample $x_{11}, x_{12}, \ldots, x_{1n_1}$ of size $n_1$, which follows a normal distribution with mean $\mu_1$ and standard deviation $\sigma_1$, and another random sample $x_{21}, x_{22}, \ldots, x_{2n_2}$ of size $n_2$, which follows a normal distribution with mean $\mu_2$ and standard deviation $\sigma_2$. We are interested in testing the null hypothesis $H_0: \mu_2 = \mu_1$ versus the two-sided alternative hypothesis $H_a: \mu_2 \neq \mu_1$, the upper one-sided alternative $H_a^+: \mu_2 > \mu_1$, or the lower one-sided alternative $H_a^-: \mu_2 < \mu_1$. Assuming known standard deviations $\sigma_1$ and $\sigma_2$, we use the following test statistic,

$$z = \frac{\bar{x}_2 - \bar{x}_1}{\sqrt{s_1^2 + s_2^2}}$$

where $\bar{x}_1 = (\sum_{i=1}^{n_1} x_{1i})/n_1$ and $\bar{x}_2 = (\sum_{i=1}^{n_2} x_{2i})/n_2$ are the two sample means and $s_1 = \sigma_1/\sqrt{n_1}$ and $s_2 = \sigma_2/\sqrt{n_2}$ are the corresponding two standard errors.

The $100(1 - \alpha)%$ confidence intervals for $\bar{x}_1$ and $\bar{x}_2$ are given by

$$\bar{x}_1 \pm z_{1-\alpha/2}s_1$$
$$\bar{x}_2 \pm z_{1-\alpha/2}s_2$$

where $z_{1-\alpha/2}$ is the $(1 - \alpha/2)th$ quantile of the standard normal distribution.

The $100(1 - \alpha)%$ confidence interval for $\bar{x}_1 - \bar{x}_2$ is given by

$$\bar{x}_1 - \bar{x}_2 \pm z_{1-\alpha/2}\sqrt{s_1^2 + s_2^2}$$

With clustered data, similar to the discussion for the one-sample test, suppose that population one has $K_1$ clusters and population two has $K_2$ clusters. Let $\rho_1$ and $\rho_2$ be the intraclass correlations, $\bar{M}_1$ and $\bar{M}_2$ be the average cluster sizes, $\bar{x}_1 = (1/n_1) \sum_{i=1}^{K_1} \sum_{j=1}^{M_i} x_{1ij}$ and $\bar{x}_2 = (1/n_2) \sum_{i=1}^{K_2} \sum_{j=1}^{M_i} x_{2ij}$ be the sample means, and $CV_{cl,1}$ and $CV_{cl,2}$ be the coefficients of variation for cluster sizes for population one and population two. Let $s_{1,cl} = C_{adj,1}s_1$ and $s_{2,cl} = C_{adj,2}s_2$ be the standard errors of the population-specific sample means adjusted for clustered data, where the population-specific adjustment factors are defined as described for the one-sample test. To adjust the two-sample test statistic and the confidence intervals for clustering, replace $s_1$ with $s_{1,cl}$ and $s_2$ with $s_{2,cl}$ in the corresponding formulas.

Paired $z$ test

Some experiments have paired observations (also known as matched observations, correlated pairs, or permanent components). Consider a sequence of $n$ paired observations denoted by $x_{ij}$ for subjects $i = 1, 2, \ldots, n$ and groups $j = 1, 2$. An individual observation corresponds to the pair $(x_{i1}, x_{i2})$, and inference is made on the differences within the pairs. Let $\mu_d = \mu_2 - \mu_1$ denote the mean difference, where $\mu_j$ is the population mean of group $j$, and let $D_i = x_{i2} - x_{i1}$ denote the difference between individual observations. $D_i$ follows a normal distribution with mean $\mu_d$ and standard deviation $\sigma_d$, where $\sigma_d = \sqrt{\sigma_1^2 + \sigma_2^2 - 2 \rho_{pair}\sigma_1\sigma_2}$, $\sigma_j$ is the population standard deviation of group $j$ and $\rho_{pair}$ is the correlation between paired observations.
We are interested in testing the null hypothesis $H_0: \mu_2 = \mu_1$ versus the two-sided alternative hypothesis $H_a: \mu_2 \neq \mu_1$, the upper one-sided alternative $H_a: \mu_2 > \mu_1$, or the lower one-sided alternative $H_a: \mu_2 < \mu_1$. Assuming the standard deviation of the differences $\sigma_d$ is known, we use the following test statistic,

$$z = \frac{\overline{d}}{s_d}$$

where $\overline{d} = (\sum_{i=1}^{n} D_i)/n$ is the sample mean of the differences between paired observations and $s_d = \sigma_d/\sqrt{n}$ is the standard error of $\overline{d}$.

The 100$(1 - \alpha)$% confidence interval for $\overline{d}$ is given by

$$\overline{d} \pm z_{1-\alpha/2}s_d$$
