<div style="border:1px solid black; padding:10px;">

fvrevar — Factor-variables operator programming command

</div>

Description

fvrevar creates a variable list that includes equivalent, temporary variables in place of the factor variables, interactions, or time-series–operated variables in *varlist*. The resulting variable list can be used by commands that do not otherwise support factor variables or time-series–operated variables. The resulting list also could be used in a program to speed execution at the cost of using more memory.

Quick start

Create temporary indicator variables for the levels of categorical variable a and store names in r(varlist)

    fvrevar i.a

Create temporary variables corresponding to the levels of a, b, and their interaction

    fvrevar i.a##i.b

Same as above, and create a temporary variable for the lag of x using tsset data

    fvrevar i.a##i.b L.x

Return the list of unoperated variables (a, b, and x) in r(varlist)

    fvrevar i.a##i.b L.x, list

Create new variables a_1, a_2, ..., corresponding to the levels of a

    fvrevar i.a, stub(a_)

Create new variables ab_1, ab_2, ..., corresponding to the levels of the interaction between a and b

    fvrevar i.a#i.b, stub(ab_)

Syntax

fvrevar [*varlist*] [*if*] [*in*] [, <u>substitute</u> <u>tso</u>nly <u>list</u> stub(*stub*)]

You must tsset your data before using fvrevar if *varlist* contains time-series operators; see [TS] **tsset**.

collect is allowed; see **[U] 11.1.10 Prefix commands**.

Options

substitute specifies that equivalent, temporary variables be substituted for any factor variables, in-teractions, or time-series–operated variables in *varlist*. substitute is the default action taken by fvrevar; you do not need to specify the option.

tsonly specifies that equivalent, temporary variables be substituted for only the time-series–operated variables in *varlist*.

list specifies that all factor-variable operators and time-series operators be removed from *varlist* and the resulting list of base variables be returned in r(varlist). No new variables are created with this option.

stub(*stub*) specifies that fvrevar generate named variables instead of temporary variables. The new variables will be named *stub#*.

Remarks and examples

fvrevar might create no new variables, one new variable, or many new variables, depending on the number of factor variables, interactions, and time-series operators appearing in *varlist*. Any new variables created are temporary. The new, equivalent varlist is returned in r(varlist). The new varlist corresponds one to one with the original *varlist*.

▷ Example 1

Typing

```
. use https://www.stata-press.com/data/r19/auto2
. fvrevar i.rep78 mpg turn
```

creates five temporary variables corresponding to the levels of rep78. No new variables are created for variables mpg and turn because they do not contain factor-variable or time-series operators.

The resulting variable list is

```
. display "'r(varlist)'"
__000000 __000001 __000002 __000003 __000004  mpg turn
```

(Your temporary variable names may be different, but that is of no consequence.)

Temporary variables automatically vanish when the program concludes.

◁

▷ Example 2

Suppose we want to create temporary variables for specific levels of a factor variable. To do this, we can use the parenthesis notation of factor-variable syntax.

```
. fvrevar i(2,3)bn.rep78 mpg
```

creates two temporary variables corresponding to levels 2 and 3 of rep78. Notice that we specified that neither level 2 nor 3 be set as the base level by using the bn notation. If we did not specify bn, level 2 would have been treated as the base level.

The resulting variable list is

```
. display "`r(varlist)'"
__000005 __000002 mpg
```

We can see the results by listing the new variables alongside the original value of rep78.

```
. list rep78 `r(varlist)' in 1/5
```

	rep78	__000005	__000002	mpg
1.	Average	0	1	22
2.	Average	0	1	17
3.	.	.	.	22
4.	Average	0	1	20
5.	Good	0	0	15

If we had needed only the base-variable names, we could have specified

```
. fvrevar i(2,3)bn.rep78 mpg, list
. display "`r(varlist)'"
mpg rep78
```

The order of the list will probably differ from that of the original list; base variables are listed only once.

◁

▷ Example 3

Now let's assume we have *varlist* containing both an interaction and time-series–operated variables. If we want to create temporary variables for the entire equivalent *varlist*, we can specify fvrevar with no options.

```
. generate t = _n
. tsset t
        time variable:  t, 1 to 74
                delta:  1 unit
. fvrevar c.turn#i(2,3).rep78 L.mpg
```

The resulting variable list is

```
. display "`r(varlist)'"
__000006 __000007 __000008
```

If we want to create temporary variables only for the time-series–operated variables, we can specify the `tsonly` option.

```
. fvrevar c.turn#i(2,3).rep78 L.mpg, tsonly
```

The resulting variable list is

```
. display "'r(varlist)'"
2.rep78#c.turn 3.rep78#c.turn __000008
```

Notice that `fvrevar` returned the expanded factor-variable list with the `tsonly` option.

◁

❑ Technical note

`fvrevar, substitute` avoids creating duplicate variables. Consider

```
. fvrevar i.rep78 turn mpg i.rep78
```

`i.rep78` appears twice in the varlist. `fvrevar` will create only one set of new variables for the five levels of `rep78` and will use these new variables once in the resulting `r(varlist)`. Moreover, `fvrevar` will do this even across multiple calls:

```
. fvrevar i.rep78 turn mpg
. fvrevar i.rep78
```

`i.rep78` appears in two separate calls. At the first call, `fvrevar` creates five temporary variables corresponding to the five levels of `rep78`. At the second call, `fvrevar` remembers what it has done and uses the same temporary variables for `i.rep78`.

❑

Stored results

`fvrevar` stores the following in `r()`:

Macros
    `r(varlist)`   the modified variable list or list of base-variable names
