**Description**

*lsens* graphs sensitivity and specificity versus probability cutoff and optionally creates new variables containing these data.

*lsens* requires that the current estimation results be from *logistic*, *logit*, *probit*, or *ivprobit*; see [R] *logistic*, [R] *logit*, [R] *probit*, or [R] *ivprobit*.

**Quick start**

Graph sensitivity and specificity versus a probability cutoff using current estimation results

```
  lsens
```

Generate variables v1, v2, and v3 to contain probability cutoffs, sensitivity, and specificity

```
  lsens, genprob(v1) gensens(v2) genspec(v3)
```

Add “My Title” to graph

```
  lsens, genprob(v1) gensens(v2) genspec(v3) title(My Title)
```

**Menu**

Statistics > Binary outcomes > Postestimation > Sensitivity/specificity plot
Syntax

\[ \text{lsens} \ [\text{depvar}] \ [\text{if}] \ [\text{in}] \ [\text{weight}] \ [, \ options] \]

Options

Main

- \text{all} \quad \text{graph all observations in the data}
- \text{genprob(\text{varname})} \quad \text{create variable containing probability cutoffs}
- \text{gensens(\text{varname})} \quad \text{create variable containing sensitivity}
- \text{genspec(\text{varname})} \quad \text{create variable containing specificity}
- \text{replace} \quad \text{overwrite existing variables}
- \text{nograph} \quad \text{suppress the graph}

Advanced

- \text{beta(\text{matname})} \quad \text{row vector containing model coefficients}

Plot

- \text{connect\_options} \quad \text{affect rendition of the plotted points connected by lines}

Add plots

- \text{addplot(\text{plot})} \quad \text{add other plots to the generated graph}

Y axis, X axis, Titles, Legend, Overall

- \text{twoway\_options} \quad \text{any options other than by()} documented in [G-3] \text{twoway\_options}

fweights are allowed; see [U] 11.1.6 weight.

\text{lsens} \text{ is not appropriate after the \text{svy} prefix.}

Options

- \text{all} \quad \text{requests that the statistic be computed for all observations in the data, ignoring any if or in restrictions specified by the estimation command.}
- \text{genprob(\text{varname}), gensens(\text{varname}), and genspec(\text{varname})} \quad \text{specify the names of new variables created to contain, respectively, the probability cutoffs and the corresponding sensitivity and specificity.}
- \text{replace} \quad \text{requests that existing variables specified for genprob(), gensens(), or genspec() be overwritten.}
- \text{nograph} \quad \text{suppresses graphical output.}

- \text{beta(\text{matname})} \quad \text{specifies a row vector containing model coefficients. The columns of the row vector must be labeled with the corresponding names of the independent variables in the data. The dependent variable \text{depvar} must be specified immediately after the command name. See Models other than the last fitted model later in this entry.}
connect\_options affect the rendition of the plotted points connected by lines; see connect\_options in [G-2] \texttt{graph twoway scatter}.

\texttt{addplot(plot)} provides a way to add other plots to the generated graph. See [G-3] \texttt{addplot\_option}.

\texttt{twoway\_options} are any of the options documented in [G-3] \texttt{twoway\_options}, excluding \texttt{by()}. These include options for titling the graph (see [G-3] \texttt{title\_options}) and for saving the graph to disk (see [G-3] \texttt{saving\_option}).

\section*{Remarks and examples}

Remarks are presented under the following headings:

\begin{itemize}
\item \textit{Introduction}
\item \textit{Models other than the last fitted model}
\end{itemize}

\subsection*{Introduction}

\texttt{lsens} plots sensitivity and specificity; it plots both sensitivity and specificity versus probability cutoff $c$. The graph is equivalent to what you would get from \texttt{estat classification} (see [R] \texttt{estat classification}) if you varied the cutoff probability $c$ from 0 to 1.

\subsection*{Example 1}

We illustrate \texttt{lsens} after \texttt{logistic}; see [R] \texttt{logistic}.

\begin{verbatim}
. use http://www.stata-press.com/data/r15/lbw
(Hosmer & Lemeshow data)
. logistic low age i.race smoke ui
(output omitted)
. lsens
\end{verbatim}

\begin{figure}
\centering
\includegraphics[width=\textwidth]{sensitivity_specificity_plot}
\caption{Sensitivity and Specificity versus Probability Cutoff}
\end{figure}
lsens optionally creates new variables containing the probability cutoff, sensitivity, and specificity.

```
  . lsens, genprob(p) gensens(sens) genspec(spec) nograph
```

The variables created will have $M + 2$ distinct nonmissing values: one for each of the $M$ covariate patterns, one for $c = 0$, and another for $c = 1$. Values are recorded for $p = 0$, for each of the observed predicted probabilities, and for $p = 1$. The total number of observations required to do this can be fewer than $N$, the same as $N$, or $N + 1$, or $N + 2$. If more observations are added, they are added at the end of the dataset and the values of the original variables are set to missing in the added observations. How the values added align with existing observations is irrelevant.

### Technical note

logistic, logit, probit, or ivprobit and lsens keep track of the estimation sample. If you type, for instance, logistic... if x==1, then when you type lsens, the statistics will be calculated on the x==1 subsample of the data automatically.

You should specify if or in with lsens only when you wish to produce graphs and calculate statistics for a set of observations other than the estimation sample.

If the logistic model was fit with fweights, lsens properly accounts for the weights in its calculations. You do not have to specify the weights when you run lsens. Weights should be specified with lsens only when you wish to use a different set of weights.

### Models other than the last fitted model

By default, lsens uses the last model fit. You may also directly specify the model to lsens by inputting a vector of coefficients with the beta() option and passing the name of the dependent variable depvar to lsens.

#### Example 2

Suppose that someone publishes the following logistic model of low birthweight:

$$
Pr(\text{low} = 1) = F(-0.02\, \text{age} - 0.01\, lwt + 1.3\, \text{black} + 1.1\, \text{smoke} + 0.5\, \text{ptl} + 1.8\, \text{ht} + 0.8\, \text{ui} + 0.5)
$$

where $F$ is the cumulative logistic distribution. These coefficients are not odds ratios; they are the equivalent of what logit produces.

We can see whether this model fits our data. First we enter the coefficients as a row vector and label its columns with the names of the independent variables plus _cons for the constant (see [P] matrix define and [P] matrix rownames).

```
  . use http://www.stata-press.com/data/r15/lbw3, clear
  (Hosmer & Lemeshow data)
  . matrix input b = (-0.02, -.01, 1.3, 1.1, .5, 1.8, .8, .5)
  . matrix colnames b = age lwt black smoke ptl ht ui _cons
```
We can use \texttt{lroc} (see \texttt{[R] lroc}) to examine the predictive ability of the model:

\begin{verbatim}
. lroc low, beta(b) nograph
Logistic model for low
  number of observations = 189
  area under ROC curve = 0.7275
\end{verbatim}

The area under the curve indicates that this model does have some predictive power. We can obtain a graph of sensitivity and specificity as a function of the cutoff probability by typing

\begin{verbatim}
. lsens low, beta(b)
\end{verbatim}

\begin{figure}
\centering
\includegraphics[width=0.8\textwidth]{sensitivity_specificity_graph.png}
\caption{Graph of sensitivity and specificity versus probability cutoff.}
\end{figure}

\section*{Stored results}
\texttt{lsens} stores the following in \texttt{r()}:  
\begin{itemize}
  \item Scalars
    \begin{itemize}
      \item \texttt{r(N)} number of observations
    \end{itemize}
\end{itemize}

\section*{Methods and formulas}

Let \( j \) index observations and \( c \) be the cutoff probability. Let \( p_j \) be the predicted probability of a positive outcome and \( y_j \) be the actual outcome, which we will treat as 0 or 1, although Stata treats it as 0 and non-0, excluding missing observations.

A prediction is classified as \textit{positive} if \( p_j \geq c \) and otherwise is classified as \textit{negative}. The classification is \textit{correct} if it is \textit{positive} and \( y_j = 1 \) or if it is \textit{negative} and \( y_j = 0 \).

\textit{Sensitivity} is the fraction of \( y_j = 1 \) observations that are correctly classified. \textit{Specificity} is the percentage of \( y_j = 0 \) observations that are correctly classified.
