Postestimation commands

The following postestimation command is of special interest after `nlogit`:

| Command | Description |
|------------------------------------|--------------------------------|
| estat alternatives | alternative summary statistics |

The following standard postestimation commands are also available:

| Command | Description |
|---------------------------------|---|
| contrast | contrasts and ANOVA-style joint tests of estimates |
| estat ic | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC) |
| estat summarize | summary statistics for the estimation sample |
| estat vce | variance–covariance matrix of the estimators (VCE) |
| estimates | cataloging estimation results |
| hausman | Hausman's specification test |
| lincom | point estimates, standard errors, testing, and inference for linear combinations of coefficients |
| lrtest | likelihood-ratio test |
| nlcom | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| predict | predictions, residuals, influence statistics, and other diagnostic measures |
| predictnl | point estimates, standard errors, testing, and inference for generalized predictions |
| pwcompare | pairwise comparisons of estimates |
| test | Wald tests of simple and composite linear hypotheses |
| testnl | Wald tests of nonlinear hypotheses |

predict

Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, conditional probabilities, and inclusive values.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic hlevel(#) altwise]
```

```
predict [type] {stub*|newvarlist} [if] [in], scores
```

statistic Description

Main

| | |
|--------------------|---|
| <code>pr</code> | predicted probabilities of choosing the alternatives at all levels of the hierarchy or at level #, where # is specified by <code>hlevel(#)</code> ; the default |
| <code>xb</code> | linear predictors for all levels of the hierarchy or at level #, where # is specified by <code>hlevel(#)</code> |
| <code>condp</code> | predicted conditional probabilities at all levels of the hierarchy or at level #, where # is specified by <code>hlevel(#)</code> |
| <code>iv</code> | inclusive values for levels 2, ..., <code>e(levels)</code> or for <code>hlevel(#)</code> |

The inclusive value for the first-level alternatives is not used in estimation; therefore, it is not calculated.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Options for predict

Main

`pr` calculates the probability of choosing each alternative at each level of the hierarchy. Use the `hlevel(#)` option to compute the alternative probabilities at level #. When `hlevel(#)` is not specified, j new variables must be given, where j is the number of levels, or use `stub*` to have `predict` generate j variables with the prefix `stub` and numbered from 1 to j . The `pr` option is the default and if one new variable is given, the probability of the bottom-level alternatives are computed. Otherwise, probabilities for all levels are computed and `stub*` is still valid.

`xb` calculates the linear prediction for each alternative at each level. Use the `hlevel(#)` option to compute the linear predictor at level #. When `hlevel(#)` is not specified, j new variables must be given, where j is the number of levels, or use `stub*` to have `predict` generate j variables with the prefix `stub` and numbered from 1 to j .

`condp` calculates the conditional probabilities for each alternative at each level. Use the `hlevel(#)` option to compute the conditional probabilities of the alternatives at level #. When `hlevel(#)` is not specified, j new variables must be given, where j is the number of levels, or use `stub*` to have `predict` generate j variables with the prefix `stub` and numbered from 1 to j .

`iv` calculates the inclusive value for each alternative at each level. Use the `hlevel(#)` option to compute the inclusive value at level `#`. There is no inclusive value at level 1. If `hlevel(#)` is not used, $j - 1$ new variables are required, where j is the number of levels, or use `stub*` to have `predict` generate $j - 1$ variables with the prefix `stub` and numbered from 2 to j . See [Methods and formulas](#) in [R] `nlogit` for a definition of the inclusive values.

`hlevel(#)` calculates the prediction only for hierarchy level `#`.

`altwise` specifies that alternativewise deletion be used when marking out observations due to missing values in your variables. The default is to use casewise deletion. The `xb` option always uses alternativewise deletion.

`scores` calculates the scores for each coefficient in `e(b)`. This option requires a new-variable list of length equal to the number of columns in `e(b)`. Otherwise, use `stub*` to have `predict` generate enumerated variables with prefix `stub`.

estat

Description for estat

`estat alternatives` displays summary statistics about the alternatives in the estimation sample for each level of the tree structure.

Menu for estat

Statistics > Postestimation

Syntax for estat

```
estat alternatives
```

Remarks and examples

[stata.com](http://www.stata.com)

`predict` may be used after `nlogit` to obtain the predicted values of the probabilities, the conditional probabilities, the linear predictions, and the inclusive values for each level of the nested logit model. Predicted probabilities for `nlogit` must be interpreted carefully. Probabilities are estimated for each case as a whole and not for individual observations.

► Example 1

Continuing with our model in [example 3](#) of [R] `nlogit`, we refit the model and then examine a summary of the alternatives and their frequencies in the estimation sample.

```
. use http://www.stata-press.com/data/r15/restaurant
. nlogitgen type = restaurant(fast: Freebirds | MamasPizza,
> family: CafeEccell | LosNortenos | WingsNmore, fancy: Christophers | MadCows)
(output omitted)
. nlogit chosen cost rating distance || type: income kids, base(family) ||
> restaurant:, noconst case(family_id)
(output omitted)
```

```
. estat alternatives
```

```
Alternatives summary for type
```

| index | Alternative value | label | Cases present | Frequency selected | Percent selected |
|-------|-------------------|--------|---------------|--------------------|------------------|
| 1 | 1 | fast | 600 | 27 | 9.00 |
| 2 | 2 | family | 900 | 222 | 74.00 |
| 3 | 3 | fancy | 600 | 51 | 17.00 |

```
Alternatives summary for restaurant
```

| index | Alternative value | label | Cases present | Frequency selected | Percent selected |
|-------|-------------------|--------------|---------------|--------------------|------------------|
| 1 | 1 | Freebirds | 300 | 12 | 4.00 |
| 2 | 2 | MamasPizza | 300 | 15 | 5.00 |
| 3 | 3 | CafeEccell | 300 | 78 | 26.00 |
| 4 | 4 | LosNortenos | 300 | 75 | 25.00 |
| 5 | 5 | WingsNmore | 300 | 69 | 23.00 |
| 6 | 6 | Christophers | 300 | 27 | 9.00 |
| 7 | 7 | MadCows | 300 | 24 | 8.00 |

Next we predict $p_2 = \Pr(\text{restaurant})$; $p_1 = \Pr(\text{type})$; $\text{condp} = \Pr(\text{restaurant} \mid \text{type})$; xb_2 , the linear prediction for the bottom-level alternatives; xb_1 , the linear prediction for the first-level alternatives; and iv , the inclusive values for the bottom-level alternatives.

```
. predict p*
(option pr assumed)
. predict condp, condp hlevel(2)
. sort family_id type restaurant
. list restaurant type chosen p2 p1 condp in 1/14, sepby(family_id) divider
```

| | restaurant | type | chosen | p2 | p1 | condp |
|-----|--------------|--------|--------|----------|----------|----------|
| 1. | Freebirds | fast | 1 | .0642332 | .1189609 | .5399519 |
