## Postestimation commands

The following postestimation commands are available after `oprobit`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>contrast</strong></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td><strong>estat ic</strong></td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td><strong>estat summarize</strong></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><strong>estat vce</strong></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><strong>estat (svy)</strong></td>
<td>postestimation statistics for survey data</td>
</tr>
<tr>
<td><strong>estimates</strong></td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td><strong>forecast</strong></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><strong>hausman</strong></td>
<td>Hausman’s specification test</td>
</tr>
<tr>
<td><strong>lincom</strong></td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td><strong>linktest</strong></td>
<td>link test for model specification</td>
</tr>
<tr>
<td><strong>lrtest</strong></td>
<td>likelihood-ratio test</td>
</tr>
<tr>
<td><strong>margins</strong></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td><strong>marginsplot</strong></td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td><strong>nlcom</strong></td>
<td>point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients</td>
</tr>
<tr>
<td><strong>predict</strong></td>
<td>predictions, residuals, influence statistics, and other diagnostic measures</td>
</tr>
<tr>
<td><strong>predictnl</strong></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td><strong>pwcompare</strong></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><strong>suest</strong></td>
<td>seemingly unrelated estimation</td>
</tr>
<tr>
<td><strong>test</strong></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><strong>testnl</strong></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.
predict

Description for predict

predict creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
outcome(outcome) nooffset]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pr</td>
<td>predicted probabilities; the default</td>
</tr>
<tr>
<td>xb</td>
<td>linear prediction</td>
</tr>
<tr>
<td>stdp</td>
<td>standard error of the linear prediction</td>
</tr>
<tr>
<td>scores</td>
<td>equation-level scores</td>
</tr>
</tbody>
</table>

You specify one or $k$ new variables with `pr`, where $k$ is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb` and `stdp`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

Options for predict

```
pr, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To
compute probabilities for all outcomes, you specify $k$ new variables, where $k$ is the number of
categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will
store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for
a specific outcome, you specify one new variable and, optionally, the outcome value in option
`outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and $y$ takes on four values. Then, you
could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could
type `predict p*` to generate the four predicted probabilities. To compute specific probabilities
one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction. You specify one new variable, for example, `predict linear, xb`. The linear prediction is defined, ignoring the contribution of the estimated cutpoints.
stdp calculates the standard error of the linear prediction. You specify one new variable, for example,
\texttt{predict se, stdp}.

\texttt{outcome(outcome)} specifies for which outcome the predicted probabilities are to be calculated.
\texttt{outcome()} should contain either one value of the dependent variable or one of \#1, \#2, \ldots, with
\#1 meaning the first category of the dependent variable, \#2 meaning the second category, etc.
\texttt{outcome()} is available only with the default \texttt{pr} option.

\texttt{nooffset} is relevant only if you specified \texttt{offset(varname)} for \texttt{oprobit}. It modifies the calculations
made by \texttt{predict} so that they ignore the offset variable; the linear prediction is treated as $x_jb$
rather than as $x_jb + \text{offset}_j$. \texttt{nooffset} is not allowed with \texttt{scores}.

\texttt{scores} calculates equation-level score variables. The number of score variables created will equal
the number of outcomes in the model. If the number of outcomes in the model was $k$, then
the first new variable will contain $\partial \ln L / \partial (x_jb)$;
the second new variable will contain $\partial \ln L / \partial \kappa_1$;
the third new variable will contain $\partial \ln L / \partial \kappa_2$;
\ldots
and the $k$th new variable will contain $\partial \ln L / \partial \kappa_{k-1}$, where $\kappa_i$ refers to the $i$th cutpoint.

\section*{margins}

\subsection*{Description for margins}
\texttt{margins} estimates margins of response for probabilities and linear predictions.

\subsection*{Menu for margins}
Statistics > Postestimation

\subsection*{Syntax for margins}
\begin{verbatim}
margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
\end{verbatim}

\begin{tabular}{ll}
\texttt{statistic} & Description \\
\hline
default & probabilities for each outcome \\
\texttt{pr} & probability for a specified outcome \\
\texttt{xb} & linear prediction \\
\texttt{stdp} & not allowed with \texttt{margins} \\
\end{tabular}

\texttt{pr} defaults to the first outcome.

Statistics not allowed with \texttt{margins} are functions of stochastic quantities other than $e(b)$.
For the full syntax, see \texttt{[R] margins}.
Remarks and examples

See [U] 20 Estimation and postestimation commands for instructions on obtaining the variance-covariance matrix of the estimators, predicted values, and hypothesis tests. Also see [R] lrtest for performing likelihood-ratio tests.

Example 1

In example 1 of [R] oprobit, we fit the model oprobit rep77 foreign length mpg. The predict command can be used to obtain the predicted probabilities. We type predict followed by the names of the new variables to hold the predicted probabilities, ordering the names from low to high. In our data, the lowest outcome is “poor” and the highest is “excellent”. We have five categories, so we must type five names following predict; the choice of names is up to us:

```
. use https://www.stata-press.com/data/r16/fullauto
(Automobile Models)
. oprobit rep77 foreign length mpg
(output omitted)
. predict poor fair avg good exc
(option pr assumed; predicted probabilities)
. list make model exc good if rep77>=., sep(4) divider
```

```

</tbody>
</table>
+------------+-----------------+--------+--------+
```

Technical note

For ordered probit, predict, xb produces \( S_j = x_1 \beta_1 + x_2 \beta_2 + \cdots + x_k \beta_k \). Ordered probit is identical to ordered logit, except that we use different distribution functions for calculating probabilities. The ordered-probit predictions are then the probability that \( S_j + u \) lies between a pair of cutpoints \( \kappa_{i-1} \) and \( \kappa_i \). The formulas for ordered probit are

\[
\Pr(S_j + u < \kappa_i) = \Phi(\kappa_i - S_j)
\]
\[
\Pr(S_j + u > \kappa_i) = 1 - \Phi(\kappa_i - S_j) = \Phi(S_j - \kappa_i)
\]
\[
\Pr(\kappa_1 < S_j + u < \kappa_2) = \Phi(\kappa_2 - S_j) - \Phi(\kappa_1 - S_j)
\]

Rather than using predict directly, we could calculate the predicted probabilities by hand.

```
. predict pscore, xb
. generate probexc = normal(pscore-_b[/cut4])
. generate probgood = normal(_b[/cut4]-pscore) - normal(_b[/cut3]-pscore)
```
