Description

tpoisson fits a truncated Poisson regression model when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. Truncated Poisson models are appropriate when neither the dependent variable nor the covariates are observed in the truncated part of the distribution. By default, tpoisson assumes left-truncation occurs at zero, but truncation may be specified at other fixed points or at values that vary across observations.

Quick start

Truncated Poisson regression of y on x1 and x2 with left-truncation at 0
   tpoisson y x1 x2

Add categorical variable a using factor-variable syntax
   tpoisson y x1 x2 i.a

As above, but report incidence-rate ratios and use a constant truncation point of 4
   tpoisson y x1 x2 i.a, irr ll(4)

With offset variable lnexp
   tpoisson y x1 x2 i.a, offset(lnexp)

As above, but with a variable truncation point stored in variable min
   tpoisson y x1 x2 i.a, offset(lnexp) ll(min)

With variable left- and right-truncation points
   tpoisson y x1 x2, ll(min) ul(max)

With variable right-truncation points
   tpoisson y x1 x2, ul(max)

Constrain the coefficients for 2.a and 3.a to equality
   constraint define 1 2.a = 3.a
   tpoisson y x1 x2 i.a, constraints(1)

Statistics > Count outcomes > Truncated Poisson regression
2  tpoisson — Truncated Poisson regression

Syntax

tpoisson  depvar  [ indepvars ]  [ if ]  [ in ]  [ weight ]  [,  options ]

options             Description

Model
   noconstant         suppress constant term
   ll(#)  |  varname   lower limit for truncation; default is ll(0) when neither
           11() nor ul() is specified
   ul(#)  |  varname   upper limit for truncation
   exposure(varname_o) include ln(varname_o) in model with coefficient constrained to 1
   offset(varname_o)  include varname_o in model with coefficient constrained to 1
   constraints(constraints) apply specified linear constraints

SE/Robust
   vce(vcetype)     vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife

Reporting
   level(#)         set confidence level; default is level(95)
   irr              report incidence-rate ratios
   nocnsreport      do not display constraints
   display_options  control columns and column formats, row spacing, line width,
                    display of omitted variables and base and empty cells, and
                    factor-variable labeling

Maximization
   maximize_options control the maximization process; seldom used
   collinear         keep collinear variables
   coeflegend       display legend instead of statistics

Options

   indepvars may contain factor variables; see [U] 11.4.3 Factor variables.
   depvar and indepvars may contain time-series operators; see [U] 11.4.4 Time-series varlists.
   bayes, bootstrap, by, collect, fmm, fp, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix
   commands. For more details, see [BAYES] bayes: tpoisson and [FMM] fmm: tpoisson.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
   vce() and weights are not allowed with the svy prefix; see [SVY] svy.
   fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.
   collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Options

   noconstant; see [R] Estimation options.

   ll(#)  |  varname   and ul(#)  |  varname   specify the lower and upper limits for truncation, respectively.
          You may specify nonnegative integer values for one or both.
          When neither ll() nor ul() is specified, the default is zero truncation, ll(0), equivalent to
          left-truncation at zero.
tpoisson — Truncated Poisson regression

exposure(varname), offset(varname), constraints(constraints); see [R] Estimation options.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

Reporting

level(#) ; see [R] Estimation options.
irr reports estimated coefficients transformed to incidence-rate ratios, that is, $e^{\beta_i}$ rather than $\beta_i$. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. irr may be specified at estimation or when replaying previously estimated results.
nocnsreport; see [R] Estimation options.
display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabels, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

Maximization

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following options are available with tpoisson but are not shown in the dialog box: collinear, coeflegend; see [R] Estimation options.

Remarks and examples

tpoisson fits a truncated Poisson regression model by maximum likelihood estimation when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. If the dependent variable is not truncated, standard Poisson regression may be more appropriate; see [R] poisson.

When the data are truncated, we do not observe either the dependent variable or the covariates. For example, consider a study about the number of days that individuals with hyperglycemia are hospitalized after presenting to the hospital. If we select our sample only from admission records, then the sample is truncated at zero because we have data only on individuals who stayed at least one day. Now assume that we are relying on billing data and that hospitals may submit either a final bill when a patient is discharged or an interim bill every 30 days. In this case, we have no information about patients who are hospitalized fewer than 1 day or more than 30 days. Our data are left-truncated at 0 and right-truncated at 30.

A related phenomenon is censoring. For censored observations, we observe complete covariate information but only a censored value of the dependent variable. Different research designs can give rise to censored data or truncated data. See [R] cpoisson for information about censored Poisson regression.

Example 1: Left-truncation at zero

Consider the Simonoff (2003) dataset of running shoes for a sample of runners who registered an online running log. A running-shoe marketing executive is interested in knowing how the number of pairs of running shoes purchased relates to other factors such as gender, marital status, age, education, income, typical number of runs per week, average miles run per week, and the preferred type of running. These data are naturally truncated at zero. A truncated Poisson model is fit to the number of pairs of shoes owned on runs per week, miles run per week, gender, age, and marital status.

No options are needed because zero truncation is the default for tpoisson.

```

Iteration 2: log likelihood = -86.257999
Iteration 3: log likelihood = -86.257994
Truncated Poisson regression                 Number of obs = 60
                                         Limits: lower = 0  LR chi2(5) = 22.75
                                         upper = +inf  Prob > chi2 = 0.0004
                                         Log likelihood = -86.257994  Pseudo R2 = 0.1165

shoes | Coefficient  Std. err.   z    P>abs(z) [95% conf. interval]
-------+---------------------------------------------------------------
 rpweek  |   .1575811   .1097893  1.44  .151   -.057602   .3727641
 mpweek  |   .0210673   .0091113  2.31  .021    .003209   .0389252
    male  |   .0446134   .0091113  4.89  <.001   .026496   .0627308
     age  |   .0185565   .0137786  1.35  .178   -.008449   .0455627
married |  -.1283912   .2785044 -0.46  .645   -.6742498  .4174674
    _cons|  -.1205844   .6619774 -1.82  .069  -.2503296  .0091078
```

Using the zero-truncated Poisson regression with these data, only the coefficient on average miles per week is statistically significant at the 5% level.

Example 2: Left-truncation with a fixed-truncation point

Semiconductor manufacturing requires that silicon wafers be coated with a layer of metal oxide. The depth of this layer is strictly controlled. In this example, a critical oxide layer is designed for 300 ± 20 angstroms (Å).

After the oxide layer is coated onto a wafer, the wafer enters a photolithography step in which the lines representing the electrical connections are printed on the oxide and later etched and filled with metal. The widths of these lines are measured. In this example, they are controlled to 90 ± 5 micrometers (µm).

After these and other steps, each wafer is electrically tested at probe. If too many failures are discovered, the wafer is rejected and sent for engineering analysis. In this example, the maximum number of probe failures tolerated for this product is 10.
A major failure at probe has been encountered—88 wafers had more than 10 failures each. The 88 wafers that failed were tested using 4 probe machines. The engineer suspects that the failures were a result of faulty probe machines, poor depth control, or poor line widths. The line widths and depths in these data are the actual measurement minus its specification target, 300 Å for the oxide depths and 90 µm for the line widths.

The following table tabulates the average failure rate for each probe using Stata’s `mean` command; see [R] `mean`.

```
. use https://www.stata-press.com/data/r17/probe
(Silicon wafers)
. mean failures, over(probe)
Mean estimation Number of obs = 88

Mean Std. err. [95% conf. interval]
c.failures@probe
1 15.875 1.186293 13.51711 18.23289
2 14.95833 .5912379 13.78318 16.13348
3 16.47059 .9279866 14.62611 18.31506
4 23.09677 .9451117 21.21826 24.97529
```

The 95% confidence intervals in this table suggest that there are about 5–11 additional failures per wafer on probe 4. These are unadjusted for varying line widths and oxide depths. Possibly, probe 4 received the wafers with larger line widths or extreme oxide depths.

Truncated Poisson regression more clearly identifies the root causes for the increased failures by estimating the differences between probes adjusted for the line widths and oxide depths. It also allows us to determine whether the deviations from specifications in line widths or oxide depths might be contributing to the problem.

```
. tpoisson failures i.probe depth width, ll(10) nolog
Truncated Poisson regression Number of obs = 88

Limits: lower = 10 LR chi2(5) = 73.70
upper = +inf Prob > chi2 = 0.0000

_cons 2.714025 .0752617 36.06 0.000 2.566515 2.861536
```

The coefficients listed for the probes are testing the null hypothesis: \( H_0: \text{probe}_i = \text{probe}_1 \), where \( i \) equals 2, 3, and 4. Because the only coefficient that is statistically significant is the one for testing for \( H_0: \text{probe}_4 = \text{probe}_1 \), \( p < 0.001 \), and because the \( p \)-values for the other probes are not statistically significant, that is, \( p \geq 0.275 \), the implication is that there is a difference between probe 4 and the other machines. Because the coefficient for this test is positive, 0.425, the conclusion is that the average failure rate for probe 4, after adjusting for line widths and oxide depths, is higher than the other probes. Possibly, probe 4 needs calibration or the head used with this machine is defective.

Line-width control is statistically significant, \( p = 0.034 \), but variation in oxide depths is not causing the increased failure rate. The engineer concluded that the sudden increase in failures is the result of
two problems. First, probe 4 is malfunctioning, and second, there is a possible lithography or etching problem.

Stored results

tpoisson stores the following in e():

Scalars

- \( e(N) \) number of observations
- \( e(k) \) number of parameters
- \( e(k_{eq}) \) number of equations in \( e(b) \)
- \( e(k_{eq \_model}) \) number of equations in overall model test
- \( e(k_{dv}) \) number of dependent variables
- \( e(df\_m) \) model degrees of freedom
- \( e(r2\_p) \) pseudo-\( R^2 \)
- \( e(ll) \) log likelihood
- \( e(ll\_0) \) log likelihood, constant-only model
- \( e(N\_clust) \) number of clusters
- \( e(chi2) \) \( \chi^2 \)
- \( e(p) \) \( p \)-value for model test
- \( e(rank) \) rank of \( e(V) \)
- \( e(ic) \) number of iterations
- \( e(rc) \) return code
- \( e(converged) \) 1 if converged, 0 otherwise

Macros

- \( e(cmd) \) tpoisson
- \( e(cmdline) \) command as typed
- \( e(depvar) \) name of dependent variable
- \( e(llopt) \) contents of \( l1() \), or 0 if neither \( ll() \) nor \( ul() \) is specified
- \( e(ulopt) \) contents of \( ul() \), if specified
- \( e(wtype) \) weight type
- \( e(wexp) \) weight expression
- \( e(title) \) title in estimation output
- \( e(clustvar) \) name of cluster variable
- \( e(offset) \) linear offset variable
- \( e(chi2type) \) Wald or LR; type of model \( \chi^2 \) test
- \( e(vce) \) \( vcetype \) specified in \( vce() \)
- \( e(vcetype) \) title used to label Std. err.
- \( e(opt) \) type of optimization
- \( e(which) \) max or min; whether optimizer is to perform maximization or minimization
- \( e(ml\_method) \) type of \( ml \) method
- \( e(user) \) name of likelihood-evaluator program
- \( e(technique) \) maximization technique
- \( e(properties) \) \( b \ V \)
- \( e(predict) \) program used to implement predict
- \( e(asbalanced) \) factor variables \( fvset \) as \( asbalanced \)
- \( e(asobserved) \) factor variables \( fvset \) as \( asobserved \)

Matrices

- \( e(b) \) coefficient vector
- \( e(Cns) \) constraints matrix
- \( e(l1log) \) iteration log (up to 20 iterations)
- \( e(gradient) \) gradient vector
- \( e(V) \) variance–covariance matrix of the estimators
- \( e(V\_modelbased) \) model-based variance

Functions

- \( e(sample) \) marks estimation sample
In addition to the above, the following is stored in \( r() \):

Matrices

\[ r(\text{table}) \]

matrix containing the coefficients with their standard errors, test statistics, \( p \)-values, and confidence intervals

Note that results stored in \( r() \) are updated when the command is replayed and will be replaced when any \( r \)-class command is run after the estimation command.

Methods and formulas

For a nonnegative count outcome \( Y \) with left-truncation point \( ll_j \) and right-truncation point \( ul_j \), we can write the truncated Poisson model as

\[
f(y_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | \xi_j)}
\]

where

\[
\xi_j = x_j \beta + \text{offset}_j
\]

\[
\lambda_j = \exp(\xi_j)
\]

and \( x_j \) is a vector of observed covariates. The conditional probability of observing \( y_j \) events, therefore given by \( ll_j < y_j < ul_j \), is

\[
\Pr(Y = y_j | ll_j < y_j < ul_j, x_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | x_j)}
\]

The log likelihood is given by

\[
\ln L = \sum_{j=1}^{n} w_j [-\lambda_j + \xi_j y_j - \ln(y_j!) - \ln \{ \Pr(ll_j < Y < ul_j | \xi_j) \}]
\]

If no weights are specified, \( w_j = 1 \).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \texttt{vce(robust)} and \texttt{vce(cluster clustvar)}, respectively. See \texttt{[P] _robust}, particularly \texttt{Maximum likelihood estimators} and \texttt{Methods and formulas}.

\texttt{tpoisson} also supports estimation with survey data. For details on VCEs with survey data, see \texttt{[SVY] Variance estimation}.
