Description

`truncreg` fits a regression model of `depvar` on `indepvars` from a sample drawn from a restricted part of the population. Under the normality assumption for the whole population, the error terms in the truncated regression model have a truncated normal distribution, which is a normal distribution that has been scaled upward so that the distribution integrates to one over the restricted range.

Quick start

Truncated regression of `y` on `x1` and `x2` truncated below 16

```
truncreg y x1 x2, ll(16)
```

Specify that `y` is truncated above 35

```
truncreg y x1 x2, ul(35)
```

With `y` truncated below 17 and above 35

```
truncreg y x1 x2, ll(17) ul(35)
```

Specify a lower truncation point that varies across observations using the variable `trunc`

```
truncreg y x1 x2, ll(trunc)
```

As above, but with bootstrapped standard errors using 200 replications

```
truncreg y x1 x2, ll(trunc) vce(bootstrap, reps(200))
```

See last estimates with legend of coefficient names instead of statistics

```
truncreg, coeflegend
```

Menu

Statistics > Linear models and related > Truncated regression
Syntax

```plaintext
truncreg depvar [indepvars] [if] [in] [weight] [, options]
```

Options

**Model**
- `noconstant` suppress constant term
- `ll(varname | #)` left-truncation variable or limit
- `ul(varname | #)` right-truncation variable or limit
- `offset(varname)` include `varname` in model with coefficient constrained to 1
- `constraints(constraints)` apply specified linear constraints

**SE/Robust**
- `vce(vcetype)` `vcetype` may be `oim`, `robust`, `cluster clustvar`, `opg`, `bootstrap`, or `jackknife`

**Reporting**
- `level(#)` set confidence level; default is `level(95)`
- `lrmodel` perform the likelihood-ratio model test instead of the default Wald test
- `nocnsreport` do not display constraints
- `display_options` control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling

**Maximization**
- `maximize_options` control the maximization process; seldom used
- `collinear` keep collinear variables
- `coeflegend` display legend instead of statistics

`indepvars` may contain factor variables; see [U] 11.4.3 Factor variables.
`depvar` and `indepvars` may contain time-series operators; see [U] 11.4.4 Time-series varlists.
`bayes`, `bootstrap`, `by`, `fmm`, `fp`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: truncreg and [FMM] fmm: truncreg.
`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] mi estimate.
Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.
`aweights` are not allowed with the `jackknife` prefix; see [R] jackknife.
`vce()`, `lrmodel`, and weights are not allowed with the `svy` prefix; see [SVY] svy.
`aweights`, `fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.
collinear and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.
offset(varname), constraints(constraints); see [R] Estimation options.

vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (oim, opg), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] vce_option.

level(#), lrmodel, nocnsreport; see [R] Estimation options.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fvwrap(#), fvwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

maximize_options: difficult, technique(algorithm_spec), iterate(#), [no]log, trace, gradient, showstep, hessian, showtolerance, tolerance(#), ltolerance(#), nrtolerance(#), nonrtolerance, and from(init_specs); see [R] Maximize. These options are seldom used, but you may use the ltolerance(#) option to relax the convergence criterion; the default is 1e-6 during specification searches.

Setting the optimization type to technique(bhhh) resets the default vcetype to vce(opg).

The following options are available with truncreg but are not shown in the dialog box:
collinear, coeflegend; see [R] Estimation options.

Remarks and examples

Truncated regression fits a model of a dependent variable on independent variables from a restricted part of a population. Truncation is essentially a characteristic of the distribution from which the sample data are drawn. If \( x \) has a normal distribution with mean \( \mu \) and standard deviation \( \sigma \), the density of the truncated normal distribution is

\[
  f(x \mid a < x < b) = \frac{f(x)}{\Phi \left( \frac{b-\mu}{\sigma} \right) - \Phi \left( \frac{a-\mu}{\sigma} \right)}
  = \frac{1}{\sigma} \frac{\phi \left( \frac{x-\mu}{\sigma} \right)}{\Phi \left( \frac{b-\mu}{\sigma} \right) - \Phi \left( \frac{a-\mu}{\sigma} \right)}
\]

where \( \phi \) and \( \Phi \) are the density and distribution functions of the standard normal distribution.

Compared with the mean of the untruncated variable, the mean of the truncated variable is greater if the truncation is from below, and the mean of the truncated variable is smaller if the truncation is from above. Moreover, truncation reduces the variance compared with the variance in the untruncated distribution.
We will demonstrate `truncreg` with part of the Mroz dataset distributed with Berndt (1996). This dataset contains 753 observations on women’s labor supply. Our subsample is of 250 observations, with 150 market laborers and 100 nonmarket laborers.

```stata
use https://www.stata-press.com/data/r16/laborsub
describe
Contains data from https://www.stata-press.com/data/r16/laborsub.dta
obs: 250
vars: 6 25 Sep 2018 18:36
storage  display value
variable name type format label variable label

  lfp byte  %9.0g  1 if woman worked in 1975
  whrs int   %9.0g  Wife’s hours of work
  k16 byte  %9.0g  # of children younger than 6
  k618 byte  %9.0g  # of children between 6 and 18
  wa byte   %9.0g  Wife’s age
  we byte   %9.0g  Wife’s educational attainment
```

Sorted by:

```stata
.summarize, sep(0)
```

We first perform ordinary least-squares estimation on the market laborers.

```stata
.regress whrs k16 k618 wa we if whrs > 0
```

Now we use `truncreg` to perform truncated regression with truncation from below zero.

```stata
.truncreg whrs k16 k618 wa we, ll(0)
```

Fitting full model:

- Iteration 0: log likelihood = -1205.6992
- Iteration 1: log likelihood = -1200.9873
- Iteration 2: log likelihood = -1200.9159
Truncated regression

Technical note

Whether truncated regression is more appropriate than the ordinary least-squares estimation depends on the purpose of that estimation. If we are interested in the mean of wife’s working hours conditional on the subsample of market laborers, least-squares estimation is appropriate. However if we are interested in the mean of wife’s working hours regardless of market or nonmarket labor status, least-squares estimates could be seriously misleading.

Truncation and censoring are different concepts. A sample has been censored if no observations have been systematically excluded but some of the information contained in them has been suppressed. In a truncated distribution, only the part of the distribution above (or below, or between) the truncation points is relevant to our computations. We need to scale it up by the probability that an observation falls in the range that interests us to make the distribution integrate to one. The censored distribution used by tobit, however, is a mixture of discrete and continuous distributions. Instead of rescaling over the observable range, we simply assign the full probability from the censored regions to the censoring points. The truncated regression model is sometimes less well behaved than the tobit model.
Davidson and MacKinnon (1993) provide an example where truncation results in more inconsistency than censoring.

**Stored results**

`truncreg` stores the following in `e()`:

**Scalars**
- `e(N)` number of observations
- `e(N_bf)` number of observations before truncation
- `e(chi2)` model $\chi^2$
- `e(k_eq)` number of equations in `e(b)`
- `e(k_eq_model)` number of equations in overall model test
- `e(k_aux)` number of auxiliary parameters
- `e(df_m)` model degrees of freedom
- `e(ll)` log likelihood
- `e(ll_0)` log likelihood, constant-only model
- `e(N_clust)` number of clusters
- `e(sigma)` estimate of sigma
- `e(p)` $p$-value for model test
- `e(rank)` rank of `e(V)`
- `e(ic)` number of iterations
- `e(rc)` return code
- `e(converged)` 1 if converged, 0 otherwise

**Macros**
- `e(cmd)` `truncreg`
- `e(cmdline)` command as typed
- `e(llopt)` contents of `ll()`, if specified
- `e(ulopt)` contents of `ul()`, if specified
- `e(depvar)` name of dependent variable
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(clustvar)` name of cluster variable
- `e(offset)` offset
- `e(chi2type)` Wald or LR; type of model $\chi^2$ test
- `e(vce)` `vcetype` specified in `vce()`
- `e(vcetype)` title used to label Std. Err.
- `e(opt)` type of optimization
- `e(which)` max or min; whether optimizer is to perform maximization or minimization
- `e(ml_method)` type of ml method
- `e(user)` name of likelihood-evaluator program
- `e(technique)` maximization technique
- `e(properties)` `b` `V`
- `e(predict)` program used to implement `predict`
- `e(marginsok)` predictions allowed by `margins`
- `e(asbalanced)` factor variables `fvset` as `asbalanced`
- `e(asobserved)` factor variables `fvset` as `asobserved`

**Matrices**
- `e(b)` coefficient vector
- `e(Cns)` constraints matrix
- `e(ilog)` iteration log (up to 20 iterations)
- `e(gradient)` gradient vector
- `e(V)` variance–covariance matrix of the estimators
- `e(V_modelbased)` model-based variance
- `e(means)` means of independent variables
- `e(dummy)` indicator for dummy variables

**Functions**
- `e(sample)` marks estimation sample
Methods and formulas

Greene (2018, 918–924) and Davidson and MacKinnon (1993, 534–537) provide introductions to the truncated regression model.

Let \( y = X\beta + \epsilon \) be the model. \( y \) represents continuous outcomes either observed or not observed. Our model assumes that \( \epsilon \sim N(0, \sigma^2 I) \).

Let \( a \) be the lower limit and \( b \) be the upper limit. The log likelihood is

\[
\ln L = \frac{-n}{2} \log(2\pi \sigma^2) - \frac{1}{2\sigma^2} \sum_{j=1}^{n} (y_j - x_j \beta)^2 - \sum_{j=1}^{n} \log \left\{ \Phi \left( \frac{b - x_j \beta}{\sigma} \right) - \Phi \left( \frac{a - x_j \beta}{\sigma} \right) \right\}
\]

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using \( vce(robust) \) and \( vce(cluster \ clustvar) \), respectively. See \([P] \_robust\), particularly Maximum likelihood estimators and Methods and formulas.

truncreg also supports estimation with survey data. For details on VCEs with survey data, see \([SVY] \ Variance\ estimation\).
