spmatrix spfrommata — Copy Mata matrix to Sp

Description	Quick start	Menu	Syntax
Options	Remarks and examples	References	Also see

Description

spmatrix spfrommata copies a weighting matrix and an ID vector from Mata to an Sp spatial weighting matrix.

Quick start

Create Sp spatial weighting matrix Wnew from Mata matrix W and vector v with the default spectral normalization

spmatrix spfrommata Wnew = W v

Menu

Statistics > Spatial autoregressive models

Syntax

spmatrix spfrommata spmatname = matamatrix matavec [, options]

options	Description
<u>norm</u> alize(<i>normalize</i>) replace	type of normalization; default is normalize(spectral) replace existing weighting matrix

Options

normalize(normalize) specifies how the resulting matrix is to be scaled. normalize(spectral) is
the default. normalize(minmax), normalize(row), and normalize(none) are also allowed. See
[SP] spmatrix create for full details of the option and Choosing weighting matrices and their normalization in [SP] spregress for details about normalization.

replace specifies that matrix *spmatname* be overwritten if it already exists.

Remarks and examples

Remarks are presented under the following headings:

W and v Simple use Advanced use

W and v

Two components are required to set an Sp spatial weighting matrix: the spatial weighting matrix itself and its vector of _ID values. Let's call them W and v, respectively. v states that the first row and column of W correspond to _ID==v[1], the second row and column correspond to _ID==v[2], and so on. The purpose of v and how it works is explained in [SP] spmatrix matafromsp.

Examples of spmatrix spfrommata can be found in [SP] spmatrix create and [SP] spmatrix matafromsp.

Simple use

We are going to show you how Mata can be used to construct complicated spatial weighting matrices. However, we will start with a simple case in which the values of the weighting matrix $W_{i,j}$ are a function of variables in observations i and j of the data in memory. Inverse-distance matrices are an example of this. The distance between i and j is a function of the values of Stata variables _CX and _CY in observations i and j.

We start by loading the Sp data into memory:

```
. use your_sp_data
```

The Mata solution is

. mata:

```
mata (type end to exit) ----
: id = st_data(., "_ID")
: location = st_data(., ("_CX", "_CY"))
: N = st nobs()
: W = J(N, N, O)
: for (i=1; i<=N; i++) {
          for (j=1; j<i; j++) {</pre>
>
                  delta = location[i,.] - location[j,.]
>
                  W[i,j] = W[j,i] = 1/sqrt(delta*delta')
>
          }
>
> }
: end
```

. spmatrix spfrommata myIdist = W id

We just created an inverse-distance matrix. If you wanted to create such matrices, it would obviously be easier to type

. spmatrix create idistance myIdist

The Mata solution has the advantage that you can substitute different inverse-distance functions, such as inverse-distance squared. There is an easier solution for that case too, namely, the one outlined in [SP] **spmatrix userdefined**.

Now that you know how Mata and spmatrix spfrommata work in simple cases, we can show you an example that could be done no other way than by direct use of Mata.

Advanced use

You have export.dta, a cross-sectional Sp dataset on countries and their characteristics. Its _ID variable contains standard country codes. You need to construct a spatial weighting matrix to use with it.

export.dta does not itself contain sufficient information to construct the matrix you want to use. Instead, you have a second dataset, which is not Sp. It contains

```
. copy https://www.stata-press.com/data/r19/exports.dta .
. use exports
(Country export data)
. describe
Contains data from https://www.stata-press.com/data/r19/exports.dta
                       38,220
 Observations:
                                                Country export data
    Variables:
                            4
                                                17 Apr 2024 08:26
Variable
              Storage
                         Display
                                     Value
    name
                          format
                                     label
                                                 Variable label
                  type
                         %9.0g
from
                int
                                                From (country code)
                         %9.0g
                                                To (country code)
to
                int
exports
                float.
                         %9.0g
                                                Exports ($ value)
                                                GDP of producer
gdp
                float
                         %9.0g
```

```
Sorted by:
```

The data record exports from one country to another for all 196 countries of the world. We say exports, but we can just as well interpret the data as imports by reversing the roles of variables from and to.

To simplify the problem, we are going to assume the country codes recorded in variables from and to are 1, 2, ..., 196 and that the same codes are recorded in variable _ID of exports.dta. If the true country codes were not 1, 2, ..., 196, you could easily construct such country codes.

We are going to create a spatial weighting matrix from these data. Potential spillover from j to i will be

$$W_{i,j} = \frac{(\text{exports from } i \text{ to } j) + (\text{exports from } j \text{ to } i)}{i' \text{s GDP}}$$

This weighting matrix is a near cousin to one developed by Badinger and Egger (2008).

W would be easy to calculate if we had a matrix E recording exports and a vector g recording GDP. $E_{i,j}$ would be the exports from i to j, and g_i would record GDP of country i. The formula for $W_{i,j}$ would then be

$$W_{i,j} = (E_{i,j} + E_{j,i})/g_i$$

E and g can be easily created in Mata:

```
. tomata from to export gdp
. mata:
                                                    mata (type end to exit) -
: g = J(196, 1, 0)
: E = J(196, 196, 0)
: for (k=1; k<=length(exports); k++) {
          i = from[k]
>
          j = to[k]
>
          g[i] = gdp[k]
>
          E[i,j] = exports[k]
>
> }
: end
```

tomata (Gould 2006) is a community-contributed command that makes it easy to create Mata matrix views of individual Stata variables. Type search tomata for details. The matrices will have the same names as the variables.

We can now calculate the weighting matrix:

```
. mata:
. mata:
. W = (E + E') :/ g
: end
mata (type end to exit)
```

Finally, we post the result to Sp. We create column vector id containing 1, 2, ..., 196 because row/column 1 of W corresponds to country code 1, row/column 2 of W corresponds to country code 2, and so on.

```
. mata:

. id = 1::196

: end
```

. spmatrix spfrommata Wt = W id

We could now use exports.dta and fit a model using Wt to create spatial lags.
