Description

`sttocc` generates a nested case–control study dataset from a cohort-study dataset by sampling controls from the risk sets. For each case, the controls are chosen randomly from those members of the cohort who are at risk at the failure time of the case. That is, the resulting case–control sample is matched with respect to analysis time—the time scale used to compute risk sets. The following variables are added to the dataset:

- `_case`: Coded 0 for controls, 1 for cases
- `_set`: Case–control ID; matches cases and controls that belong together
- `_time`: Analysis time of the case’s failure

The names of these three variables can be changed by specifying the `generate()` option. `varlist` defines variables that, in addition to those used in the creation of the case–control study, will be retained in the final dataset. If `varlist` is not specified, all variables are carried over into the resulting dataset.

When the resulting dataset is analyzed as a matched case–control study, odds ratios will estimate corresponding rate-ratio parameters in the proportional hazards model for the cohort study.

Randomness in the matching is obtained using Stata’s `runiform()` function. To ensure that the sample truly is random, you should set the random-number seed; see [R] `set seed`.

Quick start

Create a nested case–control dataset from a cohort dataset that has been `stset`, matching cases to controls based on analysis time

```
sttocc
```

Same as above, but match on analysis time and categorical variable `catvar`

```
sttocc, match(catvar)
```

Same as above, but match 3 controls for each case

```
sttocc, match(catvar) number(3)
```

Same as above, and name the case indicator `case`, the matching identifier `mid`, and the case’s failure time `ftime`

```
sttocc, match(catvar) number(3) generate(case mid ftime)
```

Menu

Statistics > Survival analysis > Setup and utilities > Convert survival-time data to case–control data
**Syntax**

```
sttocc [varlist] [ , options ]
```

**options**

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Main</strong></td>
</tr>
<tr>
<td><strong>match(matchvarlist)</strong></td>
</tr>
<tr>
<td><strong>number(#)</strong></td>
</tr>
<tr>
<td><strong>nodots</strong></td>
</tr>
<tr>
<td><strong>Options</strong></td>
</tr>
<tr>
<td><strong>generate(case set time)</strong></td>
</tr>
</tbody>
</table>

You must `stset` your data before using `sttocc`; see `[ST] stset`.

`fweights`, `iweights`, and `pweights` may be specified using `stset`; see `[ST] stset`.

**Options**

---

**Main**

- `match(matchvarlist)` specifies more categorical variables for matching controls to cases. When `match()` is not specified, cases and controls are matched with respect to time only. If `match(matchvarlist)` is specified, the cases will also be matched by `matchvarlist`.

- `number(#)` specifies the number of controls to draw for each case. The default is 1, even though this is not a sensible choice.

- `nodots` requests that dots not be placed on the screen at the beginning of each case–control group selection. By default, dots are displayed to show progress.

---

**Options**

- `generate(case set time)` specifies variable names for the three new variables; the default is _case, _set, and _time.

**Remarks and examples**

Nested case–control studies are an attractive alternative to full Cox regression analysis, particularly when time-varying explanatory variables are involved. They are also attractive when some explanatory variables involve laborious coding. For example, you can create a file with a subset of variables for all subjects in the cohort, generate a nested case–control study, and go on to code the remaining data only for those subjects selected.

In the same way as with Cox regression, the results of the analysis are critically dependent on the choice of analysis time (time scale). The choice of analysis time may be calendar time—so that controls would be chosen from subjects still being monitored on the date that the case fails—but other time scales, such as age or time in study, may be more appropriate in some studies. Remember that the analysis time set in selecting controls is implicitly included in the model in subsequent analysis.

`match()` requires that controls also be matched to the case with respect to other categorical variables, such as sex. This produces an analysis closely mirroring stratified Cox regression. If we wanted to match on calendar time and 5-year age bands, we could first type `stsplit ageband`...
to create the age bands and then specify `match(ageband)` on the `sttocc` command. Analyzing the resulting data as a matched case–control study would estimate rate ratios in the underlying cohort that are controlled for calendar time (very finely) and age (less finely). Such analysis could be carried out by Mantel–Haenszel (odds ratio) calculations, for example, using `mhodds`, or by conditional logistic regression using `clogit`.

When ties occur between entry times, censoring times, and failure times, the following convention is adopted:

\[
\text{Entry time} < \text{Failure time} < \text{Censoring time}
\]

Thus censored subjects and subjects entering at the failure time of the case are included in the risk set and are available for selection as controls. Tied failure times are broken at random.

> **Example 1: Creating a nested case–control study**

Using the `diet` data introduced in example 1 of `[ST] stsplit`, we will illustrate the use of `sttocc`, letting age be analysis time. Controls are chosen from subjects still being monitored at the age at which the case fails.

```
. use https://www.stata-press.com/data/r18/diet
   (Diet data with dates)
. stset dox, failure(fail) enter(time doe) id(id) origin(time dob) scale(365.25)
```

Survival-time data settings

- ID variable: `id`
- Failure event: `fail!=0 & fail<`
- Observed time interval: `(dox[_n-1], dox]`
- Enter on or after: `time doe`
- Exit on or before: `failure`
- Time for analysis: `(time-origin)/365.25`
- Origin: `time dob`

```
337  total observations
 0   exclusions
```

```
337  observations remaining, representing
337  subjects
 80  failures in single-failure-per-subject data
4,603.669 total analysis time at risk and under observation
```

```
. set seed 9123456
. sttocc, match(job) n(5) nodots
```

```
note: 2 sets of tied failure times detected; splitting at random.
Failures are assumed to precede censorings.
```

Survival-time data settings

- Failure _d: `fail`
- Analysis time _t: `(dox-origin)/365.25`
- Origin: `time dob`
- Enter on or after: `time doe`
- ID variable: `id`
- Matching for: `job`

Converting survival-time data to case–control data:

```
Sampling 5 controls for each of 80 cases ...
```

Data are now case–control data with new variables:

- _case Case-control indicator
- _set Case-control ID
- _time Analysis time of the case’s failure
The above two commands create a new dataset in which there are five controls per case, matched on job, with the age of the subjects when the case failed recorded in the variable time. The case indicator is given in case and the matched set number, in set. Because we did not specify the optional varlist, all variables are carried over into the new dataset.

```
. describe
Contains data from https://www.stata-press.com/data/r18/diet.dta
Observations: 480  Diet data with dates
Variables: 14  1 May 2022 19:01

Variable Storage Display Value
name type format label Variable label
id int %9.0g Subject identity number
fail byte %8.0g Outcome (CHD = 1 3 13)
job byte %8.0g Occupation
month byte %8.0g Month of survey
energy float %9.0g Total energy (1000kcals/day)
height float %9.0g Height (cm)
weight float %9.0g Weight (kg)
hienergy byte %9.0g Indicator for high energy
doe int %td Date of entry
dox int %td Date of exit
dob int %td Date of birth
_case byte %8.0g 0 for controls; 1 for cases
_set long %12.0g Case-control ID
_time double %10.0g Analysis time of the case’s failure

Sorted by: _set _case
Note: Dataset has changed since last saved.
```

We can verify that the controls were correctly selected:

```
. gen ageentry=(doe-dob)/365.25
. gen ageexit=(dox-dob)/365.25
. sort _set _case id
. list _set id _case _time ageentry ageexit job, sepby(_set)
```

```
The controls do indeed belong to the appropriate risk set. The controls in each set enter at an age that is less than the age of the case at failure, and they exit at an age that is greater than the age of the case at failure. To estimate the effect of high energy, use `clogit`, just as you would for any matched case–control study:

```
. clogit _case hienergy, group(_set) or
Iteration 0:  Log likelihood =  -143.22071
Iteration 1:  Log likelihood =  -143.22071

Conditional (fixed-effects) logistic regression              Number of obs =      480
               LR chi2(1)    =       0.24
        Prob > chi2 =       0.6241
Log likelihood =  -143.22071                              Pseudo R2 =    0.0008

                      _case |  Odds ratio   Std. err.     z  P>|z|     [95% conf. interval]
-------------|-------------------+----------------------+-------+-----------------------+---------------------+
     hienergy |         0.88683   0.217505  -0.49  0.624     0.54837   1.434191
```

### Acknowledgments

The original version of `sttocc` was written by David Clayton (retired) of the Cambridge Institute for Medical Research and Michael Hills (1934–2021) of the London School of Hygiene and Tropical Medicine.
