## Description

`svy sdr` performs successive difference replication (SDR) estimation of specified statistics (or expressions) for a Stata command or a user-written program. The command is executed once for each replicate using sampling weights that are adjusted according to the SDR methodology. Any Stata estimation command listed in [\[SVY\] svy estimation](#) may be used with `svy sdr`. User-written programs that meet the requirements in [\[P\] program properties](#) may also be used.

## Quick start

Estimate population mean of `v1` using SDR standard-error estimates with sampling weight `wvar1` and replicate weights in variables with prefix `rwvar`

```
svyset [pweight=wvar1], sdrweight(rwvar*)
svy sdr _b: mean v1
```

Same as above

```
svyset [pweight=wvar1], sdrweight(rwvar*) vce(sdr)
svy: mean v1
```

SDR estimate of the standard error of the difference between the means of `v2` and `v3` using either `svyset` command above

```
svy sdr (_b[v2]-_b[v3]): mean v2 v3
```

As above, but name the result `diff` and save results from each replication to `mydata.dta`

```
svy sdr diff=(_b[v2]-_b[v3]), saving(mydata): mean v2 v3
```

Same as above

```
sdr diff=(_b[v2]-_b[v3]), saving(mydata): mean v2 v3
```

Note: Any estimation command meeting the requirements specified in the *Description* may be substituted for `mean` in the examples above.

## Menu

Statistics > Survey data analysis > Resampling > Successive difference replications estimation

## Syntax

```
[svy] sdr exp_list [, svy_options sdr_options eform_option] : command
```

<i>svy_options</i>	Description
<i>if/in</i>	
<code>subpop([<i>varname</i>] [<i>if</i>])</code>	identify a subpopulation
<i>Reporting</i>	
<code>level(#)</code>	set confidence level; default is <code>level(95)</code>
<code>noheader</code>	suppress table header
<code>nolegend</code>	suppress table legend
<code>noadjust</code>	do not adjust model Wald statistic
<code>nocnsreport</code>	do not display constraints
<code>display_options</code>	control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling
<code>coeflegend</code>	display legend instead of statistics

`coeflegend` is not shown in the dialog boxes for estimation commands.

<i>sdr_options</i>	Description
<i>Options</i>	
<code>saving(<i>filename</i> [, ...])</code>	save results to <i>filename</i> ; save statistics in double precision; save results to <i>filename</i> every # replications
<code>mse</code>	use MSE formula for variance
<i>Reporting</i>	
<code>verbose</code>	display the full table legend
<code>nodots</code>	suppress replication dots
<code>dots(#)</code>	display dots every # replications
<code>noisily</code>	display any output from <i>command</i>
<code>trace</code>	trace <i>command</i>
<code>title(<i>text</i>)</code>	use <i>text</i> as title for SDR results
<i>Advanced</i>	
<code>nodrop</code>	do not drop observations
<code>reject(<i>exp</i>)</code>	identify invalid results
<code>dof(#)</code>	design degrees of freedom

svy requires that the survey design variables be identified using `svyset`; see [SVY] `svyset`.

*command* defines the statistical command to be executed. The `by` prefix cannot be part of *command*.

`collect` is allowed; see [U] 11.1.10 Prefix commands.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Warning: Using `if` or `in` restrictions will often not produce correct variance estimates for subpopulations. To compute estimates for subpopulations, use the `subpop()` option.

svy sdr requires that the successive difference replicate weights be identified using `svyset`.

*exp\_list* specifies the statistics to be collected from the execution of *command*. *exp\_list* is required unless *command* has the `svyb` program property, in which case *exp\_list* defaults to `_b`; see [P] [program properties](#). The expressions in *exp\_list* are assumed to conform to the following:

```
exp_list contains      (name: elist)
                      elist
                      eexp
elist contains        newvarname = (exp)
                      (exp)
eexp is               specname
                      [eqno]specname
specname is          _b
                      _b[]
                      _se
                      _se[]
eqno is              ##
                      name
```

*exp* is a standard Stata expression; see [U] [13 Functions and expressions](#).

Distinguish between `[]`, which are to be typed, and `[][]`, which indicate optional arguments.

## Options

*svy\_options*; see [SVY] [svy](#).

### Options

`saving(filename [ , suboptions ])` creates a Stata data file (`.dta` file) consisting of (for each statistic in *exp\_list*) a variable containing the replicates.

`double` specifies that the results for each replication be stored as `doubles`, meaning 8-byte reals. By default, they are stored as `floats`, meaning 4-byte reals. This option may be used without the `saving()` option to compute the variance estimates by using double precision.

`every(#)` specifies that results be written to disk every *#*th replication. `every()` should be specified in conjunction with `saving()` only when *command* takes a long time for each replication. This will allow recovery of partial results should some other software crash your computer. See [P] [postfile](#).

`replace` specifies that *filename* be overwritten if it exists. This option does not appear in the dialog box.

`mse` specifies that `svy sdr` compute the variance by using deviations of the replicates from the observed value of the statistics based on the entire dataset. By default, `svy sdr` computes the variance by using deviations of the replicates from their mean.

### Reporting

`verbose` requests that the full table legend be displayed.

`nodots` and `dots(#)` specify whether to display replication dots. By default, one dot character is displayed for each successful replication. A red 'x' is displayed if *command* returns an error, and an 'e' is displayed if at least one value in *exp\_list* is missing. You can also control whether dots are displayed using `set dots`; see [R] [set](#).

`nodots` suppresses display of the replication dots.

`dots(#)` displays dots every # replications. `dots(0)` is a synonym for `nodots`.

`noisily` requests that any output from *command* be displayed. This option implies the `nodots` option.

`trace` causes a trace of the execution of *command* to be displayed. This option implies the `noisily` option.

`title(text)` specifies a title to be displayed above the table of SDR results; the default title is “SDR results”.

*eform\_option*; see [R] [eform\\_option](#). This option is ignored if *exp\_list* is not `_b`.

---

Advanced

---

`nodrop` prevents observations outside `e(sample)` and the `if` and `in` qualifiers from being dropped before the data are resampled.

`reject(exp)` identifies an expression that indicates when results should be rejected. When *exp* is true, the resulting values are reset to missing values.

`dof(#)` specifies the design degrees of freedom, overriding the default calculation,  $df = N_{psu} - N_{strata}$ .

## Remarks and examples

[stata.com](http://www.stata.com)

SDR was first introduced by [Fay and Train \(1995\)](#) as a method of variance estimation for annual demographic supplements to the Current Population Survey (CPS). In SDR, the model is fit multiple times, once for each of a set of adjusted sampling weights. The variance is estimated using the resulting replicated point estimates.

### ► Example 1

The U.S. Census Bureau publishes public-use data from several of its surveys. These data can be downloaded from <https://factfinder.census.gov>. We downloaded the American Community Survey (ACS) Public Use Microdata Sample (PUMS) data collected in 2007. We extracted data for the state of Texas and kept the variables containing age, sex, and sampling weight for each person in the dataset. This sample dataset also contains 80 SDR weight variables.

```
. use https://www.stata-press.com/data/r17/ss07ptx
. svyset
Sampling weights: pwgtp
                  VCE: sdr
                  MSE: off
SDR weights: pwgtp1 .. pwgtp80
Single unit: missing
Strata 1: <one>
Sampling unit 1: <observations>
FPC 1: <zero>
```

This dataset was already `svyset` as

```
. svyset [pw=pwgtp], sdrweight(pwgtp1-pwgtp80) vce(sdr)
```

Here we estimate the average age of the males and of the females for our Texas subpopulation. The standard errors are estimated using SDR.

```
. svy: mean agep, over(sex)
(running mean on estimation sample)

SDR replications (80)
|-----|-----|-----|-----|-----|
| 1 | 2 | 3 | 4 | 5 |
|-----|-----|-----|-----|-----|
..... 50
.....

Survey: Mean estimation          Number of obs = 230,817
                                Population size = 23,904,380
                                Replications   = 80
```

	SDR			[95% conf. interval]
	Mean	std. err.		
c.agep@sex				
Male	33.24486	.0470986	33.15255	33.33717
Female	35.23908	.0386393	35.16335	35.31481

◀

## Stored results

In addition to the results documented in [\[SVY\] svy](#), `svy sdr` stores the following in `e()`:

### Scalars

`e(N_reps)` number of replications  
`e(N_misreps)` number of replications with missing values  
`e(k_exp)` number of standard expressions  
`e(k_eexp)` number of `_b/_se` expressions  
`e(k_extra)` number of extra estimates added to `_b`

### Macros

`e(cmdname)` command name from *command*  
`e(cmd)` same as `e(cmdname)` or `sdr`  
`e(vce)` `sdr`  
`e(exp#)` #th expression  
`e(sdrweight)` `sdrweight()` variable list

### Matrices

`e(b_sdr)` SDR means  
`e(V)` SDR variance estimates

When `exp_list` is `_b`, `svy sdr` will also carry forward most of the results already in `e()` from *command*.

## Methods and formulas

See [\[SVY\] Variance estimation](#) for details regarding SDR variance estimation.
