<div style="border: 1px solid black; padding: 10px;">

Example 4 — Table of t test results

</div>

Description

In this example, we demonstrate how to use collect to store the results of mean-comparison tests (t tests) for levels of a categorical variable in a collection and how to create a customized table with these results.

Remarks and examples

Remarks are presented under the following headings:

> *Collecting statistics*
> *Customizing the table*

Collecting statistics

Below, we use data from the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). We wish to test whether the mean systolic blood pressure (bpsystol) is the same across males and females in each category of race. To perform the test for each level of race, we use the by prefix. We first create a new collection named ex4 and then use the collect prefix to collect the results from each ttest command and store them in the new collection. All results that ttest returns in r() will be collected, but only the ones we have specified will be automatically included in our table.

```
. use https://www.stata-press.com/data/r19/nhanes2l
(Second National Health and Nutrition Examination Survey)

. collect create ex4
(current collection is ex4)

. quietly: collect r(N_1) r(mu_1) r(N_2) r(mu_2) r(p):
> by race, sort: ttest bpsystol, by(sex)
```

These results are stored in the current collection. We can then use collect layout to arrange the items from the collection into a table. We place the levels of race on the rows and the results (result) on the columns.

```
. collect layout (race) (result)
Collection: ex4
      Rows: race
   Columns: result
   Table 1: 3 x 5
  (output omitted)
```

The labels for these statistics are automatically included in the table, which makes it very wide. Therefore, we omit the table preview from the output. In the following section, we will format the table to make it ready for publication.

Example 4 — Table of t test results 2

Customizing the table

To finalize our table from the previous section, we will want to label which statistics are for males and females, shorten the labels for the statistics, and display the results with two digits to the right of the decimal.

First, let's work on the labels. The statistics are part of the dimension `result`. We list the labels for the levels of this dimension:

```
. collect label list result

  Collection: ex4
   Dimension: result
       Label: Result
Level labels:
         N_1  Sample size n₁
         N_2  Sample size n₂
        df_t  Degrees of freedom
       level  Confidence level
        mu_1  x̄₁ mean for population 1
        mu_2  x̄₂ mean for population 2
           p  Two-sided p-value
         p_l  Lower one-sided p-value
         p_u  Upper one-sided p-value
          sd  Combined std. dev.
        sd_1  Standard deviation for first variable
        sd_2  Standard deviation for second variable
          se  Std. error
           t  t statistic
```

We would like to remap the statistics for males to their own dimension and similarly for females. This will allow us to categorize the results under the labels `Males` and `Females`. The levels `N_1` and `mu_1` correspond to males, and the levels `N_2` and `mu_2` correspond to females. We also remap the p-values to their own dimension called `Difference`.

```
. collect remap result[N_1 mu_1] = Males
(6 items remapped in collection ex4)
. collect remap result[N_2 mu_2] = Females
(6 items remapped in collection ex4)
. collect remap result[p] = Difference
(3 items remapped in collection ex4)
```

Then, we use `collect style header` to specify that we want to display the title for the specified dimensions. These titles are suppressed by default. Then, we arrange our items once more with the new dimension names. Again, we place the levels of `race` on the rows, but now we place the dimensions `Males`, `Females`, and `Difference` on the columns.

Example 4 — Table of t test results 3

```
. collect style header Males Females Difference, title(name)
. collect layout (race) (Males Females Difference)
Collection: ex4
      Rows: race
   Columns: Males Females Difference
   Table 1: 3 x 5
```

	Males N_1	Males mu_1	Females N_2	Females mu_2	Difference p
White	4312	132.8476	4753	128.5264	1.78e-19
Black	500	133.69	586	133.8481	.9217363
Other	103	130.6699	97	126.7216	.3098674

Our table looks much better. Next, we will add labels to the statistics. The statistics are levels of the new dimensions that we remapped them to. To modify labels for levels of a dimension, we use collect label levels.

```
. collect label levels Males N_1 "N" mu_1 "Mean BP"
. collect label levels Females N_2 "N" mu_2 "Mean BP"
. collect label levels Difference p "p-value"
```

Previously, we saw the column headers Males and Females being repeated. We would like to display these only once and center them horizontally. We can use collect style column to make this change. We also set the columns to have the same width. Then, we center-align all the cells in the table. With collect style cell, we can modify all cells in the table or specific cells. For example, we wish to format the means and p-values to display two digits to the right of the decimal. Therefore, we specify the levels of the dimensions we want to apply this format to. Then, we get a preview of our table.

```
. collect style column, dups(center) width(equal)
. collect style cell, halign(center)
. collect style cell Males[mu_1] Females[mu_2] Difference[p], nformat(%5.2f)
. collect preview
```

	Males		Females		Difference
	N	Mean BP	N	Mean BP	p-value
White	4312	132.85	4753	128.53	0.00
Black	500	133.69	586	133.85	0.92
Other	103	130.67	97	126.72	0.31

Finally, we will modify the borders in the table by using collect style cell. First, we remove the vertical border. Because we do not want any vertical borders, we do not list any levels of the dimension border_block when we specify the border(right, pattern(nil)) option. Our next collect style cell command requires a bit more explanation. With it, we add a horizontal border below Males to indicate that the first N and Mean BP are for males. To target this very specific border, we specify cell_type[column-header]#Males. Here cell_type refers to cells in different parts of the table. We want to make a change only in the column header. We also want to make this change only for the Males dimension. By specifying the # between the tags, we direct the change only at the dimension Male within the column headers. We can also target the border under Females by specifying cell_type[column-header]#Females. To this command, we add the border(bottom, pattern(single)) option to place a single border on the bottom of these cells.

Example 4 — Table of t test results 4

```
. collect style cell border_block, border(right, pattern(nil))
. collect style cell cell_type[column-header]#Males
> cell_type[column-header]#Females, border(bottom, pattern(single))
. collect preview
```

	Males		Females		Difference
	N	Mean BP	N	Mean BP	p-value
White	4312	132.85	4753	128.53	0.00
Black	500	133.69	586	133.85	0.92
Other	103	130.67	97	126.72	0.31

After finalizing our table of results, we can export it to another format with `collect export`.
