## Postestimation commands

The following postestimation commands are of special interest after `arfima`:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>estat acplot</code></td>
<td>estimate autocorrelations and autocovariances</td>
</tr>
<tr>
<td><code>irf</code></td>
<td>create and analyze IRFs</td>
</tr>
<tr>
<td><code>psdensity</code></td>
<td>estimate the spectral density</td>
</tr>
</tbody>
</table>

The following standard postestimation commands are also available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>contrast</code></td>
<td>contrasts and ANOVA-style joint tests of estimates</td>
</tr>
<tr>
<td>* <code>estat ic</code></td>
<td>Akaike’s and Schwarz’s Bayesian information criteria (AIC and BIC)</td>
</tr>
<tr>
<td><code>estat summarize</code></td>
<td>summary statistics for the estimation sample</td>
</tr>
<tr>
<td><code>estat vce</code></td>
<td>variance–covariance matrix of the estimators (VCE)</td>
</tr>
<tr>
<td><code>estimates</code></td>
<td>cataloging estimation results</td>
</tr>
<tr>
<td><code>forecast</code></td>
<td>dynamic forecasts and simulations</td>
</tr>
<tr>
<td><code>lincom</code></td>
<td>point estimates, standard errors, testing, and inference for linear combinations of coefficients</td>
</tr>
<tr>
<td><code>lrtest</code></td>
<td>likelihood-ratio test</td>
</tr>
<tr>
<td>* <code>margins</code></td>
<td>marginal means, predictive margins, marginal effects, and average marginal effects</td>
</tr>
<tr>
<td>* <code>marginsplot</code></td>
<td>graph the results from margins (profile plots, interaction plots, etc.)</td>
</tr>
<tr>
<td>* <code>nlcom</code></td>
<td>point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients</td>
</tr>
<tr>
<td><code>predict</code></td>
<td>predictions, residuals, influence statistics, and other diagnostic measures</td>
</tr>
<tr>
<td>* <code>predictnl</code></td>
<td>point estimates, standard errors, testing, and inference for generalized predictions</td>
</tr>
<tr>
<td><code>pwcompare</code></td>
<td>pairwise comparisons of estimates</td>
</tr>
<tr>
<td><code>test</code></td>
<td>Wald tests of simple and composite linear hypotheses</td>
</tr>
<tr>
<td><code>testnl</code></td>
<td>Wald tests of nonlinear hypotheses</td>
</tr>
</tbody>
</table>

* `estat ic, margins, marginsplot, nlcom, and predictnl` are not appropriate after `arfima, mpl`. 
predict

Description for predict

predict creates a new variable containing predictions such as expected values, fractionally differenced series, and innovations. All predictions are available as static one-step-ahead predictions, and the dependent variable is also available as a dynamic multistep prediction.

Menu for predict

Statistics > Postestimation

Syntax for predict

```
predict [type] newvar [if] [in] [, statistic options]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main</td>
<td></td>
</tr>
<tr>
<td>xb</td>
<td>predicted values; the default</td>
</tr>
<tr>
<td>residuals</td>
<td>predicted innovations</td>
</tr>
<tr>
<td>rstandard</td>
<td>standardized innovations</td>
</tr>
<tr>
<td>fdifference</td>
<td>fractionally differenced series</td>
</tr>
</tbody>
</table>

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

<table>
<thead>
<tr>
<th>options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Options</td>
<td></td>
</tr>
<tr>
<td>rmse([type] newvar)</td>
<td>put the estimated root mean squared error of the predicted statistic in a new variable; only permitted with options <code>xb</code> and <code>residuals</code></td>
</tr>
<tr>
<td>dynamic(datetime)</td>
<td>forecast the time series starting at <code>datetime</code>; only permitted with option <code>xb</code></td>
</tr>
</tbody>
</table>

`datetime` is a # or a time literal, such as `td(1jan1995)` or `tq(1995q1)`; see [D] Datetime.

Options for predict

- `xb`, the default, calculates the predictions for the level of `depvar`.
- `residuals` calculates the predicted innovations.
- `rstandard` calculates the standardized innovations.
- `fdifference` calculates the fractionally differenced predictions of `depvar`. 
**Options**

- `rmse()`: Puts the root mean squared errors of the predicted statistics into the specified new variables. The root mean squared errors measure the variances due to the disturbances but do not account for estimation error. `rmse()` is only permitted with the `xb` and `residuals` options.

- `dynamic()`: Specifies when `predict` starts producing dynamic forecasts. The specified `datetime` must be in the scale of the time variable specified in `tsset`, and the `datetime` must be inside a sample for which observations on the dependent variables are available. For example, `dynamic(tq(2008q4))` causes dynamic predictions to begin in the fourth quarter of 2008, assuming that your time variable is quarterly; see [D] Datetime. If the model contains exogenous variables, they must be present for the whole predicted sample. `dynamic()` may only be specified with `xb`.

---

**margins**

**Description for margins**

`margins` estimates margins of response for expected values.

**Menu for margins**

Statistics  >  Postestimation

**Syntax for margins**

```
margins [marginlist] [ , options ]
margins [marginlist] , predict(statistic ...) [options]
```

<table>
<thead>
<tr>
<th>statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xb</code></td>
<td>predicted values; the default</td>
</tr>
<tr>
<td><code>residuals</code></td>
<td>not allowed with <code>margins</code></td>
</tr>
<tr>
<td><code>rstandard</code></td>
<td>not allowed with <code>margins</code></td>
</tr>
<tr>
<td><code>fdifference</code></td>
<td>not allowed with <code>margins</code></td>
</tr>
</tbody>
</table>

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`. For the full syntax, see [R] margins.

**Remarks and examples**

Remarks are presented under the following headings:

- Forecasting after ARFIMA
- IRF results for ARFIMA
Forecasting after ARFIMA

We assume that you have already read [TS] arfima. In this section, we illustrate some of the features of predict after fitting an ARFIMA model using arfima.

Example 1

We have monthly data on the one-year Treasury bill secondary market rate imported from the Federal Reserve Bank (FRED) database using import fred; see [D] import fred. Below we fit an ARFIMA model with two autoregressive terms and one moving-average term to the data.

```
.arfima tb1yr, ar(1/2) ma(1)
```

<table>
<thead>
<tr>
<th>Coef. Std. Err. z P&gt;</th>
<th>z</th>
<th>[95% Conf. Interval]</th>
</tr>
</thead>
<tbody>
<tr>
<td>tb1yr_ar.L1.</td>
<td>.2326113 .113682 2.05 0.041 .0097987 .4554239</td>
<td></td>
</tr>
<tr>
<td>tb1yr_ar.L2.</td>
<td>.3885213 .0835697 4.65 0.000 .2247277 .5523149</td>
<td></td>
</tr>
<tr>
<td>tb1yr_ma.L1.</td>
<td>.7755848 .0696903 11.58 0.000 .6443451 .9068245</td>
<td></td>
</tr>
<tr>
<td>d</td>
<td>.4606484 .0646628 7.12 0.000 .3339116 .5873852</td>
<td></td>
</tr>
<tr>
<td>sigma2</td>
<td>.1466495 .009232 15.88 0.000 .1285551 .1647439</td>
<td></td>
</tr>
</tbody>
</table>

Note: The test of the variance against zero is one sided, and the two-sided confidence interval is truncated at zero.

All the parameters are statistically significant at the 5% level, and they indicate a high degree of dependence in the series. In fact, the confidence interval for the fractional-difference parameter \(d\) indicates that the series may be nonstationary. We will proceed as if the series is stationary and suppose that it is fractionally integrated of order 0.46.
We begin our postestimation analysis by predicting the series in sample:

```
predict ptb
  (option xb assumed)
```

We continue by using the estimated fractional-difference parameter to fractionally difference the original series and by plotting the original series, the predicted series, and the fractionally differenced series. See 
[TS] arfima for a definition of the fractional-difference operator.

```
predict fdtb, fdifference
.twoway tsline tb1yr ptb fdtb, legend(cols(1))
```

The above graph shows that the in-sample predictions appear to track the original series well and that the fractionally differenced series looks much more like a stationary series than does the original.

Example 2

In this example, we use the above estimates to produce a dynamic forecast and a confidence interval for the forecast for the one-year treasury bill rate and plot them.

We begin by extending the dataset and using predict to put the dynamic forecast in the new ftb variable and the root mean squared error of the forecast in the new rtb variable. (As discussed in Methods and formulas, the root mean squared error of the forecast accounts for the idiosyncratic error but not for the estimation error.)

```
.tsappend, add(12)
  predict ftb, xb dynamic(tm(2001m9)) rmse(rtb)
```
Now we compute a 90% confidence interval around the dynamic forecast and plot the original series, the in-sample forecast, the dynamic forecast, and the confidence interval of the dynamic forecast.

```
. scalar z = invnormal(0.95)
. generate lb = ftb - z*rtb if month>=tm(2001m9)
   (506 missing values generated)
. generate ub = ftb + z*rtb if month>=tm(2001m9)
   (506 missing values generated)
. twoway tsline tb1yr ftb if month>tm(1998m12) ||
   tsrline lb ub if month>=tm(2001m9),
   legend(cols(1) label(3 "90% prediction interval"))
```

---

**IRF results for ARFIMA**

We assume that you have already read [TS] irf and [TS] irf create. In this section, we illustrate how to calculate the impulse–response function (IRF) of an ARFIMA model.

**Example 3**

Here we use the estimates obtained in example 1 to calculate the IRF of the ARFIMA model; see [TS] irf and [TS] irf create for more details about IRFs.
The figure shows that a shock to tb1yr causes an initial spike in tb1yr, after which the impact of the shock starts decaying slowly. This behavior is characteristic of long-memory processes.

### Methods and formulas

Denote $\gamma_h$, $h = 1, \ldots, t$, to be the autocovariance function of the ARFIMA$(p, d, q)$ process for two observations, $y_t$ and $y_{t-h}$, $h$ time periods apart. The covariance matrix $V$ of the process of length $T$ has a Toeplitz structure of

$$
V = \begin{pmatrix}
\gamma_0 & \gamma_1 & \gamma_2 & \cdots & \gamma_{T-1} \\
\gamma_1 & \gamma_0 & \gamma_1 & \cdots & \gamma_{T-2} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\gamma_{T-1} & \gamma_{T-2} & \gamma_{T-3} & \cdots & \gamma_0
\end{pmatrix}
$$

where the process variance is $\gamma_0 = \text{Var}(y_t)$. We factor $V = LDL'$, where $L$ is lower triangular and $D = \text{Diag}(\nu_t)$. The structure of $L^{-1}$ is of importance.

$$
L^{-1} = \begin{pmatrix}
1 & 0 & 0 & \cdots & 0 & 0 \\
-\tau_{1,1} & 1 & 0 & \cdots & 0 & 0 \\
-\tau_{2,1} & -\tau_{2,1} & 1 & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
-\tau_{T-1,T-1} & -\tau_{T-1,T-2} & -\tau_{T-1,T-2} & \cdots & -\tau_{T-1,1} & 1
\end{pmatrix}
$$

Let $z_t = y_t - x_t\beta$. The best linear predictor of $z_{t+1}$ based on $z_1, z_2, \ldots, z_t$ is $\hat{z}_{t+1} = \sum_{k=1}^{t} \tau_{t,k} z_{t-k+1}$. Define $-\tau_t = (-\tau_{t,1}, -\tau_{t,1}, \ldots, -\tau_{t-1,1})$ to be the $t$th row of $L^{-1}$ up to, but not including, the diagonal. Then $\tau_t = V_t^{-1} \gamma_t$, where $V_t$ is the $t \times t$ upper left submatrix of $V$ and $\gamma_t = (\gamma_1, \gamma_2, \ldots, \gamma_t)'$. Hence, the best linear predictor of the innovations is computed as $\hat{\epsilon} = L^{-1} z$, and the one-step predictions are $\hat{y} = \hat{\epsilon} + X\hat{\beta}$. In practice, the computation is
\[ \hat{y} = \hat{L}^{-1} (y - X\hat{\beta}) + X\hat{\beta} \]

where \( \hat{L} \) and \( \hat{V} \) are computed from the maximum likelihood estimates. We use the Durbin–Levinson algorithm (Palma 2007; Golub and Van Loan 2013) to factor \( \hat{V} \), invert \( \hat{L} \), and scale \( y - X\hat{\beta} \) using only the vector of estimated autocovariances \( \hat{\gamma} \).

The prediction error variances of the one-step predictions are computed recursively in the Durbin–Levinson algorithm. They are the \( \nu_t \) elements in the diagonal matrix \( D \) computed from the Cholesky factorization of \( V \). The recursive formula is \( \nu_0 = \gamma_0 \), and \( \nu_t = \nu_{t-1}(1 - \tau^2_{t,t}) \).

Forecasting is carried out as described by Beran (1994, sec. 8.7), \( \hat{z}_{T+k} = \tilde{\gamma}'_k \hat{V}^{-1}\tilde{z} \), where \( \tilde{\gamma}'_k = (\hat{\gamma}_{T+k-1}, \hat{\gamma}_{T+k-2}, \ldots, \hat{\gamma}_k) \). The forecast mean squared error is computed as \( \text{MSE} (\hat{z}_{T+k}) = \hat{\gamma}_0 - \tilde{\gamma}'_k \hat{V}^{-1}\tilde{\gamma}_k \). Computation of \( \hat{V}^{-1}\tilde{\gamma}_k \) is carried out efficiently using algorithm 4.7.2 of Golub and Van Loan (2013).
