#### tsset — Declare data to be time-series data

Description	Quick start	Menu	Syntax	Options
Remarks and examples	Stored results	References	Also see	

# **Description**

tsset manages the time-series settings of a dataset. tsset *timevar* declares the data in memory to be a time series. This allows you to use Stata's time-series operators and to analyze your data with the ts commands. tsset *panelvar timevar* declares the data to be panel data, also known as cross-sectional time-series data, which contain one time series for each value of *panelvar*. This allows you to also analyze your data with the xt commands without having to xtset your data.

tsset without arguments displays how the data are currently set and sorts the data on *timevar* or *panelvar timevar*.

tsset, clear is a rarely used programmer's command to declare that the data are no longer a time series.

### **Quick start**

Declare data to be a time series with time variable tvar

tsset tvar

Same as above, but specify that tvar records time for a weekly time series tsset tvar, weekly

Same as above, but specify that observations occur every two weeks tsset tvar, weekly delta(2)

Declare a panel dataset with panel identifier pvar and time variable tvar tsset pvar tvar

Same as above, but specify that observations on each panel are made daily tsset pvar tvar, daily

Same as above, but specify that observations on each panel are made every three days tsset pvar tvar, daily delta(3 days)

Display current time-series settings, and sort data by pvar and tvar if they are sorted differently tsset

## Menu

 $Statistics > Time\ series > Setup\ and\ utilities > Declare\ dataset\ to\ be\ time-series\ data$ 

Declare data to be time series

```
tsset timevar [ , options ]
tsset panelvar timevar [ , options ]
```

Display how data are currently tsset

tsset

Clear time-series settings

tsset, clear

In the declare syntax, panelvar identifies the panels and timevar identifies the times.

options	Description
Main unitoptions	specify units of timevar
Delta deltaoption	specify length of period of timevar
noquery	suppress summary calculations and output

collect is allowed; see [U] 11.1.10 Prefix commands. noquery is not shown in the dialog box.

unitoptions	Description
(default)	timevar's units from timevar's display format
<u>c</u> locktime	timevar is %tc: $0 = 1$ jan1960 00:00:00.000, $1 = 1$ jan1960 00:00:00.001,
<u>d</u> aily	timevar is %td: $0 = 1$ jan1960, $1 = 2$ jan1960,
<u>w</u> eekly	timevar is %tw: $0 = 1960 \text{w1}, 1 = 1960 \text{w2}, \dots$
$\underline{\mathtt{m}}\mathtt{onthly}$	timevar is $%tm: 0 = 1960m1, 1 = 1960m2,$
quarterly	timevar is $%$ tq: $0 = 1960$ q1, $1 = 1960$ q2,
$\underline{\underline{\mathtt{h}}}\mathtt{alfyearly}$	timevar is %th: $0 = 1960h1$ , $1 = 1960h2$ ,
yearly	timevar is $\%$ ty: $1960 = 1960, 1961 = 1961,$
_ generic	timevar is %tg: $0 = ?, 1 = ?, \dots$
<pre>format(%fmt)</pre>	specify timevar's format and then apply default rule

In all cases, negative timevar values are allowed.

deltaoption specifies the period between observations in timevar units and may be specified as

deltaoption	Example
delta(#)	delta(1) or delta(2)
<pre>delta((exp))</pre>	delta((7*24))
$\underline{\mathtt{del}}\mathtt{ta}(\#\mathit{units})$	delta(7 days) or delta(15 minutes) or delta(7 days 15 minutes)
$\underline{\text{del}}$ ta(( $exp$ ) units)	delta((2+3) weeks)

Allowed units for %tc and %tC timevars are

seconds second secs sec minutes minute mins min hours hour days day weeks week

and for all other %t timevars, units specified must match the frequency of the data; for example, for %ty, units must be year or years.

# **Options**

unitoptions clocktime, daily, weekly, monthly, quarterly, halfyearly, yearly, generic, and format (% fmt) specify the units in which timevar is recorded.

timevar will usually be a %t variable; see [D] Datetime. If timevar already has a %t display format assigned to it, you do not need to specify a unitoption; tsset will obtain the units from the format. If you have not yet bothered to assign the appropriate %t format, however, you can use the unitoptions to tell tsset the units. Then tsset will set timevar's display format for you. Thus, the unitoptions are convenience options; they allow you to skip formatting the time variable. The following all have the same net result:

Alternative 1	Alternative 2	Alternative 3		
format t %td (t not formatted)		(t not formatted)		
tsset t	tsset t, daily	tsset t, format(%td)		

timevar is not required to be a %t variable; it can be any variable of your own concocting so long as it takes on only integer values. In such cases, it is called generic and considered to be %tg. Specifying the unitoption generic or attaching a special format to timevar, however, is not necessary because tsset will assume that the variable is generic if it has any numerical format other than a %t format (or if it has a %tg format).

clear—used in tsset, clear—makes Stata forget that the data ever were tsset. This is a rarely used programmer's option.

delta() specifies the period between observations in timevar and is commonly used when timevar is %tc. delta() is only sometimes used with the other %t formats or with generic time variables.

If delta() is not specified, delta(1) is assumed. This means that at timevar = 5, the previous time is timevar = 5 - 1 = 4 and the next time would be timevar = 5 + 1 = 6. Lag and lead operators, for instance, would work this way. This would be assumed regardless of the units of timevar.

If you specified delta(2), then at timevar = 5, the previous time would be timevar = 5 - 2 = 3 and the next time would be timevar = 5 + 2 = 7. Lag and lead operators would work this way. In the observation with timevar = 5, L. price would be the value of price in the observation for which timevar = 3 and F. price would be the value of price in the observation for which timevar = 7. If you then add an observation with timevar = 4, the operators will still work appropriately; that is, at timevar = 5, L. price will still have the value of price at timevar = 3.

There are two aspects of *timevar*: its units and its length of period. The *unitoptions* set the units. delta() sets the length of period.

We mentioned that delta() is commonly used with %tc *timevars* because Stata's %tc variables have units of milliseconds. If delta() is not specified and in some model you refer to L.price, you will be referring to the value of price 1 ms ago. Few people have data with periodicity of a millisecond. Perhaps your data are hourly. You could specify delta(3600000). Or you could specify delta((60\*60\*1000)), because delta() will allow expressions if you include an extra pair of parentheses. Or you could specify delta(1 hour). They all mean the same thing: *timevar* has periodicity of 3,600,000 ms. In an observation for which *timevar* = 1,489,572,000,000 (corresponding to 15mar2007 10:00:00), L.price would be the observation for which *timevar* = 1,489,572,000,000 - 3,600,000 = 1,489,568,400,000 (corresponding to 15mar2007 9:00:00).

When you tsset the data and specify delta(), tsset verifies that all the observations follow the specified periodicity. For instance, if you specified delta(2), then timevar could contain any subset of  $\{..., -4, -2, 0, 2, 4, ...\}$  or it could contain any subset of  $\{..., -3, -1, 1, 3, ...\}$ . If timevar contained a mix of values, tsset would issue an error message. If you also specify panelvar—you type tsset panelvar timevar, delta(2)—the check is made on each panel independently. One panel might contain timevar values from one set and the next, another, and that would be fine.

The following option is available with tsset but is not shown in the dialog box:

noquery prevents tsset from performing most of its summary calculations and suppresses output. With this option, only the following results are posted:

```
r(tdelta) r(tsfmt)
r(panelvar) r(unit)
r(timevar) r(unit1)
```

# Remarks and examples

Remarks are presented under the following headings:

Overview Panel data Video example

#### Overview

tsset sets timevar so that Stata's time-series operators are understood in varlists and expressions. The time-series operators are

Operator	Meaning
L.	$-\log x_{t-1}$
L2.	2-period lag $x_{t-2}$
F.	lead $x_{t+1}$
F2.	2-period lead $x_{t+2}$
D.	difference $x_t - x_{t-1}$
D2.	difference of difference $x_t - x_{t-1} - (x_{t-1} - x_{t-2}) = x_t - 2x_{t-1} + x_{t-2}$
S.	"seasonal" difference $x_t - x_{t-1}$
S2.	lag-2 (seasonal) difference $x_t - x_{t-2}$
• • •	

Time-series operators may be repeated and combined. L3. gnp refers to the third lag of variable gnp, as do LLL.gnp, LL2.gnp, and L2L.gnp. LF.gnp is the same as gnp. DS12.gnp refers to the one-period difference of the 12-period difference. LDS12.gnp refers to the same concept, lagged once.

D1. = S1., but D2.  $\neq$  S2., D3.  $\neq$  S3., and so on. D2. refers to the difference of the difference. S2. refers to the two-period difference. If you wanted the difference of the difference of the 12-period difference of gnp, you would write D2S12.gnp.

Operators may be typed in uppercase or lowercase. Most users would type d2s12.gnp instead of D2S12.gnp.

You may type operators however you wish; Stata internally converts operators to their canonical form. If you typed ld2ls12d.gnp, Stata would present the operated variable as L2D3S12.gnp.

Stata also understands operator(numlist). to mean a set of operated variables; thus, typing L(1/3) .gnp in a varlist is the same as typing L .gnp L2 .gnp L3 .gnp. Here are some sample data:

. list year gnp L(1/3).gnp

	year	gnp	L. gnp	L2. gnp	L3. gnp
1. 2.	1989 1990	5452.8 5764.9	5452.8		
3. 4.	1991 1992	5932.4 6229.1	5764.9 5932.4	5452.8 5764.9	5452.8
5.	1993	6519.1	6229.1	5932.4	5764.9
6. 7. 8.	1994 1995 1996	6892.2 7330.1 7453.9	6519.1 6892.2 7330.1	6229.1 6519.1 6892.2	5932.4 6229.1 6519.1

The first two columns show variables in the dataset: year and gnp. The remaining columns show lagged values of gnp that are not in the data but become available when using time-series operators. The third column shows the lag of gnp (L.gnp). The first value of L.gnp is missing because the lag of gnp in

1989 is the gnp of 1988, which occurs before the initial period of our time series. The missing values in the remaining columns follow similar logic. When using estimators with time-series operators, it is important to remember that the size of the estimation sample decreases because of the missing values for the initial time periods.

The operators can also be applied to a list of variables by enclosing the variables in parentheses; for example,

	list	year	gnp	cpi	L(1/3).	(gnp	cpi)
•	TIDO	ycar	5111	Chi	ц(т/о/.	(Sup	CPT

	year	gnp	cpi	L. gnp	L2. gnp	L3. gnp	L. cpi	L2. cpi	L3. cpi
1. 2. 3. 4. 5.	1989 1990 1991 1992 1993	5452.8 5764.9 5932.4 6229.1 6519.1	100 105 108 110 112	5452.8 5764.9 5932.4 6229.1	5452.8 5764.9 5932.4	5452.8 5764.9	100 105 108 110	100 105 108	100 105
6. 7. 8.	1994 1995 1996	6892.2 7330.1 7453.9	119 122 126	6519.1 6892.2 7330.1	6229.1 6519.1 6892.2	5932.4 6229.1 6519.1	112 119 122	110 112 119	108 110 112

In operator#., making # zero returns the variable itself. L0.gnp is gnp. Thus, you can type list year 1(0/3).gnp to mean list year gnp L.gnp L2.gnp L3.gnp.

The parenthetical notation may be used with any operator. Typing D(1/3) . gnp would return the first through third differences.

The parenthetical notation may be used in operator lists with multiple operators, such as L(0/3)D2S12.gnp.

Operator lists may include up to one set of parentheses, and the parentheses may enclose a numlist; see [U] 11.1.8 numlist.

Before you can use these time-series operators, however, the dataset must satisfy two requirements:

- 1. the dataset must be tsset and
- 2. the dataset must be sorted by timevar or, if it is a cross-sectional time-series dataset, by panelvar timevar.

tsset handles both requirements. As you use Stata, however, you may later use a command that re-sorts that data, and if you do, the time-series operators will not work:

```
. tsset time
 (output omitted)
. regress y x 1.x
 (output omitted)
. (you continue to use Stata and, sometime later:)
. regress v x 1.x
not sorted
r(5);
```

Then typing tsset without arguments will reestablish the sort order:

(output omitted) . regress y x 1.x (output omitted)

Here typing tsset is the same as typing sort time. Had we previously tsset country time, however, typing tsset would be the same as typing sort country time. You can type the sort command or type tsset without arguments; it makes no difference.

There are two syntaxes for setting your data:

tsset timevar tsset panelvar timevar

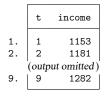

In both, timevar must contain integer values. If panelvar is specified, it too must contain integer values, and the dataset is declared to be a cross-section of time series, such as a collection of time series for different countries. Such datasets can be analyzed with xt commands as well as ts commands. If you tsset panelvar timevar, you do not need to xtset the data to use the xt commands.

If you save the data after typing tsset, the data will be remembered to be time series, and you will not have to tsset the data again.

### Example 1: Numeric time variable

You have monthly data on personal income. Variable t records the time of an observation, but there is nothing special about the name of the variable. There is nothing special about the values of the variable, either. t is not required to be %tm variable—perhaps you do not even know what that means. t is just a numeric variable containing integer values that represent the month, and we will imagine that t takes on the values 1, 2, ..., 9, although it could just as well be -3, -2, ..., 5, or 1,023, 1,024, ..., 1,031. What is important is that the values are dense: adjacent months have a time value that differs by 1.

- . use https://www.stata-press.com/data/r19/tssetxmpl
- . list t income

. tsset t

Time variable: t, 1 to 9 Delta: 1 unit . regress income l.income (output omitted)

### 4

# Example 2: Adjusting the starting date

In the example above, that t started at 1 was not important. As we said, the t variable could just as well be recorded -3, -2, ..., 5, or 1,023, 1,024, ..., 1,031. What is important is that the difference in t between observations be delta() when there are no gaps.

. generate newt = tm(1995m7) + t - 1

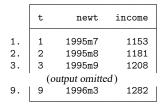

tm() is the function that returns a month equivalent; tm(1995m7) evaluates to the constant 426, meaning 426 months after January 1960. We now have variable newt containing

. list t newt income

	t	newt	income
1.	1	426	1153
2.	2	427	1181
3.	3	428	1208
	' (·	output on	nitted)
9.	9	434	1282

If we put a %tm format on newt, it will display more cleanly:

- . format newt %tm
- . list t newt income

We could now tsset newt rather than t:

. tsset newt
Time variable: newt, 1995m7 to 1996m3

Delta: 1 month

#### □ Technical note

In addition to monthly, Stata understands clock times (to the millisecond level) as well as daily, weekly, quarterly, half-yearly, and yearly data. See [D] **Datetime** for a description of these capabilities.

Let's reconsider the previous example, but rather than monthly, let's assume the data are daily, weekly, etc. The only thing to know is that, corresponding to function tm(), there are functions td(), tw(), tq(), and th() and that, corresponding to format %tm, there are formats %td, %tw, %tq, and %th. Here is what we would have typed had our data been on a different time scale:

4

```
Daily:
           if your t variable had t=1 corresponding to 15mar1993
                . generate newt = td(15mar1993) + t - 1
                . tsset newt, daily
           if your t variable had t=1 corresponding to 1994w1:
Weekly:
                . generate newt = tw(1994w1) + t - 1
                . tsset newt, weekly
Monthly:
           if your t variable had t=1 corresponding to 2004m7:
                . generate newt = tm(2004m7) + t - 1
                . tsset newt, monthly
Ouarterly:
           if your t variable had t=1 corresponding to 1994q1:
                . generate newt = tq(1994q1) + t - 1
                . tsset newt, quarterly
Half-yearly: if your t variable had t=1 corresponding to 1921h2:
                . generate newt = th(1921h2) + t - 1
                . tsset newt, halfyearly
Yearly:
           if your t variable had t=1 corresponding to 1842:
                . generate newt = 1842 + t - 1
                . tsset newt, yearly
```

In each example above, we subtracted one from our time variable in constructing the new time variable newt because we assumed that our starting time value was 1. For the quarterly example, if our starting time value were 5 and that corresponded to 1994q1, we would type

```
. generate newt = tq(1994q1) + t - 5
```

Had our initial time value been t = 742 and that corresponded to 1994q1, we would have typed

```
. generate newt = tq(1994q1) + t - 742
```

## Example 3: Time-series data but no time variable

Perhaps we have the same time-series data but no time variable:

- . use https://www.stata-press.com/data/r19/tssetxmpl2, clear
- . list income

	income	
1.	1153	
2.	1181	
3.	1208	
4.	1272	
5.	1236	
6.	1297	
7.	1265	
8.	1230	
9.	1282	

Say that we know that the first observation corresponds to July 1995 and continues without gaps. We can create a monthly time variable and format it by typing

- . generate  $t = tm(1995m7) + _n -1$
- . format t %tm

We can now tsset our dataset and list it:

. tsset t

Time variable: t, 1995m7 to 1996m3 Delta: 1 month

. list t income

	t	income
1.	1995m7	1153
2.	1995m8	1181
3.	1995m9	1208
	output o	mitted)
9.	1996m3	1282

4

## Example 4: Time variable as a string

Your data might include a time variable that is encoded into a string. In the example below each monthly observation is identified by string variable yrmo containing the month and year of the observation, sometimes with punctuation between:

- . use https://www.stata-press.com/data/r19/tssetxmpl, clear
- . list yrmo income

	yrmo	income
1.	7/1995	1153
2.	8/1995	1181
3.	9/1995	1208
4.	10/1995	1272
5.	11/1995	1236
6.	12/1995	1297
7.	1/1996	1265
8.	2.1996	1230
9.	3- 1996	1282

The first step is to convert the string to a numeric representation. Doing so is easy using the monthly() function; see [D] **Datetime**.

- . generate mdate = monthly(yrmo, "MY")
- . list yrmo mdate income

	yrmo	mdate	income
1.	7/1995	426	1153
2.	8/1995	427	1181
3.	9/1995	428	1208
	output o	mitted)	'
9.	3- 1996	434	1282

Our new variable, mdate, contains the number of months from January 1960. Now that we have numeric variable mdate, we can tsset the data:

- . format mdate %tm
- . tsset mdate

Time variable: mdate, 1995m7 to 1996m3
Delta: 1 month

In fact, we can combine the two and type

. tsset mdate, format(%tm)

Time variable: mdate, 1995m7 to 1996m3
Delta: 1 month

or type

. tsset mdate, monthly

Time variable: mdate, 1995m7 to 1996m3

Delta: 1 month

In all cases, we obtain

. list yrmo mdate income

	yrmo	mdate	income
1.	7/1995	1995m7	1153
2.	8/1995	1995m8	1181
3.	9/1995	1995m9	1208
4.	10/1995	1995m10	1272
5.	11/1995	1995m11	1236
6.	12/1995	1995m12	1297
7.	1/1996	1996m1	1265
8.	2.1996	1996m2	1230
9.	3- 1996	1996m3	1282

Stata can convert many different date formats, including strings like 12jan2009; January 12, 2009; 12-01-2009; 01/12/2009; 01/12/09; 12jan2009 8:14; 12-01-2009 13:12; 01/12/09 1:12 pm; Wed Jan 31 13:03:25 CST 2009; 1998q1; and more. See [D] **Datetime**.

Gaps in the time series cause no difficulties:

- . use https://www.stata-press.com/data/r19/tssetxmpl3, clear
- . list yrmo income

	yrmo	income
1.	7/1995	1153
2.	8/1995	1181
3.	11/1995	1236
4.	12/1995	1297
5.	1/1996	1265
6.	3- 1996	1282

- . generate mdate = monthly(yrmo, "MY")
- . tsset mdate, monthly

Time variable: mdate, 1995m7 to 1996m3, but with gaps

Delta: 1 month

Once the dataset has been tsset, we can use the time-series operators. The D operator specifies first differences:

. list mdate income d.income

	mdate	income	D. income
1.	1995m7	1153	
2.	1995m8	1181	28
3.	1995m11	1236	
4.	1995m12	1297	61
5.	1996m1	1265	-32
6.	1996m3	1282	•

We can use the operators in an expression or variist context; we do not have to create a new variable to hold D.income. We can use D.income with the list command, with regress or any other Stata command that allows time-series variists.

4

### > Example 6: Clock times

We have data from a large hotel in Las Vegas that changes the reservation prices for its rooms hourly. A piece of the data looks like

- . use https://www.stata-press.com/data/r19/tssetxmpl4, clear
- . list in 1/5

	time	price
02.13.2007	09:00	140 155 160
		155 160
	02.13.2007 02.13.2007 02.13.2007	time  02.13.2007 08:00 02.13.2007 09:00 02.13.2007 10:00 02.13.2007 11:00 02.13.2007 12:00

Variable time is a string variable. The first step in making this dataset a time-series dataset is to convert the string to a numeric variable:

- . generate double t = clock(time, "MDY hm")
- . list in 1/5

		time	price	t
1.	02.13.2007	08:00	140	1.487e+12
2.	02.13.2007	09:00	155	1.487e+12
3.	02.13.2007	10:00	160	1.487e+12
4.	02.13.2007	11:00	155	1.487e+12
5.	02.13.2007	12:00	160	1.487e+12

See [D] Datetime conversion for an explanation of what is going on here. clock() is the function that converts strings to datetime (%tc) values. We typed clock(time, "MDY hm") to convert string variable time, and we told clock() that the values in time were in the order month, day, year, hour, and minute. We stored new variable t as a double because time values are large and that is required to prevent rounding. Even so, the resulting values 1.487e+12 look rounded, but that is only because of the default display format for new variables. We can see the values better if we change the format:

- . format t %20.0gc
- . list in 1/5

	time	price	t
1.	02.13.2007 08:00	140	1,486,972,800,000
2.	02.13.2007 09:00	155	1,486,976,400,000
3.	02.13.2007 10:00	160	1,486,980,000,000
4.	02.13.2007 11:00	155	1,486,983,600,000
5.	02.13.2007 12:00	160	1,486,987,200,000

Even better would be to change the format to %tc—Stata's clock-time format:

- . format t %tc
- . list in 1/5

		time	price		t
1.	02.13.2007	08:00	140	13feb2007	08:00:00
2.	02.13.2007	09:00	155	13feb2007	09:00:00
3.	02.13.2007	10:00	160	13feb2007	10:00:00
4.	02.13.2007	11:00	155	13feb2007	11:00:00
5.	02.13.2007	12:00	160	13feb2007	12:00:00

We could drop variable time. New variable t contains the same information as time and t is better because it is a Stata time variable, the most important property of which being that it is numeric rather than string. We can tsset it. Here, however, we also need to specify the length of the periods with tsset's delta() option. Stata's time variables are numeric, but they record milliseconds since 01jan1960 00:00:00. By default, tsset uses delta(1), and that means the time-series operators would not work as we want them to work. For instance, L. price would look back only 1 ms (and find nothing). We want L. price to look back 1 hour (3,600,000 ms):

. tsset t, delta(1 hour)

Time variable: t. 13feb2007 08:00:00 to 13feb2007 14:00:00

Delta: 1 hour

. list t price 1.price in 1/5

	t	price	L. price
1.	13feb2007 08:00:00	140	
2.	13feb2007 09:00:00	155	140
3.	13feb2007 10:00:00	160	155
4.	13feb2007 11:00:00	155	160
5.	13feb2007 12:00:00	160	155

4

## Example 7: Clock times must be double

In the previous example, it was of vital importance that when we generated the "tc variable t,

. generate double t = clock(time, "MDY hm")

we generated it as a double. Let's see what would have happened had we forgotten and just typed generate t = clock(time, "MDY hm"). Let's go back and start with the same original data:

- . use https://www.stata-press.com/data/r19/tssetxmpl4, clear
- . list in 1/5

		time	price
1. 2. 3. 4. 5.	02.13.2007 02.13.2007 02.13.2007 02.13.2007 02.13.2007	09:00 10:00 11:00	140 155 160 155 160

Remember, variable time is a string variable, and we need to convert it to numeric. So we convert, but this time we forget to make the new variable a double:

- . generate t = clock(time, "MDY hm")
- . list in 1/5

	time	price	t
02.13.2007	08:00	140	1.49e+12
02.13.2007	09:00	155	1.49e+12
02.13.2007	10:00	160	1.49e+12
02.13.2007	11:00	155	1.49e+12
02.13.2007	12:00	160	1.49e+12
	02.13.2007 02.13.2007 02.13.2007	time  02.13.2007 08:00 02.13.2007 09:00 02.13.2007 10:00 02.13.2007 11:00 02.13.2007 12:00	02.13.2007 08:00 140 02.13.2007 09:00 155 02.13.2007 10:00 160 02.13.2007 11:00 155

We see the first difference—t now lists as 1.49e+12 rather than 1.487e+12 as it did previously—but this is nothing that would catch our attention. We would not even know that the value is different. Let's continue.

We next put a %20.0gc format on t to better see the numerical values. In fact, that is not something we would usually do in an analysis. We did that in the example to emphasize to you that the t values were really big numbers. We will repeat the exercise just to be complete, but in real analysis, we would not bother.

- . format t %20.0gc
- . list in 1/5

	time	price	t
1.	02.13.2007 08:00	140	1,486,972,780,544
2.	02.13.2007 09:00	155	1,486,976,450,560
3.	02.13.2007 10:00	160	1,486,979,989,504
4.	02.13.2007 11:00	155	1,486,983,659,520
5.	02.13.2007 12:00	160	1,486,987,198,464

Okay, we see big numbers in t. Let's continue.

Next we put a %tc format on t, and that is something we would usually do, and you should always do. You should also list a bit of the data, as we did:

- . format t %tc
- . list in 1/5

	time	price	t
1.	02.13.2007 08:00	140	13feb2007 07:59:40
2.	02.13.2007 09:00	155	13feb2007 09:00:50
3.	02.13.2007 10:00	160	13feb2007 09:59:49
4.	02.13.2007 11:00	155	13feb2007 11:00:59
5.	02.13.2007 12:00	160	13feb2007 11:59:58

By now, you should see a problem: the converted datetime values are off by a second or two. That was caused by rounding. Dates and times should be the same, not approximately the same, and when you see a difference like this, you should say to yourself, "The conversion is off a little. Why is that?" and then you should think, "Of course, rounding. I bet that I did not create t as a double."

4

```
. tsset t, delta(1 hour)
time values with period less than delta() found
r(451);
```

And that is what will happen when you forget to create t as a double. The rounding will cause uneven period, and tsset will complain.

By the way, it is important only that clock times (%tc and %tC variables) be stored as doubles. The other date values %td, %tw, %tm, %tq, %th, and %ty are small enough that they can safely be stored as floats, although forgetting and storing them as doubles does no harm.

### □ Technical note

Stata provides two clock-time formats, %tc and %tC. %tC provides a clock with leap seconds. Leap seconds are occasionally inserted to account for randomness of the earth's rotation, which gradually slows. Unlike the extra day inserted in leap years, the timing of when leap seconds will be inserted cannot be foretold. The authorities in charge of such matters announce a leap second approximately 6 months before insertion. Leap seconds are inserted at the end of the day, and the leap second is called 23:59:60 (that is, 11:59:60 p.m.), which is then followed by the usual 00:00:00 (12:00:00 a.m.). Most nonastronomers find these leap seconds vexing. The added seconds cause problems because of their lack of predictability—knowing how many seconds there will be between 01jan2012 and 01jan2013 is not possible—and because there are not necessarily 24 hours in a day. If you use a leap second—adjusted clock, most days have 24 hours, but a few have 24 hours and 1 second. You must look at a table to find out.

From a time-series analysis point of view, the nonconstant day causes the most problems. Let's say that you have data on blood pressure for a set of patients, taken hourly at 1:00, 2:00, ..., and that you have tsset your data with delta(1 hour). On most days, L24. bp would be blood pressure at the same time yesterday. If the previous day had a leap second, however, and your data were recorded using a leap second—adjusted clock, there would be no observation L24. bp because 86,400 seconds before the current reading does not correspond to an on-the-hour time; 86,401 seconds before the current reading corresponds to yesterday's time. Thus, whenever possible, using Stata's %tc encoding rather than %tC is better.

When times are recorded by computers using leap second—adjusted clocks, however, avoiding %tC is not possible. For performing most time-series analysis, the recommended procedure is to map the %tC values to %tc and then tsset those. You must ask yourself whether the process you are studying is based on the clock—the nurse does something at 2 o'clock every day—or the true passage of time—the emitter spits out an electron every 86,400,000 ms.

When dealing with computer-recorded times, first find out whether the computer (and its time-recording software) use a leap second—adjusted clock. If it does, convert that to a %tC value. Then use function cofC() to convert to a %tc value and tsset that. If variable T contains the %tC value,

```
. generate double t = cofC(T)
. format t %tc
. tsset t, delta(...)
```

Function cofC() moves leap seconds forward: 23:59:60 becomes 00:00:00 of the next day.

## Example 8: Time-series data for multiple groups

Assume that we have a time series on average annual income and that we have the series for two groups: individuals who have not completed high school (edlevel = 1) and individuals who have (edlevel = 2).

- . use https://www.stata-press.com/data/r19/tssetxmpl5, clear
- . list edlevel year income, sep(0)

	edlevel	year	income
1.	1	1988	14500
2.	1	1989	14750
3.	1	1990	14950
4.	1	1991	15100
5.	2	1989	22100
6.	2	1990	22200
7.	2	1992	22800
	I		

We declare the data to be a panel by typing

```
. tsset edlevel year, yearly
Panel variable: edlevel (unbalanced)
Time variable: year, 1988 to 1992, but with a gap
Delta: 1 year
```

Having tsset the data, we can now use time-series operators. The difference operator, for example, can be used to list annual changes in income:

. list edlevel year income d.income, sep(0)

	edlevel	year	income	D.
1.	1	1988	14500	
2.	1	1989	14750	250
3.	1	1990	14950	200
4.	1	1991	15100	150
5.	2	1989	22100	
6.	2	1990	22200	100
7.	2	1992	22800	

We see that in addition to producing missing values due to missing times, the difference operator correctly produced a missing value at the start of each panel. Once we have tsset our panel data, we can use time-series operators and be assured that they will handle missing time periods and panel changes correctly.

# Video example

Formatting and managing dates

## Stored results

tsset stores the following in r():

Scalars	
r(imin)	minimum panel ID
r(imax)	maximum panel ID
r(tmin)	minimum time
r(tmax)	maximum time
r(tdelta)	delta
r(gaps)	1 if there are gaps, 0 otherwise
Macros	
r(panelvar)	name of panel variable
r(timevar)	name of time variable
r(tdeltas)	formatted delta
r(tmins)	formatted minimum time
r(tmaxs)	formatted maximum time
r(tsfmt)	%fmt of time variable
r(unit)	units of time variable: Clock, clock, daily, weekly, monthly, quarterly, halfyearly, yearly, or generic
r(unit1)	units of time variable: C, c, d, w, m, q, h, y, or ""
r(balanced)	unbalanced, weakly balanced, or strongly balanced; panels are strongly balanced if they all have the same time values, weakly balanced if same number of observations but different time values, otherwise unbalanced
