xtivreg offers five different estimators for fitting panel-data models in which some of the right-hand-side covariates are endogenous. These estimators are two-stage least-squares generalizations of simple panel-data estimators for exogenous variables. xtivreg with the be option uses the two-stage least-squares between estimator. xtivreg with the fe option uses the two-stage least-squares within estimator. xtivreg with the re option uses a two-stage least-squares random-effects estimator. There are two implementations: G2SLS from Balestra and Varadharajan-Krishnakumar (1987) and EC2SLS from Baltagi. The Balestra and Varadharajan-Krishnakumar G2SLS is the default because it is computationally less expensive. Baltagi’s EC2SLS can be obtained by specifying the ec2sls option. xtivreg with the fd option requests the two-stage least-squares first-differenced estimator.

See Baltagi (2013) for an introduction to panel-data models with endogenous covariates. For the derivation and application of the first-differenced estimator, see Anderson and Hsiao (1981).

Quick start

Random-effects linear panel-data model with outcome y, exogenous x1, and x2 instrumented by x3 using xtset data

```
xtset data
xtivreg y x1 (x2 = x3)
```

Use fixed-effects estimator and include indicators for each level of categorical variable a

```
xtivreg y x1 i.a (x2 = x3), fe
```

Use between-effects estimator and include indicators for levels of b as instruments

```
xtivreg y x1 i.a (x2 = x3 i.b), be
```

First-differenced model of y as a function of x1 and x2 and the lag of y instrumented by its third lag

```
xtivreg y x1 x2 (L.y = L3.y), fd
```
Syntax

GLS random-effects (RE) model

```
xтивreg depvar [varlist] (varlist2 = varlistiv) [if] [in] [, re RE_options]
```

Between-effects (BE) model

```
xтивreg depvar [varlist] (varlist2 = varlistiv) [if] [in], be [BE_options]
```

Fixed-effects (FE) model

```
xтивreg depvar [varlist] (varlist2 = varlistiv) [if] [in], fe [FE_options]
```

First-differenced (FD) estimator

```
xтивreg depvar [varlist] (varlist2 = varlistiv) [if] [in], fd [FD_options]
```

**SE/Robust**

- `vce(vcetype)`
  - `vcetype` may be `conventional`, `robust`, `cluster clustvar`, `bootstrap`, or `jackknife`

**Reporting**

- `level(#)`
  - set confidence level; default is `level(95)`
- `first`
  - report first-stage estimates
- `small`
  - report $t$ and $F$ statistics instead of $Z$ and $\chi^2$ statistics
- `display_options`
  - control columns and column formats, row spacing, line width, and display of omitted variables
- `coeflegend`
  - display legend instead of statistics

A panel variable must be specified. For `xtivreg`, `fd`, a time variable must also be specified. Use `xtset`; see [XT] `xtset`.

- `varlist1` and `varlist_{iv}` may contain factor variables, except for the `fd` estimator; see [U] 11.4.3 Factor variables.
- `depvar`, `varlist1`, `varlist2`, and `varlist_{iv}` may contain time-series operators; see [U] 11.4.4 Time-series varlists.
- `by` and `statsby` are allowed; see [U] 11.1.10 Prefix commands.
- `coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

**Options for RE model**

- `re` requests the G2SLS random-effects estimator. `re` is the default.
- `ec2sle` requests Baltagi’s EC2SLS random-effects estimator instead of the default Balestra and Varadharajan-Krishnakumar estimator.
- `nosa` specifies that the Baltagi–Chang estimators of the variance components be used instead of the default adapted Swamy–Arora estimators.
- `regress` specifies that all the covariates be treated as exogenous and that the instrument list be ignored. Specifying `regress` causes `xtivreg` to fit the requested panel-data regression model of `depvar` on `varlist1` and `varlist2`, ignoring `varlist_{iv}`.

- `vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster `clustvar`), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] `vce_options`.

- `vce(conventional)`, the default, uses the conventionally derived variance estimator for generalized least-squares regression.
xtivreg — Instrumental variables and two-stage least squares for panel-data models

Specifying `vce(robust)` is equivalent to specifying `vce(cluster panelvar)`; see `xtreg, re` in Methods and formulas of [XT] xtreg.

Reporting

level(#)'; see [R] Estimation options.

first specifies that the first-stage regressions be displayed.

small specifies that t statistics be reported instead of Z statistics and that F statistics be reported instead of \( \chi^2 \) statistics.

theta specifies that the output include the estimated value of \( \theta \) used in combining the between and fixed estimators. For balanced data, this is a constant, and for unbalanced data, a summary of the values is presented in the header of the output.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#), fvwrapon(style), cformat(\%,fmt), pformat(\%,fmt), sformat(\%,fmt), and nolstretch; see [R] Estimation options.

The following option is available with xtivreg but is not shown in the dialog box:

coeflegend; see [R] Estimation options.

Options for BE model

be requests the between regression estimator.

regress specifies that all the covariates be treated as exogenous and that the instrument list be ignored. Specifying `regress` causes xtivreg to fit the requested panel-data regression model of `depvar` on `varlist_1` and `varlist_2`, ignoring `varlist_1v`.

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster `clustvar`), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce options.

`vce(conventional)`, the default, uses the conventionally derived variance estimator for generalized least-squares regression. Specifying `vce(robust)` is equivalent to specifying `vce(cluster panelvar)`; see `xtreg, fe` in Methods and formulas of [XT] xtreg.

Reporting

level(#)'; see [R] Estimation options.

first specifies that the first-stage regressions be displayed.

small specifies that t statistics be reported instead of Z statistics and that F statistics be reported instead of \( \chi^2 \) statistics.

display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nolabel, fvwrap(#), fvwrapon(style), cformat(\%,fmt), pformat(\%,fmt), sformat(\%,fmt), and nolstretch; see [R] Estimation options.
The following option is available with `xtivreg` but is not shown in the dialog box:
`coeflegend`; see [R] Estimation options.

**Options for FE model**

`fe` requests the fixed-effects (within) regression estimator.

`regress` specifies that all the covariates be treated as exogenous and that the instrument list be ignored. Specifying `regress` causes `xtivreg` to fit the requested panel-data regression model of `depvar` on `varlist1` and `varlist2`, ignoring `varlistiv`.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster `clustvar`), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce_options.

`vce(conventional)`, the default, uses the conventionally derived variance estimator for generalized least-squares regression.

Specifying `vce(robust)` is equivalent to specifying `vce(cluster panelvar)`; see `xtreg, fe` in Methods and formulas of [XT] xtreg.

`level(#)`; see [R] Estimation options.

`first` specifies that the first-stage regressions be displayed.

`small` specifies that $t$ statistics be reported instead of $Z$ statistics and that $F$ statistics be reported instead of $\chi^2$ statistics.

(display_options: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%,fmt)`, `pformat(%,fmt)`, `sformat(%,fmt)`, and `nolstretch`; see [R] Estimation options.

The following option is available with `xtivreg` but is not shown in the dialog box:
`coeflegend`; see [R] Estimation options.

**Options for FD model**

`noconstant`; see [R] Estimation options.

`fd` requests the first-differenced regression estimator.

`regress` specifies that all the covariates be treated as exogenous and that the instrument list be ignored. Specifying `regress` causes `xtivreg` to fit the requested panel-data regression model of `depvar` on `varlist1` and `varlist2`, ignoring `varlistiv`. 
vce(vcetype) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional), that are robust to some kinds of misspecification (robust), that allow for intragroup correlation (cluster clustvar), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [XT] vce_options.

vce(conventional), the default, uses the conventionally derived variance estimator for generalized least-squares regression.

Specifying vce(robust) is equivalent to specifying vce(cluster panelvar); see xtreg, fe in Methods and formulas of [XT] xtreg.

level(#); see [R] Estimation options.

first specifies that the first-stage regressions be displayed.

small specifies that t statistics be reported instead of Z statistics and that F statistics be reported instead of χ² statistics.

display_options: noci, nopvalues, noomitted, vsquish, cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch; see [R] Estimation options.

The following option is available with xtivreg but is not shown in the dialog box:

coeflegend; see [R] Estimation options.

Remarks and examples

If you have not read [XT] xt, please do so.

Consider an equation of the form

\[ y_{it} = Y_{it} \gamma + X_{1it} \beta + \mu_i + \nu_{it} = Z_{it} \delta + \mu_i + \nu_{it} \] (1)

where

- \( y_{it} \) is the dependent variable;
- \( Y_{it} \) is an \( 1 \times g_2 \) vector of observations on \( g_2 \) endogenous variables included as covariates, and these variables are allowed to be correlated with the \( \nu_{it} \);
- \( X_{1it} \) is an \( 1 \times k_1 \) vector of observations on the exogenous variables included as covariates;
- \( Z_{it} = [Y_{it}, X_{1it}] \);
- \( \gamma \) is a \( g_2 \times 1 \) vector of coefficients;
- \( \beta \) is a \( k_1 \times 1 \) vector of coefficients; and
- \( \delta \) is a \( K \times 1 \) vector of coefficients, where \( K = g_2 + k_1 \).

Assume that there is a \( 1 \times k_2 \) vector of observations on the \( k_2 \) instruments in \( X_{2it} \). The order condition is satisfied if \( k_2 \geq g_2 \). Let \( X_{it} = [X_{1it}, X_{2it}] \). xtivreg handles exogenously unbalanced panel data. Thus define \( T_i \) to be the number of observations on panel \( i \), \( n \) to be the number of panels and \( N \) to be the total number of observations; that is, \( N = \sum_{i=1}^{n} T_i \).
xtivreg offers five different estimators, which may be applied to models having the form of (1). The first-differenced estimator (FD2SLS) removes the $\mu_i$ by fitting the model in first differences. The within estimator (FE2SLS) fits the model after sweeping out the $\mu_i$ by removing the panel-level means from each variable. The between estimator (BE2SLS) models the panel averages. The two random-effects estimators, G2SLS and EC2SLS, treat the $\mu_i$ as random variables that are independent and identically distributed (i.i.d.) over the panels. Except for (FD2SLS), all of these estimators are generalizations of estimators in xtreg. See [XT] xtreg for a discussion of these estimators for exogenous covariates.

Although the estimators allow for different assumptions about the $\mu_i$, all the estimators assume that the idiosyncratic error term $\nu_{it}$ has zero mean and is uncorrelated with the variables in $X_{it}$. Just as when there are no endogenous covariates, as discussed in [XT] xtreg, there are various perspectives on what assumptions should be placed on the $\mu_i$. If they are assumed to be fixed, the $\mu_i$ may be correlated with the variables in $X_{it}$, and the within estimator is efficient within a class of limited information estimators. Alternatively, if the $\mu_i$ are assumed to be random, they are also assumed to be i.i.d. over the panels. If the $\mu_i$ are assumed to be uncorrelated with the variables in $X_{it}$, the GLS random-effects estimators are more efficient than the within estimator. However, if the $\mu_i$ are correlated with the variables in $X_{it}$, the random-effects estimators are inconsistent but the within estimator is consistent. The price of using the within estimator is that it is not possible to estimate coefficients on time-invariant variables, and all inference is conditional on the $\mu_i$ in the sample. See Mundlak (1978) and Hsiao (2014) for discussions of this interpretation of the within estimator.

Example 1: Fixed-effects model

For the within estimator, consider another version of the wage equation discussed in [XT] xtreg. The data for this example come from an extract of women from the National Longitudinal Survey of Youth that was described in detail in [XT] xt. Restricting ourselves to only time-varying covariates, we might suppose that the log of the real wage was a function of the individual’s age, age$^2$, her tenure in the observed place of employment, whether she belonged to union, whether she lives in metropolitan area, and whether she lives in the south. The variables for these are, respectively, age, c.age#c.age, tenure, union, not_smsa, and south. If we treat all the variables as exogenous, we can use the one-stage within estimator from xtreg, yielding

F test that all u_i=0: F(4133, 14867) = 8.31 Prob > F = 0.0000

All the coefficients are statistically significant and have the expected signs.

Now suppose that we wish to model tenure as a function of union and south and that we believe that the errors in the two equations are correlated. Because we are still interested in the within estimates, we now need a two-stage least-squares estimator. The following output shows the command and the results from fitting this model:
xtivreg — Instrumental variables and two-stage least squares for panel-data models

```
. xtivreg ln_w age c.age#c.age not_smsa (tenure = union south), fe
```

Fixed-effects (within) IV regression

```
Number of obs = 19,007
Group variable: idcode Number of groups = 4,134
```

R-sq:

```
within = 0.1304
dependent variable: ln_w
between = 0.0897
average = 4.6
overall = 0.0897
```

Wald chi2(4) = 147926.58

```
corr(u_i, Xb) = -0.6843
```

```
ln_wage
     Coef.  Std. Err.   z     P>|z|    [95% Conf. Interval]
```

```

_cons    1.678287   .1626657  10.32  0.000    1.359468    1.997106
```

sigma_u .70661941
sigma_e .63029359
rho .55690561 (fraction of variance due to u_i)

F test that all u_i=0: F(4133,14869) = 1.44  Prob > F = 0.0000

Instrumented: tenure
Instruments: age c.age#c.age not_smsa union south

Although all the coefficients still have the expected signs, the coefficients on age and not_smsa are no longer statistically significant. Given that these variables have been found to be important in many other studies, we might want to rethink our specification.
(3) given in *Methods and formulas*. If the `ec2sls` option is specified, *xtivreg* performs Baltagi's EC2SLS. In EC2SLS, the instruments are $\tilde{X}_{it}$ and $X_{it}$, where $\tilde{X}_{it}$ is constructed by passing each of the variables in $X_{it}$ through the within transform, and $X_{it}$ is constructed by passing each variable through the between transform. The within and between transforms are given in the *Methods and formulas* section. Baltagi and Li (1992) show that, although the G2SLS instruments are a subset of those contained in EC2SLS, the extra instruments in EC2SLS are redundant in the sense of White (2001). Given the extra computational cost, G2SLS is the default.

**Example 2: GLS random-effects model**

Here is the output from applying the G2SLS estimator to this model:

```plaintext
. xtivreg ln_w age c.age#c.age not_smsa 2.race (tenure = union birth south), re

sigma_u .36582493
sigma_e .63031479
rho .25197078 (fraction of variance due to u_i)

Instrumented: tenure
Instruments: age c.age#c.age not_smsa 2.race union birth_yr south
```

We have included two time-invariant covariates, `birth_yr` and `2.race`. All the coefficients are statistically significant and are of the expected sign.
Applying the EC2SLS estimator yields similar results:

```
.xtivreg ln_w age c.age#c.age not_smsa 2.race (tenure = union birth south), re
> ec2sls
EC2SLS random-effects IV regression Number of obs = 19,007

➢ Example 3: First-differenced estimator

The two-stage least-squares first-differenced estimator (FD2SLS) has been used to fit both fixed-effect and random-effect models. If the \( \mu_i \) are truly fixed-effects, the FD2SLS estimator is not as efficient as the two-stage least-squares estimator for finite \( T_i \). Similarly, if none of the endogenous variables are lagged dependent variables, the exogenous variables are all strictly exogenous, and the random effects are i.i.d. and independent of the \( X_{it} \), the two-stage GLS estimators are more efficient than the FD2SLS estimator. However, the FD2SLS estimator has been used to obtain consistent estimates when one of these conditions fails. Anderson and Hsiao (1981) used a version of the FD2SLS estimator to fit a panel-data model with a lagged dependent variable.

Arellano and Bond (1991) develop new one-step and two-step GMM estimators for dynamic panel data. See [XT] xtabond for a discussion of these estimators and Stata’s implementation of them. In their article, Arellano and Bond (1991) apply their new estimators to a model of dynamic labor demand that had previously been considered by Layard and Nickell (1986). They also compare the results of their estimators with those of the Anderson–Hsiao estimator using data from an unbalanced panel of firms from the United Kingdom. As is conventional, all variables are indexed over the firm \( i \) and time \( t \). In this dataset, \( n_{it} \) is the log of employment in firm \( i \) inside the United Kingdom at time \( t \), \( w_{it} \) is the natural log of the real product wage, \( k_{it} \) is the natural log of the gross capital stock, and \( y_{it} \) is the natural log of industry output. The model also includes time dummies \( yr_{1980}, yr_{1981}, yr_{1982}, yr_{1983}, \) and \( yr_{1984} \). In Arellano and Bond (1991, table 5, column e), the authors present the results from applying one version of the Anderson–Hsiao estimator to these data. This example reproduces
their results for the coefficients, though standard errors are slightly different because Arellano and Bond are using robust standard errors from GMM while we obtain our robust standard errors from 2SLS.

Methods and formulas

Consider an equation of the form

\[ y_{it} = Y_{it} \gamma + X_{1it} \beta + \mu_i + \nu_{it} = Z_{it} \delta + \mu_i + \nu_{it} \quad (2) \]

where
- \( y_{it} \) is the dependent variable;
- \( Y_{it} \) is an \( 1 \times g_2 \) vector of observations on \( g_2 \) endogenous variables included as covariates, and these variables are allowed to be correlated with the \( \nu_{it} \);
- \( X_{1it} \) is an \( 1 \times k_1 \) vector of observations on the exogenous variables included as covariates;
- \( Z_{it} = [Y_{it} \ X_{it}] \);
- \( \gamma \) is a \( g_2 \times 1 \) vector of coefficients;
- \( \beta \) is a \( k_1 \times 1 \) vector of coefficients; and
- \( \delta \) is a \( K \times 1 \) vector of coefficients, where \( K = g_2 + k_1 \).

Assume that there is a \( 1 \times k_2 \) vector of observations on the \( k_2 \) instruments in \( X_{2it} \). The order condition is satisfied if \( k_2 \geq g_2 \). Let \( X_{it} = [X_{1it} \ X_{2it}] \). \texttt{xtivreg} handles exogenously unbalanced panel data. Thus define \( T_i \) to be the number of observations on panel \( i \), \( n \) to be the number of panels, and \( N \) to be the total number of observations; that is, \( N = \sum_{i=1}^{n} T_i \).

Methods and formulas are presented under the following headings:

\texttt{xtivreg, fd}
\texttt{xtivreg, fe}
\texttt{xtivreg, be}
\texttt{xtivreg, re}

\texttt{xtivreg, fd}

As the name implies, this estimator obtains its estimates and conventional VCE from an instrumental-variables regression on the first-differenced data. Specifically, first differencing the data yields

\[ y_{it} - y_{it-1} = (Z_{it} - Z_{i,t-1}) \delta + \nu_{it} - \nu_{i,t-1} \]

With the \( \mu_i \) removed by differencing, we can obtain the estimated coefficients and their estimated variance–covariance matrix from a two-stage least-squares regression of \( \Delta y_{it} \) on \( \Delta Z_{it} \) with instruments \( \Delta X_{it} \).

\( R^2 \) within is reported as \( \left[ \text{corr}\{ (Z_{it} - Z_i) \hat{\delta}, y_{it} - \bar{y}_i \} \right]^2 \).

\( R^2 \) between is reported as \( \left\{ \text{corr}(Z_i \hat{\delta}, \bar{y}_i) \right\}^2 \).

\( R^2 \) overall is reported as \( \left\{ \text{corr}(Z_{it} \hat{\delta}, y_{it}) \right\}^2 \).

\texttt{xtivreg, fe}

At the heart of this model is the within transformation. The within transform of a variable \( w \) is

\[ \tilde{w}_{it} = w_{it} - \bar{w}_i + \bar{w} \]
where
\[ \bar{w}_i = \frac{1}{n} \sum_{t=1}^{T_i} w_{it} \]
\[ \bar{w} = \frac{1}{N} \sum_{i=1}^{n} \sum_{t=1}^{T_i} w_{it} \]
and \( n \) is the number of groups and \( N \) is the total number of observations on the variable.

The within transform of (2) is
\[ \tilde{y}_{it} = \tilde{Z}_{it} + \tilde{\nu}_{it} \]
The within transform has removed the \( \mu_i \). With the \( \mu_i \) gone, the within 2SLS estimator can be obtained from a two-stage least-squares regression of \( \tilde{y}_{it} \) on \( \tilde{Z}_{it} \) with instruments \( \tilde{X}_{it} \).

Suppose that there are \( K \) variables in \( Z_{it} \), including the mandatory constant. There are \( K + n - 1 \) parameters estimated in the model, and the conventional VCE for the within estimator is
\[ \frac{N - K}{N - n - K + 1} V_{IV} \]
where \( V_{IV} \) is the VCE from the above two-stage least-squares regression. The robust and cluster–robust variance–covariance matrices are the robust and cluster–robust variance–covariance matrices from a two-stage least-squares regression of \( \tilde{y}_{it} \) on \( \tilde{Z}_{it} \) with instruments \( \tilde{X}_{it} \).

From the estimate of \( \hat{\delta} \), estimates \( \hat{\mu}_i \) of \( \mu_i \) are obtained as \( \hat{\mu}_i = \tilde{y}_i - \tilde{Z}_i \hat{\delta} \). Reported from the calculated \( \hat{\mu}_i \) is its standard deviation and its correlation with \( \tilde{Z}_i \hat{\delta} \). Reported as the standard deviation of \( \nu_{it} \) is the regression’s estimated root mean squared error, \( s^2 \), which is adjusted (as previously stated) for the \( n - 1 \) estimated means.

\( R^2 \) within is reported as the \( R^2 \) from the mean-deviated regression.
\( R^2 \) between is reported as \( \left\{ \text{corr}(\tilde{Z}_i \hat{\delta}, \tilde{y}_i) \right\}^2 \).
\( R^2 \) overall is reported as \( \left\{ \text{corr}(\tilde{Z}_{it} \hat{\delta}, y_{it}) \right\}^2 \).

At the bottom of the output, an \( F \) statistics against the null hypothesis that all the \( \mu_i \) are zero is reported. This \( F \) statistic is an application of the results in Wooldridge (1990).

xtivreg, be

After passing (2) through the between transform, we are left with
\[ \bar{y}_i = \alpha + \bar{Z}_i \delta + \mu_i + \bar{\nu}_i \]
(3)
where
\[ \bar{w}_i = \frac{1}{T_i} \sum_{t=1}^{T_i} w_{it} \quad \text{for} \quad w \in \{ y, Z, \nu \} \]
Similarly, define $\bar{X}_i$ as the matrix of instruments $X_{it}$ after they have been passed through the between transform.

The BE2SLS estimator of (3) obtains its coefficient estimates and its VCE, a two-stage least-squares regression of $\bar{y}_i$ on $\bar{Z}_i$ with instruments $\bar{X}_i$ in which each average appears $T_i$ times.

$R^2$ between is reported as the $R^2$ from the fitted regression.

$R^2$ within is reported as $\left[ \text{corr}\left( (Z_{it} - \bar{Z}_i)\hat{\delta}, y_{it} - \bar{y}_i \right) \right]^2$.

$R^2$ overall is reported as $\left\{ \text{corr}(Z_{it}\hat{\delta}, y_{it}) \right\}^2$.

**xtivreg, re**

Per Baltagi and Chang (2000), let $u = \mu_i + \nu_{it}$ be the $N \times 1$ vector of combined errors. Then under the assumptions of the random-effects model,

$$E(uu') = \sigma_\nu^2 \text{diag} \left[ I_{T_i} - \frac{1}{T_i} \tau_i \tau_i' \right] + \text{diag} \left[ w_i \frac{1}{T_i} \tau_i \tau_i' \right]$$

where

$$\omega_i = T_i \sigma_\mu^2 + \sigma_\nu^2$$

and $\tau_i$ is a vector of ones of dimension $T_i$.

Because the variance components are unknown, consistent estimates are required to implement feasible GLS. *xtivreg* offers two choices. The default is a simple extension of the Swamy–Arora method for unbalanced panels.

Let

$$u_{it}^w = \tilde{y}_{it} - \tilde{Z}_{it}\hat{\delta}_w$$

be the combined residuals from the within estimator. Let $\tilde{u}_{it}$ be the within-transformed $u_{it}$. Then

$$\hat{\sigma}_\nu = \frac{\sum_{i=1}^n \sum_{t=1}^{T_i} \tilde{u}_{it}^2}{N - n - K + 1}$$

Let

$$u_{it}^b = y_{it} - Z_{it}\delta_b$$

be the combined residual from the between estimator. Let $\tilde{u}_{it}$ be the residuals after they have been passed through the between transform. Then

$$\hat{\sigma}_\mu^2 = \frac{\sum_{i=1}^n \sum_{t=1}^{T_i} \tilde{u}_{it}^2 - (n - K)\hat{\sigma}_\nu^2}{N - r}$$

where

$$r = \text{trace} \left\{ \left( \bar{Z}_i' \bar{Z}_i \right)^{-1} \bar{Z}_i Z_{it} Z_{it}' \bar{Z}_i \right\}$$

where

$$Z_{it} = \text{diag} \left( \tau_i \tau_i' \right)$$
If the \texttt{nosa} option is specified, the consistent estimators described in Baltagi and Chang (2000) are used. These are given by

\[
\hat{\sigma}_\nu^2 = \frac{\sum_{i=1}^n \sum_{t=1}^{T_i} \tilde{u}^2_{it}}{N - n}
\]

and

\[
\hat{\sigma}_\mu^2 = \frac{\sum_{i=1}^n \sum_{t=1}^{T_i} \bar{u}^2_{it} - n\hat{\sigma}_\nu^2}{N}
\]

The default Swamy–Arora method contains a degree-of-freedom correction to improve its performance in small samples.

Given estimates of the variance components, \(\hat{\sigma}_\nu^2\) and \(\hat{\sigma}_\mu^2\), the feasible GLS transform of a variable \(w\) is

\[
w^* = w_{it} - \hat{\theta}_{it} \bar{w}_i. \tag{4}
\]

where

\[
\bar{w}_i = \frac{1}{T_i} \sum_{t=1}^{T_i} w_{it}
\]

\[
\hat{\theta}_{it} = 1 - \left(\frac{\hat{\sigma}_\nu^2}{\hat{\omega}_i}\right)^{-\frac{1}{2}}
\]

and

\[
\hat{\omega}_i = T_i \hat{\sigma}_\mu^2 + \hat{\sigma}_\nu^2
\]

Using either estimator of the variance components, xtivreg contains two GLS estimators of the random-effects model. These two estimators differ only in how they construct the GLS instruments from the exogenous and instrumental variables contained in \(X_{it} = [X_{1it}X_{2it}]\). The default method, \text{G2SLS}, which is from Balestra and Varadharajan-Krishnakumar, uses the exogenous variables after they have been passed through the feasible GLS transform. Mathematically, \text{G2SLS} uses \(X^*\) for the GLS instruments, where \(X^*\) is constructed by passing each variable in \(X\) though the GLS transform in (4). The \text{G2SLS} estimator obtains its coefficient estimates and VCE from an instrumental variable regression of \(y^*_{it}\) on \(Z^*_{it}\) with instruments \(X^*_{it}\).

If the \texttt{ec2sls} option is specified, xtivreg performs Baltagi’s \text{EC2SLS}. In \text{EC2SLS}, the instruments are \(\widetilde{X}_{it}\) and \(\overline{X}_{it}\), where \(X_{it}\) is constructed by each of the variables in \(X_{it}\) throughout the GLS transform in (4), and \(\overline{X}_{it}\) is made of the group means of each variable in \(X_{it}\). The \text{EC2SLS} estimator obtains its coefficient estimates and its VCE from an instrumental variables regression of \(y^*_{it}\) on \(Z^*_{it}\) with instruments \(\widetilde{X}_{it}\) and \(\overline{X}_{it}\).

Baltagi and Li (1992) show that although the \text{G2SLS} instruments are a subset of those in \text{EC2SLS}, the extra instruments in \text{EC2SLS} are redundant in the sense of White (2001). Given the extra computational cost, \text{G2SLS} is the default.
The standard deviation of $\mu_i + \nu_{it}$ is calculated as $\sqrt{\hat{\sigma}_\mu^2 + \hat{\sigma}_\nu^2}$.

$R^2$ between is reported as $\left\{ \text{corr}(\mathbf{Z}_i \hat{\delta}, \bar{y}_i) \right\}^2$.

$R^2$ within is reported as $\left[ \text{corr}\{ (\mathbf{Z}_{it} - \mathbf{Z}_i) \hat{\delta}, y_{it} - \bar{y}_i \} \right]^2$.

$R^2$ overall is reported as $\left\{ \text{corr}(\mathbf{Z}_{it} \hat{\delta}, y_{it}) \right\}^2$.

Acknowledgment

We thank Mead Over of the Center for Global Development, who wrote an early implementation of `xtivreg`.
