Description

Remarks and examples

Syntax

```
cross using filename
```

Menu

Data > Combine datasets > Form every pairwise combination of two datasets

Description

`cross` forms every pairwise combination of the data in memory with the data in *filename*. If *filename* is specified without a suffix, `.dta` is assumed.

Remarks and examples

stata.com

This command is rarely used; also see [\[D\] joinby](#), [\[D\] merge](#), and [\[D\] append](#).

Crossing refers to merging two datasets in every way possible. That is, the first observation of the data in memory is merged with every observation of *filename*, followed by the second, and so on. Thus the result will have N_1N_2 observations, where N_1 and N_2 are the number of observations in memory and in *filename*, respectively.

Typically, the datasets will have no common variables. If they do, such variables will take on only the values of the data in memory.

► Example 1

We wish to form a dataset containing all combinations of three age categories and two sexes to serve as a stub. The three age categories are 20, 30, and 40. The two sexes are male and female:

```
. input str6 sex
      sex
  1. male
  2. female
  3. end
. save sex
file sex.dta saved
. drop _all
. input agecat
      agecat
  1. 20
  2. 30
  3. 40
  4. end
. cross using sex
```

```
. list
```

	agecat	sex
1.	20	male
2.	30	male
3.	40	male
4.	20	female
5.	30	female
6.	40	female
