Syntax

Basic syntax

    ratio [name:] varname [ / ] varname

Full syntax

    ratio ([name:] varname [ / ] varname)
        ( [ (name:] varname [ / ] varname ) ... ) [ if ] [ in ] [ weight ] [ , options ]

options                  Description

Model
    stdize(varname)       variable identifying strata for standardization
    stdweight(varname)    weight variable for standardization
    nostdrescale          do not rescale the standard weight variable

if/in/over
    over(varlist[, nolabel])  group over subpopulations defined by varlist; optionally,
                              suppress group labels

SE/Cluster
    vce(vcetype)          vcetype may be linearized, cluster clustvar, bootstrap, or
                           jackknife

Reporting
    level(#)              set confidence level; default is level(95)
    noheader              suppress table header
    nolegend              suppress table legend
    display_options       control column formats and line width
    coeflegend            display legend instead of statistics

bootstrap, jackknife, mi estimate, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.
    vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.
Weights are not allowed with the bootstrap prefix; see [R] bootstrap.
    vce() and weights are not allowed with the svy prefix; see [SVY] svy.
fweight, iweight, and pweight are allowed; see [U] 11.1.6 weight.
coeflegend does not appear in the dialog box.
See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

Description

ratio produces estimates of ratios, along with standard errors.

Options

\texttt{stdize(varname)} specifies that the point estimates be adjusted by direct standardization across the strata identified by \texttt{varname}. This option requires the \texttt{stdweight()} option.

\texttt{stdweight(varname)} specifies the weight variable associated with the standard strata identified in the \texttt{stdize()} option. The standardization weights must be constant within the standard strata.

\texttt{nostdrescale} prevents the standardization weights from being rescaled within the \texttt{over()} groups. This option requires \texttt{stdize()} but is ignored if the \texttt{over()} option is not specified.

\texttt{over(varlist[, nolabel])} specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in \texttt{varlist}.

When this option is supplied with one variable name, such as \texttt{over(varname)}, the value labels of \texttt{varname} are used to identify the subpopulations. If \texttt{varname} does not have labeled values (or there are unlabeled values), the values themselves are used, provided that they are nonnegative integers. Noninteger values, negative values, and labels that are not valid Stata names are substituted with a default identifier.

When \texttt{over()} is supplied with multiple variable names, each subpopulation is assigned a unique default identifier.

\texttt{nolabel} requests that value labels attached to the variables identifying the subpopulations be ignored.

\texttt{vce(vcetype)} specifies the type of standard error reported, which includes types that are derived from asymptotic theory (linearized), that allow for intragroup correlation (cluster \texttt{clustvar}), and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] \texttt{vce option}.

\texttt{vce(linearized)}, the default, uses the linearized or sandwich estimator of variance.

\texttt{level(#)}; see [R] estimation options.

\texttt{noheader} prevents the table header from being displayed. This option implies \texttt{nolegend}.

\texttt{nolegend} prevents the table legend identifying the subpopulations from being displayed.

\textit{display_options}: \texttt{cformat(\%fmt)} and \texttt{nolstretch}; see [R] estimation options.

The following option is available with \texttt{ratio} but is not shown in the dialog box:

\texttt{coeflegend}; see [R] estimation options.
Remarks and examples

Example 1

Using the fuel data from example 3 of [R] \texttt{ttest}, we estimate the ratio of mileage for the cars without the fuel treatment (\texttt{mpg1}) to those with the fuel treatment (\texttt{mpg2}).

\begin{verbatim}
. use http://www.stata-press.com/data/r13/fuel
. ratio myratio: mpg1/mpg2
  Ratio estimation  Number of obs = 12
       myratio: mpg1/mpg2

  Linearized
  Ratio   Std. Err.   [95% Conf. Interval]
  myratio   .9230769   .0324931    .8515603    .9945936
\end{verbatim}

Using these results, we can test to see if this ratio is significantly different from one.

\begin{verbatim}
. test _b[myratio] = 1
  ( 1) myratio = 1
   F(  1,   11) = 5.60
   Prob > F = 0.0373
\end{verbatim}

We find that the ratio is different from one at the 5\% significance level but not at the 1\% significance level.

Example 2

Using state-level census data, we want to test whether the marriage rate is equal to the death rate.

\begin{verbatim}
. use http://www.stata-press.com/data/r13/census2
  (1980 Census data by state)
. ratio (deathrate: death/pop) (marrate: marriage/pop)
  Ratio estimation  Number of obs = 50
       deathrate: death/pop
       marrate: marriage/pop

  Linearized
  Ratio   Std. Err.   [95% Conf. Interval]
  deathrate   .0087368   .0002052    .0083244    .0091492
  marrate   .0105577   .0006184    .0093150    .0118005
\end{verbatim}

\begin{verbatim}
. test _b[deathrate] = _b[marrate]
  ( 1) deathrate - marrate = 0
   F(  1,   49) = 6.93
   Prob > F = 0.0113
\end{verbatim}
Stored results

`ratio` stores the following in `e()`:

Scalars

- `e(N)` number of observations
- `e(N_over)` number of subpopulations
- `e(N_stdize)` number of standard strata
- `e(N_clust)` number of clusters
- `e(k_eq)` number of equations in `e(b)`
- `e(df_r)` sample degrees of freedom
- `e(rank)` rank of `e(V)`

Macros

- `e(cmd)` `ratio`
- `e(cmdline)` command as typed
- `e(varlist)` `varlist`
- `e(stdize)` `varname` from `stdize()`
- `e(stdweight)` `varname` from `stdweight()`
- `e(wtype)` weight type
- `e(wexp)` weight expression
- `e(title)` title in estimation output
- `e(cluster)` name of cluster variable
- `e(over)` `varlist` from `over()`
- `e(over_labels)` labels from `over()` variables
- `e(over_namelist)` names from `e(over_labels)`
- `e(namelist)` ratio identifiers
- `e(vce)` `vcetype` specified in `vce()`
- `e(vcetype)` title used to label Std. Err.
- `e(properties)` `b V` 
- `e(estat_cmd)` program used to implement `estat` 
- `e(marginsnotok)` predictions disallowed by `margins`

Matrices

- `e(b)` vector of ratio estimates
- `e(V)` (co)variance estimates
- `e(N)` vector of numbers of nonmissing observations
- `e(N_stdsum)` number of nonmissing observations within the standard strata
- `e(p_stdize)` standardizing proportions
- `e(error)` error code corresponding to `e(b)`

Functions

- `e(sample)` marks estimation sample

Methods and formulas

Methods and formulas are presented under the following headings:

- The ratio estimator
- Survey data
- The survey ratio estimator
- The standardized ratio estimator
- The poststratified ratio estimator
- The standardized poststratified ratio estimator
- Subpopulation estimation
The ratio estimator

Let \( R = Y/X \) be the ratio to be estimated, where \( Y \) and \( X \) are totals; see [R total]. The estimate for \( R \) is \( \hat{R} = \hat{Y}/\hat{X} \) (the ratio of the sample totals). From the delta method (that is, a first-order Taylor expansion), the approximate variance of the sampling distribution of the linearized \( \hat{R} \) is

\[
V(\hat{R}) \approx \frac{1}{\hat{X}^2} \left\{ V(\hat{Y}) - 2R\text{Cov}(\hat{Y}, \hat{X}) + R^2V(\hat{X}) \right\}
\]

Direct substitution of \( \hat{X}, \hat{R} \), and the estimated variances and covariance of \( \hat{X} \) and \( \hat{Y} \) leads to the following variance estimator:

\[
\hat{V}(\hat{R}) = \frac{1}{\hat{X}^2} \left\{ \hat{V}(\hat{Y}) - 2\hat{R}\text{Cov}(\hat{Y}, \hat{X}) + \hat{R}^2\hat{V}(\hat{X}) \right\}
\] (1)

Survey data

See [SVY] variance estimation, [SVY] direct standardization, and [SVY] poststratification for discussions that provide background information for the following formulas.

The survey ratio estimator

Let \( Y_j \) and \( X_j \) be survey items for the \( j \)th individual in the population, where \( j = 1, \ldots, M \) and \( M \) is the size of the population. The associated population ratio for the items of interest is \( R = Y/X \) where

\[
Y = \sum_{j=1}^{M} Y_j \quad \text{and} \quad X = \sum_{j=1}^{M} X_j
\]

Let \( y_j \) and \( x_j \) be the corresponding survey items for the \( j \)th sampled individual from the population, where \( j = 1, \ldots, m \) and \( m \) is the number of observations in the sample.

The estimator \( \hat{R} \) for the population ratio \( R \) is \( \hat{R} = \hat{Y}/\hat{X} \), where

\[
\hat{Y} = \sum_{j=1}^{m} w_j y_j \quad \text{and} \quad \hat{X} = \sum_{j=1}^{m} w_j x_j
\]

and \( w_j \) is a sampling weight. The score variable for the ratio estimator is

\[
z_j(\hat{R}) = \frac{y_j - \hat{R}x_j}{\hat{X}} = \frac{\hat{X}y_j - \hat{Y}x_j}{\hat{X}^2}
\]
The standardized ratio estimator

Let \( D_g \) denote the set of sampled observations that belong to the \( g \)th standard stratum and define \( I_{D_g}(j) \) to indicate if the \( j \)th observation is a member of the \( g \)th standard stratum; where \( g = 1, \ldots, L_D \) and \( L_D \) is the number of standard strata. Also, let \( \pi_g \) denote the fraction of the population that belongs to the \( g \)th standard stratum, thus \( \pi_1 + \cdots + \pi_{L_D} = 1 \). Note that \( \pi_g \) is derived from the stdweight() option.

The estimator for the standardized ratio is

\[
\hat{R}_D = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g}{\hat{X}_g}
\]

where

\[
\hat{Y}_g = \sum_{j=1}^{m} I_{D_g}(j) w_j y_j
\]

and \( \hat{X}_g \) is similarly defined. The score variable for the standardized ratio is

\[
z_j(\hat{R}_D) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) \frac{\hat{X}_g y_j - \hat{Y}_g x_j}{\hat{X}_g^2}
\]

The poststratified ratio estimator

Let \( P_k \) denote the set of sampled observations that belong to poststratum \( k \), and define \( I_{P_k}(j) \) to indicate if the \( j \)th observation is a member of poststratum \( k \), where \( k = 1, \ldots, L_P \) and \( L_P \) is the number of poststrata. Also, let \( M_k \) denote the population size for poststratum \( k \). \( P_k \) and \( M_k \) are identified by specifying the poststrata() and postweight() options on svyset; see [SVY] svyset.

The estimator for the poststratified ratio is

\[
\hat{R}_P = \frac{\hat{Y}_P}{\hat{X}_P}
\]

where

\[
\hat{Y}_P = \sum_{k=1}^{L_P} \frac{M_k}{M_k} \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{M_k} \sum_{j=1}^{m} I_{P_k}(j) w_j y_j
\]

and \( \hat{X}_P \) is similarly defined. The score variable for the poststratified ratio is

\[
z_j(\hat{R}_P) = \frac{z_j(\hat{Y}_P) - \hat{R}_P z_j(\hat{X}_P)}{\hat{X}_P} = \frac{\hat{X}_P z_j(\hat{Y}_P) - \hat{Y}_P z_j(\hat{X}_P)}{(\hat{X}_P)^2}
\]

where

\[
z_j(\hat{Y}_P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{M_k} \left( y_j - \frac{\hat{Y}_k}{M_k} \right)
\]

and \( z_j(\hat{X}_P) \) is similarly defined.
The standardized poststratified ratio estimator

The estimator for the standardized poststratified ratio is

\[
\hat{R}_{DP} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g^P}{\hat{X}_g^P}
\]

where

\[
\hat{Y}_g^P = \sum_{k=1}^{L_P} \frac{M_k}{M} \hat{Y}_{g,k} = \sum_{k=1}^{L_P} \frac{M_k}{M} \sum_{j=1}^{m} I_{D_g}(j)I_{P_k}(j) w_j y_j
\]

and \(\hat{X}_g^P\) is similarly defined. The score variable for the standardized poststratified ratio is

\[
z_j(\hat{R}_{DP}) = \sum_{g=1}^{L_D} \pi_g \frac{\hat{X}_g^P z_j(\hat{Y}_g^P) - \hat{Y}_g^P z_j(\hat{X}_g^P)}{(\hat{X}_g^P)^2}
\]

Subpopulation estimation

Let \(S\) denote the set of sampled observations that belong to the subpopulation of interest, and define \(I_S(j)\) to indicate if the \(j\)th observation falls within the subpopulation.

The estimator for the subpopulation ratio is \(\hat{R}^S = \hat{Y}^S / \hat{X}^S\), where

\[
\hat{Y}^S = \sum_{j=1}^{m} I_S(j) w_j y_j \quad \text{and} \quad \hat{X}^S = \sum_{j=1}^{m} I_S(j) w_j x_j
\]

Its score variable is

\[
z_j(\hat{R}^S) = I_S(j) \frac{y_j - \hat{X}^S x_j}{\hat{X}^S} = I_S(j) \frac{\hat{X}^S y_j - \hat{Y}^S x_j}{(\hat{X}^S)^2}
\]

The estimator for the standardized subpopulation ratio is

\[
\hat{R}^{DS} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g^S}{\hat{X}_g^S}
\]

where

\[
\hat{Y}_g^S = \sum_{j=1}^{m} I_{D_g}(j)I_S(j) w_j y_j
\]

and \(\hat{X}_g^S\) is similarly defined. Its score variable is

\[
z_j(\hat{R}^{DS}) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j)I_S(j) \frac{\hat{X}_g^S y_j - \hat{Y}_g^S x_j}{(\hat{X}_g^S)^2}
\]
The estimator for the poststratified subpopulation ratio is

$$\hat{R}^{PS} = \frac{\hat{Y}^{PS}}{\hat{X}^{PS}}$$

where

$$\hat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{M} \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{M} \sum_{j=1}^{m} I_{P_k}(j) I_S(j) w_j y_j$$

and $\hat{X}^{PS}$ is similarly defined. Its score variable is

$$z_j(\hat{R}^{PS}) = \frac{\hat{X}^{PS} z_j(\hat{Y}^{PS}) - \hat{Y}^{PS} z_j(\hat{X}^{PS})}{(\hat{X}^{PS})^2}$$

where

$$z_j(\hat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{M} \left\{ I_S(j) y_j - \frac{\hat{Y}_k}{M_k} \right\}$$

and $z_j(\hat{X}^{PS})$ is similarly defined.

The estimator for the standardized poststratified subpopulation ratio is

$$\hat{R}^{DPS} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g^{PS}}{\hat{X}_g^{PS}}$$

where

$$\hat{Y}_g^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{M} \hat{Y}_{g,k} = \sum_{k=1}^{L_P} \frac{M_k}{M} \sum_{j=1}^{m} I_{D_g}(j) I_{P_k}(j) I_S(j) w_j y_j$$

and $\hat{X}_g^{PS}$ is similarly defined. Its score variable is

$$z_j(\hat{R}^{DPS}) = \sum_{g=1}^{L_D} \pi_g \frac{\hat{X}_g^{PS} z_j(\hat{Y}_g^{PS}) - \hat{Y}_g^{PS} z_j(\hat{X}_g^{PS})}{(\hat{X}_g^{PS})^2}$$

where

$$z_j(\hat{Y}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{M} \left\{ I_{D_g}(j) I_S(j) y_j - \frac{\hat{Y}_{g,k}}{M_k} \right\}$$

and $z_j(\hat{X}_g^{PS})$ is similarly defined.
