tabulate

Statistics > Summaries, tables, and tests > Frequency tables > Two-way table with measures of association

tab2

Statistics > Summaries, tables, and tests > Frequency tables > All possible two-way tables

tabi

Statistics > Summaries, tables, and tests > Frequency tables > Table calculator

Description

tabulate produces a two-way table of frequency counts, along with various measures of association, including the common Pearson's χ^2 , the likelihood-ratio χ^2 , Cramér's V, Fisher's exact test, Goodman and Kruskal's gamma, and Kendall's τ_b .

Line size is respected. That is, if you resize the Results window before running tabulate, the resulting two-way tabulation will take advantage of the available horizontal space. Stata for Unix(console) users can instead use the set linesize command to take advantage of this feature.

tab2 produces all possible two-way tabulations of the variables specified in varlist.

tabi displays the $r \times c$ table, using the values specified; rows are separated by '\'. If no options are specified, it is as if exact were specified for a 2×2 table and chi2 were specified otherwise. See [U] 19 Immediate commands for a general description of immediate commands. See Tables with immediate data below for examples using tabi.

See [R] tabulate oneway if you want a one-way table of frequencies. See [R] table and [R] tabstat if you want one-, two-, or n-way table of frequencies and a wide variety of summary statistics. See [R] tabulate, summarize() for a description of tabulate with the summarize() option; it produces a table (breakdowns) of means and standard deviations. table is better than tabulate, summarize(), but tabulate, summarize() is faster. See [ST] epitab for a 2×2 table with statistics of interest to epidemiologists.

^{*}firstonly is available only for tab2.

[†]replace is available only for tabi.

by is allowed with tabulate and tab2; see [D] by.

Options

Main

- chi2 calculates and displays Pearson's χ^2 for the hypothesis that the rows and columns in a two-way table are independent. chi2 may not be specified if aweights or iweights are specified.
- exact [(#)] displays the significance calculated by Fisher's exact test and may be applied to $r \times c$ as well as to 2×2 tables. For 2×2 tables, both one- and two-sided probabilities are displayed. For $r \times c$ tables, one-sided probabilities are displayed. The optional positive integer # is a multiplier on the amount of memory that the command is permitted to consume. The default is 1. This option should not be necessary for reasonable $r \times c$ tables. If the command terminates with error 910, try exact(2). The maximum row or column dimension allowed when computing Fisher's exact test is the maximum row or column dimension for tabulate (see [R] limits).
- gamma displays Goodman and Kruskal's gamma along with its asymptotic standard error. gamma is appropriate only when both variables are ordinal. gamma may not be specified if aweights or iweights are specified.
- 1rchi2 displays the likelihood-ratio χ^2 statistic. 1rchi2 may not be specified if aweights or iweights are specified.
- taub displays Kendall's τ_b along with its asymptotic standard error. taub is appropriate only when both variables are ordinal. taub may not be specified if aweights or iweights are specified.
- V (note capitalization) displays Cramér's V. V may not be specified if aweights or iweights are specified.
- cchi2 displays each cell's contribution to Pearson's chi-squared in a two-way table.
- column displays the relative frequency of each cell within its column in a two-way table.
- row displays the relative frequency of each cell within its row in a two-way table.
- clrchi2 displays each cell's contribution to the likelihood-ratio chi-squared in a two-way table.
- cell displays the relative frequency of each cell in a two-way table.
- expected displays the expected frequency of each cell in a two-way table.
- nofreq suppresses the printing of the frequencies.
- missing requests that missing values be treated like other values in calculations of counts, percentages, and other statistics.
- wrap requests that Stata take no action on wide, two-way tables to make them readable. Unless wrap is specified, wide tables are broken into pieces to enhance readability.
- [no] key suppresses or forces the display of a key above two-way tables. The default is to display the key if more than one cell statistic is requested, and otherwise to omit it. key forces the display of the key. nokey suppresses its display.
- nolabel causes the numeric codes to be displayed rather than the value labels.
- nolog suppresses the display of the log for Fisher's exact test. Using Fisher's exact test requires counting all tables that have a probability exceeding that of the observed table given the observed row and column totals. The log counts down each stage of the network computations, starting from the number of columns and counting down to 1, displaying the number of nodes in the network at each stage. A log is not displayed for 2×2 tables.
- firstonly, available only with tab2, restricts the output to only those tables that include the first variable in *varlist*. Use this option to interact one variable with a set of others.

Advanced

matcell(matname) saves the reported frequencies in matname. This option is for use by programmers.

matrow(matname) saves the numeric values of the $r \times 1$ row stub in matname. This option is for use by programmers. matrow() may not be specified if the row variable is a string.

matcol(matname) saves the numeric values of the $1 \times c$ column stub in matname. This option is for use by programmers. matcol() may not be specified if the column variable is a string.

replace indicates that the immediate data specified as arguments to the tabi command be left as the current data in place of whatever data were there.

The following option is available with tabulate but is not shown in the dialog box:

all is equivalent to specifying chi2 lrchi2 V gamma taub. Note the omission of exact. When all is specified, no may be placed in front of the other options. all noV requests all association measures except Cramér's V (and Fisher's exact). all exact requests all association measures, including Fisher's exact test. all may not be specified if aweights or iweights are specified.

Limits

Two-way tables may have a maximum of 1,200 rows and 80 columns (Stata/MP and Stata/SE), 300 rows and 20 columns (Stata/IC), or 160 rows and 20 columns (Small Stata). If larger tables are needed, see [R] table.

Remarks and examples

stata.com

Remarks are presented under the following headings:

tabulate
Measures of association
N-way tables
Weighted data
Tables with immediate data
tab2
Video examples

For each value of a specified variable (or a set of values for a pair of variables), tabulate reports the number of observations with that value. The number of times a value occurs is called its frequency.

tabulate

Example 1

tabulate will make two-way tables if we specify two variables following the word tabulate. In our highway dataset, we have a variable called rate that divides the accident rate into three categories: below 4, 4–7, and above 7 per million vehicle miles. Let's make a table of the speed limit category and the accident-rate category:

. use http://www.stata-press.com/data/r13/hiway2 (Minnesota Highway Data, 1973)

. tabulate spdcat rate

Speed	Accident rate per million				
Limit	vehicle miles				
Category	Below 4	4-7	Above 7	Total	
40 to 50	3	5	3	11	
55 to 50	19	6	1	26	
Above 60	2	0	0	2	
Total	24	11	4	39	

The table indicates that three stretches of highway have an accident rate below 4 and a speed limit of 40 to 50 miles per hour. The table also shows the row and column sums (called the *marginals*). The number of highways with a speed limit of 40 to 50 miles per hour is 11, which is the same result we obtained in our previous one-way tabulations.

Stata can present this basic table in several ways—16, to be precise—and we will show just a few below. It might be easier to read the table if we included the row percentages. For instance, of 11 highways in the lowest speed limit category, three are also in the lowest accident-rate category. Three-elevenths amounts to some 27.3%. We can ask Stata to fill in this information for us by using the row option:

. tabulate spdcat rate, row

Key
frequency row percentage

Speed Limit		rate per hicle mile		
Category	Below 4	4-7	Above 7	Total
40 to 50	3	5	3	11
	27.27	45.45	27.27	100.00
55 to 50	19	6	1	26
	73.08	23.08	3.85	100.00
Above 60	2 100.00	0.00	0.00	100.00
Total	24	11	4	39
	61.54	28.21	10.26	100.00

The number listed below each frequency is the percentage of cases that each cell represents out of its row. That is easy to remember because we see 100% listed in the "Total" column. The bottom row is also informative. We see that 61.54% of all the highways in our dataset fall into the lowest accident-rate category, that 28.21% are in the middle category, and that 10.26% are in the highest.

tabulate can calculate column percentages and cell percentages, as well. It does so when we specify the column or cell options, respectively. We can even specify them together. Below is a table that includes everything:

. tabulate spdcat rate, row column cell

Speed Limit	Acciden v			
Category	Below 4	4-7	Above 7	Total
40 to 50	3	5	3	11
	27.27	45.45	27.27	100.00
	12.50	45.45	75.00	28.21
	7.69	12.82	7.69	28.21
55 to 50	19	6	1	26
	73.08	23.08	3.85	100.00
	79.17	54.55	25.00	66.67
	48.72	15.38	2.56	66.67
Above 60	2	0	0	2
	100.00	0.00	0.00	100.00
	8.33	0.00	0.00	5.13
	5.13	0.00	0.00	5.13
Total	24	11	4	39
	61.54	28.21	10.26	100.00
	100.00	100.00	100.00	100.00
	61.54	28.21	10.26	100.00

The number at the top of each cell is the frequency count. The second number is the row percentage—they sum to 100% going across the table. The third number is the column percentage—they sum to 100% going down the table. The bottom number is the cell percentage—they sum to 100% going down all the columns and across all the rows. For instance, highways with a speed limit above 60 miles per hour and in the lowest accident rate category account for 100% of highways with a speed limit above 60 miles per hour; 8.33% of highways in the lowest accident-rate category; and 5.13% of all our data.

A fourth option, nofreq, tells Stata not to print the frequency counts. To construct a table consisting of only row percentages, we type

. tabulate spdcat rate, row nofreq

Speed Limit	Accident rate per million vehicle miles				
Category	Below 4	4-7	Above 7	Total	
40 to 50 55 to 50 Above 60	27.27 73.08 100.00	45.45 23.08 0.00	27.27 3.85 0.00	100.00 100.00 100.00	
Total	61.54	28.21	10.26	100.00	

Measures of association

Example 2

tabulate will calculate the Pearson χ^2 test for the independence of the rows and columns if we specify the chi2 option. Suppose that we have 1980 census data on 956 cities in the United States and wish to compare the age distribution across regions of the country. Assume that agecat is the median age in each city and that region denotes the region of the country in which the city is located.

- . use http://www.stata-press.com/data/r13/citytemp2 (City Temperature Data)
- . tabulate region agecat, chi2

Census Region	19-29	agecat 30-34	35+	Total
NE	46	83	37	166
N Cntrl	162	92	30	284
South	139	68	43	250
West	160	73	23	256
Total	507	316	133	956

Pearson chi2(6) = 61.2877Pr = 0.000

We obtain the standard two-way table and, at the bottom, a summary of the χ^2 test. Stata informs us that the χ^2 associated with this table has 6 degrees of freedom and is 61.29. The observed differences are significant.

The table is, perhaps, easier to understand if we suppress the frequencies and print just the row percentages:

. tabulate region agecat, row nofreq chi2

Census		agecat		
Region	19-29	30-34	35+	Total
NE	27.71	50.00	22.29	100.00
N Cntrl	57.04	32.39	10.56	100.00
South	55.60	27.20	17.20	100.00
West	62.50	28.52	8.98	100.00
Total	53.03	33.05	13.91	100.00

Pearson chi2(6) = 61.2877Pr = 0.000

Example 3

We have data on dose level and outcome for a set of patients and wish to evaluate the association between the two variables. We can obtain all the association measures by specifying the all and exact options:

1

```
. use http://www.stata-press.com/data/r13/dose
```

. tabulate dose function, all exact

Enumerating sample-space combinations:

stage 3: enumerations = 1
stage 2: enumerations = 9
stage 1: enumerations = 0

Dosage		nction 1 to 4	4+	Total
1/day 2/day 3/day	20 16 10	10 12 16	2 4 6	32 32 32
Total	46	38	12 Pr = 0 1/18	96

```
Total | 46 38 12 |

Pearson chi2(4) = 6.7780 Pr = 0.148
likelihood-ratio chi2(4) = 6.9844 Pr = 0.137

Cramr's V = 0.1879

gamma = 0.3689 ASE = 0.129

Kendall's tau-b = 0.2378 ASE = 0.086

Fisher's exact = 0.145
```

We find evidence of association but not enough to be truly convincing.

If we had not also specified the exact option, we would not have obtained Fisher's exact test. Stata can calculate this statistic both for 2×2 tables and for $r \times c$. For 2×2 tables, the calculation is almost instant. On more general tables, however, the calculation can take longer.

We carefully constructed our example so that all would be meaningful. Kendall's τ_b and Goodman and Kruskal's gamma are relevant only when both dimensions of the table can be ordered, say, from low to high or from worst to best. The other statistics, however, are always applicable.

1

□ Technical note

Be careful when attempting to compute the p-value for Fisher's exact test because the number of tables that contribute to the p-value can be extremely large and a solution may not be feasible. The errors that are indicative of this situation are errors 910, exceeded memory limitations, and 1401, integer overflow due to large row-margin frequencies. If execution terminates because of memory limitations, use exact(2) to permit the algorithm to consume twice the memory, exact(3) for three times the memory, etc. The default memory usage should be sufficient for reasonable tables.

N-way tables

If you need more than two-way tables, your best alternative to is use table, not tabulate; see [R] table.

The technical note below shows you how to use tabulate to create a sequence of two-way tables that together form, in effect, a three-way table, but using table is easy and produces prettier results:

- . use http://www.stata-press.com/data/r13/birthcat (City data)
- . table birthcat region agecat, c(freq)

birthcat		19		cat and C		_)-34	
	NE	N Cntrl	South	West	NE	N Cntrl	South	West
29-136	11	23	11	11	34	27	10	8
137-195	31	97	65	46	48	58	45	42
196-529	4	38	59	91	1	3	12	21

birthcat	a	gecat and		gion
DII theat	NE	N Cntrl	South	West
29-136	34	26	27	18
137-195	3	4	7	4
196-529			4	

□ Technical note

We can make n-way tables by combining the by varlist: prefix with tabulate. Continuing with the dataset of 956 cities, say that we want to make a table of age category by birth-rate category by region of the country. The birth-rate category variable is named birthcat in our dataset. To make separate tables for each age category, we would type

. by agecat, sort: tabulate birthcat region

-> agecat =	19-29				
		Census R	egion		
birthcat	NE	N Cntrl	South	West	Total
29-136	11	23	11	11	 56
137-195	31	97	65	46	239
196-529	4	38	59	91	192
T	4.0	450	4.0.5	1.10	407
Total	46	158	135	148	487

->	agecat	=	30-34
----	--------	---	-------

		Census	Region		
birthcat	NE	N Cntrl	South	West	Total
29-136	34	27	10	8	79
137-195	48	58	45	42	193
196-529	1	3	12	21	37
Total	83	88	67	71	309

-> agecat = 35+

birthcat	NE	Census N Cntrl	Region South	West	Total
29-136 137-195 196-529	34 3 0	26 4 0	27 7 4	18 4 0	105 18 4
Total	37	30	38	22	127

Weighted data

Example 4

tabulate can process weighted as well as unweighted data. As with all Stata commands, we indicate the weight by specifying the [weight] modifier; see [U] 11.1.6 weight.

Continuing with our dataset of 956 cities, we also have a variable called pop, the population of each city. We can make a table of region by age category, weighted by population, by typing

. tabulate region agecat [freq=pop]

Census Region	19-29	agecat 30-34	35+	Total
NE N Cntrl South West	4,721,387 16,901,550 13,894,254 16,698,276	10,421,387 8,964,756 7,686,531 7,755,255	5,323,610 4,015,593 4,141,863 2,375,118	20,466,384 29,881,899 25,722,648 26,828,649
Total	52,215,467	34,827,929	15,856,184	102899580

If we specify the cell, column, or row options, they will also be appropriately weighted. Below we repeat the table, suppressing the counts and substituting row percentages:

. tabulate region agecat [freq=pop], nofreq row

Census Region	19-29	agecat 30-34	35+	Total
NE N Cntrl South West	23.07 56.56 54.02 62.24	50.92 30.00 29.88 28.91	26.01 13.44 16.10 8.85	100.00 100.00 100.00 100.00
Total	50.74	33.85	15.41	100.00

Tables with immediate data

Example 5

tabi ignores the dataset in memory and uses as the table the values that we specify on the command line:

. tabi 30 18 \ 38 14

		col			
row		1	2	Total	Ĺ
1 2		30 38	18 14	48 52	
Total		68	32	100)
l-sided l	Fisher's Fisher's				0.289

We may specify any of the options of tabulate and are not limited to 2×2 tables:

. tabi 30 18 38 \ 13 7 22, chi2 exact

Enumerating sample-space combinations:

stage 3: enumerations = 1 stage 2: enumerations = 3 stage 1: enumerations = 0

		col		
row	1	2	3	Total
1 2	30 13	18 7	38 22	86 42
Total	43	25	60	128

Pearson chi2(2) =0.7967 Pr = 0.6710.707 Fisher's exact =

. tabi 30 13 \ 18 7 \ 38 22, all exact col

Key
frequency column percentage

Enumerating sample-space combinations:

stage 3: enumerations = 1 stage 2: enumerations = 3 stage 1: enumerations = 0

_	l c	ol	
row	1	2	Total
1	30	13	43
	34.88	30.95	33.59
2	18	7	25
	20.93	16.67	19.53
3	38	22	60
	44.19	52.38	46.88
Total	86	42	128
	100.00	100.00	100.00

```
Pearson chi2(2) =
                             0.7967
                                      Pr = 0.671
                             0.7985
likelihood-ratio chi2(2) =
                                      Pr = 0.671
             Cramr's V =
                            0.0789
                   gamma =
                             0.1204 ASE = 0.160
         Kendall's tau-b =
                             0.0630 ASE = 0.084
         Fisher's exact =
                                           0.707
```

For 2×2 tables, both one- and two-sided Fisher's exact probabilities are displayed; this is true of both tabulate and tabi. See Cumulative incidence data and Case-control data in [ST] epitab for more discussion on the relationship between one- and two-sided probabilities.

□ Technical note

tabi, as with all immediate commands, leaves any data in memory undisturbed. With the replace option, however, the data in memory are replaced by the data from the table:

. tabi 30 18 \ 38 14, replace

	col		
row	1	2	Total
1	30	18	48
2	38	14	52
Total	68	32	100
I	Fisher's exact =		0.2

289 1-sided Fisher's exact = 0.179

. list

	row	col	pop
1.	1	1	30
2.	1	2	18
3.	2	1	38
4.	2	2	14

With this dataset, you could re-create the above table by typing

. tabulate row col [freq=pop], exact

		col				
row		1	2	2	Total	
1		30	18	3	48	
2		38	14	1	52	
Total		68	32	2	100	
]	Fisher's	exact	=		0.	289
1-sided l	Fisher's	exact	=		0.	179

1

tab2

tab2 is a convenience tool. Typing

. tab2 myvar thisvar thatvar, chi2

is equivalent to typing

- . tabulate myvar thisvar, chi2
- . tabulate myvar thatvar, chi2
- . tabulate this var that var, chi2

Video examples

Pearson's chi2 and Fisher's exact test in Stata

Tables and cross-tabulations in Stata

Immediate commands in Stata: Cross-tabulations and chi-squared tests from summary data

Stored results

tabulate, tab2, and tabi store the following in r():

Scalars			
r(N)	number of observations	$r(p_exact)$	Fisher's exact p
r(r)	number of rows	r(chi2_lr)	likelihood-ratio χ^2
r(c)	number of columns	$r(p_lr)$	significance of likelihood-ratio χ^2
r(chi2)	Pearson's χ^2	r(CramersV)	Cramér's V
r(p)	significance of Pearson's χ^2	$r(ase_gam)$	ASE of gamma
r(gamma)	gamma	r(ase_taub)	ASE of $\tau_{\rm b}$
r(p1_exact)	one-sided Fisher's exact p	r(taub)	$ au_{ m b}$

 $r(p1_exact)$ is defined only for 2×2 tables. Also, the matrow(), matcol(), and matcell() options allow you to obtain the row values, column values, and frequencies, respectively.

Methods and formulas

Let n_{ij} , $i=1,\ldots,I$ and $j=1,\ldots,J$, be the number of observations in the *i*th row and *j*th column. If the data are not weighted, n_{ij} is just a count. If the data are weighted, n_{ij} is the sum of the weights of all data corresponding to the (i,j) cell.

Define the row and column marginals as

$$n_{i.} = \sum_{i=1}^{J} n_{ij}$$
 $n_{.j} = \sum_{i=1}^{I} n_{ij}$

and let $n = \sum_{i} \sum_{j} n_{ij}$ be the overall sum. Also, define the concordance and discordance as

$$A_{ij} = \sum_{k>i} \sum_{l>j} n_{kl} + \sum_{ki} \sum_{l$$

along with twice the number of concordances $P = \sum_i \sum_j n_{ij} A_{ij}$ and twice the number of discordances $Q = \sum_i \sum_j n_{ij} D_{ij}$.

The Pearson χ^2 statistic with (I-1)(J-1) degrees of freedom (so called because it is based on Pearson (1900); see Conover [1999, 240] and Fienberg [1980, 9]) is defined as

$$X^{2} = \sum_{i} \sum_{j} \frac{(n_{ij} - m_{ij})^{2}}{m_{ij}}$$

where $m_{ij} = n_i . n_{.j} / n$.

The likelihood-ratio χ^2 statistic with (I-1)(J-1) degrees of freedom (Fienberg 1980, 40) is defined as

$$G^2 = 2\sum_{i}\sum_{j}n_{ij}\ln(n_{ij}/m_{ij})$$

Cramér's V (Cramér 1946) is a measure of association designed so that the attainable upper bound is 1. For 2×2 tables, $-1 \le V \le 1$, and otherwise, $0 \le V \le 1$.

$$V = \begin{cases} (n_{11}n_{22} - n_{12}n_{21})/(n_1.n_2.n_{\cdot 1}n_{\cdot 2})^{1/2} & \text{for } 2 \times 2\\ \left\{ (X^2/n)/\text{min}(I-1,J-1) \right\}^{1/2} & \text{otherwise} \end{cases}$$

Gamma (Goodman and Kruskal 1954, 1959, 1963, 1972; also see Agresti [2010,186–188]) ignores tied pairs and is based only on the number of concordant and discordant pairs of observations, $-1 \le \gamma \le 1$,

$$\gamma = (P - Q)/(P + Q)$$

with asymptotic variance

$$16\sum_{i}\sum_{j}n_{ij}(QA_{ij}-PD_{ij})^{2}/(P+Q)^{4}$$

Kendall's τ_b (Kendall 1945; also see Agresti 2010, 188–189), $-1 \le \tau_b \le 1$, is similar to gamma, except that it uses a correction for ties,

$$\tau_b = (P - Q)/(w_r w_c)^{1/2}$$

with asymptotic variance

$$\frac{\sum_{i} \sum_{j} n_{ij} (2w_r w_c d_{ij} + \tau_b v_{ij})^2 - n^3 \tau_b^2 (w_r + w_c)^2}{(w_r w_c)^4}$$

where

$$w_r = n^2 - \sum_{i} n_{i}^2$$

$$w_c = n^2 - \sum_{j} n_{.j}^2$$

$$d_{ij} = A_{ij} - D_{ij}$$

$$v_{ij} = n_{i}.w_c + n_{.j}w_r$$

Fisher's exact test (Fisher 1935; Finney 1948; see Zelterman and Louis [1992, 293–301] for the 2×2 case) yields the probability of observing a table that gives at least as much evidence of association as the one actually observed under the assumption of no association. Holding row and column marginals fixed, the hypergeometric probability P of every possible table A is computed, and the

$$P = \sum_{T \in A} \Pr(T)$$

where A is the set of all tables with the same marginals as the observed table, T^* , such that $\Pr(T) \leq \Pr(T^*)$. For 2×2 tables, the one-sided probability is calculated by further restricting A to tables in the same tail as T^* . The first algorithm extending this calculation to $r \times c$ tables was Pagano and Halvorsen (1981); the one implemented here is the FEXACT algorithm by Mehta and Patel (1986). This is a search-tree clipping method originally published by Mehta and Patel (1983) with further refinements by Joe (1988) and Clarkson, Fan, and Joe (1993). Fisher's exact test is a permutation test. For more information on permutation tests, see Good (2005 and 2006) and Pesarin (2001).
